This example resumes all messages being sent from any sender in the Contoso.com domain.

```
Resume-Message -Filter {FromAddress -eq "*contoso.com"}
```

This example resumes the message with the message ID 3 in the unreachable queue on server Hub01.

```
Resume-Message -Identity Hub01\Unreachable\3
```

To resubmit messages from the poison message queue, perform the following steps:

How do you know this worked?

To verify that you have successfully resume messages in queues, do one of the following:

- In Queue Viewer, select the queue or create a filter to verify the messages are no longer suspended.
- Use the **Get-Message** cmdlet with the *Queue* or *Filter* parameters to verify the messages are no longer suspended. For more information, see Get-Message.

Note that if you can't find the message in any queues on the server, that probably indicates the message was successfully delivered to the next hop.

Suspend messages in queues

When you suspend a message, you prevent delivery of the message. A message that appears in the queue but is already in delivery won't be suspended. Delivery will continue, and the message status will be **PendingSuspend**. If the delivery fails, the message will re-enter the queue, and the message will then be suspended. You can't suspend a message in the Submission queue or in the poison message queue.

A message being sent to multiple recipients might be located in multiple queues. To suspend a message in more than one queue in a single operation, you need to use a filter.

Use Queue Viewer in the Exchange Toolbox to suspend messages

1. Click **Start** > **All Programs** > **Microsoft Exchange 2013** > **Exchange Toolbox**.
2. In the **Mail flow tools** section, double-click **Queue Viewer** to open the tool in a new window.
3. In Queue Viewer, click the **Messages** tab. A list of all messages on the server to which you're connected is displayed. To limit the view to a single queue, click the **Queues** tab, double-click the queue name, and then click the *Server**Queue* tab that appears.
4. Select one or more messages, right-click, and then select **Suspend**.

Use the Shell to suspend messages

To suspend messages, use the following syntax:

```
Suspend-Message <-Identity MessageIdentity | -Filter {MessageFilter}>
```

This example suspends all messages in the queues that are from any sender in the domain contoso.com.

```
Suspend-Message -Filter {FromAddress -eq "*contoso.com"}
```

This example suspends the message with the message ID 3 in the unreachable queue on server named Mailbox01:

```
Suspend-Message -Identity Mailbox01\Unreachable\3
```

How do you know this worked?

To verify that you have successfully suspended messages in queues, do one of the following:

- In Queue Viewer, select the queue or create a filter to verify messages are suspended.
- Use the **Get-Message** cmdlet with the *Queue* or *Filter* parameters to verify the messages are suspended. For more information, see Get-Message.

Queue Viewer

Exchange Server 2013 > Mail flow > Queues >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-25*

Queue Viewer is a Microsoft Management Console snap-in that's installed on a Mailbox server or the Edge Transport server. Queue Viewer is located in the **Mail flow tools** section of the Exchange Toolbox console. You can use this tool to view information about queues on a transport server and the messages that are present in those queues and to perform management actions on queues and mail items. Queue Viewer is useful for troubleshooting mail flow and identifying spam.

When you're using Queue Viewer to manage queues, consider the following:

- You must connect to a transport server. By default, Queue Viewer opens the queue database on the server where you opened Queue Viewer. However, you can also connect to different servers. For more information, see Connect to a server in Queue Viewer.
- The list of queues and messages can be large, depending on current mail flow, and the list of queues and messages changes when messages enter and leave the server. You can configure the options for Queue Viewer to control the interval at which the list of queues and messages is refreshed and the number of items displayed on each page. For more information, see Set Queue Viewer options.
- You can create a filter to display the specific set of queues or messages that you want to monitor. After you locate the queues and messages that you want to monitor, you can view the property information for these queues and messages. This information is helpful when you troubleshoot the cause of mail flow problems. For more information, see Queue filters and Message filters.
- You can use the **Export List** link in the action pane to export the list of queues or a list of messages. For more information, see Export lists from Queue Viewer.

Connect to a server in Queue Viewer

Mail flow > Queues > Queue Viewer >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

When you use Queue Viewer in the Exchange Toolbox on a Microsoft Exchange Server 2013 server that's located inside the Exchange organization, you can connect to other Mailbox servers. By default, when you open Queue View on a Mailbox server, Queue Viewer connects to the queue database on the local server. However, you can start more than one instance of Queue Viewer so that each instance focuses on a different server. You can also tile Queue Viewer windows so you can easily monitor more than one Mailbox server at a time.

You can also specify the server that Remote PowerShell uses to perform the specified tasks in Queue Viewer. This server doesn’t need to match the remote server you're managing in Queue Viewer.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Queues" entry in the Mail flow permissions topic.
- The procedures in this topic don't apply to Edge Transport servers. When you use Queue Viewer on an Edge Transport server, you can't change the focus of the tool.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Exchange Toolbox to specify the server you want to manage in Queue Viewer

1. Click **Start** > **All Programs** > **Microsoft Exchange Server 2013** > **Exchange Toolbox**.
2. In the **Mail flow tools** section, double-click **Queue Viewer**.
3. In the action pane, click **Connect to server**.
4. In the **Connect to Server** window, click **Browse** to view a list of the available Mailbox servers.
5. In the **Select Exchange Server** window, select a Mailbox server. To search for a Mailbox server, use one of the following procedures:
   - Enter the exact server name or the first few letters of the server name in the **Search** field, and then click **Find Now**. Select a server from the result pane.
   - Select the **View** menu, and then click **Show Filter**. In the **Name** column or **Version** column, click the filter icon, and then select the filter operator. Type the filter criteria in the **Enter text here** field. Press ENTER. Select a server from the result pane.
6. Click **OK** to close the **Select Exchange Server** window.
7. After you select a server, in the **Connect to server** window, select the **Set as default server** check box if you want Queue Viewer to focus on this server first whenever Queue Viewer is opened.
8. In the **Connect to server** window, click **Connect**.

Use the Exchange Toolbox to specify the server that Queue Viewer uses to run Remote PowerShell

1. Click **Start** > **All Programs** > **Microsoft Exchange Server 2013** > **Exchange Toolbox**.
2. In the **Mail flow tools section**, double-click **Queue Viewer**.

3. In the action pane, click **Properties**.
4. In the **Queue Viewer - <server name> Properties** dialog box, select one of the following options:
   - **Connect to the automatically selected server** Select this option to automatically connect to the server where you're managing queues to run Remote PowerShell.
   - **Specify a server to connect to** Select this option to specify a server to run Remote PowerShell. If you select this option, click **Browse** to open the **Select Exchange Server** dialog box. Select the server where you want to run Remote PowerShell, and then click **OK**.

How do you know this worked?

You should be able to manage the queues on the Mailbox server you specified.

Set Queue Viewer options

Mail flow > Queues > Queue Viewer >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

You can set options in Queue Viewer to adjust the number of items that are displayed on the page and adjust the auto-refresh interval. The auto-refresh interval determines how frequently the results in Queue Viewer are updated.

What do you need to know before you begin?

- Estimated time to complete: 10 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Queues" entry in the Mail flow permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

⚠**Warning:**
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Exchange Toolbox to set Queue Viewer options

1. Click **Start** > **All Programs** > **Microsoft Exchange Server 2013** > **Exchange Toolbox**.
2. In the **Mail flow tools** section, double-click **Queue Viewer**.
3. In Queue Viewer, click **View** > **Options** to configure the following settings in the **Queue Viewer Options** dialog box:

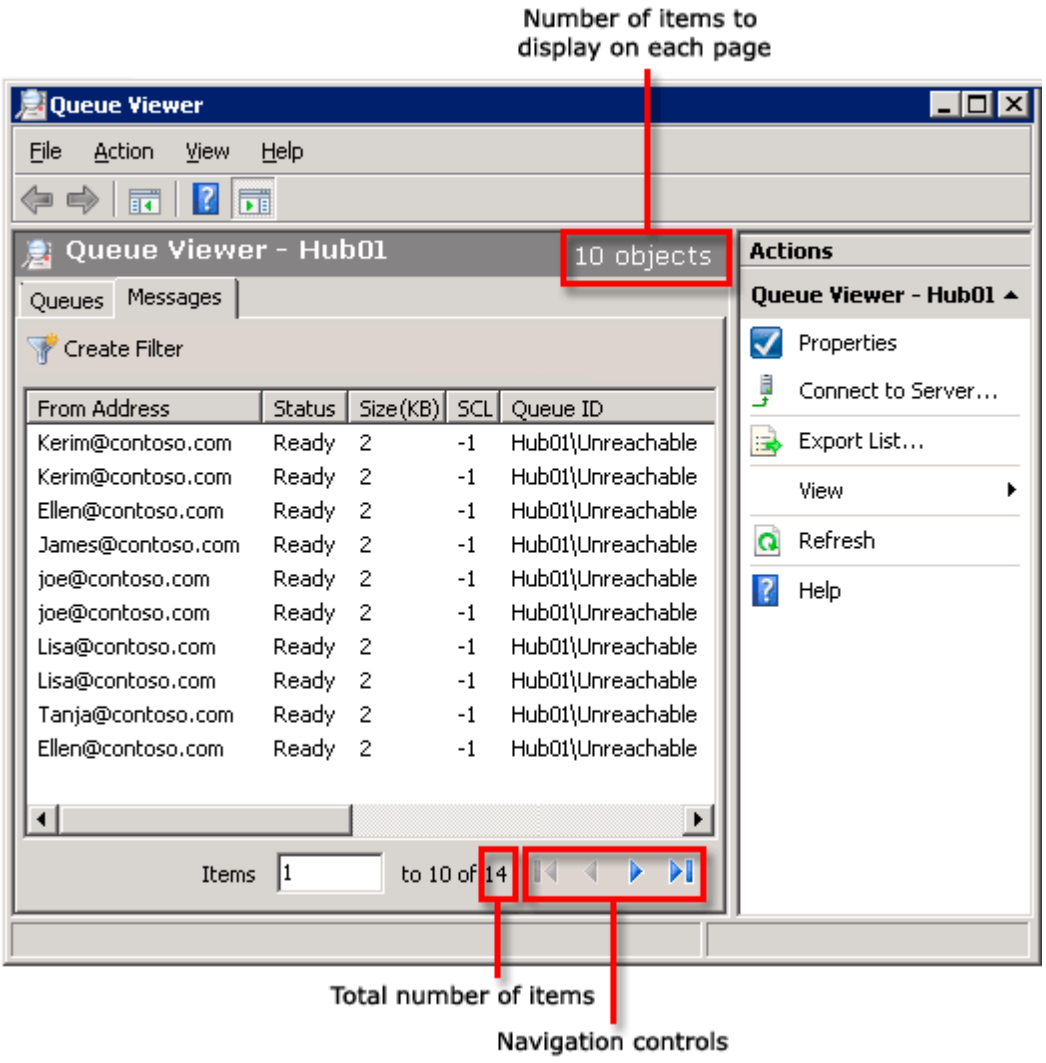
a. In the **Refresh interval (seconds)** field, enter the frequency at which Queue Viewer should update the display.

Note:
The default auto-refresh interval is 30 seconds and can't be set for a shorter time. If you disable auto-refresh functionality by clearing the **Auto-refresh screen** check box on the **Queue Viewer Options** page, you must manually update the results that are displayed in Queue Viewer by clicking **Refresh**.

b. In the **Number of items to display on each page** field, enter the maximum number of items to display in Queue Viewer. This number must be from 1 through 10,000. If you have more items than the limit, you will see the items in groups of the maximum number of items. For example, the following figure shows a queue with 14 messages with Queue Viewer configured to display 10 items on each page. The number of objects on the page is displayed on the upper right. At the bottom of the page, you can see the total number of items in the queue. You can use the navigation controls to see the additional items in the queue.

4. When you are finished, click **OK**.

Queue Viewer



How do you know this worked?

You'll know this procedure worked if Queue Viewer uses the refresh interval and number of items per page settings.

View queued message properties in Queue Viewer

Mail flow > Queues > Queue Viewer >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-01-17*

You can use the Queue Viewer in the Exchange Toolbox to view the properties of a message that is queued for delivery.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Queues" entry in the Mail flow permissions topic.
- You can also use the Get-Message cmdlet in the Exchange Management Shell to view additional message properties that aren't visible in Queue Viewer. For more information, see Message filters and Use the Exchange Management Shell to manage queues.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What Do You Want to Do?

Use Queue Viewer in the Exchange Toolbox to view the properties of a message

1. Click **Start** > **All Programs** > **Microsoft Exchange 2013** > **Exchange Toolbox**.
2. In the **Mail flow tools** section, double-click **Queue Viewer** to open the tool in a new window.
3. In Queue Viewer, select the **Messages** tab to see the list of messages that are currently queued for delivery in your organization.
4. Right-click the message whose properties you want to view and then select **Properties**.

5. The **General** tab displays the following detailed information about the message:
   - **Identity** This field shows the integer that represents a particular message. The message identity is assigned by the queuing database when the message is received for processing. You can include an optional server and queue identity to identify a unique instance of the message.
   - **Subject** This field shows the subject of a message and is expressed as a text string. The value is taken from the `Subject:` header field.
   - **Internet Message ID** This field shows the value of the `MessageID:` header field. The value of this property is expressed as a GUID followed by the SMTP address of the sending server, as in this example: 67D754D6103DC4FB3BA6BC7205DACABA61231@exchange.contoso.com
   - **From Address** This field shows the SMTP address of the sender of the message. This value is taken from MAIL FROM: in the message envelope.
   - **Status** This field shows the current message status. A message can have one of the following status values:
     - **Active** If the message is in a delivery queue, the message is being delivered to its destination. If the message is in the Submission queue, the message is being processed by the categorizer.
     - **Pending Remove** The message was deleted by the administrator but was already in delivery. The message will be deleted if the delivery ends in an error that causes the message to re-enter the queue. Otherwise, delivery will continue.
     - **Pending Suspend** The message was suspended by the administrator but was already in delivery. The message will be suspended if the delivery ends in an error that causes the message to re-enter the queue. Otherwise, delivery will continue.
     - **Ready** The message is waiting in the queue and is ready to be processed.
     - **Retry** The last connection attempt failed for the queue in which this message is located. The message is waiting for the next queue retry.
     - **Suspended** The message was suspended by the administrator.
   - **Size (KB)** This field shows the size of the message rounded up to the nearest kilobyte (KB).
   - **Message Source Name** This field shows the name of the component that submitted this message to the queue.
   - **Source IP** This field shows the IP address of the external server that submitted the message to the Exchange organization.
   - **SCL** This field shows the spam confidence Level (SCL) rating of the message. Valid SCL entries are integers 0 through 9 or -1. An empty SCL entry indicates that the message hasn't been processed by the Content Filter agent.
   - **Date Received** This field shows the date-time when the message was received by the server that holds the queue in which the message is located.
   - **Expiration Time** This field shows the date-time when the message will expire and will be deleted from the queue if the message can't be delivered.
   - **Last Error** This field shows the last error that was recorded for a message.
   - **Queue ID** This field shows the identity of the queue that holds the message. The queue identity is expressed in the form *Server**destination*, where *destination* is a delivery group, routing destination, persistent queue name, or the queue database identifier. The queue

database identifier is represented as an integer and can be determined by viewing the message properties.

- **Recipients** This field shows the list of recipients to which the message is addressed.
- **Retry Count** This field shows the number of times that delivery of a message to a destination was tried.

6. The **Recipient Information** tab displays the following information about the message recipients:
   - **Address** This field shows the SMTP address of the recipient of the message. This value is taken from `RCPT TO:` in the message envelope.
   - **Status** This field shows the current message status. A message can have one of the following status values:
     - **Active** If the message is in a delivery queue, the message is being delivered to its destination. If the message is in the Submission queue, the message is being processed by the categorizer.
     - **Pending Remove** The message has been deleted by the administrator but was already in delivery. The message will be deleted if the delivery ends in an error that causes the message to re-enter the queue. Otherwise, delivery will continue.
     - **Pending Suspend** The message has been suspended by the administrator but was already in delivery. The message will be suspended if the delivery ends in an error that causes the message to re-enter the queue. Otherwise, delivery will continue.
     - **Ready** The message is waiting in the queue and is ready to be processed.
     - **Retry** The last connection attempt failed for the queue in which this message is located. The message is waiting for the next queue retry.
     - **Suspended** The message has been suspended by the administrator.
   - **Last Error** This field shows the last error that was recorded for a message.

Use the Shell to view the properties of a message

You use the **Get-Message** cmdlet to view the properties of a message that is currently queued for delivery. The following example tabulates the sender address, recipients, subject, and received date information for all messages that are currently in retry state:

```
Get-Message -IncludeRecipientInfo -Filter {Status -eq
"Retry"} | Format-Table
FromAddress,Recipients,Subject,DateReceived
```

For detailed syntax and parameter information, see Get-Message.

Export lists from Queue Viewer

Mail flow > Queues > Queue Viewer >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-25*

This topic explains how to use Queue Viewer in the Exchange Toolbox to export lists of messages or queues.

You can export lists to the following file formats:

- Text (tab delimited)
- Text (comma delimited)
- Unicode text (tab delimited)
- Unicode text (comma delimited)

What do you need to know before you begin?

- Estimated time to complete: 10 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Queues" entry in the Mail flow permissions.
- By default, the result pane in Queue Viewer displays only the first 1,000 objects. To change this value, see Set Queue Viewer options.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Export a list from the result pane in Queue Viewer

1. Click **Start** > **All Programs** > **Microsoft Exchange 2013** > **Exchange Toolbox**.
2. In the **Mail flow** section, double-click **Queue Viewer**.
3. In Queue Viewer, select the **Queues** tab or the **Messages** tab. On either tab, you can click **Create Filter** to restrict the results.

Note:

If the result pane doesn't refresh, in the action pane, click **Refresh**. Long lists may take several minutes to refresh.

4. In the action pane, click **Export List**. The **Export List** dialog box appears.
5. In **Export List**, type the name of the file in the **File name** box, and then select the file format from the **Save as type** list.
6. Click **Save**.

Message filters

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-14*

Filtering generates different views of the messages in queues. By specifying filter criteria, you can quickly locate messages and take action on them. When an email message is sent to multiple recipients, the message may be located in multiple queues. When you filter by message properties, you can locate messages across all queues. The following scenarios are examples of how you might use message filtering to manage mail flow:

- The Submission queue on the Mailbox server or Edge Transport server that receives email from the Internet has a high volume of messages that are queued for delivery. Many of the messages have the same subject. Therefore, you suspect that spam is being sent to your organization. You can create a filter to view all the messages that meet the subject criteria. If you determine that the messages are spam, you can select them all and delete them from the delivery queue without sending an NDR.
- A user reports that mail flow is slow. You examine the queues and see that many messages that have random subjects appear to be coming from a single domain. You can create a filter to view all the queued messages from that domain. If you determine that the messages are spam, you can select them all and delete them from the queues without sending an NDR.

Message properties as filters

You can use message properties to create a filter and locate messages that meet specified criteria. You can create filters in Queue Viewer, or by using the *Filter* parameter on the message management cmdlets. Note that the message management cmdlets support more filterable properties than the Queue Viewer. The following table lists the message properties by which you can filter and the values that are associated with those properties.

Message properties to use when filtering messages

Queue Viewer message property	Shell message property	Description
Date Received	`DateReceived`	The date/time when the message was placed in the queue.
n/a	`DeferReason`	This property identifies why the message was deferred. If the message wasn't deferred, this property has the value `None`. A deferred message is returned

		to the Submission queue because of transient errors that were encountered during recipient resolution. For more information about deferred messages, see Recipient resolution. The possible values are:
		`AD Transient Failure During Content Conversion`
		`AD Transient Failure During Resolve`
		`Agent`
		`Ambiguous Recipient`
		`Loop Detected`
		`Marked As Retry Delivery If Rejected`
		`Rerouted By Store Driver`
		`Storage Transient Failure During Content Conversion`
		`Transient Failure`
		`Target Site Inbound Mail Disabled`
		`Recipient Thread Limit Exceeded`
		`Transient Attribution Failure`
		`Transient Accepted Domains Load Failure`

Expiration Time	`ExpirationTime`	This property contains the date/time when the message will expire and be deleted from the queue if the message can't be delivered.
From Address	`FromAddress`	This property contains the SMTP address of the sender.
n/a	`Identity`	This property is the identity of the message in the form of *<Server>\<Queue>*

		\<*MessageInteger*>. For more information see the "Message identity" section in the Queues topic.
Internet Message ID	`InternetMessageId`	This property contains the value of the `Message-ID:` header field that's located in the message header. The value is expressed as an email address that contains a GUID and the FQDN the sending SMTP server. For example: `<67D754D6103DC4FB3BA6BC7205DACABA61231@mailbox01.contoso.com>`
Last Error	`LastError`	This property contains the text of the last error that was recorded for a message. For example, `A matching connector cannot be found to route the external recipient`.
n/a	`MessageLatency`	This property contains the amount of time elapsed between when the message first entered the Submission queue on the server, and when the message was placed in the queue. The value uses the syntax *hh:mm:ss.ff*, where *hh* = hour, *mm* = minute, *ss* = second, and *ff* = fractions of a second.

Message Source Name	`MessageSourceName`	This property contains a text string that indicates the name of the transport component that submitted the message to the queue. For example, if the message came in through a Receive connector, the value is: `SMTP:`<*ConnectorName*>. If the message is a delivery status notification (DSN), the value is `DSN`.
n/a	`Priority`	This property contains the priority of the message that's assigned by the user in Outlook or Outlook Web App. The possible values are `Low`, `Normal`, and `High`. For more information, see Priority queuing.
Queue ID	`Queue`	This property is the identity of the queue that holds the message. The queue identity uses the syntax <*Server*>\<*Queue*>. For more information, see the "Queue identity" section in the Queues topic.
n/a	`RetryCount`	This property identifies the number of times that delivery of the message to the destination was tried, either

		automatically or manually.
SCL	`SCL`	The value of the spam confidence level (SCL) property specifies the SCL of the message. Valid SCL entries are integers from 0 through 9. An empty SCL property value indicates that the message hasn't been processed by the Content Filter agent. This property contains the spam confidence level (SCL) value of the message. Valid SCL entries are integers from 0 through 9 and -1. For more information, see Spam Confidence Level Threshold.
Size (KB)	`Size`	This property indicates the size of the message.
Source IP	`SourceIP`	This property contains the IP address of the server that submitted the message to the Exchange server that holds the message in the queue. The address could be the IP address of a remote SMTP server, or the IP address of the local Exchange server.
Status	`Status`	This property indicates the current message status. A message can have one of the

		following status values:
		`Active`
		`Locked`
		`None`
		`Pending Remove`
		`Pending Suspend`
		`Ready`
		`Retry`
		`Suspended`
		For more information, see the "Message properties" section in the Queues topic.

Subject	`Subject`	This property indicates the subject of a message that's found in the `Subject:` header field in the message header.

Export messages from queues

Exchange Server 2013 > Mail flow > Queues >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-05-05*

When you export a message from a queue to a file, the message isn't removed from the queue. A copy of the message is made in the specified location as a plain text file. The resulting file can be viewed in an application, such as a text editor or an email client application, or the message file can be resubmitted by using the Replay directory on any other Mailbox server or Edge Transport server inside or outside the Exchange organization.

What do you need to know before you begin?

- Estimated time to complete each procedure: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Queues" entry in Mail flow permissions topic.
- The messages must be in a Suspended state for the export process to be successful. You can export messages from delivery queues, the Unreachable queue, or the poison message queue. Messages in the poison message queue are already in the Suspended state. You can't suspend or

export messages that are in the Submission queue.

- You can't use Queue Viewer in the Exchange Toolbox to export messages. However, you can use Queue Viewer to locate, identify, and suspend the messages before you export them using the Shell.
- Verify the following information about the target directory location for the message files:
  - The target directory must exist before you export any messages. The directory won't be created for you. If an absolute path isn't specified, the current Exchange Management Shell working directory is used.
  - The path may be local to the Exchange server, or it may be a Universal Naming Convention (UNC) path to a share on a remote server.
  - Your account must have the **Write** permission to the target directory.
  - When you specify a file name for the exported messages, be sure to include the .eml file name extension so the files can be opened easily by email client applications or processed correctly by the Replay directory.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to export a specific message from a specific queue

To export a specific message from a specific queue, run the following command:

```
Export-Message -Identity <MessageIdentity> |
AssembleMessage -Path <FilePath>\<FileName>.eml
```

This example exports a copy of a message that has the **InternalMessageID** value 1234 that's located in the contoso.com delivery queue on the server named Mailbox01 to the file named export.eml in the path D:\Contoso Export.

```
Export-Message -Identity Exchange01\Contoso.com\1234 |
AssembleMessage -Path "D:\Contoso Export\export.eml"
```

Use the Shell to export all messages from a specific queue

To export all messages from a specific queue and use the **InternetMessageID** value of each message as the file name, use the following syntax.

```
Get-Message -Queue <QueueIdentity> | ForEach-Object
{$Temp=<Path>+$_.InternetMessageID
+".eml";$Temp=$Temp.Replace("<","_");$Temp=$Temp.Replace(">
","_");Export-Message $_.Identity | AssembleMessage -Path
$Temp}
```

Note that the **InternetMessageID** value contains angled brackets (> and <), which need to be removed because they aren't allowed in file names.

This example exports a copy of all the messages from the contoso.com delivery queue on the server named Mailbox01 to the local directory named D:\Contoso Export.

```
Get-Message -Queue Mailbox01\Contoso.com | ForEach-Object
{$Temp="D:\Contoso Export\"+$_.InternetMessageID
+".eml";$Temp=$Temp.Replace("<","_");$Temp=$Temp.Replace(">
","_");Export-Message $_.Identity | AssembleMessage -Path
$Temp}
```

Use the Shell to export specific messages from all the queues on a server

To export specific messages from all queues on a server and use the **InternetMessageID** value of each message as the file name, use the following syntax.

```
Get-Message -Filter {<MessageFilter>} [-Server
<ServerIdentity>] | ForEach-Object {$Temp=<Path>
+$_.InternetMessageID
+".eml";$Temp=$Temp.Replace("<","_");$Temp=$Temp.Replace(">
","_");Export-Message $_.Identity | AssembleMessage -Path
$Temp}
```

Note that the **InternetMessageID** value contains angled brackets (> and <), which need to be removed because they aren't allowed in file names.

This example exports a copy of all the messages from senders in the contoso.com domain from all queues on the server named Mailbox01 to the local directory named D:\Contoso Export.

```
Get-Message -Filter {FromAddress -like "*@contoso.com"} -
Server Mailbox01 | ForEach-Object {$Temp="D:\Contoso Export
\"+$_.InternetMessageID
+".eml";$Temp=$Temp.Replace("<","_");$Temp=$Temp.Replace(">
```

```
","_");Export-Message $_.Identity | AssembleMessage -Path
$Temp}
```

Note:
If you omit the *Server* parameter, the command operates on the local server.

Message retry, resubmit, and expiration intervals

Exchange Server 2013 > Mail flow > Queues >

Topic Last Modified: *2013-02-21*

In Microsoft Exchange Server 2013, messages that can't be successfully delivered are subject to various retry, resubmit, and expiration deadlines based on the message's source and destination. *Retry* is a renewed connection attempt with the destination. *Resubmit* is the act of sending messages back to the Submission queue for the categorizer to reprocess. The message timeout*expires* after all delivery efforts have failed over a specified period of time. After a message expires, the sender is notified of the delivery failure. Then the message is deleted from the queue.

In all three cases of retry, resubmit, or expire, you can manually intervene before the automatic actions are performed on the messages.

For instructions on how to configure these intervals, see Configure message retry, resubmit, and expiration intervals.

Configuration options for message retry

When a transport server can't connect to the next hop, the queue is put in a status of Retry. Connection attempts continue until the queue expires or a connection is made.

Configuration Options for Automatic Message Retry

The configuration options that are available for message retry intervals are described in the following table.

Configuration options that are available for message retry intervals

Parameter or key name	Default value	Where to configure	Description
QueueGlitchRetryCount	4	EdgeTransport.exe.config	This key specifies the number of connection

			attempts that are immediately tried when a transport server has trouble connecting with the destination server. Such connection problems are typically caused by very brief network outages. Valid input for this key is an integer from 0 through 15. Typically, you don't have to modify this key unless the network is unreliable and continues to experience many accidentally dropped connections.
QueueGlitchRetryInterval	`00:01:00` or 1 minute	EdgeTransport.exe.config	This key controls the connection interval between each connection attempt that's specified by the *QueueGlitchRetryCount* key. Typically, you don't have to modify this parameter unless the network is unreliable

			and continues to experience many accidentally dropped connections.
TransientFailureRetryCount	6	**Set-TransportService**cmdlet or server properties in the Exchange Administration Center (EAC)	This parameter specifies the number of connection attempts that are tried after the connection attempts that are controlled by the *QueueGlitchRetryCount* and *QueueGlitchRetryInterval* keys have failed. Connection problems that exhaust the *QueueGlitchRetryCount* and *QueueGlitchRetryInterval* keys can be caused by server restarts or cached DNS lookup failures. Valid input for this parameter is an integer from 0 through 15. If you set this parameter to 0, the next connection attempt is controlled by the

			OutboundConnectionFailureRetryInterval parameter.
TransientFailureRetryInterval	• Transport service on Mailbox servers: `00:05:00` or 5 minutes • Edge Transport servers: `00:01:00` or 10 minutes	**Set-TransportService**cmdlet or server properties in the EAC	This parameter controls the connection interval between each connection attempt that's specified by the *TransientFailureRetryCount* parameter. To specify a value, enter it as a time span: dd.hh:mm:ss where d = days, h = hours, m = minutes, and s = seconds.
OutboundConnectionFailureRetryInterval	• Transport service on Mailbox servers: `00:10:00` or 10 minutes • Edge Transport Servers: `00:30:00` or 30 minutes	**Set-TransportService** cmdlet or server properties in the EAC	This parameter specifies the retry interval for outbound connection attempts that have previously failed. The previously failed connection attempts are controlled by the *TransientFailureRetryCount* and *TransientFailureRetryInterval* parameters. To specify a value,

			enter it as a time span: dd.hh:mm:ss where d = days, h = hours, m = minutes, and s = seconds.
MessageRetryInterval	`00:01:00` or 1 minute	**Set-TransportService** cmdlet	This parameter specifies the retry interval for individual messages that have a status of Retry. We recommend that you don't modify the default value unless Microsoft Customer Service and Support advises you to do this.
MailboxDeliveryQueueRetryInterval	`00:05:00` or 5 minutes	EdgeTransport.exe.config	This key specifies how frequently the queues try to connect to the Mailbox Transport Delivery service for a destination mailbox database that can't be successfully reached. To specify a value, enter it as a time span: dd.hh:mm:ss where d = days, h = hours, m = minutes, and s = seconds. Valid input for this key

			is from 00:00:01 through 1.00:00:00.

Return to top

Configuration options for manual message retry

When a delivery queue is in the status of Retry, you can manually force an immediate connection attempt by using Queue Viewer in the Exchange toolbox or the **Retry-Queue** cmdlet in the Shell. The manual retry attempt overrides the next scheduled retry time. If the connection isn't successful, the retry interval timer is reset. The delivery queue must be in a status of Retry for this action to have any effect.

For more information, see the "Retry queues" section in Manage queues.

Return to top

Configuration options for delay DSN messages

After each message delivery failure, the Edge Transport server or the Transport service on the Mailbox server generates a delay delivery status notification (DSN) message and queues it for delivery to the sender of the undeliverable message. This delay DSN message is sent only after a specified delay notification timeout interval, and only if the failed message wasn't successfully delivered during that time. By default, the delay notification timeout interval is 4 hours. This delay prevents the sending of unnecessary delay DSN messages that may be caused by temporary message transmission failures. The sending of delay DSN notification messages can be selectively enabled or disabled for messages that originate inside or outside the Exchange organization.

The configuration options that are available for delay DSN notification messages are described in the following table.

Configuration options that are available for delay DSN notification messages

Parameter name	Default value	Location	Description
DelayNotificationTimeOut	`4:00:00`4 hours	**Set-TransportService** or server properties in the EAC	This parameter specifies how long the server waits before it sends a delay DSN message to the sender. The value of this parameter should always be greater than

			the value of the *TransientFailureRetryCount* parameter multiplied by the value of the *TransientFailureRetryInterval* parameter. To specify a value, enter it as a time span: dd.hh:mm:ss where d = days, h = hours, m = minutes, and s = seconds.
ExternalDelayDSNEnabled	`$true`	**Set-TransportConfig**	This parameter specifies whether delay DSN messages can be sent to message senders who are outside the Exchange organization. Valid input for this parameter is `$true` or `$false`.
InternalDelayDSNEnabled	`$true`	**Set-TransportConfig**	This parameter specifies whether delay DSN messages can be sent to message senders who are inside the Exchange organization. Valid input for this

			parameter is `$true` or `$false`.

Note:

On Exchange 2007 Hub Transport servers, all *ExternalDSN** and *InternalDSN** parameters are available on the **Set-TransportServer** cmdlet, not the **Set-TransportConfig** cmdlet. If you have any Exchange 2007 Hub Transport servers in your organization, you need to make changes to these values using the **Set-TransportServer** cmdlet on each Exchange 2007 Hub Transport server.

Return to top

Configuration options for message resubmission

Message resubmission sends undelivered messages back to the Submission queue to be reprocessed by the categorizer.

Automatic message resubmission

Undelivered messages are automatically resubmitted if the delivery queue is in the status of Retry and has been unable to successfully deliver any messages for a specified period of time. That period of time is controlled by the *MaxIdleTimeBeforeResubmit* key in the EdgeTransport.exe.config application configuration file. Only messages in delivery queues are candidates for automatic resubmission.

To specify a value, enter it as a time span: dd.hh:mm:ss where d = days, h = hours, m = minutes, and s = seconds.

The default value is `12:00:00` or 12 hours.

Manual Message Resubmission

You can manually resubmit messages that have the following status on a Hub Transport server or an Edge Transport server:

- Delivery queues that have the status of Retry. The messages in the queues must not be in the Suspended state.
- Messages that are in the Unreachable queue and aren't in the Suspended state.
- Messages that are in the poison message queue.

For more information about the poison message queue and the Unreachable queue, see "About the Poison Message Queue and the Unreachable Queue" in the topic Queues.

If you want to manually resubmit messages that are located in delivery queues or the Unreachable queue without waiting for the time that's specified by the *MaxIdleTimeBeforeResubmit* parameter to pass, you need to use the **Retry-Queue** cmdlet with the *Resubmit* parameter. To manually resubmit

messages that are located in the poison message queue, you can use Queue Viewer or the **Resume-Message** cmdlet to resume the message. For more information, see the "Resubmit messages in queues" section in Manage queues.

Another way that you can manually resubmit messages is to suspend the messages, export the messages to text files that have the .eml file name extension, and then copy the .eml files to the Replay directory on any Mailbox server or Edge Transport server. This resubmission method works for messages that are located in delivery queues or the Unreachable queue. Messages that are located in the poison message queue are already in the Suspended state. Messages that are located in the Submission queue can't be suspended or exported.

Note:
When you export messages from a queue, you don't remove the messages from the queue. After you export the messages and successfully resubmit them by using the Replay directory, you should remove the suspended messages to avoid duplicate message delivery.

For more information, see Export messages from queues.

Return to top

Configuration options for message expiration

The *message expiration timeout interval* specifies the maximum length of time that an Edge Transport server or a Hub Transport server tries to deliver a failed message. If the message can't be successfully delivered before the expiration timeout interval has passed, an NDR that contains the original message or the message headers is delivered to the sender.

Automatic message expiration

The message expiration timeout interval is controlled by the *MessageExpirationTimeOut* parameter in the **Set-TransportService** cmdlet or in the server properties in the EAC.

To specify a value, enter it as a time span: dd.hh:mm:ss where d = days, h = hours, m = minutes, and s = seconds.

The default value is `2.00:00:00` or 2 days. The valid input range for this parameter is from `00:00:05` through `90.00:00:00`.

Manual Message Expiration

Although you can't manually force messages to expire, you can manually remove messages from any queue, except the Submission queue, with or without an NDR.

For more information, see the "Remove messages from queues" section in Manage messages in queues.

Return to top

Configure message retry, resubmit, and expiration intervals

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-03-20*

In Microsoft Exchange Server 2013, you can configure message retry, resubmit, and expiration intervals in the Transport service on Mailbox servers and on Edge Transport servers. For descriptions of these settings, see Message retry, resubmit, and expiration intervals.

What do you need to know before you begin?

- Estimated time to complete each procedure: 10 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport service" and "Edge Transport server" entries in the Mail flow permissions topic.
- Any customized per-server settings you make in Exchange XML application configuration files, for example, web.config files on Client Access servers or the EdgeTransport.exe.config file on Mailbox servers, will be overwritten when you install an Exchange Cumulative Update (CU). Make sure that you save this information so you can easily re-configure your server after the install. You must re-configure these settings after you install an Exchange CU.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use EdgeTransport.exe.config to configure the queue glitch retry count, the queue glitch retry interval, the mailbox delivery queue retry interval, and the maximum idle time before resubmit interval.

To configure the queue glitch retry count, the queue glitch retry interval, the mailbox delivery queue retry interval, and the maximum idle time before resubmit interval you modify keys in the %ExchangeInstallPath%Bin\EdgeTransport.exe.config XML application configuration file on the Mailbox server or Edge Transport server. Changes you save to this file are applied after you restart the Microsoft Exchange Transport service. When you restart this service, mail flow on the server is temporarily interrupted.

1. In a Command prompt window on the Mailbox server or Edge Transport server, open the EdgeTransport.exe.config file in Notepad by running the following command:

```
Notepad %ExchangeInstallPath%Bin\EdgeTransport.exe.config
```

2. Locate the following keys in the `<appSettings>` section.

```
<add key="QueueGlitchRetryCount" value="<Integer>" />
<add key="QueueGlitchRetryInterval" value="<hh:mm:ss>" />
<add key="MailboxDeliveryQueueRetryInterval"
value="<hh:mm:ss>" />
<add key="MaxIdleTimeBeforeResubmit" value="<hh:mm:ss>" />
```

This example changes the queue glitch retry count to 6, the queue glitch retry interval to 30 seconds, the mailbox delivery queue retry interval to 3 minutes, and the maximum idle time before resubmit interval to 6 hours.

```
<add key="QueueGlitchRetryCount" value="6" />
<add key="QueueGlitchRetryInterval" value="00:00:30" />
<add key="MailboxDeliveryQueueRetryInterval"
value="00:03:00" />
<add key="MaxIdleTimeBeforeResubmit" value="6:00:00" />
```

3. When you are finished save and close the EdgeTransport.exe.config file.
4. Restart the Microsoft Exchange Transport service by running the following command:

```
net stop MSExchangeTransport && net start
MSExchangeTransport
```

Configure the transient failure retry attempts, the transient failure retry interval, and the outbound connection failure retry interval

The transient failure retry attempts specifies the number of connection attempts that are tried after the connection attempts controlled by the `QueueGlitchRetryCount` and `QueueGlitchRetryInterval`

keys have failed. The default number of transient failure retry attempts is 6. The valid input range for this parameter is from 0 through 15. If you set the number of transient failure retry attempts to 0, the next connection attempt is controlled by the *outbound connection failure retry interval*.

The transient failure retry interval specifies the interval between each connection attempt that's specified by the number of transient failure retry attempts. In the Transport service on a Mailbox server, the default transient failure retry interval is 5 minutes. On an Edge Transport server, the default transient failure retry interval is 10 minutes.

The outbound connection failure retry interval specifies the retry interval for outgoing connection attempts that have previously failed. The previously failed connection attempts are controlled by the transient failure retry attempts and the transient failure retry interval. The default value for the outbound connection failure retry interval in the Transport service on a Mailbox server is 10 minutes. The default value on an Edge Transport server is 30 minutes.

Use the EAC to configure the transient failure retry attempts, the transient failure retry interval, or the outbound connection failure retry interval

1. In the Exchange admin center (EAC), click **Servers** > **Servers**, select the server, click **Edit** , and then click **Transport limits**.
2. In the **Retries** section, enter a value for **Outbound connection failure retry interval (seconds)**, the **Transient failure retry interval (minutes)**, or the **Transient failure retry attempts**.
3. When you are finished, click **Save**.

Use the Shell to configure the transient failure retry attempts, the transient failure retry interval, and the outbound connection failure retry interval

Use the following syntax to configure the transient failure retry attempts, the transient failure retry interval, and the outbound connection failure retry interval in the Transport service on a Mailbox server or on an Edge Transport server.

```
Set-TransportService <ServerIdentity> -
TransientFailureRetryCount <Integer> -
TransientFailureRetryInterval <hh:mm:ss> -
OutboundConnectionFailureRetryInterval <dd.hh:mm:ss>
```

This example changes the following values on the Mailbox server named Mailbox01: on the Edge Transport server Exchange01.

- The number of transient failure retry attempts is set to 8.
- The transient failure retry interval is set to 1 minute.
- The outbound connection failure retry interval is set to 45 minutes.

```
Set-TransportService Mailbox01 -TransientFailureRetryCount
8 -TransientFailureRetryInterval 00:01:00 -
OutboundConnectionFailureRetryInterval 00:45:00
```

Note:
The *TransientFailureRetryCount* and *TransientFailureRetryInterval* parameters are also available on the **Set-FrontEndTransportService** cmdlet for the Front End Transport service on Client Access servers.

Configure the transient failure retry attempts, the transient failure retry interval, and the outbound connection failure retry interval

Use the EAC to configure the transient failure retry attempts, the transient failure retry interval, and the outbound connection failure retry interval

1. In the EAC, click **Servers** > **Servers**, select the server, click **Edit** , and then click **Transport limits**.
2. In the **Retries** section, enter a value for **Outbound connection failure retry interval (seconds)**, the **Transient failure retry interval (minutes)**, or the **Transient failure retry attempts**.
3. When you are finished, click **Save**.

Use the Shell to configure the transient failure retry attempts, the transient failure retry interval, and the outbound connection failure retry interval

Use the following syntax to configure the transient failure retry attempts, the transient failure retry interval, and the outbound connection failure retry interval in the Transport service on a Mailbox server or on an Edge Transport server.

```
Set-TransportService <ServerIdentity> -
TransientFailureRetryCount <Integer> -
TransientFailureRetryInterval <hh:mm:ss> -
OutboundConnectionFailureRetryInterval <dd.hh:mm:ss>
```

This example changes the following values on the Mailbox server named Mailbox01: on the Edge Transport server Exchange01.

- The number of transient failure retry attempts is set to 8.
- The transient failure retry interval is set to 1 minute.
- The outbound connection failure retry interval is set to 45 minutes.

```
Set-TransportService Mailbox01 -TransientFailureRetryCount
8 -TransientFailureRetryInterval 00:01:00 -
OutboundConnectionFailureRetryInterval 00:45:00
```

Note:
The *TransientFailureRetryCount* and *TransientFailureRetryInterval* parameters are also available on the **Set-FrontEndTransportService** cmdlet for the Front End Transport service

on Client Access servers.

Use the Shell to configure the message retry interval

By default, the message retry interval is `00:01:00` or 1 minute. We recommend that you don't modify the default value unless Microsoft Customer Service and Support advises you to do this.

Use the following syntax to set the message retry interval.

```
Set-TransportService <ServerIdentity> -MessageRetryInterval
<dd.hh:mm:ss>
```

This example changes the message retry interval to 2 minutes on the Mailbox server named Mailbox01.

```
Set-TransportService Mailbox01 -MessageRetryInterval
00:02:00
```

Configure the delay DSN timeout settings

You can use the EAC or the Shell to configure the delay DSN notification timeout interval. This setting is applied to the local transport server only. You can only use the Shell to enable or disable the sending of delay DSN messages to internal and external senders. These setting are applied to all transport servers in your organization.

Note:

On Exchange 2007 Hub Transport servers, all *ExternalDSN** and *InternalDSN** parameters are available on the **Set-TransportServer** cmdlet, not the **Set-TransportConfig** cmdlet. If you have any Exchange 2007 Hub Transport servers in your organization, you need to make changes to these values using the **Set-TransportServer** cmdlet on each Exchange 2007 Hub Transport server.

Use the EAC to configure the delay DSN message notification timeout interval

1. In the EAC, click **Servers** > **Servers**, select the server, click **Edit** , and then click **Transport limits**.
2. In the **Notifications** section, enter a value for **Notify sender when message is delayed after (hours)**.
3. When you are finished, click **Save**.

Use the Shell to configure the delay DSN message notification timeout interval

Use the following syntax to set the message retry interval.

```
Set-TransportService <ServerIdentity> -
DelayNotificationTimeout <dd.hh:mm:ss>
```

This example changes the delay DSN message notification timeout interval to 6 hours on the

Mailbox server named Mailbox01.

```
Set-TransportService Mailbox01 -DelayNotificationTimeout
06:00:00
```

Use the Shell to enable or disable the sending of delay DSN notifications to external or internal message senders

Use the following syntax to configure the delay DSN notification settings.

```
Set-TransportConfig -ExternalDelayDSNEnabled <$true |
$false> -InternalDelayDSNEnabled <$true |$false>
```

This example prevents the sending of delay DSN notification messages to external senders.

```
Set-TransportConfig -ExternalDelayDSNEnabled $false
```

This example prevents the sending of delay DSN notification messages to internal senders.

```
Set-TransportConfig -InternalDelayDSNEnabled $false
```

Configure the message expiration timeout interval

Use the EAC to configure the message expiration timeout interval

1. In the EAC, click **Servers** > **Servers**, select the server, click **Edit** , and then click **Transport limits**.
2. In the **Message expiration** section, enter a value for **Maximum time since submission (days)**.
3. When you are finished, click **Save**.

Use the Shell to configure the message expiration timeout interval

To configure the message expiration timeout interval, use the following syntax.

```
Set-TransportService <ServerIdentity> -
MessageExpirationTimeout <dd.hh:mm:ss>
```

This example changes the message expiration timeout interval to 4 days on the Exchange server named Mailbox01.

```
Set-TransportService Mailbox01 -MessageExpirationTimeout
4.00:00:00
```

Priority queuing

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-01-17*

Priority queuing is a feature of Microsoft Exchange Server 2013 that enables the sender-defined priority of a message to influence the processing of the message by the Transport service on the Mailbox server.

The message priority is assigned by the sender in Microsoft Outlook when the sender creates and sends the message. The sender can set any of the following message priority values in Outlook:

- Low importance
- Normal importance
- High importance

The default priority for a message created in Outlook or Outlook Web App is Normal priority. The message priority is stored in the `X-Priority` header field in the message header.

Every message sent or received in an Exchange 2013 organization must be categorized by the Transport service on a Mailbox server before it can be routed and delivered. The categorizer in the Transport service on a Mailbox server picks up one message at a time from the Submission queue and performs recipient resolution, routing resolution, and content conversion on the message before putting the message in a delivery queue. For more information, see Mail flow.

Delivery queues are dynamically created based on the destination of a message. For more information, see Queues.

All messages that have the same destination are put in the same delivery queue. Priority queuing affects the transmission of messages from a delivery queue to the destination messaging server. When priority queuing is enabled, High priority messages are transmitted to their destinations before Normal priority messages, and Normal priority messages are transmitted to their destinations before Low priority messages. The prioritized delivery of messages based on the message priority can help you define specific service level agreement (SLA) requirements for message delivery times.

Options for configuring priority queuing

Support for priority queuing is controlled by keys in the `%ExchangeInstallPath%bin\EdgeTransport.exe.config` XML application configuration file. For instructions on how to configure priority queuing, see Enable and configure priority queuing.

The following table explains each key in more detail.

Priority queuing keys in the EdgeTransport.exe.config file

Key	Default value	Description
PriorityQueuingEnabled	`false`	This key enables or disables

		priority queuing in the Transport service on the Mailbox server. Valid input for this key is `true` or `false`. When this key is `false`, priority queuing is disabled, and all the priority queuing message limits that exist in the EdgeTransport.exe.config file are ignored.
MaxHighPriorityMessageSize	`250KB`	This key specifies the maximum allowed size of a High priority message. If a High priority message is larger than the value specified by this key, the message is automatically downgraded from High priority to Normal priority. The value of this key should be significantly less than the value of the *MaxSendMessageSize* parameter on the **Set-TransportConfig** cmdlet. The default value of this parameter is `10 MB`. The difference in these two values helps ensure consistent and predictable delivery times for High priority messages. When you enter a value, qualify the value with one of the following units: • KB (kilobytes)

		• MB (megabytes)
LowPriorityDelayNotificationTimeout *NormalPriorityDelayNotificationTimeout* *HighPriorityDelayNotificationTimeout*	**Low** `8:00:00` (8 hours) **Normal** `4:00:00` (4 hours) **High** `00:30:00` (30 minutes)	These keys specify the timeout interval for delay delivery status notification (DSN) messages based on the message priority. After each message delivery failure, the Transport service generates a delay DSN message and queues it for delivery to the sender of the undeliverable message. This delay DSN message is sent only after a specified delay notification time-out interval, and only if the failed message wasn't successfully delivered during that time. This delay prevents the sending of unnecessary delay DSN messages that may be caused by temporary message transmission failures. To specify a value, enter it as a time span: dd.hh:mm:ss where d = days, h = hours, m = minutes, and s = seconds.
LowPriorityMessageExpirationTimeout *NormalPriorityMessageExpirationTimeout* *HighPriorityMessageExpirationTimeout*	**Low** `2.00:00:00` (2 days) **Normal** `2.00:00:00` (2 days) **High** `8:00:00` (8 hours)	These keys specify the maximum length of time that the Transport service tries to deliver a failed message. If the message can't be successfully delivered before the expiration time-out interval has passed, a non-delivery report (NDR) that contains the original

		message or the message headers is delivered to the sender. To specify a value, enter it as a time span: dd.hh:mm:ss where d = days, h = hours, m = minutes, and s = seconds.
MaxPerDomainLowPriorityConnections *MaxPerDomainNormalPriorityConnections* *MaxPerDomainHighPriorityConnections*	**Low** 2 **Normal** 15 **High** 3	These keys specify the maximum number of connections that the Transport service can have open to any single remote domain. The outgoing connections to remote domains occur by using the delivery queues and Send connectors that exist on the Mailbox server. The sum these three keys should be less than or equal to the value of the *MaxPerDomainOutboundConnections* parameter on the **Set-TransportService** cmdlet. The default value of this parameter is 20.

How priority queuing affects other message limits on Mailbox servers

All messages that pass through the Transport service are subject to a variety of message retry, resubmit, and expiration limits. For more information, see Message size limits.

Some message limits available in the **Set-TransportService** cmdlet have corresponding priority queuing message limits available in the EdgeTransport.exe.config application configuration file. The following table shows these corresponding message limits.

Message limits in the Set-TransportService cmdlet that correspond to priority queuing message limits in the EdgeTransport.exe.config file

Source	Parameter or key	Default value
Set-TransportService	*DelayNotificationTimeOut*	`4:00:00` (4 hours)
EdgeTransport.exe.config	*NormalPriorityDelayNotificationTimeout*	`4:00:00` (4 hours)
Set-TransportService	*MessageExpirationTimeOut*	`2.00:00:00` (2 days)
EdgeTransport.exe.config	*NormalPriorityMessageExpirationTimeout*	`2.00:00:00` (2 days)

When priority queuing is disabled, all the priority queuing message limits that exist in the EdgeTransport.exe.config configuration file are ignored. All the message limits on the **Set-TransportService** cmdlet apply to all messages that travel through the Transport service on the Mailbox server.

When priority queuing is enabled, the priority queuing message limits in the EdgeTransport.exe.config configuration file override the corresponding message limits in the **Set-TransportService** cmdlet. All other message limits in the **Set-TransportService** cmdlet still apply to Low priority, Normal priority, and High priority messages that travel through the Transport service on the Mailbox server.

User Settings for Priority Queuing

The **Set-Mailbox** cmdlet has the *DowngradeHighPriorityMessagesEnabled* parameter. The default value is `$false`. When this parameter is set to `$true`, any High priority messages sent from the mailbox are automatically downgraded to Normal priority.

Enable and configure priority queuing

Mail flow > Queues > Priority queuing >

Topic Last Modified: *2013-02-22*

Priority queuing is a feature of Microsoft Exchange Server 2013 that enables the message priority that's configured by the sender in Microsoft Outlook or Outlook Web Access to influence the processing of the message by the Transport service on the Mailbox server. When priority queuing is enabled, High priority messages are transmitted to their destinations before Normal priority

messages, and Normal priority messages are transmitted to their destinations before Low priority messages. For more information, see Priority queuing.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- Exchange permissions don't apply to the procedures in this topic. These procedures are performed in the operating system of the Exchange Server.
- Changes you save to the EdgeTransport.exe.config application configuration file are applied after you restart the Microsoft Exchange Transport service.
- When you restart the Microsoft Exchange Transport service, mail flow on the server is temporarily interrupted.
- Any customized per-server settings you make in Exchange XML application configuration files, for example, web.config files on Client Access servers or the EdgeTransport.exe.config file on Mailbox servers, will be overwritten when you install an Exchange Cumulative Update (CU). Make sure that you save this information so you can easily re-configure your server after the install. You must re-configure these settings after you install an Exchange CU.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Command Prompt to enable and configure priority queuing in the EdgeTransport.exe.config file

1. In a Command prompt window, open the EdgeTransport.exe.config application configuration file in Notepad by running the following command:

```
Notepad %ExchangeInstallPath%Bin\EdgeTransport.exe.config
```

2. Find the following keys in the `<appSettings>` section.

```
<add key="PriorityQueuingEnabled" value="false" />
<add key="MaxPerDomainHighPriorityConnections" value="3" />
<add key="MaxPerDomainNormalPriorityConnections" value="15"
/>
<add key="MaxPerDomainLowPriorityConnections" value="2" />
<add key="HighPriorityMessageExpirationTimeout"
value="8:00:00" />
<add key="NormalPriorityMessageExpirationTimeout"
```

```
value="2.00:00:00" />
<add key="LowPriorityMessageExpirationTimeout"
value="2.00:00:00" />
<add key="HighPriorityDelayNotificationTimeout"
value="00:30:00" />
<add key="NormalPriorityDelayNotificationTimeout"
value="4:00:00" />
<add key="LowPriorityDelayNotificationTimeout"
value="8:00:00" />
<add key="MaxHighPriorityMessageSize" value="250KB" />
```

To enable priority queuing in the Transport service on the Mailbox server, use the following value:

```
<add key="PriorityQueuingEnabled" value="true" />
```

Configure the remaining priority queuing values, or leave them at their default values.

3. When you are finished, save and close the EdgeTransport.exe.config file.
4. Restart the Microsoft Exchange Transport service by running the following command:

```
net stop MSExchangeTransport && net start
MSExchangeTransport
```

How do you know this worked?

To verify that you have successfully enabled and configured priority queuing, do the following:

1. Verify the **PriorityQueueinEnabled** key in the EdgeTransport.exe.config file has the value `"true"`.
2. Use Outlook to create a high priority test message that's larger than the value specified by the **MaxHighPriorityMessageSize** key, and verify the message arrives as a normal priority message.
3. Try to verify that higher priority messages arrive before lower priority messages sent to the same recipient or destination. You can try to use multiple mailboxes to send multiple, similar test messages with different priority values to the same recipient simultaneously.

Change the location of the queue database

Exchange Server 2013 > Mail flow > Queues >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-22*

A *queue* is a temporary holding location for messages that are waiting to enter the next stage of processing. Each queue represents a logical set of messages that a transport server processes in a specific order.

Like the previous versions of Exchange, Microsoft Exchange Server 2013 uses an Extensible Storage Engine (ESE) database for queue message storage. All the different queues are stored in a single ESE database. Queues exist only on Mailbox servers or on Edge Transport servers.

The location of the queue database and the queue database transaction logs is controlled by keys in the `%ExchangeInstallPath%Bin\EdgeTransport.exe.config` XML application configuration file. This file is associated with the Microsoft Exchange Transport service. The following table explains each key in more detail.

Key	Description
QueueDatabasePath	This key specifies the location of the queue database files. The files are: • Mail.que • Trn.chk The default location is `%ExchangeInstallPath%TransportRoles\data\Queue`.
QueueDatabaseLoggingPath	This key specifies the location of the queue database transaction log files. The files are: • Trn.log • Trntmp.log • Trn*nnn*.log • Trnres00001.jrs • Trnres00002.jrs • Temp.edb Note that Temp.edb is used to verify the queue database schema when the Microsoft Exchange Transport service starts. Although Temp.edb isn't a transaction log file, it's kept in the same location as the transaction log files. The default location is `%ExchangeInstallPath%TransportRoles\data\Queue`.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes.
- Exchange permissions don't apply to the procedures in this topic. These procedures are performed in the operating system of the Exchange Server.
- When you stop or restart the Microsoft Exchange Transport service, mail flow on the server is interrupted.
- When you change the location of the queue database or the transaction logs, the existing queue database and transaction log files aren't moved. A new queue database and new transaction logs are created at the new location. The existing files are left at the old location. However, they're no longer used. If you want to reuse the existing queue database or transaction log files at the new location, you must move the existing files to the new location after the Microsoft Exchange Transport service is stopped, but before the service is started.
- If the target folder for the queue database or transaction logs doesn't exist, it will be created for you if the parent folder has the following permissions applied to it:
  - Network Service: Full Control
  - System: Full Control
  - Administrators: Full Control
- Any customized per-server settings you make in Exchange XML application configuration files, for example, web.config files on Client Access servers or the EdgeTransport.exe.config file on Mailbox servers, will be overwritten when you install an Exchange Cumulative Update (CU). Make sure that you save this information so you can easily re-configure your server after the install. You must re-configure these settings after you install an Exchange CU.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

What do you want to do?

Use the Command Prompt to create a new queue database and transaction logs in a new location

1. Create the folders where you want to keep the queue database and transaction logs. Make sure that the correct permissions are applied to the folders.
2. In a Command prompt window, open the EdgeTransport.exe.config file in Notepad by running the following command:

```
Notepad %ExchangeInstallPath%Bin\EdgeTransport.exe.config
```

3. Modify the following keys in the `<appSettings>` section.

```
<add key="QueueDatabasePath" value="<LocalPath>" />
```

```
<add key="QueueDatabaseLoggingPath" value="<LocalPath>" />
```

For example, to create a new queue database in D:\Queue\QueueDB and new transaction logs in D:\Queue\QueueLogs, use the following values:

```
<add key="QueueDatabasePath" value="D:\Queue\QueueDB" />
<add key="QueueDatabaseLoggingPath" value="D:\Queue
\QueueLogs" />
```

4. When you are finished, save and close the EdgeTransport.exe.config file.
5. Restart the Microsoft Exchange Transport service by running the following command:

```
net stop MSExchangeTransport && net start
MSExchangeTransport
```

How do you know this worked?

To verify that you successfully created a new queue database and new transaction logs at a new location, do the following:

1. Verify the new database files Mail.que and Trn.chk exist at the new location.
2. Verify the new transaction log files Trn.log, Trntmp.log, Trnres00001.jrs, Trnres00002.jrs, and Temp.edb files exist at the new location.
3. If you can delete the old queue database and transaction log files from the old location after the Microsoft Exchange Transport service has started, those files are no longer being used.

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Return to top

Use the Command Prompt to move the existing queue database and transaction logs to a new location

Only disaster recovery scenarios where the Microsoft Exchange Transport service wasn't shut down correctly or a hard disk drive failure would require that you restore and relocate an existing queue database and its existing transaction logs.

Under ordinary circumstances, you shouldn't have to reuse existing transaction logs. An ordinary shutdown of the Microsoft Exchange Transport service writes all uncommitted transaction log entries to the queue database. And, circular logging is used, so transaction logs that contain previously committed database changes aren't preserved.

Use the following procedure to move the existing queue database and transaction logs at a new location:

1. Create the folders where you want to keep the queue database and transaction logs. Make sure that the correct permissions are applied to the folders.

2. In a Command prompt window, open the EdgeTransport.exe.config file in Notepad by running the following command:

```
Notepad %ExchangeInstallPath%Bin\EdgeTransport.exe.config
```

3. Modify the following keys in the `<appSettings>` section:

```
<add key="QueueDatabasePath" value="<LocalPath>" />
<add key="QueueDatabaseLoggingPath" value="<LocalPath>" />
```

For example, to change the location of the queue database to D:\Queue\QueueDB and the transaction logs to D:\Queue\QueueLogs, use the following values:

```
<add key="QueueDatabasePath" value="D:\Queue\QueueDB" />
<add key="QueueDatabaseLoggingPath" value="D:\Queue
\QueueLogs" />
```

4. When you are finished, save and close the EdgeTransport.exe.config file.
5. Stop the Microsoft Exchange Transport service by running the following command:

```
net stop MSExchangeTransport
```

6. Move the existing database files Mail.que and Trn.chk from the original location to the new location.
7. Move the existing transaction log files Trn.log, Trntmp.log, Trn*nnnnn*.log, Trnres00001.jrs, Trnres00002.jrs, and Temp.edb from the old location to the new location.
8. Start the Microsoft Exchange Transport service by running the following command:

```
net start MSExchangeTransport
```

How do you know this worked?

To verify that you successfully moved the existing queue database and transaction logs to the new location, do the following:

1. Verify the queue database files Mail.que and Trn.chk exist at the new location.
2. Verify the transaction log files Trn.log, Trntmp.log, Trnres00001.jrs, Trnres00002.jrs, and Temp.edb files exist at the new location.
3. Verify there are no queue database or transaction log files at the original location.

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Pickup directory and Replay directory

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-10*

By default, the Pickup and Replay directories exist on every Microsoft Exchange Server 2013 Mailbox server or Edge Transport server. Correctly formatted email message files that you copy to the Pickup or Replay directories are submitted for delivery. The Pickup directory is used by administrators for mail flow testing, or by applications that must create and submit their own messages. The Replay directory receives messages from foreign gateway servers and can also be used to resubmit messages that administrators export from the queues of Exchange servers.

Contents

Anatomy of an email message file

A standard SMTP email message consists of a *message envelope* and message content. The message envelope contains information required for transmitting and delivering the message. The message content contains message header fields (collectively called the *message header*) and the message body. The message envelope is described in RFC 2821, and the message header is described in RFC 2822.

When a sender composes an email message and submits it for delivery, the message contains the basic information required to comply with SMTP standards, such as a sender, a recipient, the date and time that the message was composed, an optional subject line, and an optional message body. This information is contained in the message itself and, by definition, is contained in the message header.

The sender's messaging server generates a message envelope for the message by using the sender and recipient information found in the message header and transmits the message to the Internet for delivery to the recipient's messaging server. Recipients never see the message envelope, because it's generated by the message transmission process and isn't actually part of the message.

Each server involved in the transmission of the message may insert message header fields related to the server's role in delivering the message or other application-specific message header fields into the message header. When the recipient opens the message by using an email client, the email client displays some of the more relevant information from the message header, such as the sender, the recipients, and the subject together with the message body.

Return to top

How the Pickup and Replay directories process messages

In Exchange 2013, the default location of the Pickup directory is `%ExchangeInstallPath%TransportRoles\Pickup`. The default location of the Replay directory is `%ExchangeInstallPath%TransportRoles\Replay`. A correctly formatted .eml message file copied to the Pickup or Replay directory is processed for submission in the following steps:

1. The Pickup and Replay directories are checked for new message files every five seconds. You can't modify this polling interval. You can adjust the rate of message file processing by using the *PickupDirectoryMaxMessagesPerMinute* parameter on the **Set-TransportService** cmdlet. This parameter affects the Pickup directory and the Replay directory. The default value is 100 messages per minute. Files that can't be opened are left in the Pickup directory and are reevaluated at the next poll.
2. Limits put on message files in the Pickup directory, such as the maximum header size and the maximum number of recipients, are checked. By default, the maximum header size is 64 kilobytes (KB), and the maximum number of recipients is 100. You change these limits by using the **Set-TransportService** cmdlet. These settings affect the Pickup directory only.
3. The file is renamed from <*filename*>.eml to <*filename*>.tmp. If the <*filename*>.tmp file already exists, the file is renamed as <*filename*><*datetime*>.tmp. If the file renaming fails, an event log error is generated, and the pickup process proceeds to the next file.
4. After the .tmp file is successfully converted into an email message, a **delete on close** command is issued to the .tmp file. The .tmp file appears to remain in the Pickup directory, but the file can't be opened.
5. After the message is successfully queued for delivery, a **close** command is issued, and the .tmp file is deleted from the Pickup directory. If the deletion fails, an event log error is generated. If the Microsoft Exchange Transport service is restarted when there are .tmp files in the Pickup directory, all .tmp files are renamed as .eml files and are reprocessed. This could lead to duplicate message transmission.

Return to top

Pickup directory message file requirements

A message file copied to the Pickup directory must meet the following requirements for successful delivery:

- The message file must be a text file that complies with the basic SMTP message format. MIME

message header fields and content are supported.

- The message file must have an .eml file name extension.
- At least one email address must exist in the `Sender` or `From` message header fields in the message header. If a single email address exists in both the `Sender` and `From` fields, the email address in the `From` field is used as the originator of the message in the message envelope.
- Only one email address can exist in the `Sender` field. Multiple email addresses aren't allowed. The `Sender` field is optional if only one email address exists in the `From` field.
- Multiple email addresses are allowed in the `From` field, but a single email address must also exist in the `Sender` field. The address in the `Sender` field is then used as the originator of the message in the message envelope.
- At least one email address must exist in the `To`, `Cc`, or `Bcc` fields.
- A blank line must exist between the message header and the message body.

This example shows a plain text message that uses acceptable formatting for the Pickup directory.

```
To: mary@contoso.com
From: bob@fabrikam.com
Subject: Message subject
This is the body of the message.
```

MIME content is also supported in Pickup directory message files. MIME defines a broad range of message content that includes languages that can't be represented in 7-bit ASCII text, HTML, and other multimedia content. A complete description of MIME and its requirements is beyond the scope of this topic. This example shows a simple MIME message that uses acceptable formatting for the Pickup directory.

```
To: mary@contoso.com
From: bob@fabrikam.com
Subject: Message subject
MIME-Version: 1.0
Content-Type: text/html; charset="iso-8859-1"
Content-Transfer-Encoding: 7bit
<HTML><BODY>
<TABLE>
<TR><TD>cell 1</TD><TD>cell 2</TD></TR>
<TR><TD>cell 3</TD><TD>cell 4</TD></TR>
</TABLE>
</BODY></HTML>
```

Return to top

Pickup directory message header modifications

The Pickup directory removes any of the following message header fields from the message header:

- `Received`
- `Resent-*`
- `Bcc`

Note:

Any email addresses found in the optional `Bcc` message header fields in the message header are correctly processed. After the `Bcc` recipients are promoted to invisible message envelope recipients, they are removed from the message header to protect their identity. If a message contains only `Bcc` recipients, the value of **Undisclosed Recipients** is added to the `To` field in the message header.

The Pickup directory adds its own `Received` header field to a message as part of the message submission process. The `Received` header field is applied in the following format.

```
Received: from localhost by Pickup with Microsoft SMTP
Server id <ExchangeServerVersion><datetime>
```

The Pickup directory modifies the following message header fields if they're missing or malformed:

- **Message-Id** If the `Message-Id` field is missing or empty, the Pickup directory adds a Message-Id field by using the format <*GUID*>@<*defaultdomain*>.
- **Date** If the `Date` field is missing or malformed, the Pickup directory adds the date and time of message processing by the Pickup directory.

Return to top

Replay directory message file requirements

The Replay directory is used to resubmit exported Exchange messages and to receive messages from foreign gateway servers. These messages are already formatted for the Replay directory. There is little or no need for administrators or applications to compose and submit new message files by using the Replay directory. The Pickup directory should be used to create and submit new message files.

The Replay directory messages make extensive use of *X-Headers*. X-Headers are user-defined, unofficial message header fields that exist in the message header. X-Headers aren't specifically mentioned in RFC 2822, but the use of an undefined message header field starting with "X-" has become an accepted way to add unofficial message header fields to a message. The Exchange-specific X-Headers used in the message files in the Replay directory can actually set delivery information that normally exists in the message envelope. This feature is required to preserve original message information when you use the Replay directory to process exported messages from another Exchange server.

A message file copied to the Replay directory must meet the following requirements for successful delivery:

- The message file must be a text file that complies with the basic SMTP message format. MIME message header fields and content are supported.
- The message file must have an .eml file name extension.
- X-Headers must occur before all regular header fields.
- A blank line must exist between the header fields and the message body.

The X-Headers described in the following list are required by messages in the Replay directory:

- **X-Sender** This X-Header replaces the `From` message header field requirement in a typical SMTP message. One `X-Sender` field that contains one email address must exist. The Replay directory ignores the `From` message header field if it's present, although the recipient's email client displays the value of the `From` message header field as the sender of the message. Other parameters usually exist in the `X-Sender` field, as shown in the following example.

```
X-Sender: <bob@fabrikam.com> BODY=7bit RET=HDRS
ENVID=12345ABCD auth=<someAuth>
```

Note:

These parameters are message envelope values that are ordinarily generated by the sending server. You may see parameters similar to this in exported message files.
`RET` specifies whether the whole message or only the headers should be returned to the sender if the message can't be delivered. `RET` can have a value of `HDRS` or `FULL`. `ENVID` is a message envelope identifier. `BODY` specifies the text encoding of the message. `auth` specifies an authentication mechanism to the messaging server as described in RFC 2554.

- **X-Receiver** This X-Header replaces the `To` message header field requirement in a typical SMTP message. At least one `X-Receiver` field that contains one email address must exist. Multiple `X-Receiver` fields are allowed for multiple recipients. The Replay directory ignores the `To` message header fields if they're present, although the recipient's email client displays the values of the `To` message header fields as the recipients of the message. Other optional parameters may exist in the `X-Receiver` fields, as shown in the following example.

```
X-Receiver: <mary@contoso.com> NOTIFY=NEVER
ORcpt=mary@contoso.com
```

Note:

These parameters are message envelope values that are ordinarily generated by the sending server. You may see parameters similar to this in exported message files. These parameters are related to delivery status notification (DSN) messages as described in RFC 1891.
`NOTIFY` can have a value of `NEVER`, `DELAY`, or `FAILURE`. `ORcpt` preserves the original recipient of the message.

The X-Headers described in the following list are optional for message files in the Replay directory:

- **X-CreatedBy** Used for header firewall functionality. If this X-Header exists, it must not be blank. If the `X-CreatedBy` field doesn't exist, it's added with a value of **Unspecified**. Typically, the value of this field is **MSExchange15**, but it also may contain the non-SMTP address space type set on a Send connector, such as **Notes**.

- **X-EndOfInjectedXHeaders** Size in bytes of all the X-Headers present. This X-Header may be used as a marker to indicate the last X-Header before the regular message header fields start.
- **X-ExtendedMessageProps** Extended message properties for the message.
- **X-HeloDomain** HELO/EHLO domain string presented during the initial SMTP protocol conversation.
- **X-Source** Used by Queue Viewer under the **MessageSourceName** column. If the value of this X-Header isn't specified, the value of **Replay** is used. Other possible values for this X-Header are **Smtp Receive Connector** and **Smtp Send Connector**.
- **X-SourceIPAddress** IP address of the sending server. This field is `0.0.0.0` if no IP address is specified.

This example shows a plain text message that uses acceptable formatting for the Replay directory.

```
X-Receiver: <mary@contoso.com> NOTIFY=NEVER
ORcpt=mary@contoso.com
X-Sender: <bob@fabrikam.com> BODY=7bit ENVID=12345AB
auth=<someAuth>
Subject: Optional message subject
This is the body of the message.
```

MIME content is also supported in Replay directory message files. MIME defines a broad range of message content that includes languages that can't be represented in 7-bit ASCII text, HTML, and other multimedia content. A complete description of MIME and its requirements is beyond the scope of this topic. This example shows a simple MIME message that uses acceptable formatting for the Replay directory.

```
X-Receiver: <mary@contoso.com> NOTIFY=NEVER
ORcpt=mary@contoso.com
X-Sender: <bob@fabrikam.com> BODY=7bit ENVID=12345ABCD
auth=<someAuth>
To: mary@contoso.com
From: bob@fabrikam.com
Subject: Optional message subject
MIME-Version: 1.0
Content-Type: text/html; charset="iso-8859-1"
Content-Transfer-Encoding: 7bit
<HTML><BODY>
<TABLE>
<TR><TD>cell 1</TD><TD>cell 2</TD></TR>
<TR><TD>cell 3</TD><TD>cell 4</TD></TR>
</TABLE>
</BODY></HTML>
```

Return to top

Replay directory message header modifications

The Replay directory deletes the `Bcc` message header field from the message file.

The Replay directory adds its own `Received` message header field to a message as part of the message submission process. The Received message header field is applied in the following format.

```
Received: from <ReceivingServerName> by Replay with
<ExchangeServerVersion><DateTime>
```

The Replay directory modifies the following message header fields in the message header:

- **Message-ID** If this message header field is missing or empty, the Replay directory adds a Message-ID message header field by using the format <*GUID*>@<*defaultdomain*>.
- **Date** If this message header field is missing or malformed, the Replay directory adds the Date message header field using the date and time of message processing by the Replay directory.

Return to top

Failures in Pickup and Replay directory message processing

A message file copied to the Pickup or Replay directories may not be successfully queued for delivery. The following categories of message submission failure can occur:

- **Delivery failures** A correctly formatted message file together with a valid sender that can't be successfully submitted for delivery generates a non-delivery report (NDR). Malformed content or Pickup directory message restriction violations could also cause an NDR. When an NDR is generated during message processing, the original message file is attached to the NDR message, and the message file is deleted from the Pickup directory or the Replay directory.

Note:

A correctly formatted message submitted into the transport pipeline may later experience a delivery failure and be returned to the sender with an NDR. This kind of failure may be caused by transmission issues unrelated to the Pickup or Replay directories, such as messaging server failures or routing failures along the delivery path of the message.

- **Badmail** A message classified as *badmail* has serious problems that prevent the Pickup or Replay directories from submitting the message for delivery. The other condition that causes badmail is when the message is formatted correctly, but the recipients aren't valid, and an NDR message can't be sent to the sender because the sender isn't valid.

Message files determined to be badmail are left in the Pickup or Replay directories and are renamed from <*filename*>.eml to <*filename*>.bad. If the <*filename*>.bad file already exists, the file

is renamed to <*filename*><*datetime*>.bad. If badmail exists in the Pickup or Replay directories, an event log error is generated, but the same badmail messages don't generate repeated event log errors.

Note:

Always compose and save message files in a different location before you copy them into the Pickup directory for delivery. The Pickup directory polls for new messages every five seconds. Therefore, if you try to compose and save the message files in the Pickup directory itself, the Pickup directory may try to process the message files before you finish composing them.

Return to top

Security considerations for the Pickup and Replay directories

The following list describes security concerns that are common to the Pickup directory and the Replay directory:

- Any security checks configured on a Receive connector, such as anti-spam, anti-malware, sender filtering, or recipient filtering actions, aren't performed on messages submitted through the Pickup directory or the Replay directory.
- A compromised Pickup directory or Replay directory can act as an open relay. This enables messages to be resubmitted or *relayed* by using a different server to mask the true source of the messages.

The following list describes additional security concerns that apply to the Replay directory:

- The X-Headers used by the Replay directory allow for the manual creation of the message envelope. The information in the `X-Sender` and `X-Receiver` fields can be completely different from the `To` or `From` message header fields displayed by email clients. Such an impersonation of a sender and a domain is frequently called *spoofing*. A *spoofed mail* is an email message that has a sending address that was modified to appear as if it originates from a sender other than the actual sender of the message.
- If the `X-CreatedBy` field has the value of **MSExchange15**, the destination is considered trustworthy, and header firewall isn't applied. *Header firewall* is a way for Exchange to preserve X-Headers in messages transmitted between trusted Exchange servers or to remove potentially revealing X-Headers from messages transmitted to untrusted destinations outside the Exchange organization. These X-Headers can be used to share Exchange information such as spam confidence level (SCL), message signing, or encryption between authorized Exchange servers. Revealing this information to unauthorized sources could pose a potential security risk. For more information about header firewall, see Understanding Header Firewall.

Tighter security should be applied to the Replay directory because of the additional security risks associated with the Replay directory. Users or applications that must generate and submit messages can be granted access to the Pickup directory, but they shouldn't require access to the Replay directory.

Both the Pickup directory and the Replay directory are enabled by default on all Mailbox servers and Edge Transport servers. If the Pickup directory or the Replay directory isn't required on a specific Mailbox server or Edge Transport server in your organization, you can disable the Pickup directory or the Replay directory on that server by setting the Pickup directory path or Replay directory path to the value `$null`. For more information, see Configure the Pickup directory and the Replay directory.

Return to top

Permissions for the Pickup and Replay directories

The following permissions are required on the Pickup and Replay directories:

- Administrator: Full Control
- System: Full Control
- Network Service: Read, Write, and Delete Subfolders and Files

By default, the Microsoft Exchange Transport service uses the security credentials of the Network Service user account to manage the location and permissions of the Pickup and Replay directories. The Network Service account requires these permissions on the Pickup directory so that .eml files can be opened, renamed to .tmp and deleted, or renamed to .bad if the message is classified as badmail.

You can move the location of these directories by using the *PickupDirectoryPath* and *ReplayDirectoryPath* parameters on the **Set-TransportService** cmdlet. Successfully changing the location of the Pickup directory depends on the rights granted to the Network Service account at the new directory locations, and whether the new directories already exist. If the directory doesn't exist, and the Network Service account has the rights required to create folders and apply permissions at the new location, the directory is created, and the correct permissions are applied to it. If the new directory already exists, the existing folder permissions aren't checked. Whenever you move the directory locations by using the *PickupDirectoryPath* or *ReplayDirectoryPath* parameter with the **Set-TransportService** cmdlet, always verify that the new directory exists and that the new directory has the correct permissions applied to it.

Return to top

Configure the Pickup directory and the Replay directory

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-03-04*

The Pickup and replay directories are used by the Transport service on Mailbox servers and Edge Transport servers to insert message files directly into the transport pipeline. Correctly formatted email message files that you copy to the Pickup or Replay directories are submitted for delivery. The Pickup directory is used by administrators for mail flow testing, or by applications that must create and submit their own messages. The Replay directory receives messages from non-SMTP foreign gateway servers and resubmits messages that you exported from the queues of Microsoft Exchange servers.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport service" entry in the Mail flow permissions topic.
- You can only use the Shell to perform this procedure.
- The value of the *PickupDirectoryMaxMessagesPerMinute* parameter on the **Set-TransportService** cmdlet is used by the Pickup and Replay directories.
- Changing the location of the Pickup or Replay directories doesn't copy any existing message files from the old location to the new location. The new Pickup or Replay directory location is active almost immediately after the configuration change, but any existing message files are left in the old location.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What Do You Want to Do?

Use the Shell to configure the Pickup directory

To configure the Pickup directory, use the following syntax.

```
Set-TransportService <ServerIdentity> -PickupDirectoryPath
<LocalFilePath> -PickupDirectoryMaxHeaderSize <Size> -
PickupDirectoryMaxRecipientsPerMessage <Integer> -
PickupDirectoryMaxMessagesPerMinute <Integer>
```

This example makes the following changes to the Pickup directory on the Mailbox server named Exchange01:

- The Pickup directory location is set to D:\Pickup Directory.
- The maximum size allowed for message headers in a message file is increased to 96 KB.
- The maximum number of recipients allowed in a message file is increased to 250.
- The maximum rate of message processing for the Pickup and Replay directories is increased to 200 messages per minute.

```
Set-TransportService Exchange01 -PickupDirectoryPath "D:
\Pickup Directory" -PickupDirectoryMaxHeaderSize 96KB -
PickupDirectoryMaxRecipientsPerMessage 250 -
PickupDirectoryMaxMessagesPerMinute 200
```

Note:

- Setting the *PickupDirectoryPath* parameter to the value `$null` disables the Pickup directory.
- The directory specified by the *PickupDirectoryPath* parameter and the *ReplayDirectoryPath* parameter can't be the same.

Use the Shell to configure the Replay directory

To configure the Replay directory, use the following syntax.

```
Set-TransportService <ServerIdentity> -ReplayDirectoryPath
"C:\Replay Directory" <LocalFilePath> -
PickupDirectoryMaxMessagesPerMinute <Integer>
```

This example makes the following changes to the Replay directory on the Mailbox server named Exchange01:

- The Replay directory location is set to D:\Replay Directory.
- The maximum rate of message processing for the Pickup and Replay directories is increased to 200 messages per minute.

```
Set-TransportService Exchange01 -ReplayDirectoryPath "D:
\Replay Directory" -PickupDirectoryMaxMessagesPerMinute 200
```

Note:

- Setting the *ReplayDirectoryPath* parameter to the value `$null` disables the Replay directory.
- The directory specified by the *PickupDirectoryPath* parameter and the *ReplayDirectoryPath* parameter can't be the same.

How do you know this worked?

To verify that you have successfully configured the Pickup and Replay directories, do the following:

1. Run the following command:

```
Get-TransportService <ServerIdentity> | Format-List
Pickup*,Replay*
```

2. Verify the values displayed are the values you configured.

TLS functionality and related terminology

Exchange Server 2013 > Mail flow >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-06-18*

Microsoft Exchange Server 2013 provides administrative functionality and other enhancements that improve the overall management of Transport Layer Security (TLS). As you work with this functionality, you need to learn about some TLS-related features and functionality. Some terms and concepts apply to more than one TLS-related feature. In this topic, a brief explanation of each feature is provided, which is intended to help you understand some differences and general terminology related to TLS and the Domain Security feature set:

- **Transport Layer Security** TLS is a standard protocol that's used to provide secure Web communications on the Internet or intranets. It enables clients to authenticate servers or, optionally, servers to authenticate clients. It also provides a secure channel by encrypting communications. TLS is the latest version of the Secure Sockets Layer (SSL) protocol.
- **Mutual TLS** Mutual TLS authentication differs from TLS as TLS is usually deployed. Typically, when TLS is deployed, it's used only to provide confidentiality in the form of encryption. No authentication occurs between the sender and receiver. Additionally, sometimes when TLS is deployed, only the receiving server is authenticated. This deployment of TLS is typical of the HTTP implementation of TLS. This implementation, where only the receiving server is authenticated, is SSL.

With mutual TLS authentication, each server verifies the identity of the other server by validating a certificate that's provided by that other server. In this scenario, where messages are received from external domains over verified connections in an Exchange 2013 environment, Microsoft Outlook displays a **Domain Secured** icon.

- **Domain Security** Domain Security is the set of features, such as certificate management, connector functionality, and Outlook client behavior that enables mutual TLS as a manageable and useful technology. Domain Security isn't supported when outbound email is routed through an Exchange 2013 Client Access server.
- **Opportunistic TLS** In Exchange 2013, Setup creates a self-signed certificate. By default, TLS is

enabled. This enables any sending system to encrypt the inbound SMTP session to Exchange. By default, Exchange 2013 also attempts TLS for all remote connections.

- **Direct trust** By default, all traffic between Edge Transport servers and Mailbox servers is authenticated and encrypted. Again, the underlying mechanism for authentication and encryption is mutual TLS. Instead of using X.509 validation, Exchange 2013 uses direct trust to authenticate the certificates. Direct trust means that the presence of the certificate in Active Directory or Active Directory Lightweight Directory Services (AD LDS) validates the certificate. Active Directory is considered a trusted storage mechanism. When direct trust is used, it doesn't matter if the certificate is self-signed or signed by a certification authority. When you subscribe an Edge Transport server to the Exchange organization, the Edge Subscription publishes the Edge Transport server certificate in Active Directory for the Mailbox servers to validate. The Microsoft Exchange EdgeSync service updates AD LDS with the set of Mailbox server certificates for the Edge Transport server to validate.

Scenario: Configure Exchange to support WAN Optimization Controllers

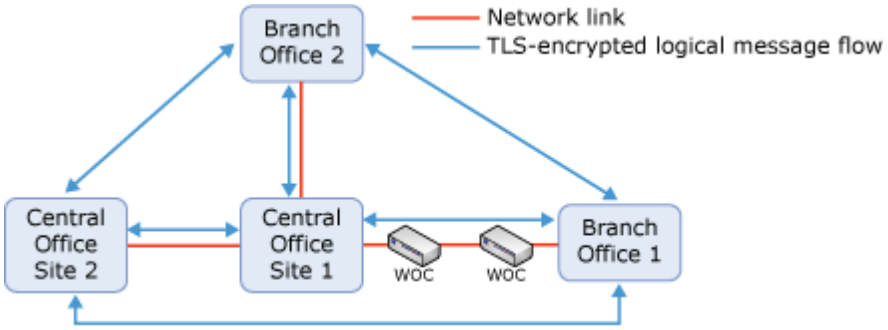
Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-28*

In Microsoft Exchange Server 2013, Transport Layer Security (TLS) encryption is mandatory for all SMTP communication in the Transport service between Mailbox servers. This increases overall security of Transport service communication between Mailbox servers. However, in certain topologies where WAN Optimization Controller (WOC) devices are used, the TLS encryption of SMTP traffic may be undesirable. You can disable TLS for Transport service communication between Mailbox servers for these specific scenarios.

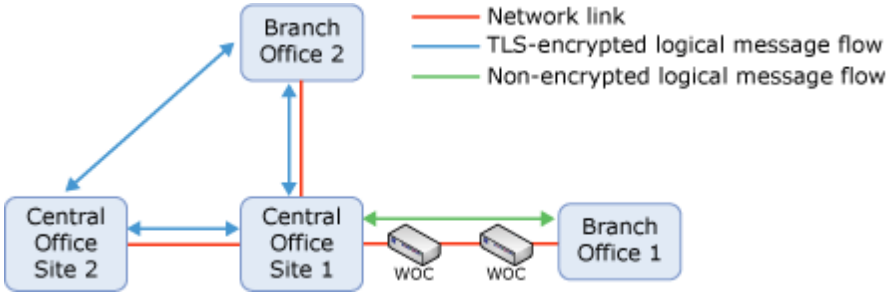
Consider the topology shown in the following figure. The assumption for this four-site topology is that the two central office sites and Branch Office 2 are well-connected, whereas the connection between Central Office Site 1 and Branch Office 1 is over a WAN link. The company has installed WOC devices on this link to compress and optimize traffic over the WAN.

Sample network topology with WOC devices



In this topology, because Exchange 2013 uses TLS encryption for communication between Mailbox servers, the SMTP traffic that goes over the WAN link can't be compressed. Ideally, all SMTP traffic that goes over the WAN link should be unencrypted SMTP, while retaining TLS security within well-connected sites. Exchange 2013 gives you the option to disable TLS encryption for traffic between sites by configuring Receive connectors. Using this ability in Exchange 2013, you can configure an exception to the SMTP traffic between Central Office Site 1 and Branch Office 1, as shown in the following figure.

Preferred logical message flow



The recommended configuration is to limit the non-encrypted SMTP traffic to only those messages that pass over the WAN link. Therefore, the intrasite Transport service communication between Mailbox servers in all sites, and the cross-site Transport service communication between Mailbox servers that don't involve Branch Office 1 should all be TLS encrypted.

To achieve this end result, you need to do the following actions, in the specified order, on every Mailbox server in the sites that contain the WOC devices (Central Office Site 1 and Branch Office 1 in the sample topology):

1. Enable downgraded Exchange Server authentication.
2. Create a dedicated Receive connector to handle the traffic over the connection that has WOC devices.
   a. Configure the remote IP address range property of the dedicated Receive connector to the IP address ranges of the Mailbox servers in the remote Active Directory site.
   b. Disable TLS on the dedicated Receive connector.

In addition, you need to do the following actions to ensure all SMTP traffic over the WAN is handled by the dedicated Receive connectors you created:

- Configure the Active Directory sites that will participate in the non-TLS communication as hub sites to force all message flow through the dedicated Receive connectors (Central Office Site 1 and Branch Office Site 1 in the sample topology).
- Verify that the Active Directory IP site link costs are configured in a way that ensures the least cost

routing path to your remote site (Branch Office 1 in the sample topology) goes through the network link that has the WOC devices. Assign an Exchange-specific cost to the Active Directory site links as necessary.

The following sections provide an overview of these steps. For step-by-step instructions on how to configure your organization for this scenario, see Disable TLS between Active Directory sites.

Contents

Downgrade authentication over TLS-disabled connections

Kerberos authentication is used with TLS encryption in Exchange. When you disable TLS on the Transport service communication between Mailbox servers, you need to perform another form of authentication. When Exchange 2013 communicates with other servers running Exchange that don't support **X-ANONYMOUSTLS**, it falls back to using Generic Security Services Application Programming Interface (GSSAPI) authentication. All Transport service communications between Exchange 2013 Mailbox servers use **X-ANONYMOUSTLS**. When you configure the Transport service on your Mailbox server to use downgraded Exchange Server authentication, you are in effect enabling GSSAPI authentication for Transport service communication with other Exchange 2013 Mailbox servers.

Return to top

Create and configure dedicated Receive connectors

You need to create Receive connectors that will solely be responsible for handling the non-TLS encrypted traffic. Using separate Receive connectors for this purpose ensures that all traffic that doesn't pass through the WAN link remains protected by TLS encryption.

To restrict the dedicated Receive connectors to only the traffic over the WAN, you need to configure the remote IP address range property. Exchange always uses the connector with the most specific remote IP address range. Therefore, these new connectors will be preferred over the default Receive connector configured to receive messages from anywhere.

Going back to the sample topology, assume that the class C subnet 10.0.1.0/24 is used for the Central Office Site 1 and 10.0.2.0/24 is used for the Branch Office 1. To prepare for disabling TLS between these two sites, you need to:

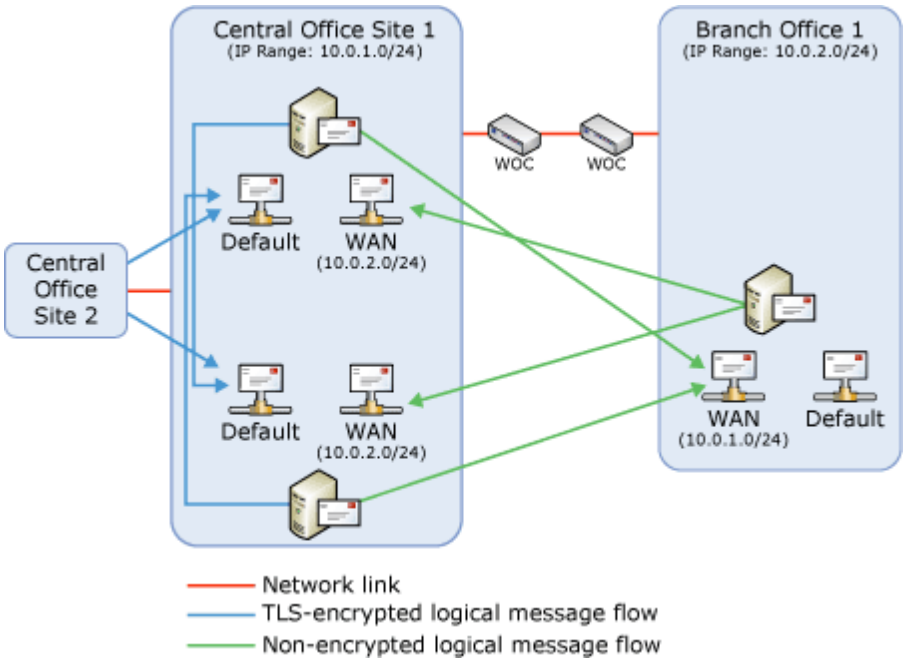
1. Create a Receive connector named WAN on each Mailbox server in Central Office Site 1 and Branch Office 1.
2. Configure the remote IP address range of 10.0.2.0/24 on each dedicated Receive connector in

Central Office Site 1.

3. Configure the remote IP address range of 10.0.1.0/24 on each dedicated Receive connector in Branch Office 1.
4. Disable TLS on all of the dedicated Receive connectors.

The end result is shown in the following figure (with the remote IP address range property of the Receive connectors named WAN shown in parentheses). Only a single Mailbox server is shown in Branch Office 1, and Branch Office 2 is omitted for clarity purposes.

Receive connector configuration



Return to top

Configure Hub sites

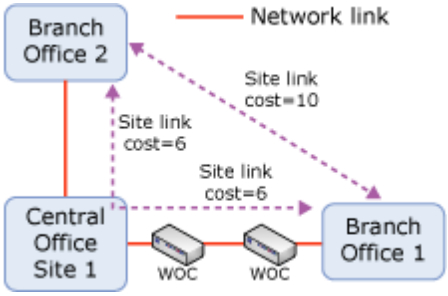
By default, an Exchange 2013 Mailbox server will attempt a direct connection to the Mailbox server closest to the final destination of a specific message. In the sample topology, if a user in Branch Office 2 sends a message to a user in Branch Office 1, the Mailbox server in Branch Office 2 will connect to the Mailbox server in Branch Office 1 directly to deliver that message. That connection will be encrypted and therefore not desirable in the specific topology. To have such messages pass through the Mailbox servers on Central Office Site 1, thereby ensuring they aren't encrypted while in transit over the WAN link, Central Office Site 1 and Branch Office 1 need to be configured as hub sites. In short, any site where you have a Mailbox server with a Receive connector with TLS disabled needs to be configured as a hub site, so you can force servers in other sites to route traffic through that site. For more information, see Configure Exchange mail routing settings in Active Directory.

Return to top

Configure Exchange-specific Active Directory site link costs

Configuring hub sites alone isn't sufficient to ensure that all traffic is unencrypted over the WAN link. This is because Exchange will route messages through hub sites only if the hub site lies within the least cost routing path. For example, assume that the IP site link costs for our sample topology are configured in Active Directory as shown in the following figure (Central Office Site 2 is omitted for clarity).

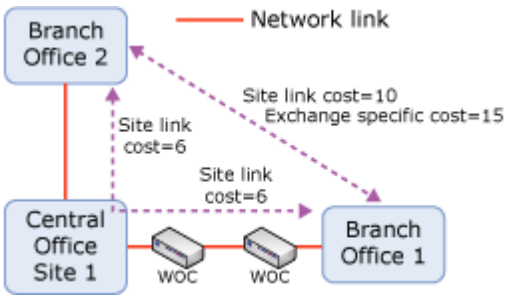
IP site link costs for the sample topology



In this case, the path from Branch Office 2 to Branch Office 1 that goes through the hub site has a total cost of 12 (6+6), whereas the cost of the direct path is 10. Therefore, none of the messages from Branch Office 2 to Branch Office 1 will go through Central Office Site 1 and therefore all of that traffic will still be TLS encrypted.

To avoid this issue, you need to designate an Exchange-specific cost that is higher than 12 for the IP site link between Branch Office 2 and Branch Office 1, as shown in the following figure. This will ensure that all messages go through the unencrypted channel between Central Office Site 1 and Branch Office 1.

Sample topology configured with Exchange-specific IP site link costs



For more information, see Configure Exchange mail routing settings in Active Directory.

Return to top

Disable TLS between Active Directory sites

Exchange Server 2013 > Mail flow > TLS functionality and related terminology >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-19*

Microsoft Exchange Server 2013 supports disabling TLS for SMTP communication between Mailbox servers in certain topologies where WAN Optimization Controller (WOC) devices that compress SMTP traffic are used.

This topic provides step-by-step instructions on how to configure the Transport service in your affected Mailbox servers to disable TLS, and to ensure your Active Directory routing topology is configured to correctly route messages. To learn more about this scenario, see Scenario: Configure Exchange to support WAN Optimization Controllers.

What do you need to know before you begin?

- Estimated time to complete this task: 60 minutes.
- Even though individual configuration steps within this scenario can be accomplished with lesser rights, to complete the entire end-to-end scenario tasks, your account needs to be a member of the Organization Management role group.
- Make sure you disable TLS only on connections that pass through WOC devices.
- This procedure requires that Exchange 2013 is deployed in multiple Active Directory sites, with at least one site connected to the other sites over a WAN link.
- This procedure requires that WOC devices are deployed to compress SMTP traffic over the WAN link.
- This procedure requires that a logical message flow path exists for Exchange going over the WAN link that has the WOC devices deployed.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Step 1: Use the Shell to configure the Transport service on the Mailbox server to use downgraded Exchange Server authentication

To configure the Transport service on a Mailbox server to use downgraded Exchange server authentication, run the following command:

```
Set-TransportService <ServerIdentity> -
```

```
UseDowngradedExchangeServerAuth $true
```

This example makes this configuration change on the server named Mailbox01.

```
Set-TransportService Mailbox01 -
UseDowngradedExchangeServerAuth $true
```

Step 2: Create a dedicated Receive connector on the Mailbox server for the target Active Directory site

Use the EAC to create the Receive connector

1. In the Exchange admin center (EAC), click **Mail flow** > **Receive connectors**, and then click **Add +** .
2. On the first page of the **New Receive connector** wizard, enter the following values
   - **Name** Enter a descriptive value.
   - **Type** Internal

When you are finished, click **Next**.

3. On the second page of the **New Receive connector** wizard, in the **Remote settings** section, enter the IP addresses or IP address ranges for the target Active Directory site. When you are finished, click **Finish**.

Use the Shell to create the Receive connector

To create a Receive connector on the Mailbox server, run the following command:

```
New-ReceiveConnector -Name <Name> -Server <ServerIdentity>
-RemoteIPRanges <IPAddressRange> -Internal
```

This example creates the Receive connector named WAN on server named Mailbox01 with the following settings:

- The *RemoteIPRanges* parameter is set to 10.0.2.0/24. This IP address range should correspond to the remote Active Directory site from where this Receive connector will receive unencrypted connections. If there's more than one IP subnet in the remote site, you can enter them all separated by commas.
- The usage type is set to Internal.

```
New-ReceiveConnector -Name WAN -Server Hub01 -
RemoteIPRanges 10.0.2.0/24 -Internal
```

Step 3: Use the Shell to disable TLS on the dedicated

Receive connector

To disable TLS on the Receive connector, run the following command:

```
Set-ReceiveConnector <ReceiveConnectorIdentity> -
SuppressXAnonymousTLS $true
```

This example disables TLS on the Receive connector named WAN on Mailbox server named Mailbox01.

```
Set-ReceiveConnector Mailbox01\WAN -SuppressXAnonymousTLS
$true
```

Step 4: Use the Shell to designate the Active Directory sites as hub sites

To designate an Active Directory site as a hub site, run the following command:

```
Set-AdSite <ADSiteIdentity> -HubSiteEnabled $true
```

You need to perform this procedure once in each Active Directory site that has Mailbox servers that participate in non-encrypted traffic.

This example configures the Active Directory site named Central Office Site 1 as a hub site.

```
Set-AdSite "Central Office Site 1" -HubSiteEnabled $true
```

Step 5: Use the Shell to configure the least cost routing path through the WAN connection

Depending on how the IP site link costs are configured in Active Directory, this step may not be necessary. You need to verify that the network link with the WOC devices deployed is in the leastcost routing path. To view the Active Directory site link costs, and the Exchange-specific site link costs, run the following command:

```
Get-AdSiteLink
```

If the network link with the WOC devices deployed isn't on the least cost routing path, you'll need to assign an Exchange-specific cost to the particular IP site link to ensure messages are routed correctly. To learn more about this particular issue, see the "Configure Exchange-specific Active Directory site link costs" section in Scenario: Configure Exchange to support WAN Optimization

Controllers.

This example configures an Exchange-specific cost of 15 on the IP site link named Branch Office 2-Branch Office 1.

```
Set-AdSiteLink "Branch Office 2-Branch Office 1" -
ExchangeCost 15
```

Recipients

Exchange Server 2013 >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-08-13*

The people and resources that send and receive messages are the core of any messaging and collaboration system. In an Exchange organization, these people and resources are referred to as *recipients*. A recipient is any mail-enabled object in Active Directory to which Microsoft Exchange can deliver or route messages.

Exchange recipient types

Exchange includes several explicit recipient types. Each recipient type is identified in the Exchange Administration Center (EAC) and has a unique value in the *RecipientTypeDetails* property in the Exchange Management Shell. The use of explicit recipient types has the following benefits:

- At a glance, you can differentiate between various recipient types.
- You can search and sort by each recipient type.
- You can more easily perform bulk management operations for selected recipient types.
- You can more easily view recipient properties because the EAC uses the recipient types to render different property pages. For example, the resource capacity is displayed for a room mailbox, but isn't present for a user mailbox.

The following table lists the available recipient types. All these recipient types are discussed in more detail later in this topic.

Recipient type	Description
Dynamic distribution group	A distribution group that uses recipient filters and conditions to derive its membership at the time messages are sent.
Equipment mailbox	A resource mailbox that's assigned to a

	resource that's not location-specific, such as a portable computer, projector, microphone, or a company car. Equipment mailboxes can be included as resources in meeting requests, providing a simple and efficient way of using resources for your users.
Linked mailbox	A mailbox that's assigned to an individual user in a separate, trusted forest.
Mail contact	A mail-enabled Active Directory contact that contains information about people or organizations that exist outside the Exchange organization. Each mail contact has an external email address. All messages sent to the mail contact are routed to this external email address.
Mail forest contact	A mail contact that represents a recipient object from another forest. Mail forest contacts are typically created by Microsoft Identity Integration Server (MIIS) synchronization. **Important:** Mail forest contacts are read-only recipient objects that are updated only through MIIS or similar custom synchronization. You can't use the EAC or the Shell to remove or modify a mail forest contact.
Mail user	A mail-enabled Active Directory user that represents a user outside the Exchange organization. Each mail user has an external email address. All messages sent to the mail user are routed to this external email address. A mail user is similar to a mail contact, except that a mail user has Active Directory logon

	credentials and can access resources.
Mail-enabled non-universal group	A mail-enabled Active Directory global or local group object. Mail-enabled non-universal groups were discontinued in Exchange Server 2007 and can exist only if they were migrated from Exchange 2003 or earlier versions of Exchange. You can't use Exchange Server 2013 to create non-universal distribution groups.
Mail-enabled public folder	An Exchange public folder that's configured to receive messages.
Distribution groups	A distribution group is a mail-enabled Active Directory distribution group object that can be used only to distribute messages to a group of recipients.
Mail-enabled security group	A mail-enabled security group is an Active Directory universal security group object that can be used to assign access permissions to resources in Active Directory and can also be used to distribute messages.
Microsoft Exchange recipient	A special recipient object that provides a unified and well-known message sender that differentiates system-generated messages from other messages. It replaces the System Administrator sender used for system-generated messages in earlier versions of Exchange.
Room mailbox	A resource mailbox that's assigned to a meeting location, such as a conference room, auditorium, or training room. Room mailboxes can be included as resources in meeting

	requests, providing a simple and efficient way of organizing meetings for your users.
Shared mailbox	A mailbox that's not primarily associated with a single user and is generally configured to allow access for multiple users.
Site mailbox	A mailbox comprised of an Exchange mailbox to store email messages and a SharePoint site to store documents. Users can access both email messages and documents using the same client interface. For more information, see Site mailboxes.
User mailbox	A mailbox that's assigned to an individual user in your Exchange organization. It typically contains messages, calendar items, contacts, tasks, documents, and other important business data.
Office 365 mailbox	In hybrid deployments, an Office 365 mailbox consists of a mail user that exists in Active Directory on-premises and an associated cloud mailbox that exists in Exchange Online.
Linked user	A linked user is a user whose mailbox resides in a different forest than the forest in which the user resides.

Mailboxes

Mailboxes are the most common recipient type used by information workers in an Exchange organization. Each mailbox is associated with an Active Directory user account. The user can use the mailbox to send and receive messages, and to store messages, appointments, tasks, notes, and documents. Mailboxes are the primary messaging and collaboration tool for the users in your Exchange organization.

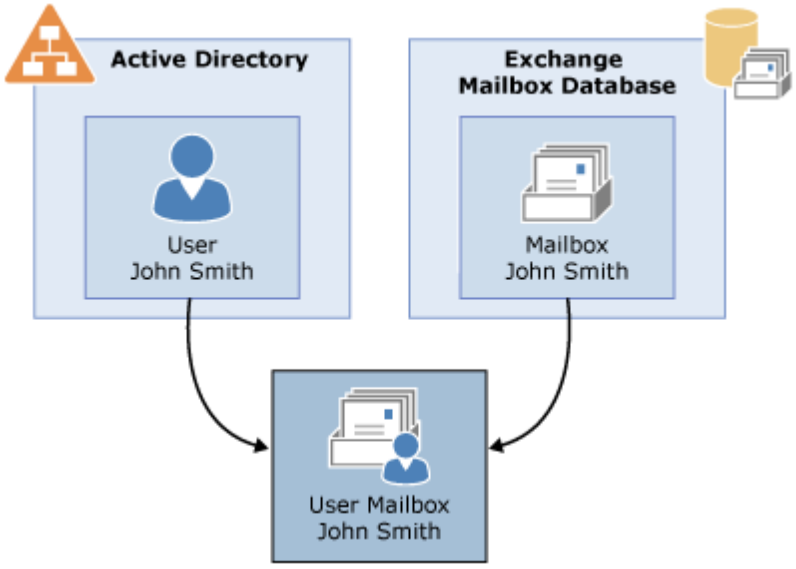
Mailbox components

Each mailbox consists of an Active Directory user and the mailbox data that's stored in the Exchange mailbox database (as shown in the following figure). All configuration data for the mailbox is stored in the Exchange attributes of the Active Directory user object. The mailbox database contains the actual data that's in the mailbox associated with the user account.

Important:

When you create a mailbox for a new or existing user, the Exchange attributes required for a mailbox are added to the user object in Active Directory. The associated mailbox data isn't created until the mailbox either receives a message or the user signs in to it.

Mailbox components



Warning:

If you remove a mailbox, the mailbox data stored in the Exchange mailbox database is marked for deletion and the associated user account is also deleted from Active Directory. To retain the user account and delete only the mailbox data, you must disable the mailbox.

Mailbox types

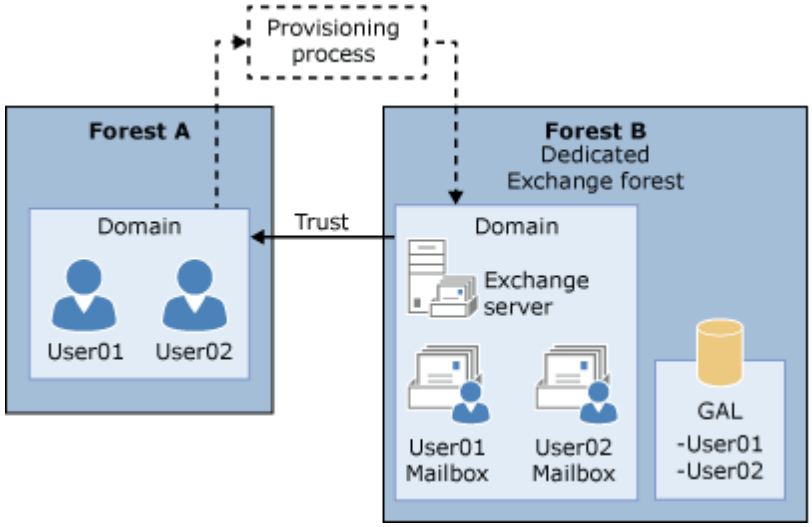
Exchange supports the following mailbox types:

- **User mailboxes** User mailboxes are assigned to individual users in your Exchange organization. User mailboxes provide your users with a rich collaboration platform. Users can send and receive messages, manage their contacts, schedule meetings, and maintain a task list. They can also have voice mail messages delivered to their mailboxes. User mailboxes are the most commonly used mailbox type and are typically the mailbox type assigned to users in your organization.
- **Linked mailboxes** Linked mailboxes are mailboxes that are accessed by users in a separate, trusted forest. Linked mailboxes may be necessary for organizations that deploy Exchange in a resource forest. The resource forest scenario allows an organization to centralize Exchange in a single forest, while allowing access to the Exchange organization with user accounts in one or more trusted forests.

As stated earlier, every mailbox must have a user account associated with it. However, the user account that accesses the linked mailbox doesn't exist in the forest where Exchange is deployed. Therefore, a disabled user account that exists in the same forest as Exchange is associated with

each linked mailbox. The following figure illustrates the relationship between the linked user account used to access the linked mailbox and the disabled user account in the Exchange resource forest associated with the linked mailbox.

Linked mailbox



- **Office 365 mailboxes** When you create an Office 365 mailbox in Exchange Online in a hybrid deployment, the mail user is created in Active Directory on-premises. Directory synchronization, if it's configured, automatically synchronizes this new user object to Office 365, where it's converted to a cloud mailbox in Exchange Online. You can create Office 365 mailboxes as regular user mailboxes, resource mailboxes for meeting rooms and equipment, and shared mailboxes.
- **Shared mailboxes** Shared mailboxes aren't primarily associated with individual users and are generally configured to allow access by multiple users.

Although it's possible to assign additional users the logon access permissions to any mailbox type, shared mailboxes are dedicated for this functionality. The Active Directory user associated with a shared mailbox must be a disabled account. After you create a shared mailbox, you must assign permissions to all users that require access to the shared mailbox.

- **Resource mailboxes** Resource mailboxes are special mailboxes designed to be used for scheduling resources. Like all mailbox types, a resource mailbox has an associated Active Directory user account, but it must be a disabled account. The following are the types of resource mailboxes:
  - **Room mailboxes** These mailboxes are assigned to meeting locations, such as conference rooms, auditoriums, and training rooms.
  - **Equipment mailboxes** These mailboxes are assigned to resources that aren't location-specific, such as portable computers, projectors, microphones, or company cars.

You can include both types of resource mailboxes in meeting requests, providing a simple and efficient way for your users to use resources. You can configure resource mailboxes to automatically process incoming meeting requests based on the resource booking policies that are defined by the resource owners. For example, you can configure a conference room to automatically accept incoming meeting requests except recurring meetings, which can be subject to approval by the resource owner.

System mailboxes

System mailboxes are created by Exchange in the root domain of the Active Directory forest during installation. Users or administrators can't sign in to these mailboxes. System mailboxes are created for Exchange features such as Unified Messaging (UM), migration, message approval, and In-Place eDiscovery. This table lists information about system mailboxes as they're displayed in Active Directory.

Mailbox	Name
Organization	SystemMailbox {bb558c35-97f1-4cb9-8ff7-d53741dc928c}
Message approval	SystemMailbox {1f05a927-*xxxx*- *xxxx* - *xxxx* - *xxxxxxxxxxxx*} where *x* is a randomly assigned and unique number for each Exchange forest
UM data storage	SystemMailbox {e0dc1c29-89c3-4034-b678-e6c29d823ed9}
Discovery	DiscoverySearchMailbox {D919BA05-46A6-415f-80AD-7E09334BB852}
Federated email	FederatedEmail.4c1f4d8b-8179-4148-93bf-00a95fa1e042
Migration	Migration.8f3e7716-2011-43e4-96b1-aba62d229136

If you want to decommission the last Mailbox server in your Exchange organization, you should first disable these system mailboxes by using the Disable-Mailbox cmdlet. When you decommission a Mailbox server that contains these system mailboxes, you should move the system mailboxes to another Mailbox server to make sure that you don't lose functionality.

Planning for mailboxes

Mailboxes are created in mailbox databases on Exchange servers that have the Mailbox server role installed. To help provide a reliable and effective platform for your mailbox users, detailed planning for the deployment of Mailbox servers and databases is essential. To learn more about planning for Mailbox servers and databases, see Planning and deployment.

Distribution groups

Distribution groups are mail-enabled Active Directory group objects that are primarily used for distributing messages to multiple recipients. Any recipient type can be a member of a distribution group.

Important:

Note the terminology differences between Active Directory and Exchange. In Active Directory, a distribution group refers to any group that doesn't have a security context, whether it's mail-enabled or not. In Exchange, all mail-enabled groups are referred to as distribution groups, whether they have a security context or not.

Exchange supports the following types of distribution groups:

- **Distribution groups** These are Active Directory universal distribution group objects that are mail-enabled. They can be used only to distribute messages to a group of recipients.
- **Mail-enabled security groups** These are Active Directory universal security group objects that are mail-enabled. They can be used to assign access permissions to resources in Active Directory and can also be used to distribute messages.
- **Mail-enabled non-universal groups** These are Active Directory global or local group objects that are mail-enabled. You can create or mail-enable only universal distribution groups. You may have mail-enabled groups that were migrated from previous versions of Exchange that aren't universal groups. These groups can still be managed by using the EAC or the Shell.

Note:

To convert a domain-local or a global group to a universal group, you can use the Set-Group cmdlet in the Shell.

Dynamic distribution groups

Dynamic distribution groups are distribution groups whose membership is based on specific recipient filters rather than a defined set of recipients.

Unlike regular distribution groups, the membership list for dynamic distribution groups is calculated each time a message is sent to them, based on the filters and conditions that you specify. When an email message is sent to a dynamic distribution group, it's delivered to all recipients in the organization that match the criteria defined for that dynamic distribution group.

Important:

A dynamic distribution group includes any recipient in Active Directory that has attributes that match the group's filter at the time a message is sent. If a recipient's properties are modified to match the group's filter, that recipient could inadvertently become a group member and start receiving messages that are sent to the dynamic distribution group. Well-defined, consistent account provisioning processes can reduce the chances of this issue occurring.

To help you create recipient filters for dynamic distribution groups, you can use precanned filters. A *precanned filter* is a commonly used filter that you can use to meet a variety of recipient-filtering criteria. You can use these filters to specify the recipient types that you want to include in a dynamic distribution group. In addition, you can also specify a list of conditions that the recipients must

meet. You can create precanned conditions based on the following properties:

- Custom attributes 1–15
- State or province
- Company
- Department
- Recipient container

You can also specify conditions based on recipient properties other than those previously listed. To do this, you must use the Shell to create a custom query for the dynamic distribution group. Remember that the filter and condition settings for dynamic distribution groups that have custom recipient filters can be managed only by using the Shell. For an example of how to create a dynamic distribution group by using a custom query, see Manage dynamic distribution groups.

Mail contacts

Mail contacts typically contain information about people or organizations that exist outside your Exchange organization. Mail contacts can appear in your organization's shared address book (also called the global address list or GAL) and other address lists, and can be added as members to distribution groups. Each contact has an external email address, and all email messages that are sent to a contact are automatically forwarded to that address. Contacts are ideal for representing people external to your Exchange organization (in the shared address book) who don't need access to any internal resources. The following are mail contact types:

- **Mail contacts** These are mail-enabled Active Directory contacts that contain information about people or organizations that exist outside your Exchange organization.
- **Mail forest contacts** These represent recipient objects from another forest. These contacts are typically created by directory synchronization. Mail forest contacts are read-only recipient objects that can be updated or removed only by means of synchronization. You can't use Exchange management interfaces to modify or remove a mail forest contact.

Mail users

Mail users are similar to mail contacts. Both have external email addresses, both contain information about people outside your Exchange organization, and both can be displayed in the shared address book and other address lists. However, unlike a mail contact, mail users have Active Directory logon credentials and can access resources to which they are assigned permissions.

If a person external to your organization requires access to resources on your network, you should create a mail user instead of a mail contact. For example, you may want to create mail users for short-term consultants who require access to your server infrastructure, but who will use their own external addresses.

Another scenario is to create mail users in your organization for users who you don't want to maintain an Exchange mailbox. For example, after an acquisition, the acquired company may maintain their separate messaging infrastructure, but may also need access to resources on your

network. For those users, you may want to create mail users instead of mailbox users.

Note:
In the EAC, you use the **Recipients** > **Contacts** page to create and manage mail users. There isn't a separate page for mail users.

Mail-enabled public folders

Public folders are intended to serve as a repository for information shared among many users. Mail-enabling a public folder provides an extra level of functionality to users. In addition to being able to post messages to the folder, users can send email messages to, and sometimes receive email messages from, the public folder. Each mail-enabled folder has an object in Active Directory that stores its email address, address book name, and other mail-related attributes.

You can manage public folders by using either the EAC or the Shell. For more information about managing public folders, see Public folders.

Microsoft Exchange recipient

The Microsoft Exchange recipient is a special recipient object that provides a unified and well-known message sender that differentiates system-generated messages from other messages. It replaces the System Administrator sender that was used for system-generated messages in earlier versions of Exchange.

The Microsoft Exchange recipient isn't a typical recipient object, such as a mailbox, mail user, or mail contact, and it isn't managed by using the typical recipient tools. However, you can use the Set-OrganizationConfig cmdlet in the Shell to configure the Microsoft Exchange recipient.

Note:
When system-generated messages are sent to an external sender, the Microsoft Exchange recipient isn't used as the sender of the message. Instead, the email address specified by the *ExternalPostmasterAddress* parameter in the Set-TransportConfig cmdlet is used.

Recipients documentation

The following table contains links to topics that will help you learn about and manage Exchange recipients.

Topic	Description
Create user mailboxes	Learn how to create user mailboxes using the Exchange admin center or the Exchange Management Shell.
Manage user mailboxes	Learn how to create user mailboxes, change

	mailbox properties, and bulk-edit selected properties for multiple mailboxes.
Manage linked mailboxes	Learn about the requirements for linked mailboxes, how to create and link them to a master account, and change linked mailbox properties.
Manage Distribution Groups	Learn how to create and manage distribution groups, and create a group naming policy for your organization.
Manage mail-enabled security groups	Learn how to create and manage mail-enabled security groups.
Manage dynamic distribution groups	Learn how to create dynamic distribution groups and manage dynamic distribution group properties, such as using custom attributes and other properties to determine group membership.
Manage mail contacts	Learn how to create and manage mail contacts.
Manage mail users	Learn how to create and manage mail users.
Create and Manage Room Mailboxes	Learn how to create room mailboxes and manage room mailbox properties, such as enabling recurring meetings and configuring booking and scheduling options.
Manage equipment mailboxes	Learn how to create equipment mailboxes, configure booking and scheduling options, and manage other mailbox properties.
Disconnected mailboxes	Learn about the two types of disconnected mailboxes and how to work with them.
Custom attributes	Learn how to add information about a recipient

	by using custom attributes.
Filters in recipient Shell commands	Learn how to use precanned or custom filters with commands to filter a set of recipients.
Manage Permissions for Recipients	Learn how to use the EAC or the Shell to assign permissions to users and groups.
Automatic mailbox distribution	Learn about how automatic mailbox distribution works and how to control which mailbox databases are selected for new and moved mailboxes.

Create user mailboxes

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-04-12*

Mailboxes are the most common recipient type used by information workers in an Exchange organization. Each mailbox is associated with an Active Directory user account. The user can use the mailbox to send and receive messages, and to store messages, appointments, tasks, notes, and documents. Use the EAC or the Shell to create user mailboxes.

You can also create user mailboxes for existing users that have an Active Directory user account but don't have a corresponding mailbox. This is known as *mailbox-enabling* existing users.

What do you need to know before you begin?

- Estimated time to complete each user mailbox task: 2 to 5 minutes.
- When you create a new user mailbox, you can't use an apostrophe (') or a quotation mark (") in the alias or the user logon name because these characters aren't supported. Although you might not receive an error if you create a new mailbox using unsupported characters, these characters can cause problems later. For example, users that have been assigned access permissions to a mailbox that was created using an unsupported character may experience problems or unexpected behavior.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the

Recipients Permissions topic.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Create a user mailbox

Use the EAC to create a user mailbox

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. Click **New** > **User mailbox**.
3. On the **New user mailbox** page, in the **Alias** box, type the user's alias, which specifies the email alias for the user. The user's alias is the portion of the email address on the left side of the at (@) symbol. It must be unique in the forest.

Note:
If you leave this box blank, the value from the user name portion of the **User logon name** is used for the email alias.

4. Select one of the following options:
   - **Existing user** Select to mail-enable and create a mailbox for an existing user.

Click **Browse** to open the **Select User – Entire Forest** dialog box. This dialog box displays a list of Active Directory user accounts in the forest that aren't mail-enabled or don't have Exchange mailboxes. Select the user account you want to mail-enable, and then click **OK**. If you select this option, you don't have to provide user account information because this information already exists in Active Directory.

   - **New user** Select to create a new user account in Active Directory and create a mailbox for this user. If you select this option, you'll have to provide the required user account information.

Note:
The Active Directory account that is associated with user mailboxes must reside in the same forest as the Exchange server. To create a mailbox for a user account that resides in a trusted forest, you have to create a linked mailbox. See Manage linked mailboxes.

5. If you selected **New user** in Step 4, complete the following boxes on the **New user mailbox** page. Otherwise skip to Step 7.
   - **First name** Use this box to type the first name of the user.
   - **Initials** Use this box to type the initials of the user.
   - **Last name** Use this box to type the last name of the user.
   - *** Display name** Use this box to type a display name for the user. This is the name that's listed in the mailbox list in the EAC and in the shared address book. By default, this box is populated

with the names you enter in the **First name**, **Initials**, and **Last name** boxes. If you didn't use those boxes, you must still type a name in this box because it's required. The name can't exceed 64 characters.

- *** Name** Use this box to type a name for the user. This is the name that's listed in Active Directory. This box is also populated with the names you enter in the **First name**, **Initials**, and **Last name** boxes. If you didn't use those boxes, you must still type a name because this box is required. This name also can't exceed 64 characters.
- **Organizational unit** You can select an organizational unit (OU) other than the default (which is the recipient scope). If the recipient scope is set to the forest, the default value is set to the Users container in the Active Directory domain that contains the computer on which the EAC is running. If the recipient scope is set to a specific domain, the Users container in that domain is selected by default. If the recipient scope is set to a specific OU, that OU is selected by default.

To select a different OU, click **Browse**. The dialog box displays all OUs in the forest that are within the specified scope. Select the desired OU, and then click **OK**.

- *** User logon name** Use this box to type the name that the user will use to sign in to the mailbox and to log on to the domain. The user logon name consists of a user name on the left side of the at (@) symbol and a suffix on the right side. Typically, the suffix is the domain name in which the user account resides. Note that you can't use an apostrophe (') or a quotation mark (") in the user logon name because these characters aren't supported.

Note:

If the value for the user name is different than the value used in the **Alias** box, then the user's email address and the user logon name will be different.

- *** New Password** Use this box to type the password that the user must use to sign in to his or her mailbox.

Note:

Make sure that the password you supply complies with the password length, complexity, and history requirements of the domain in which you are creating the user account.

- *** Confirm password** Use this box to confirm the password that you typed in the **Password** box.
- **Require password change on next logon** Select this check box if you want the user to reset the password when they first sign in to the mailbox.

If you select this check box, at first sign-in, the new user will be prompted with a dialog box in which to change the password. The user won't be allowed to perform any tasks until the password is successfully changed.

6. Click **More options** to configure the following boxes. Otherwise, skip to Step 7 to save the new user mailbox.
   - **Specify the mailbox database** Use this option to specify a mailbox database instead of allowing Exchange to select a database for you. Click **Browse** to open the **Select Mailbox Database** dialog box. This dialog box lists all the mailbox databases in your Exchange organization. By default, the mailbox databases are sorted by name. You can also click the title of the corresponding column to sort the databases by server name or version. Select the

mailbox database you want to use, and then click **OK**.

- **Create local archive storage for this user** Select this check box to create an archive mailbox for the mailbox. If you create an archive mailbox, mailbox items will be moved automatically from the primary mailbox to the archive, based on the default retention policy settings or those you define.

Click **Browse** to select a database that resides in the local forest to store the archive mailbox.

To learn more, see In-Place Archiving.

- **Address book policy** Use this option to specify an address book policy (ABP) for the mailbox. ABPs contain a global address list (GAL), an offline address book (OAB), a room list, and a set of address lists. When assigned to mailbox users, an ABP provides them with access to a customized GAL in Outlook and Outlook Web App. To learn more, see Address book policies.

In the drop-down list, select the policy that you want associated with this mailbox.

7. When you're finished, click **Save** to create the mailbox.

Use the Shell to create a user mailbox

This example creates a new user account and mailbox for Pilar Pinilla with the following details:

- The alias is pilarp
- The first name is Pilar and the last name is Pinilla
- The name and display name is Pilar Pinilla
- The user logon name is pilarp@contoso.com
- The password is Pa$$word1
- The mailbox will be created in the default OU. To specify a different OU, you can use the *OrganizationalUnit* parameter.

```
New-Mailbox -Alias pilarp -Name "Pilar Pinilla" -FirstName
Pilar -LastName Pinilla -DisplayName "Pilar Pinilla" -
UserPrincipalName pilarp@contoso.com -Password (ConvertTo-
SecureString -String 'Pa$$word1' -AsPlainText -Force)
```

For syntax and parameter information, see New-Mailbox.

How do you know this worked?

To verify that you've successfully created a user mailbox, do one of the following:

- In the EAC, navigate to **Recipients** > **Mailboxes**. The new user mailbox is displayed in the mailbox list. Under **Mailbox Type**, the type is **User**.
- In the Shell, run the following command to display information about the new user mailbox.

```
Get-Mailbox <Name> | FL
Name,RecipientTypeDetails,PrimarySmtpAddress
```

Create a mailbox for an existing user

You can also create user mailboxes for existing users that have an Active Directory user account but don't have a corresponding mailbox. This is known as *mailbox-enabling* existing users. After you mailbox-enable an existing user, the user can send and receive email messages.

Use the EAC to create a mailbox for an existing user

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. Click **New** > **User mailbox**.
3. On the **New user mailbox** page, in the **Alias** box, type the user's alias, which specifies the email alias for the user. The user's alias is the portion of the email address on the left side of the at (@) symbol. It must be unique in the forest.

Note:
If you leave this box blank, the value from the user name portion of the **User logon name** is used for the email alias.

4. Click **Existing user**.
5. Click **Browse** to open the **Select User – Entire Forest** dialog box. This dialog box displays a list of Active Directory user accounts in the forest that aren't mail-enabled or don't have Exchange mailboxes. Select the user account you want to mail-enable, and then click **OK**.

When you create a mailbox for an existing user, you don't have to provide account information because this information already exists in Active Directory.

Note:
The Active Directory account that is associated with user mailboxes must reside in the same forest as the Exchange server. To create a mailbox for a user account that resides in a trusted forest, you have to create a linked mailbox. See Manage linked mailboxes.

6. Click **More options** to configure the following boxes. Otherwise, skip to Step 7 to save the new user mailbox.
   - **Specify the mailbox database** Use this option to specify a mailbox database instead of allowing Exchange to select a database for you. Click **Browse** to open the **Select Mailbox Database** dialog box. This dialog box lists all the mailbox databases in your Exchange organization. By default, the mailbox databases are sorted by name. You can also click the title of the corresponding column to sort the databases by server name or version. Select the mailbox database you want to use, and then click **OK**.
   - **Create local archive storage for this user** Select this check box to create an archive mailbox for the mailbox. If you create an archive mailbox, mailbox items will be moved automatically from the primary mailbox to the archive, based on the default retention policy settings or those you define.

Click **Browse** to select a database that resides in the local forest to store the archive mailbox.

To learn more, see In-Place Archiving.

   - **Address book policy** Use this option to specify an address book policy (ABP) for the mailbox. ABPs contain a global address list (GAL), an offline address book (OAB), a room list,

and a set of address lists. When assigned to mailbox users, an ABP provides them with access to a customized GAL in Outlook and Outlook Web App. To learn more, see Address book policies.

In the drop-down list, select the policy that you want associated with this mailbox.

7. When you're finished, click **Save** to create the mailbox.

Use the Shell to create a mailbox for an existing user

This example creates a mailbox for the existing user estherv@contoso.com on the Exchange database named UsersMailboxDatabase.

```
Enable-Mailbox estherv@contoso.com -Database
UsersMailboxDatabase
```

You can also use the **Enable-Mailbox** cmdlet to mail-enable multiple users. You can do this by piping the results of the **Get-User** cmdlet to the **Enable-Mailbox** cmdlet. When you run the **Get-User** cmdlet, you must return only users that aren't already mail-enabled. To do this, you need to specify the value User with the *RecipientTypeDetails* parameter. You can also limit the results returned by using the *Filter* parameter to request only users that meet the criteria you specify. You then pipe the results to the **Enable-Mailbox** cmdlet.

For example, the following command mailbox-enables users who aren't already mail-enabled and that have a value in the **UserPrincipalName** property, which helps ensure that you don't inadvertently convert a system account to a mailbox.

```
Get-User -RecipientTypeDetails User -Filter
{ UserPrincipalName -ne $Null } | Enable-Mailbox
```

For syntax and parameter information, see Enable-Mailbox and Get-User.

For more information about pipelining, see Pipelining.

How do you know this worked?

To verify that you've successfully created a mailbox for an existing user, do one of the following:

- In the EAC, navigate to **Recipients** > **Mailboxes**. The new mailbox-enabled user is displayed in the mailbox list. Under **Mailbox Type**, the type is **User**.
- In the Shell, run the following command to display information about the new mailbox-enabled user.

```
Get-Mailbox <Name> | FL
Name,RecipientTypeDetails,PrimarySmtpAddress
```

Note that value for the *RecipientTypeDetails* property is `UserMailbox`.

Manage user mailboxes

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-05-27*

After you create a user mailbox, you can make changes and set additional properties by using the EAC or the Shell.

You can also change properties for multiple user mailboxes at the same time. For more information, see Bulk edit user mailboxes.

What do you need to know before you begin?

- Estimated time to complete each user mailbox task: 2 to 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Change user mailbox properties

Use the EAC to change user mailbox properties

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of user mailboxes, click the mailbox that you want to change the properties for, and then click **Edit** .
3. On the mailbox properties page, click one of the following sections to view or change properties.
   - General
   - Mailbox Usage
   - Contact Information
   - Organization
   - Email Address
   - Mailbox Features

- Member Of
- MailTip
- Mailbox Delegation

General

Use the **General** section to view or change basic information about the user.

- **First name**, **Initials**, **Last name**
- *** Name** This is the name that's listed in Active Directory. If you change this name, it can't exceed 64 characters.
- *** Display name** This name appears in your organization's address book, on the To: and From: lines in email, and in the Mailbox list. This name can't contain empty spaces before or after the display name.
- *** Alias** This specifies the email alias for the user. The user's alias is the portion of the email address on the left side of the at (@) symbol. It must be unique in the forest.
- *** User logon name** This is the name that the user uses to sign in to their mailbox and to log on to the domain. Typically the user logon name consists of the user's alias on the left side of the @ symbol, and the domain name in which the user account resides on the right side of the @ symbol.

Note:
This box is labeled **User ID** In Exchange Online.

- **Require password change on next logon** Select this check box if you want the user to reset their password the next time they sign in to their mailbox.

Note:
This check box isn't available in Exchange Online.

- **Hide from address lists** Select this check box to prevent the recipient from appearing in the address book and other address lists that are defined in your Exchange organization. After you select this check box, users can still send messages to the recipient by using the email address.

Click **More options** to view or change these additional properties:

- **Organizational unit** This read-only box displays the organizational unit (OU) that contains the user account. You have to use Active Directory Users and Computers to move the user account to a different OU.

Note:
This box isn't available in Exchange Online.

- **Mailbox database** This read-only box displays the name of the mailbox database that hosts the mailbox. To move the mailbox to a different database, select it in the mailbox list, and then click **Move mailbox to another database** in the Details pane.

Note:
This option isn't available in Exchange Online.

- **Custom attributes** This section displays the custom attributes defined for the user mailbox. To specify custom attribute values, click **Edit**. You can specify up to 15 custom attributes for the

recipient.

Mailbox Usage

Use the **Mailbox Usage** section to view or change the mailbox storage quota and deleted item retention settings for the mailbox. These settings are configured by default when the mailbox is created. They use the values that are configured for the mailbox database and apply to all mailboxes in that database. You can customize these settings for each mailbox instead of using the mailbox database defaults.

- **Last logon** This read-only box displays the last time that the user signed in to their mailbox.
- **Mailbox usage** This area shows the total size of the mailbox and the percentage of the total mailbox quota that has been used.

Note:

To obtain the information that's displayed in the previous two boxes, the EAC queries the mailbox database that hosts the mailbox. If the EAC is unable to communicate with the Exchange store that contains the mailbox database, these boxes will be blank. A warning message is displayed if the user hasn't signed in to the mailbox for the first time.

Click **More options** to view or change the mailbox storage quota and the deleted item retention settings for the mailbox.

Note:

These settings aren’t available in the EAC in Exchange Online.

- **Storage quota settings** To customize these settings for the mailbox and not use the mailbox database defaults, click **Customize the settings for this mailbox**, type a new value, and then click **Save**.

The value range for any of the storage quota settings is from 0 through 2047 gigabytes (GB).

  - **Issue a warning at (GB)** This box displays the maximum storage limit before a warning is issued to the user. If the mailbox size reaches or exceeds the value specified, Exchange sends a warning message to the user.
  - **Prohibit send at (GB)** This box displays the *prohibit send* limit for the mailbox. If the mailbox size reaches or exceeds the specified limit, Exchange prevents the user from sending new messages and displays a descriptive error message.
  - **Prohibit send and receive at (GB)** This box displays the *prohibit send and receive* limit for the mailbox. If the mailbox size reaches or exceeds the specified limit, Exchange prevents the mailbox user from sending new messages and won't deliver any new messages to the mailbox. Any messages sent to the mailbox are returned to the sender with a descriptive error message.

- **Deleted item retention settings** To customize these settings for the mailbox and not use the mailbox database defaults, click **Customize the settings for this mailbox**, type a new value, and then click **Save**.
  - **Keep deleted items for (days)** This box displays the length of time that deleted items are retained before they are permanently deleted and can’t be recovered by the user. When the mailbox is created, this value is based on the deleted item retention settings configured for the mailbox database. By default, a mailbox database is configured to retain deleted items for 14

days. The value range for this property is from 0 through 24855 days.

- **Don’t permanently delete items until the database is backed up** Select this check box to prevent mailboxes and email messages from being deleted until after the mailbox database on which the mailbox is located has been backed up.

Contact Information

Use the **Contact Information** section to view or change the user's contact information. The information on this page is displayed in the address book. Click **More options** to display additional boxes.

Tip:
You can use the **State/Province** box to create recipient conditions for dynamic distribution groups, email address policies, or address lists.

Mailbox users can use Outlook or Outlook Web App to view and change their own contact information. But they can’t change the information in the **Notes** and **Web page** boxes.

Organization

Use the **Organization** section to record detailed information about the user's role in the organization. This information is displayed in the address book. Also, you can create a virtual organization chart that is accessible from email clients such as Outlook.

- **Title** Use this box to view or change the recipient's title.
- **Department** Use this box to view or change the department in which the user works. You can use this box to create recipient conditions for dynamic distribution groups, email address policies, or address lists.
- **Company** Use this box to view or change the company for which the user works. You can use this box to create recipient conditions for dynamic distribution groups, email address policies, or address lists.
- **Manager** To add a manager, click **Browse**. In **Select Manager**, select a person, and then click **OK**.
- **Direct reports** You can't modify this box. A *direct report* is a user who reports to a specific manager. If you’ve specified a manager for the user, that user appears as a direct report in the details of the manager's mailbox. For example, Kari manages Chris and Kate, so Kari's mailbox is specified in the **Manager** box of Chris's mailbox and Kate's mailbox, and Chris and Kate appear in the **Direct reports** box in the properties of Kari's mailbox.

Email Address

Use the **Email Address** section to view or change the email addresses associated with the user mailbox. This includes the user’s primary SMTP address and any associated proxy addresses. The primary SMTP address (also known as the *default reply address*) is displayed in bold text in the address list, with the uppercase **SMTP** value in the **Type** column.

- **Add** Click **Add +** to add a new email address for this mailbox. Select one of following address types:

- **SMTP** This is the default address type. Click this button and then type the new SMTP address in the *** Email address** box.
- **EUM** An EUM (Exchange Unified Messaging) address is used by the Microsoft Exchange Unified Messaging service to locate UM-enabled users within an Exchange organization. EUM addresses consist of the extension number and the UM dial plan for the UM-enabled user. Click this button and type the extension number in the **Address/Extension** box. Then click **Browse** and select a dial plan for the user.
- **Custom address type** Click this button and type one of the supported non-SMTP email address types in the *** Email address** box.

Note:

With the exception of X.400 addresses, Exchange doesn't validate custom addresses for proper formatting. You must make sure that the custom address you specify complies with the format requirements for that address type.

- **Make this the reply address** In Exchange Online, you can select this check box to make the new email address the primary SMTP address for the mailbox. This check box isn't available in the EAC in Exchange 2013.

- **Automatically update email addresses based on the email address policy applied to this recipient** Select this check box to have the recipient's email addresses automatically updated based on changes made to email address policies in your organization. This box is selected by default.

Note:

This check box isn't available in Exchange Online.

- **Make this the reply address**

Mailbox Features

Use the **Mailbox Features** section to view or change the following mailbox features and settings:

- **Sharing policy** This box shows the sharing policy applied to the mailbox. A sharing policy controls how users in your organization can share calendar and contact information with users outside your Exchange organization. The Default Sharing Policy is assigned to mailboxes when they are created. To change the sharing policy that's assigned to the user, select a different one from the drop-down list.
- **Role assignment policy** This box shows the role assignment policy assigned to the mailbox. The role assignment policy specifies the role-based access control (RBAC) roles that are assigned to the user and control what specific mailbox and distribution group configuration settings users can modify. To change the role assignment policy that's assigned to the user, select a different one from the drop-down list.
- **Retention policy** This box shows the retention policy assigned to the mailbox. A retention policy is a group of retention tags that are applied to the user's mailbox. They allow you to control how long to keep items in users' mailboxes and define what action to take on items that have reached a certain age. A retention policy isn't assigned to mailboxes when they are created. To assign a retention policy to the user, select one from the drop-down list.

- **Address book policy** This box shows the address book policy applied to the mailbox. An address book policy allows you to segment users into specific groups to provide customized views of the address book. To apply or change the address book policy applied to the mailbox, select one from the drop-down list.
- **Unified Messaging** This feature is disabled by default. When you enable Unified Messaging (UM), the user will be able to use your organization's UM features and a default set of UM properties are applied to the user. Click **Enable** to enable UM for the mailbox. For information about how to enable UM, see Enable a user for voice mail.

Note:
A UM dial plan and a UM mailbox policy must exist before you can enable UM.

- **Mobile Devices** Use this section to view and change the settings for Exchange ActiveSync, which is enabled by default. Exchange ActiveSync enables access to an Exchange mailbox from a mobile device. Click **Disable Exchange ActiveSync** to disable this feature for the mailbox.
- **Outlook Web App** This feature is enabled by default. Outlook Web App enables access to an Exchange mailbox from a web browser. Click **Disable** to disable Outlook Web App for the mailbox. Click **Edit details** to add or change an Outlook Web App mailbox policy for the mailbox.
- **IMAP** This feature is enabled by default. Click **Disable** to disable IMAP for the mailbox.
- **POP3** This feature is enabled by default. Click **Disable** to disable POP3 for the mailbox.
- **MAPI** This feature is enabled by default. MAPI enables access to an Exchange mailbox from a MAPI client such as Outlook. Click **Disable** to disable MAPI for the mailbox.
- **Litigation hold** This feature is disabled by default. Litigation hold preserves deleted mailbox items and records changes made to mailbox items. Deleted items and all instances of changed items are returned in a discovery search. Click **Enable** to put the mailbox on litigation hold. If the mailbox is on litigation hold, click **Disable** to remove the litigation hold. Mailboxes on litigation hold are inactive mailboxes and can't be deleted. To delete the mailbox, remove the litigation hold. If the mailbox is on litigation hold, click **Edit details** to view and change the following litigation hold settings:
  - **Hold date** This read-only box indicates the date and time when the mailbox was put on litigation hold.
  - **Put on hold by** This read-only box indicates the user who put the mailbox on litigation hold.
  - **Note** Use this box to notify the user about the litigation hold, explain why the mailbox is on litigation hold, or provide additional guidance to the user, such as informing them that the litigation hold won't affect their day-to-day use of email.
  - **URL** Use this box to provide a URL to a website that provides information or guidance about the litigation hold on the mailbox.

Note:
The text from these boxes appears in the user's mailbox only if they are using Outlook 2010 or later versions. It doesn't appear in Outlook Web App or other email clients. To view the text from the Note and URL boxes in Outlook, click the **File** tab, and on the **Info** page, under **Account Settings**, you'll see the litigation hold comment.

- **Archiving** If an archive mailbox doesn't exist for the user, this feature is disabled. To enable an

archive mailbox, click **Enable**. If the user has an archive mailbox, the size of the archive mailbox and usage statistics are displayed. Click **Edit details** to view and change the following archive mailbox settings:

- **Status** This read-only box indicates whether an archive mailbox exists.
- **Database** This read-only box shows the name of the mailbox database that hosts the archive mailbox. This box isn't available in Exchange Online.
- **Name** Type the name of the archive mailbox in this box. This name is displayed under the folder list in Outlook or Outlook Web App.
- **Archive quota (GB)** This box shows the total size of the archive mailbox. To change the size, type a new value in the box or select a value from the drop-down list.
- **Issue warning at (GB)** This box shows the maximum storage limit for the archive mailbox before a warning is issued to the user. If the archive mailbox size reaches or exceeds the value specified, Exchange sends a warning message to the user. To change this limit, type a new value in the box or select a value from the drop-down list.

Note:
The archive quota and the issue warning quota for the archive mailbox can't be changed in Exchange Online.

- **Delivery Options** Use to forward email messages sent to the user to another recipient and to set the maximum number of recipients that the user can send a message to. Click **View details** to view and change these settings.
  - **Forwarding address** Select the **Enable forwarding** check box and then click **Browse** to display the **Select Mail User and Mailbox** page. Use this page to select a recipient to whom you want to forward all email messages that are sent to this mailbox.
  - **Deliver message to both forwarding address and mailbox** Select this check box so that messages will be delivered to both the forwarding address and the user's mailbox.
  - **Recipient limit** This setting controls the maximum number of recipients the user can send a message to. Select the **Maximum recipients** check box to limit the number of recipients allowed in the To:, Cc:, and Bcc: boxes of an email message and then specify the maximum number of recipients.

Note:
For on-premises Exchange organizations, the recipient limit is unlimited. For Exchange Online organizations, the limit is 500 recipients.

- **Message Size Restrictions** These settings control the size of messages that the user can send and receive. Click **View details** to view and change maximum size for sent and received messages.

Note:
These settings can't be changed in Exchange Online.

  - **Sent messages** To specify a maximum size for messages sent by this user, select the **Maximum message size (KB)** check box and type a value in the box. The message size must be between 0 and 2,097,151 KB. If the user sends a message larger than the specified size, the message will be returned to the user with a descriptive error message.

- **Received messages** To specify a maximum size for messages received by this user, select the **Maximum message size (KB)** check box and type a value in the box. The message size must be between 0 and 2,097,151 KB. If the user receives a message larger than the specified size, the message will be returned to the sender with a descriptive error message.

- **Message Delivery Restrictions** These settings control who can send email messages to this user. Click **View details** to view and change these restrictions.
  - **Accept messages from** Use this section to specify who can send messages to this user.
    - **All senders** Select this option to specify that the user can accept messages from all senders. This includes both senders in your Exchange organization and external senders. This option is selected by default. This option includes external users only if you clear the **Require that all senders are authenticated** check box. If you select this check box, messages from external users will be rejected.
    - **Only senders in the following list** Select this option to specify that the user can accept messages only from a specified set of senders in your Exchange organization. Click **Add +** to display the **Select Recipients** page, which displays a list of all recipients in your Exchange organization. Select the recipients you want, add them to the list, and then click **OK**. You can also search for a specific recipient by typing the recipient's name in the search box and then clicking **Search** 🔍.
    - **Require that all senders are authenticated** Select this option to prevent anonymous users from sending messages to the user.
  - **Reject messages from** Use this section to block people from sending messages to this user.
    - **No senders** Select this option to specify that the mailbox won't reject messages from any senders in the Exchange organization. This option is selected by default.
    - **Senders in the following list** Select this option to specify that the mailbox will reject messages from a specified set of senders in your Exchange organization. Click **Add+** to display the **Select Recipients** page, which displays a list of all recipients in your Exchange organization. Select the recipients you want, add them to the list, and then click **OK**. You can also search for a specific recipient by typing the recipient's name in the search box and then clicking **Search** 🔍.

Member Of

Use the **Member Of** section to view a list of the distribution groups or security groups to which this user belongs. You can't change membership information on this page. Note that the user may match the criteria for one or more dynamic distribution groups in your organization. However, dynamic distribution groups aren't displayed on this page because their membership is calculated each time they are used.

MailTip

Use the **MailTip** section to add a MailTip to alert users of potential issues if they send a message to this recipient. A MailTip is text that is displayed in the InfoBar when this recipient is added to the To, Cc, or Bcc boxes of a new email message.

Note:

MailTips can include HTML tags, but scripts aren't allowed. The length of a custom MailTip can't exceed 175 displayed characters. HTML tags aren't counted in the limit.

Mailbox Delegation

Use the **Mailbox Delegation** section to assign permissions to other users (also called *delegates*) to allow them to sign in to the user's mailbox or send messages on behalf of the user. You can assign the following permissions:

- **Send As** This permission allows users other than the mailbox owner to use the mailbox to send messages. After this permission is assigned to a delegate, any message that a delegate sends from this mailbox will appear as if it was sent by the mailbox owner. However, this permission doesn't allow a delegate to sign in to the user's mailbox.
- **Send on Behalf Of** This permission also allows a delegate to use this mailbox to send messages. However, after this permission is assigned to a delegate, the **From:** address in any message sent by the delegate indicates that the message was sent by the delegate on behalf of the mailbox owner.
- **Full Access** This permission allows a delegate to sign in to the user's mailbox and view the contents of the mailbox. However, after this permission is assigned to a delegate, the delegate can't send messages from the mailbox. To allow a delegate to send email from the user's mailbox, you still have to assign the delegate the Send As or the Send on Behalf Of permission.

To assign permissions to delegates, click **Add +** under the appropriate permission to display a page that displays a list of all recipients in your Exchange organization that can be assigned the permission. Select the recipients you want, add them to the list, and then click **OK**. You can also search for a specific recipient by typing the recipient's name in the search box and then clicking **Search** .

Use the Shell to change user mailbox properties

Use the **Get-Mailbox** and **Set-Mailbox** cmdlets to view and change properties for user mailboxes. One advantage of using the Shell is the ability to change the properties for multiple mailboxes. For information about what parameters correspond to mailbox properties, see the following topics:

- Get-Mailbox
- Set-Mailbox

Here are some examples of using the Shell to change user mailbox properties.

This example shows how to forward Pat Coleman's email messages to Sunil Koduri's (sunilk@contoso.com) mailbox.

```
Set-Mailbox -Identity patc -DeliverToMailboxAndForward
$true -ForwardingAddress sunilk@contoso.com
```

This example uses the **Get-Mailbox** command to find all user mailboxes in the organization, and then uses the **Set-Mailbox** command to set the recipient limit to 500 recipients allowed in the To:,

Cc:, and Bcc: boxes of an email message.

```
Get-Mailbox -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'UserMailbox')} | Set-Mailbox -
RecipientLimits 500
```

This example uses the **Get-Mailbox** command to find all the mailboxes in the Marketing organizational unit, and then uses the **Set-Mailbox** command to configure these mailboxes. The custom warning, prohibit send, and prohibit send and receive limits are set to 200 megabytes (MB), 250 MB, and 280 MB respectively, and the mailbox database's default limits are ignored. This command can be used to configure a specific set of mailboxes to have larger or smaller limits than other mailboxes in the organization.

```
Get-Mailbox -OrganizationalUnit "Marketing" | Set-Mailbox -
IssueWarningQuota 209715200 -ProhibitSendQuota 262144000 -
ProhibitSendReceiveQuota 293601280 -
UseDatabaseQuotaDefaults $false
```

This example uses the **Get-Mailbox** cmdlet to find all users in the Customer Service department, and then uses the **Set-Mailbox** cmdlet to change the maximum message size for sending messages to 2 MB.

```
Get-Mailbox -Filter "Department -eq 'Customer Service'" |
Set-Mailbox -MaxSendSize 2097152
```

This example sets the MailTip translation in French and Chinese.

```
Set-Mailbox john@contoso.com -MailTipTranslations ("FR:
C'est la langue française", "CHT: 這是漢語語言")
```

How do you know this worked?

To verify that you've successfully changed properties for a user mailbox, do the following:

- In the EAC, select the mailbox and then click **Edit** ✎ to view the property or feature that you changed. Depending on the property that you changed, it might be displayed in the Details pane for the selected mailbox.
- In the Shell, use the **Get-Mailbox** cmdlet to verify the changes. One advantage of using the Shell is that you can view multiple properties for multiple mailboxes. In the example above where the recipient limit was changed, run the following command to verify the new value.

```
Get-Mailbox -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'UserMailbox')} | fl
Name,RecipientLimits
```

For the example above where the message limits were changed, run this command.

```
Get-Mailbox -OrganizationalUnit "Marketing" | fl
Name,IssueWarningQuota,ProhibitSendQuota,ProhibitSendReceiv
eQuota,UseDatabaseQuotaDefaults
```

Bulk edit user mailboxes

You can use the EAC to change the properties for multiple user mailboxes. When you select two or more user mailboxes from the mailbox list in the EAC, the properties that can be bulk edited are displayed in the Details pane. When you change one of these properties, the change is applied to all selected mailboxes.

Here's a list of the user mailbox properties and features that can be bulk edited. Note that not all properties in each area are available to be changed.

- **Contact Information** Change shared properties such as street, postal code, and city name.
- **Organization** Change shared properties such as department name, company name, and the manager that the selected users report to.
- **Custom attributes** Change or add values for custom attributes 1 – 15.
- **Mailbox quota** Change the mailbox quota values and the retention period for deleted items. This isn't available in Exchange Online.
- **Email connectivity** Enable or disable Outlook Web App, POP3, IMAP, MAPI, and Exchange ActiveSync.
- **Archive** Enable or disable the archive mailbox.
- **Retention policy, role assignment policy, and sharing policy** Update the settings for each of these mailbox features.
- **Move mailboxes to another database** Move the selected mailboxes to a different database.
- **Delegate permissions** Assign permissions to users or groups that allow them to open or send messages from other mailboxes. You can assign Full, Send As and Send on Behalf permissions to users or groups. Check out Manage Permissions for Recipients for more details.

Note:

The estimated time to complete this task is 2 minutes, but may take longer if you change multiple properties or features.

Use the EAC to bulk edit user mailboxes

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of mailboxes, select two or more mailboxes.

Tip:

You can select multiple adjacent mailboxes by holding down the Shift key and clicking the first mailbox, and then clicking the last mailbox you want to edit. You can also select multiple non-adjacent mailboxes by holding down the Ctrl key and clicking each mailbox that you want to edit.

3. In the Details pane, under **Bulk Edit**, select the mailbox properties or feature that you want to edit.
4. Make the changes on the properties page and then save your changes.

How do you know this worked?

To verify that you've successfully bulk edited user mailboxes, do one of the following:

- In the EAC, select each of the mailboxes that you bulk edited and then click **Edit** to view the property or feature that you changed.
- In the Exchange Management Shell, use the **Get-Mailbox** cmdlet to verify the changes. One advantage of using the Shell is that you can view multiple properties for multiple mailboxes. For example, say you used the bulk edit feature in the EAC to enable the archive mailbox and assign a retention policy to all users in your organization. To verify these changes, you could run the following command:

```
Get-Mailbox -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'UserMailbox')} | fl
Name,ArchiveDatabase,RetentionPolicy
```

For more information about the available parameters for the **Get-Mailbox** cmdlet, see Get-Mailbox.

Add or remove email addresses for a mailbox

Exchange Server 2013 > Recipients > Manage user mailboxes >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-06-07*

You can use the EAC or the Shell to add or remove an email address for a user mailbox. You can configure more than one email address for the same mailbox. The additional addresses are called *proxy addresses*. A proxy address lets a user receive email that's sent to a different email address. Any email message sent to the user's proxy address is delivered to their primary email address, which is also known as the *primary SMTP address* or the *default reply address*.

Note:
The procedures in this topic show how to add or remove email addresses for a user mailbox. You can use similar procedures to add or remove email addresses for other recipient types.

For additional management tasks related to managing recipients, see the "Recipients documentation" table in Recipients.

What do you need to know before you begin?

- Estimated time to complete each procedure: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Add an email address to a user mailbox

Use the EAC to add an email address

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of user mailboxes, click the mailbox that you want to add an email address to, and then click **Edit** .
3. On the mailbox properties page, click **Email Address**.

Note:

On the **Email Address** page, the primary SMTP address is displayed in bold text in the address list, with the uppercase **SMTP** value in the **Type** column.

4. Click **Add +**, and then click **SMTP** to add an SMTP email address to this mailbox.

Note:

SMTP is the default email address type. You can also add Exchange Unified Messaging (EUM) addresses or custom addresses to a mailbox. For more information, see "Change user mailbox properties" in the Manage user mailboxes topic.

5. Type the new SMTP address in the **Email address** box, and then click **OK**.

The new address is displayed in the list of email addresses for the selected mailbox.

6. Click **Save** to save the change.

Use the Shell to add an email address

The email addresses associated with a mailbox are contained in the *EmailAddresses* property for the mailbox. Because it can contain more than one email address, the *EmailAddresses* property is known as a *multivalued* property. The following examples show different ways to modify a multivalued property.

This example shows how to add an SMTP address to the mailbox of Dan Jump.

```
Set-Mailbox "Dan Jump" -EmailAddresses
@{add="dan.jump@northamerica.contoso.com"}
```

This example shows how to add multiple SMTP addresses to a mailbox.

```
Set-Mailbox "Dan Jump" -EmailAddresses
@{add="dan.jump@northamerica.contoso.com","danj@tailspintoy
s.com"}
```

For more information about how to use this method of adding and removing values for multivalued properties, see Modifying multivalued properties.

This example shows another way to add email addresses to a mailbox by specifying all addresses associated with the mailbox. In this example, danj@tailspintoys.com is the new email address that you want to add. The other two email addresses are existing addresses. The address with the case-sensitive qualifier SMTP is the primary SMTP address. You have to include all email addresses for the mailbox when you use this command syntax. If you don't, the addresses specified in the command will overwrite the existing addresses.

```
Set-Mailbox "Dan Jump" -EmailAddresses
SMTP:dan.jump@contoso.com,dan.jump@northamerica.contoso.com
,danj@tailspintoys.com
```

For detailed syntax and parameter information, see Set-Mailbox.

How do you know this worked?

To verify that you've successfully added an email address to a mailbox, do one of the following:

- In the EAC, navigate to **Recipients** > **Mailboxes**, click the mailbox, and then click **Edit** ✎.
- On the mailbox properties page, click **Email Address**.
- In the list of email addresses for the mailbox, verify that the new email address is included.

Or

- Run the following command in the Shell.

```
Get-Mailbox <identity> | fl EmailAddresses
```

- Verify that the new email address is included in the results.

Remove an email address from a user mailbox

Use the EAC to remove an email address

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of user mailboxes, click the mailbox that you want to remove an email address from, and then click **Edit** ✎.

3. On the mailbox properties page, click **Email Address**.
4. In the list of email addresses, select the address you want to remove, and then click **Remove** —.
5. Click **Save** to save the change.

Use the Shell to remove an email address

This example shows how to remove an email address from the mailbox of Janet Schorr.

```
Set-Mailbox "Janet Schorr" -EmailAddresses
@{remove="janets@corp.contoso.com"}
```

This example shows how to remove multiple addresses from a mailbox.

```
Set-Mailbox "Janet Schorr" -EmailAddresses
@{remove="janet.schorr@corp.contoso.com","janets@tailspinto
ys.com"}
```

For more information about how to use this method of adding and removing values for multivalued properties, see Modifying multivalued properties.

You can also remove an email address by omitting it from the command to set email addresses for a mailbox. For example, let's say Janet Schorr's mailbox has three email addresses: janets@contoso.com (the primary SMTP address), janets@corp.contoso.com, and janets@tailspintoys.com. To remove the address janets@corp.contoso.com, you would run the following command.

```
Set-Mailbox "Janet Schorr" -EmailAddresses
SMTP:janets@contoso.com,janets@tailspintoys.com
```

Because janets@corp.contoso.com was omitted in the previous command, it's removed from the mailbox.

For detailed syntax and parameter information, see Set-Mailbox.

How do you know this worked?

To verify that you've successfully removed an email address from a mailbox, do one of the following:

- In the EAC, navigate to **Recipients** > **Mailboxes**, click the mailbox, and then click **Edit** ✎.
- On the mailbox properties page, click **Email Address**.
- In the list of email addresses for the mailbox, verify that the email address isn't included.

Or

- Run the following command in the Shell.

```
Get-Mailbox <identity> | fl EmailAddresses
```

- Verify that the email address isn't included in the results.

Use the Shell to add email addresses to multiple mailboxes

You can add a new email address to multiple mailboxes at one time by using the Shell and a comma separated values (CSV) file.

This example imports data from C:\Users\Administrator\Desktop\AddEmailAddress.csv, which has the following format.

```
Mailbox,NewEmailAddress
Dan Jump,danj@northamerica.contoso.com
David Pelton,davidp@northamerica.contoso.com
Kim Akers,kima@northamerica.contoso.com
Janet Schorr,janets@northamerica.contoso.com
Jeffrey Zeng,jeffreyz@northamerica.contoso.com
Spencer Low,spencerl@northamerica.contoso.com
Toni Poe,tonip@northamerica.contoso.com
...
```

Run the following command to use the data in the CSV file to add the email address to each mailbox specified in the CSV file.

```
Import-CSV "C:\Users\Administrator\Desktop
\AddEmailAddress.csv" | ForEach {Set-Mailbox $_.Mailbox -
EmailAddresses @{add=$_.NewEmailAddress}}
```

Note:

The column names in the first row of this CSV file (`Mailbox,NewEmailAddress`) are arbitrary. Whatever you use for column names, make sure you use the same column names in the Shell command.

How do you know this worked?

To verify that you've successfully added an email address to multiple mailboxes, do one of the following:

- In the EAC, navigate to **Recipients** > **Mailboxes**, click a mailbox that you added the address to, and then click **Edit** ✎.
- On the mailbox properties page, click **Email Address**.
- In the list of email addresses for the mailbox, verify that the new email address is included.

Or

- Run the following command in the Shell, using the same CSV file that you used to add the new email address.

```
Import-CSV "C:\Users\Administrator\Desktop
```

```
\AddEmailAddress.csv" | ForEach {Get-Mailbox $_.Mailbox |
fl Name,EmailAddresses}
```

- Verify that the new email address is included in the results for each mailbox.

Configure email forwarding for a mailbox

Exchange Server 2013 > Recipients > Manage user mailboxes >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-08-26*

As an Office 365 admin of an Office 365 Enterprise or Office 365 Midsize organization, you might have company requirements to set up email forwarding for a user's mailbox. Email forwarding lets you to set up a mailbox to forward email messages sent to that mailbox to another user's mailbox in or outside of your organization.

Use the Exchange Admin Center and Exchange Management Shell

You can use either the Exchange Admin Center (EAC) or Exchange Management Shell to set up email forwarding.

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" entry in the Recipients Permissions topic.

Use the Exchange Admin Center to configure email forwarding

1. In the Exchange Admin Center, navigate to **Recipients** > **Mailboxes**.
2. In the list of user mailboxes, click or tap the mailbox that you want to configure mail forwarding for, and then click or tap **Edit** ✎.
3. On the mailbox properties page, click **Mailbox Features**.
4. Under **Mail Flow**, select **View details** to view or change the setting for forwarding email messages.

On this page, you can set the maximum number of recipients that the user can send a message to. For on-premises Exchange organizations, the recipient limit is unlimited. For Exchange Online

organizations, the limit is 500 recipients.

5. Check the **Enable forwarding** check box, and then click or tap **Browse**.
6. On the **Select Recipient** page, select a user you want to forward all email to. Select the **Deliver message to both forwarding address and mailbox** check box if you want both the recipient and the forwarding email address to get copies of the emails sent. Click or tap **OK**, and then click or tap **Save**.

Note:
What if you want to forward emails to an email address outside your organization? You can use Exchange Management Shell to do this. See the example in the "Use Exchange Management Shell to configure mail forwarding".

Use Exchange Management Shell to configure mail forwarding

Haven't used Exchange Management Shell much? Check out the Exchange Management Shell topic to learn more. Take a look at the Get-Mailbox and Set-Mailbox topics for more details on the cmdlets used here.

This example delivers email to the mailbox of Douglas Kohn and, at the same time, forwards all mail sent to Douglas Kohn to douglaskohn.parents@fineartschool.net.

```
Set-Mailbox -Identity "Douglas Kohn" -
DeliverToMailboxAndForward $true -ForwardingSMTPAddress
"douglaskohn.parents@fineartschool.net"
```

This example forwards all email sent to the mailbox of Ken Sanchez, an employee of Contoso Suites, to one of his coworkers, pilarp@contoso.com.

```
Set-Mailbox -Identity "Ken Sanchez" -ForwardingSMTPAddress
"pilarp@contoso.com"
```

For detailed syntax and parameter information, see Set-Mailbox.

How do you know this worked?

To make sure that you've successfully configured email forwarding, do one of the following:

1. In the Exchange Admin Center, go to **Recipients** > **Mailboxes**.
2. In the list of user mailboxes, click or tap the mailbox that you configured email forwarding for, and then click **Edit** ✎.
3. On the mailbox properties page, click or tap **Mailbox Features**.
4. Under **Mail Flow**, click or tap **View details** to view the mail forwarding settings.

Or

Run the following command in the Shell.

```
Get-Mailbox <identity> | fl
ForwardingSMTPAddress,DeliverToMailboxandForward
```

Make sure that the forwarding address is listed in the *ForwardingSMTPAddress* parameter. Also, if the *DeliverToMailboxAndForward* parameter is set to `$true`, messages will be delivered to the mailbox and to the forwarding address. If the parameter is set to `$false`, messages are delivered only to the forwarding address.

End users

Check out the following topics on how to forward your email to another email address by using Outlook and Outlook Web App.

- Forward email to another email account
- Manage email messages by using rules

Additional information

For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Configure message delivery restrictions for a mailbox

Exchange Server 2013 > Recipients > Manage user mailboxes >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-29*

You can use the EAC or the Shell to place restrictions on whether messages are delivered to individual recipients. Message delivery restrictions are useful to control who can send messages to users in your organization. For example, you can configure a mailbox to accept or reject messages sent by specific users or to accept messages only from users in your Exchange organization.

The message delivery restrictions covered in this topic apply to all recipient types. To learn more about the different recipient types, see Recipients.

For additional management tasks related to recipients, see the following topics:

- Manage user mailboxes
- Manage Distribution Groups
- Manage dynamic distribution groups
- Manage mail users
- Manage mail contacts

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to configure message delivery restrictions

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of user mailboxes, click the mailbox that you want to configure message delivery restrictions for, and then click **Edit** .
3. On the mailbox properties page, click **Mailbox Features**.
4. Under **Message Delivery Restrictions**, click **View details** to view and change the following delivery restrictions:
   - **Accept messages from** Use this section to specify who can send messages to this user.
     - **All senders** This option specifies that the user can accept messages from all senders. This includes both senders in your Exchange organization and external senders. This is the default option. It includes external users only if you clear the **Require that all senders are authenticated** check box. If you select this check box, messages from external users will be rejected.
     - **Only senders in the following list** This option specifies that the user can accept messages only from a specified set of senders in your Exchange organization. Click **Add +** to display a list of all recipients in your Exchange organization. Select the recipients you want, add them to the list, and then click **OK**. You can also search for a specific recipient by typing the recipient's name in the search box and then clicking **Search** .
     - **Require that all senders are authenticated** This option prevents anonymous users from sending messages to the user. This includes external users that are outside of your Exchange

organization.

- **Reject messages from** Use this section to block people from sending messages to this user.
  - **No senders** This option specifies that the mailbox won't reject messages from any senders in the Exchange organization. This is the default option.
  - **Senders in the following list** This option specifies that the mailbox will reject messages from a specified set of senders in your Exchange organization. Click **Add +** to display a list of all recipients in your Exchange organization. Select the recipients you want, add them to the list, and then click **OK**. You can also search for a specific recipient by typing the recipient's name in the search box and then clicking **Search**.

5. Click **OK** to close the **Message Delivery Restrictions** page, and then click **Save** to save your changes.

Use the Shell to configure message delivery restrictions

The following examples show how to use the Shell to configure message delivery restrictions for a mailbox. For other recipient types, use the corresponding **Set-** cmdlet with the same parameters.

This example configures the mailbox of Robin Wood to accept messages only from the users Lori Penor, Jeff Phillips, and members of the distribution group Legal Team 1.

```
Set-Mailbox -Identity "Robin Wood" -AcceptMessagesOnlyFrom
"Lori Penor","Jeff Phillips" -
AcceptMessagesOnlyFromDLMembers "Legal Team 1"
```

Note:

If you're configuring a mailbox to accept messages only from individual senders, you have to use the *AcceptMessagesOnlyFrom* parameter. If you're configuring a mailbox to accept messages only from senders that are members of a specific distribution group, use the *AcceptMessagesOnlyFromDLMembers* parameter.

This example adds the user named David Pelton to the list of users whose messages will be accepted by the mailbox of Robin Wood.

```
Set-Mailbox -Identity "Robin Wood" -AcceptMessagesOnlyFrom
@{add="David Pelton"}
```

This example configures the mailbox of Robin Wood to require all senders to be authenticated. This means the mailbox will only accept messages sent by other users in your Exchange organization.

```
Set-Mailbox -Identity "Robin Wood" -
RequireSenderAuthenticationEnabled $true
```

This example configures the mailbox of Robin Wood to reject messages from the users Joe Healy, Terry Adams, and members of the distribution group Legal Team 2.

```
Set-Mailbox -Identity "Robin Wood" -RejectMessagesFrom "Joe
Healy","Terry Adams" -RejectMessagesFromDLMembers "Legal
Team 2"
```

This example configures the mailbox of Robin Wood to also reject messages sent by members of the group Legal Team 3.

```
Set-Mailbox -Identity "Robin Wood" -
RejectMessagesFromDLMembers @{add="Legal Team 3"}
```

Note:

If you're configuring a mailbox to reject messages from individual senders, you have to use the *RejectMessagesFrom* parameter. If you're configuring a mailbox to reject messages from senders that are members of a specific distribution group, use the *RejectMessagesFromDLMembers* parameter.

For detailed syntax and parameter information related to configuring delivery restrictions for different types of recipients, see the following topics:

- Set-DistributionGroup
- Set-DynamicDistributionGroup
- Set-Mailbox
- Set-MailContact
- Set-MailUser

How do you know this worked?

To verify that you've successfully configured message delivery restrictions for a user mailbox, do one the following:

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of user mailboxes, click the mailbox that you want to verify the message delivery restrictions for, and then click **Edit** .
3. On the mailbox properties page, click **Mailbox Features**.
4. Under **Message Delivery Restrictions**, click **View details** to verify the delivery restrictions for the mailbox.

Or

Run the following command in the Shell.

```
Get-Mailbox <identity> | fl
AcceptMessagesOnlyFrom,AcceptMessagesOnlyFromDLMembers,Reje
ctMessagesFrom,RejectMessagesFromDLMembers,RequireSenderAut
henticationEnabled
```

Configure message size limits for a mailbox

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-11-12*

You can use the EAC and the Shell to configure message size limits for a user mailbox. These limits control the size of messages that a user can send and receive. By default, when a mailbox is created, there isn't a size limit for sent and received messages.

Keep in mind that there are other settings in an Exchange organization that determine the maximum message size a mailbox can send and receive (for example, the maximum message size configured on a Mailbox server). To learn more about the message size restrictions in Exchange, including the types of message size limits, their scope, and the order of precedence, see Message size limits.

For additional management tasks related to user mailboxes, see Manage user mailboxes.

Note:

You can also control the size of messages sent and received by mail users and from shared mailboxes.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to configure message size limits

1. In the EAC, navigate to **Recipients** > **Mailboxes**.

2. In the list of user mailboxes, click the mailbox that you want to change the message size limits for, and then click **Edit** ✎.
3. On the mailbox properties page, click **Mailbox Features**.
4. Under **Message Size Restrictions**, click **View details** to view and change the following message size limits:
   - **Sent messages** To specify a maximum size for messages sent by this user, select the **Maximum message size (KB)** check box and type a value in the box. The message size must be between 0 and 2,097,151 KB. If the user sends a message larger than the specified size, the message will be returned to the user with a descriptive error message.
   - **Received messages** To specify a maximum size for messages received by this user, select the **Maximum message size (KB)** check box and type a value in the box. The message size must be between 0 and 2,097,151 KB. If the user receives a message larger than the specified size, the message will be returned to the sender with a descriptive error message.
5. Click **OK**, and then click **Save** to save your changes.

Use the Shell to configure message size limits

This example sets the maximum size for sent messages to 25 MB and the maximum size for received messages to 35 MB for the mailbox of Debra Garcia.

```
Set-Mailbox "Debra Garcia" -MaxSendSize 25mb -
MaxReceiveSize 35mb
```

For detailed syntax and parameter information, see Set-Mailbox.

How do you know this worked?

To verify that you've successfully configured message size limits for a mailbox, do one of the following:

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of user mailboxes, click the mailbox that you want to verify the message size limits for, and then click **Edit** ✎.
3. On the mailbox properties page, click **Mailbox Features**.
4. Under **Message Size Restrictions**, click **View details** to verify the message size limits for the mailbox.

Or

Run the following command in the Shell.

```
Get-Mailbox <identity> | fl MaxSendSize,MaxReceiveSize
```

Configure storage quotas for a mailbox

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-11-29*

You can use the EAC or the Shell to customize the mailbox storage quotas for specific mailboxes. Storage quotas let you control the size of mailboxes and manage the growth of mailbox databases. When a mailbox reaches or exceeds a specified storage quota, Exchange sends a descriptive notification to the mailbox owner.

Storage quotas are typically configured on a per-database basis. This means that the quotas configured for a mailbox database apply to all mailboxes in that database. For more information about managing per-database mailbox settings, see Manage mailbox databases in Exchange 2013.

This topic shows you how to customize storage settings for a specific mailbox instead of using the storage settings from the mailbox database. For additional management tasks related to user mailboxes, see Manage user mailboxes.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to configure storage quotas for a mailbox

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of user mailboxes, click the mailbox that you want to change the storage quotas for, and then click **Edit** .
3. On the mailbox properties page, click **Mailbox Usage**, and then click **More options**.
4. Click **Customize the settings for this mailbox**, and then configure the following boxes. The value range for any of the storage quota settings is from 0 through 2047 gigabytes (GB).

- **Issue a warning at (GB)** This box displays the maximum storage limit before a warning is issued to the user. If the mailbox size reaches or exceeds the value specified, Exchange sends a warning message to the user.

Important:
The message associated with the **Issue warning** quota won't be sent to the user unless the value of this setting is greater than 50% of the value specified in the **Prohibit send** quota. For example, if you set the **Prohibit send** quota to 8 MB, you must set the **Issue warning** quota to at least 4 MB. If you don't, the **Issue warning** quota message won't be sent.

- **Prohibit send at (GB)** This box displays the *prohibit send* limit for the mailbox. If the mailbox size reaches or exceeds the specified limit, Exchange prevents the user from sending new messages and displays a descriptive error message.
- **Prohibit send and receive at (GB)** This box displays the *prohibit send and receive* limit for the mailbox. If the mailbox size reaches or exceeds the specified limit, Exchange prevents the mailbox user from sending new messages and won't deliver any new messages to the mailbox. Any messages sent to the mailbox are returned to the sender with a descriptive error message.

5. Click **Save** to save your changes.

Use the Shell to configure storage quotas for a mailbox

This example sets the issue warning, prohibit send, and prohibit send and receive quotas for Joe Healy's mailbox to 24.5 GB, 24.75 GB, and 25 GB respectively.

Note:
To ensure that the custom settings for the mailbox are used rather than the mailbox database defaults, you must set the *UseDatabaseQuotaDefaults* parameter to `$false`.

```
Set-Mailbox -Identity "Joe Healy" -IssueWarningQuota 24.5gb
-ProhibitSendQuota 24.75gb -ProhibitSendReceiveQuota 25gb -
UseDatabaseQuotaDefaults $false
```

This example sets the issue warning, prohibit send, and prohibit send and receive quotas for Ayla Kol's mailbox to 900 megabytes (MB), 950 MB, and 1 GB respectively, and configures the mailbox to use custom settings.

```
Set-Mailbox -Identity "Ayla Kol" -IssueWarningQuota 900mb -
ProhibitSendQuota 950mb -ProhibitSendReceiveQuota 1gb -
UseDatabaseQuotaDefaults $false
```

For detailed syntax and parameter information, see Set-Mailbox.

How do you know this worked?

To verify that you've successfully set the storage quotas for a mailbox, do one of the following:

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of user mailboxes, click the mailbox that you want to verify the storage quotas for, and then click **Edit** ✎.
3. On the mailbox properties page, click **Mailbox Usage**, and then click **More options**.
4. Verify that **Customize the settings for this mailbox** is selected.
5. Verify the storage quota settings.

Or

Run the following command in the Shell.

```
Get-Mailbox <identity> | fl
IssueWarningQuota,ProhibitSendQuota,ProhibitSendReceiveQuot
a,UseDatabaseQuotaDefaults
```

Convert a Mailbox

Exchange Server 2013 > Recipients > Manage user mailboxes >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-01-08*

Converting a mailbox to a different type of mailbox is very similar to the experience in Exchange 2010. You must still use the Set-Mailbox cmdlet in the Shell to do the conversion.

You can convert the following mailboxes from one type to another:

- User mailbox to resource mailbox
- Shared mailbox to user mailbox
- Shared mailbox to resource mailbox
- Resource mailbox to user mailbox
- Resource mailbox to shared mailbox

Use the Shell to convert a mailbox

Estimated time to complete: 5 minutes.

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.

This example converts the shared mailbox, MarketingDept1 to a user mailbox.

```
Set-Mailbox MarketingDept1 -Type Regular
```

You can use the following values for the *Type* parameter:

- Regular
- Room
- Equipment
- Shared

For detailed syntax and parameter information, see Set-Mailbox.

How do you know this worked?

To verify that you have successfully converted the mailbox, run the following Shell command:

```
Get-Mailbox -Identity MarketingDept1 | Format-List
RecipientTypeDetails
```

The value for *RecipientTypeDetails* should be *UserMailbox*.

For detailed syntax and parameter information, see Get-Mailbox.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Enable or disable Exchange ActiveSync for a mailbox

Exchange Server 2013 > Recipients > Manage user mailboxes >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-13*

You can use the EAC or the Shell to enable or disable Microsoft Exchange ActiveSync for a user mailbox. Exchange ActiveSync is a client protocol that lets users synchronize a mobile device with their Exchange mailbox. Exchange ActiveSync is enabled by default when a user mailbox is created. To learn more, see Exchange ActiveSync.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Exchange ActiveSync settings" entry in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see

Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to enable or disable Exchange ActiveSync

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of user mailboxes, click the mailbox that you want to enable or disable Exchange ActiveSync for, and then click **Edit** .
3. On the mailbox properties page, click **Mailbox Features**.
4. Under **Mobile Devices**, do one of the following:
   - To disable Exchange ActiveSync click **Disable Exchange ActiveSync**.

A warning appears asking if you're sure you want to disable Exchange ActiveSync. Click **Yes**.

   - To enable Exchange ActiveSync, click **Enable Exchange ActiveSync**.
5. Click **Save** to save your change.

Note:

You can enable and disable Exchange ActiveSync for multiple user mailboxes by using the EAC bulk edit feature. For more information about how to do this, see the "Bulk edit user mailboxes" section in Manage user mailboxes.

Use the Shell to enable or disable Exchange ActiveSync

This example disables Exchange ActiveSync for the mailbox of Yan Li.

```
Set-CASMailbox -Identity "Yan Li" -ActiveSyncEnabled $false
```

This example enables Exchange ActiveSync for the mailbox of Elly Nkya.

```
Set-CASMailbox -Identity Ellyn@contoso.com -
ActiveSyncEnabled $true
```

For detailed syntax and parameter information, see Set-CASMailbox.

How do you know this worked?

To verify that you've successfully enabled or disabled Exchange ActiveSync for a user mailbox, do one of the following:

- In the EAC, navigate to **Recipients** > **Mailboxes**, click the mailbox, and then click **Edit** .
- On the mailbox properties page, click **Mailbox Features**.

- Under **Mobile Devices**, verify whether Exchange ActiveSync is enabled or disabled.

Or

- Run the following command in the Shell.

```
Get-CASMailbox <identity>
```

If Exchange ActiveSync is enabled, the value for the *ActiveSyncEnabled* property is `True`. If Exchange ActiveSync is disabled, the value is `False`.

Enable or disable MAPI for a mailbox

Exchange Server 2013 > Recipients > Manage user mailboxes >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-26*

You can use the EAC or the Shell to enable or disable MAPI for a user mailbox. When MAPI is enabled, a user's mailbox can be accessed by Microsoft Outlook or other MAPI email clients. When MAPI is disabled, it can't be accessed by Outlook or other MAPI clients. But the mailbox will continue to receive email messages, and a user can access it to send and receive email by using Outlook Web App, a POP email client, or an IMAP client, assuming that the mailbox is enabled to support access by those clients.

Note:

Support for Outlook Web App and MAPI, POP3, and IMAP4 email clients is enabled by default when a user mailbox is created.

For additional management tasks related to managing email client access to a mailbox, see the following topics:

- Enable or disable Outlook Web App for a mailbox
- Enable or disable IMAP4 access for a user
- Enable or disable POP3 access for a user

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Client Access user settings" entry in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to enable or disable MAPI

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of user mailboxes, click the mailbox that you want to enable or disable MAPI, and then click **Edit** ✎.
3. On the mailbox properties page, click **Mailbox Features**.
4. Under **Email Connectivity**, do one of the following.
   - To disable MAPI, under **MAPI: Enabled**, click **Disable**.

A warning appears asking if you're sure you want to disable MAPI. Click **Yes**.

   - To enable MAPI, under **MAPI: Disabled**, click **Enable**.
5. Click **Save** to save your change.

Use the Shell to enable or disable MAPI

This example disables MAPI for the mailbox of Ken Sanchez.

```
Set-CASMailbox -Identity "Ken Sanchez" -MAPIEnabled $false
```

This example enables MAPI for the mailbox of Esther Valle.

```
Set-CASMailbox -Identity "Esther Valle" -MAPIEnabled $true
```

For detailed syntax and parameter information, see Set-CASMailbox.

How do you know this worked?

To verify that you've successfully enabled or disabled MAPI for a user mailbox, do one of the following:

- In the EAC, navigate to **Recipients** > **Mailboxes**, click the mailbox, and then click **Edit** ✎.
- On the mailbox properties page, click **Mailbox Features**.
- Under **Email Connectivity**, verify whether MAPI is enabled or disabled.

Or

- Run the following command in the Shell.

```
Get-CASMailbox <identity>
```

If MAPI is enabled, the value for the *MapiEnabled* property is `True`. If MAPI is disabled, the value is `False`.

Enable or disable Outlook Web App for a mailbox

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-14*

You can use the EAC or the Shell to enable or disable Outlook Web App for a user mailbox. When Outlook Web App is enabled, a user can use Outlook Web App to send and receive email. When Outlook Web App is disabled, the mailbox will continue to receive email messages, and a user can access it to send and receive email by using a MAPI client, such as Microsoft Outlook, or with a POP or IMAP email client, assuming that the mailbox is enabled to support access by those clients.

Note:
Support for Outlook Web App and MAPI, POP3, and IMAP4 email clients is enabled by default when a user mailbox is created.

For additional management tasks related to managing email client access to a mailbox, see the following topics:

- Enable or disable MAPI for a mailbox
- Enable or disable IMAP4 access for a user
- Enable or disable POP3 access for a user

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Client Access user settings" entry in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to enable or disable Outlook Web App

1. In the EAC, navigate to **Recipients** > **Mailboxes**.

2. In the list of user mailboxes, click the mailbox that you want to enable or disable Outlook Web App for, and then click **Edit** .
3. On the mailbox properties page, click **Mailbox Features**.
4. Under **Email Connectivity**, do one of the following:
   - To disable Outlook Web App, under **Outlook Web App: Enabled**, click **Disable**.

A warning appears asking if you're sure you want to disable Outlook Web App. Click **Yes**.

   - To enable Outlook Web App, under **Outlook Web App: Disabled**, click **Enable**.
5. Click **Save** to save your change.

Note:

You can enable and disable Outlook Web App for multiple user mailboxes by using the EAC bulk edit feature. For more information about how to do this, see the "Bulk edit user mailboxes" section in Manage user mailboxes.

Use the Shell to enable or disable Outlook Web App

This example disables Outlook Web App for the mailbox of Yan Li.

```
Set-CASMailbox -Identity "Yan Li" -OWAEnabled $false
```

This example enables Outlook Web App for the mailbox of Elly Nkya.

```
Set-CASMailbox -Identity Ellyn@contoso.com -OWAEnabled
$true
```

For detailed syntax and parameter information, see Set-CASMailbox.

How do you know this worked?

To verify that you've successfully enabled or disabled Outlook Web App for a user mailbox, do one of the following:

- In the EAC, navigate to **Recipients** > **Mailboxes**, click the mailbox, and then click **Edit** .
- On the mailbox properties page, click **Mailbox Features**.
- Under **Email Connectivity**, verify whether Outlook Web App is enabled or disabled.

Or

- Run the following command in the Shell.

```
Get-CASMailbox <identity>
```

If Outlook Web App is enabled, the value for the *OWAEnabled* property is `True`. If Outlook Web App is disabled, the value is `False`.

Enable single item recovery for a mailbox

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-03-11*

You can use the Shell to enable single item recovery on a mailbox. By default, single item recovery is disabled when a mailbox is created. If single item recovery is enabled, messages that are permanently deleted by the user are retained in the Recoverable Items folder of the mailbox until the deleted item retention period expires. If a message is changed by a user or a process, copies of the original item are also retained. In an on-premises Exchange organization, the mailbox uses the deleted item retention settings of the mailbox database, by default. The deleted item retention period for a mailbox database is set to 14 days, but you can override the default by configuring this setting on a per-mailbox basis.

If a mailbox is placed on In-Place Hold or litigation hold, deleted items are retained until the hold is removed.

To learn more about single item recovery, see Recoverable Items folder. To recover messages deleted by the user before the deleted item retention period expires, see Perform single item recovery.

Note:
In Exchange Online, the deleted item retention period is set to 14 days, by default. You can change this setting to a maximum of 30 days.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Retention and legal holds" entry in the Recipients Permissions topic.
- You can't use the Exchange admin center (EAC) to enable single item recovery. But in an on-premises Exchange organization, you can use the EAC to change the deleted item retention period. For details, see Configure Deleted Item retention and Recoverable Items quotas.

In Exchange Online, you have to use the Shell to change the deleted item retention period. For details, see **Change the Deleted Item Retention Period for a Mailbox in Exchange Online**.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

Use the Shell to enable single item recovery

This example enables single item recovery for the mailbox of April Summers.

```
Set-Mailbox -Identity "April Summers" -
SingleItemRecoveryEnabled $true
```

This example enables single item recovery for the mailbox of Pilar Pinilla and sets the number of days that deleted items are retained to 30 days.

```
Set-Mailbox -Identity "Pilar Pinilla" -
SingleItemRecoveryEnabled $true -RetainDeletedItemsFor 30
```

This example enables single item recovery for all user mailboxes in the organization.

```
Get-Mailbox -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'UserMailbox')} | Set-Mailbox -
SingleItemRecoveryEnabled $true
```

For detailed syntax and parameter information, see Set-Mailbox.

How do you know this worked?

To verify that you've enabled single item recovery for a mailbox and display the value for how long deleted items will be retained (in days), run the following command.

```
Get-Mailbox <Name> | FL
SingleItemRecoveryEnabled,RetainDeletedItemsFor
```

Manage linked mailboxes

Exchange Server 2013 > Recipients >

Applies to: *Exchange Server 2013*

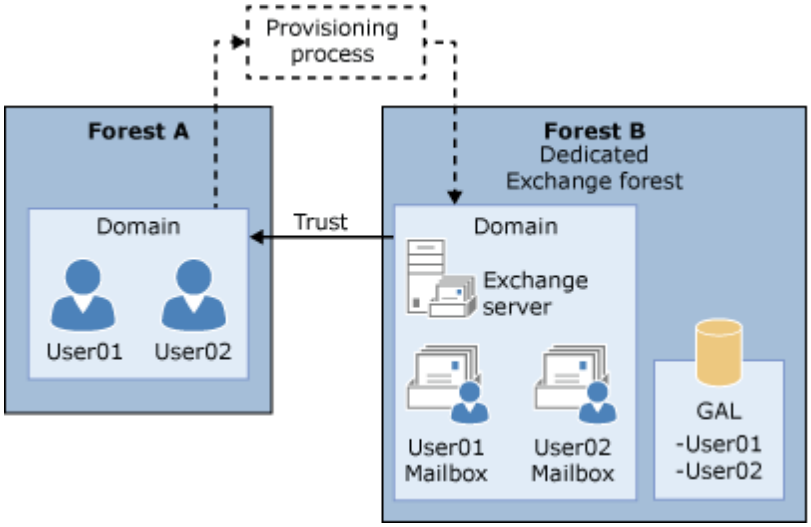
Topic Last Modified: *2012-11-27*

Linked mailboxes are mailboxes that are accessed by users in a separate, trusted forest. Linked mailboxes may be necessary for organizations that deploy Exchange in a resource forest. The

resource forest scenario allows an organization to centralize Exchange in a single forest, while allowing access to the Exchange organization with user accounts that are located in one or more trusted forests (called *account forests*). The user account that accesses the linked mailbox doesn't exist in the forest where Exchange is deployed. Therefore, a disabled user account that exists in the same forest as Exchange is created and associated with the corresponding linked mailbox.

The following figure illustrates the relationship between the linked user account used to access the linked mailbox (located in the account forest) and the disabled user account in the Exchange resource forest that's associated with the linked mailbox.

Linked mailboxes



Note:

A trust between the Exchange forest and at least one account forest must be set up before you can create linked mailboxes. At a minimum, you must set up a one-way, outgoing trust so that the Exchange forest trusts the account forest. For more information, see Learn more about setting up a forest trust to support linked mailboxes.

What do you need to know before you begin?

- Estimated time to complete: 2 to 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.
- A user account (called the *linked master account*) must exist in the account forest before you can create a linked mailbox. This is because the linked mailbox is associated with a user in the account forest.
- If you've configured a one-way outgoing trust where the Exchange forest trusts the account forest, you'll need administrator credentials in the account forest to create a linked mailbox.

To create a linked mailbox without being prompted for administrator credentials in the account forest, you have to create a two-way trust, or create another one-way outgoing trust where the account forest also trusts the Exchange forest. This step also requires administrator credentials in the account forest.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Create a linked mailbox

Use the EAC to create a linked mailbox

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. Click **New** > **Linked mailbox**.
3. On the **New linked mailbox** page, in the **Trusted forest or domain** box, select the name of the account forest that contains the user account that you're creating the linked mailbox for. Click **Next**.
4. If your organization has configured a one-way outgoing trust where the Exchange forest trusts the account forest, you're prompted for administrator credentials in the account forest so that you can gain access to a domain controller in the trusted forest. Type the user name and password for an administrator account in the account forest, and then click **Next**.

Note:
You won't be prompted for administrator credentials if you've created a two-way trust or have created another one-way outgoing trust where the account forest trusts the Exchange forest.

5. Complete the following boxes on the **Select linked master account** page.
   - **Linked domain controller** Select a domain controller in the account forest. Exchange will connect to this domain controller to retrieve the list of user accounts in the account forest so that you can select the linked master account.
   - **Linked master account** Click **Browse**, select a user account in the account forest, and then click **OK**. The new linked mailbox will be associated with this account.
6. Click **Next** and complete the following boxes on the **Enter general information** page.
   - *** Name** Use this box to type a name for the user. This is the name used as the display name in the EAC and your organization's address book, and the name that's listed in Active Directory. This name is required.
   - **Organizational unit** You can select an organizational unit (OU) other than the default (which is the recipient scope). If the recipient scope is set to the forest, the default value is set to the Users container in the Active Directory domain that contains the computer on which the EAC is running. If the recipient scope is set to a specific domain, the Users container in that domain is selected by default. If the recipient scope is set to a specific OU, that OU is selected by default.

To select a different OU, click **Browse**. The dialog box displays all OUs in the Exchange forest that are within the specified scope. Select the OU you want, and then click **OK**.

- *** User logon name** Use this box to type the user logon name, which is required to create a linked mailbox. Type the user name here. This name will be used in the left portion of the email address for the linked mailbox if you don't specify an alias.

Note:

Because the user account that is created in the Exchange forest is disabled when you create a linked mailbox, the user doesn't use the user logon name to sign in to the linked mailbox. They sign in using their credentials from the account forest.

7. Click **More options** to configure the following boxes. Otherwise, skip to Step 8 to save the new linked mailbox.
   - **Alias** Type the alias, which specifies the email alias for the linked mailbox. The user's alias is the portion of the email address on the left side of the at (@) symbol. It must be unique in the forest.

Note:

If you leave this box blank, the value from the user name portion of the **User Logon Name** is used for the email alias.

   - **First name**, **Initials**, **Last name**
   - **Mailbox database** Use this option to specify a mailbox database instead of allowing Exchange to choose a database for you. Click **Browse** to open the **Select Mailbox Database** dialog box. This dialog box lists all the mailbox databases in your Exchange organization. By default, the mailbox databases are sorted by name. You can also click the title of the corresponding column to sort the databases by server name or version. Select the mailbox database you want to use, and then click **OK**.
   - **Address book policy** Use this option to specify an address book policy (ABP) for the linked mailbox. ABPs contain a global address list (GAL), an offline address book (OAB), a room list, and a set of address lists. When assigned to users, an ABP provides them with access to a customized GAL in Outlook and Outlook Web App. To learn more, see Address book policies.

In the drop-down list, select the policy that you want associated with this mailbox.

8. When you're finished, click **Save** to create the new linked mailbox.

Use the Shell to create a linked mailbox

This example creates a linked mailbox for Ayla Kol in the CONTOSO Exchange resource forest. The FABRIKAM domain is in the account forest. The administrator account FABRIKAM \administrator is used to access the linked domain controller.

```
New-Mailbox -Name "Ayla Kol" -LinkedDomainController
"DC1_FABRIKAM" -LinkedMasterAccount " FABRIKAM\aylak" -
OrganizationalUnit Users -UserPrincipalName
aylak@contoso.com -LinkedCredential:(Get-Credential
FABRIKAM\administrator)
```

For syntax and parameter information, see New-Mailbox.

How do you know this worked?

To verify that you've successfully created a linked mailbox, do one of the following:

- In the EAC, navigate to **Recipients** > **Mailboxes**. The new linked mailbox is displayed in the mailbox list. Under **Mailbox Type**, the type is **Linked**.
- In the Shell, run the following command to display information about the new linked mailbox.

```
Get-Mailbox <Name> | FL
Name,RecipientTypeDetails,IsLinked,LinkedMasterAccount
```

Change linked mailbox properties

After you create a linked mailbox, you can make changes and set additional properties by using the Exchange Administration Center (EAC) or the Exchange Management Shell.

You can also change properties for multiple linked mailboxes at the same time. For more information, see the section, "Bulk edit user mailboxes" section in the Manage user mailboxes topic.

Important:
The estimated time to complete this task will vary based on the number of properties you want to view or change.

Use the EAC to change linked mailbox properties

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of mailboxes, click the linked mailbox that you want to change the properties for, and then click **Edit** .
3. On the mailbox properties page, click one of the following sections to view or change properties.
   - General
   - Mailbox Usage
   - Email Address
   - Mailbox Features
   - Member Of
   - MailTip
   - Mailbox Delegation

General

Use the **General** section to view or change basic information about the user.

- *** Linked mailbox name** This is the name that's listed in Active Directory. If you change this name, it can't exceed 64 characters.
- *** Display name** This name appears in your organization's address book, on the To: and From: lines in email, and in the Mailboxes list in the EAC. This name can't contain empty spaces before or after the display name.
- *** User logon name** For user mailboxes, this is the name that the user uses to sign in to their mailbox and to log on to the domain. For linked mailboxes, the corresponding user account that

is created in the Exchange forest when the linked mailbox was created is disabled. The user uses their credentials from the account forest to sign in to the linked mailbox.

If you change this name, it must be unique in your organization.

- **Linked master account** This read-only box displays the user (in the format domain\username format) from the account forest that is associated with the linked mailbox. To change the linked master account associated with the linked mailbox, you have to use the **Set-Mailbox** cmdlet in the Shell. If you change the linked master account, the user will have to use the credentials for the new linked master account to sign in to the linked mailbox. For the command syntax to change the linked master account, see Use the Shell to change linked mailbox properties.
- **Hide from address lists** Select this check box to prevent the linked mailbox from appearing in the address book and other address lists that are defined in your Exchange organization. After you select this check box, users can still send messages to this user by using the email address.

Click **More options** to view or change these additional properties:

- **Organizational unit** This read-only box displays the organizational unit (OU) that contains the user account. You have to use Active Directory Users and Computers to move the user account to a different OU.
- **Mailbox database** This read-only box displays the name of the mailbox database that hosts the mailbox. To move the mailbox to a different database, select it in the mailbox list, and then click **Move mailbox to a different database** in the Details pane.
- *** Alias** This specifies the email alias for the linked mailbox. The alias is the portion of the email address on the left side of the at (@) symbol. It must be unique in the forest.
- **First name**, **Initials**, **Last name**
- **Custom attributes** This section displays the custom attributes defined for the linked mailbox. To specify custom attribute values, click **Edit** . You can specify up to 15 custom attributes for the recipient.

Mailbox Usage

Use the **Mailbox Usage** section to view or change the mailbox storage quota and deleted item retention settings for the linked mailbox. These settings are configured by default when the linked mailbox is created. They use the values that are configured for the mailbox database and apply to all mailboxes in that database. You can customize these settings for each mailbox instead of using the mailbox database defaults.

- **Last logon** This read-only box displays the last time that the user signed in to the mailbox.
- **Mailbox usage** This area shows the total size of the mailbox and the percentage of the total mailbox quota that has been used.

Note:

To obtain the information that's displayed in the previous two boxes, the EAC queries the mailbox database that hosts the mailbox. If the EAC can’t communicate with the Exchange store that contains the mailbox database, these boxes will be blank. A warning message is displayed if the user hasn't signed in to the mailbox for the first time.

Click **More options** to view or change the mailbox storage quota and the deleted item retention

settings for the mailbox.

- **Storage quota settings** To customize these settings for the mailbox and not use the mailbox database defaults, click **Customize settings for this mailbox**, type a new value, and then click **Save**.

The value range for any of the storage quota settings is from 0 through 2047 gigabytes (GB).

  - **Issue a warning at (GB)** This box displays the maximum storage limit before a warning is issued to the user. If the mailbox size reaches or exceeds the value specified, Exchange sends a warning message to the user.
  - **Prohibit send at (GB)** This box displays the *prohibit send* limit for the mailbox. If the mailbox size reaches or exceeds the specified limit, Exchange prevents the user from sending new messages and displays a descriptive error message.
  - **Prohibit send and receive at (GB)** This box displays the *prohibit send and receive* limit for the mailbox. If the mailbox size reaches or exceeds the specified limit, Exchange prevents the mailbox user from sending new messages and won't deliver any new messages to the mailbox. Any messages sent to the mailbox are returned to the sender with a descriptive error message.

- **Deleted item retention settings** To customize these settings for the mailbox and not use the mailbox database defaults, click **Customize settings for this mailbox**, type a new value, and then click **Save**.
  - **Keep deleted items for (days)** This box displays the length of time that deleted items are retained before they're permanently deleted and can't be recovered by the user. When the mailbox is created, this length of time is based on the deleted item retention settings configured for the mailbox database. By default, a mailbox database is configured to retain deleted items for 14 days. The value range for this property is from 0 through 24855 days.
  - **Don't permanently delete items until the database is backed up** Select this check box to prevent mailboxes and email messages from being deleted until after the mailbox database on which the mailbox is located has been backed up.

Email Address

Use the **Email address** section to view or change the email addresses associated with the linked mailbox. This includes the user's primary SMTP addresses and any associated proxy addresses. The primary SMTP address (also known as the *default reply address*) is displayed in bold text in the address list, with the uppercase **SMTP** value in the **Type** column.

- **Add** Click **Add +** to add a new email address for this mailbox. Select one of following address types:
  - **SMTP** This is the default address type. Click this radio button and then type the new SMTP address in the *** Email address** box.
  - **EUM** An EUM (Exchange Unified Messaging) address is used by the Microsoft Exchange Unified Messaging service to locate UM-enabled users within an Exchange organization. EUM addresses consist of the extension number and the UM dial plan for the UM-enabled user. Click this radio button and type the extension number in the **Address/Extension** box. Then click **Browse** and select a dial plan for the user.
  - **Custom address type** Click this button and type one of the supported non-SMTP email

address types in the *** Email address** box.

Note:

With the exception of X.400 addresses, Exchange doesn't validate custom addresses for proper formatting. You must make sure that the custom address you specify complies with the format requirements for that address type.

- **Automatically update email addresses based on the email address policy applied to this recipient** Select this check box if you want the recipient's email addresses to be updated automatically when changes are made to email address policies in your organization. This box is selected by default.

Mailbox Features

Use the **Mailbox Features** section to view or change the following mailbox features and settings:

- **Sharing policy** This box shows the sharing policy applied to the mailbox. A sharing policy controls how users in your organization can share calendar and contact information with users outside your Exchange organization. The Default Sharing Policy is assigned to mailboxes when they are created. To change the sharing policy that's assigned to the user, select a different one from the drop-down list.
- **Role assignment policy** This box shows the role assignment policy assigned to the mailbox. The role assignment policy specifies the role-based access control (RBAC) roles that are assigned to the user and controls which mailbox and distribution group configuration settings users can modify. To change the role assignment policy that's assigned to the user, select a different one from the drop-down list.
- **Retention policy** This box shows the retention policy assigned to the mailbox. A retention policy is a group of retention tags that are applied to the user's mailbox. The tags allow you to control how long to keep items in users' mailboxes and define which action to take on items that have reached a certain age. A retention policy isn't assigned to mailboxes when they are created. To assign a retention policy to the user, select one from the drop-down list.
- **Address Book policy** This box shows the address book policy applied to the mailbox. An address book policy allows you to segment users into specific groups to provide customized views of the address book. To apply or change the address book policy that's applied to the mailbox, select one from the drop-down list.
- **Unified Messaging** This feature is disabled by default. When you enable Unified Messaging (UM) the user will be able to use your organization's UM features and a default set of UM properties are applied to the user. Click **Enable** to enable UM for the mailbox. For information about how to enable UM, see Enable a user for voice mail.

Note:

A UM dial plan and a UM mailbox policy must exist before you can enable UM.

- **Mobile Devices** Use this section to view and change the settings for Exchange ActiveSync, which is enabled by default. Exchange ActiveSync enables access to an Exchange mailbox from a mobile device. Click **Disable Exchange ActiveSync** to disable this feature for the mailbox.
- **Outlook Web App** This feature is enabled by default. Outlook Web App provides access to an

Exchange mailbox via a web browser. Click **Disable** to disable Outlook Web App for the mailbox. Click **Edit details** to add or change an Outlook Web App mailbox policy for the mailbox.

- **IMAP** This feature is enabled by default. Click **Disable** to disable IMAP for the mailbox.
- **POP3** This feature is enabled by default. Click **Disable** to disable POP3 for the mailbox.
- **MAPI** This feature is enabled by default. MAPI enables access to an Exchange mailbox from a MAPI client such as Outlook. Click **Disable** to disable MAPI for the mailbox.
- **Litigation hold** This feature is disabled by default. Litigation hold preserves deleted mailbox items and records changes made to mailbox items. Deleted items and all instances of changed items are returned in a discovery search. Click **Enable** to put the mailbox on litigation hold. If the mailbox is on litigation hold, click **Disable** to remove the litigation hold. If the mailbox is on litigation hold, click **Edit details** to view and change the following litigation hold settings:
  - **Hold date** This read-only box indicates date and time when the mailbox was put on litigation hold.
  - **Put on hold by** This read-only box indicates the user who put the mailbox on litigation hold.
  - **Note** Use this box to notify the user about the litigation hold, explain why the mailbox is on litigation hold, or provide additional guidance to the user, such as informing them that the litigation hold won't affect their day-to-day use of email.
  - **URL** Use this box to provide a URL to a website that provides information or guidance about the litigation hold on the mailbox.

Note:

The text from these boxes appears in the user's mailbox only if they're using Outlook 2010 or later versions. It doesn't appear in Outlook Web App or other email clients. To view the text from the Note and URL boxes in Outlook, click the **File** tab and, on the **Info** page, under **Account Settings**, you'll see the litigation hold comment.

- **Archiving** If an archive mailbox doesn't exist for the user, this feature is disabled. To enable an archive mailbox, click **Enable**. If the user has an archive mailbox, the size of the archive mailbox and usage statistics are displayed. Click **Edit details** to view and change the following archive mailbox settings:
  - **Status** This read-only box indicates whether an archive mailbox exists.
  - **Database** This read-only box shows the name of the mailbox database that hosts the archive mailbox.
  - **Name** Type the name of the archive mailbox in this box. This name is displayed under the folder list in Outlook or Outlook Web App.
  - **Quota usage** This read-only area shows the total size of the archive mailbox and the percentage of the total archive mailbox quota that has been used.
  - **Quota value (GB)** This box shows the total size of the archive mailbox. To change the size, type a new value in the box or select a value from the drop-down list.
  - **Issue warning at (GB)** This box shows the maximum storage limit for the archive mailbox before a warning is issued to the user. If the archive mailbox size reaches or exceeds the value specified, Exchange sends a warning message to the user. To change this limit, type a new value in the box or select a value from the drop-down list.
- **Delivery Options** Use Delivery Options to forward email messages sent to the user to another

recipient and to set the maximum number of recipients that the user can send a message to. Click **Edit details** to view and change these settings.

- **Forwarding address** Select the **Enable forwarding** check box and then click **Browse** to display the **Select Mail User and Mailbox** page. Use this page to select a recipient to whom you want to forward all email messages that are sent to this mailbox. Messages will be delivered to both the linked mailbox and the forwarding address.
- **Recipient limit** This setting controls the maximum number of recipients the user can send a message to. Select the **Maximum recipients** check box to limit the number of recipients allowed on the To:, Cc:, and Bcc: lines of an email message, and then specify the maximum number of recipients.

Note:

For on-premises Exchange organizations, the recipient limit is unlimited. For Exchange Online organizations, the limit is 500 recipients.

- **Message Size Restrictions** These settings control the size of messages that the user can send and receive. Click **Edit details** to view and change the maximum size for sent and received messages.
  - **Sent messages** To specify a maximum size for messages sent by this user, select the **Maximum message size (KB)** check box and type a value in the box. The message size must be between 0 and 2,097,151 KB. If the user sends a message larger than the specified size, the message will be returned to the user with a descriptive error message.
  - **Received messages** To specify a maximum size for messages received by this user, select the **Maximum message size (KB)** check box and type a value in the box. The message size must be between 0 and 2,097,151 KB. If the user receives a message larger than the specified size, the message will be returned to the sender with a descriptive error message.
- **Message Delivery Restrictions** These settings control who can send email messages to this user. Click **Edit details** to view and change these restrictions.
  - **Accept messages from** Use this section to specify who can send messages to this user.
    - **All senders** Select this option to specify that the user can accept messages from all senders. This includes both senders in your Exchange organization and external senders. This option is selected by default. This option includes external users only if you clear the **Require that all senders are authenticated** check box. If you select this check box, messages from external users will be rejected.
    - **Only senders in the following list** Select this option to specify that the user can accept messages only from a specified set of senders in your Exchange organization. Click **Add** to display the **Select Recipients** page, which displays a list of all recipients in your Exchange organization. Select the recipients you want, add them to the list, and then click **OK**. You can also search for a specific recipient by typing the recipient's name in the search box and then clicking **Search**.
    - **Require that all senders are authenticated** Select this option to prevent anonymous users from sending messages to the user.
  - **Reject messages from** Use this section to block people from sending messages to this user.
    - **No senders** Select this option to specify that the mailbox won't reject messages from any

senders in the Exchange organization. This option is selected by default.

- **Senders in the following list** Select this option to specify that the mailbox will reject messages from a specified set of senders in your Exchange organization. Click **Add** to display the **Select Recipient** page, which displays a list of all recipients in your Exchange organization. Select the recipients you want to reject messages from, add them to the list, and then click **OK**. You can also search for a specific recipient by typing the recipient's name in the search box and then clicking **Search**.

Member Of

Use the **Member Of** section to view a list of the distribution groups or security groups to which this user belongs. You can't change membership information on this page. Note that the user may match the criteria for one or more dynamic distribution groups in your organization. However, dynamic distribution groups aren't displayed on this page because their membership is calculated each time they're used.

MailTip

Use the **MailTip** section to add a MailTip to alert users of potential issues if they send a message to this recipient. A MailTip is text that's displayed in the InfoBar when a recipient is added to the To, Cc, or Bcc lines of a new email message.

Note:
MailTips can include HTML tags, but scripts aren't allowed. The length of a custom MailTip can't exceed 175 displayed characters. HTML tags aren't counted in the limit.

Mailbox Delegation

Use the **Mailbox Delegation** section to assign permissions to other users (also called *delegates*) to allow them to sign in to the user's mailbox or send messages on behalf of the user. You can assign the following permissions:

- **Send As** This permission allows users other than the mailbox owner to use the mailbox to send messages. After this permission is assigned to a delegate, any message that a delegate sends from this mailbox will appear as if it was sent by the mailbox owner. However, this permission doesn't allow a delegate to sign in to the user's mailbox.
- **Send on Behalf Of** This permission also allows a delegate to use this mailbox to send messages. However, after this permission is assigned to a delegate, the **From:** address in any message sent by the delegate indicates that the message was sent by the delegate on behalf of the mailbox owner.
- **Full Access** This permission allows a delegate to sign in to the user's mailbox and view the contents of the mailbox. However, after this permission is assigned to a delegate, the delegate can't send messages from the mailbox. To allow a delegate to send email from the user's mailbox, you still have to assign the delegate the Send As or the Send on Behalf Of permission.

To assign permissions to delegates, click **Add** under the appropriate permission to display the **Select Recipient** page, which displays a list of all recipients in your Exchange organization that can

be assigned the permission. Select the recipients you want assign delegate permissions to, add them to the list, and then click **OK**. You can also search for a specific recipient by typing the recipient's name in the search box and then clicking **Search**.

Use the Shell to change linked mailbox properties

Use the **Get-Mailbox** and **Set-Mailbox** cmdlets to view and change properties for linked mailboxes. One advantage of using the Shell is the ability to change the properties for multiple linked mailboxes. For information about what parameters correspond to mailbox properties, see the following topics:

- Get-Mailbox
- Set-Mailbox

Here are some examples of using the Shell to change linked mailbox properties.

This example uses the **Get-Mailbox** command to find all the linked mailboxes in the organization.

```
Get-Mailbox -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'LinkedMailbox')}
```

This example uses the **Set-Mailbox** command to limit the number of recipients allowed on the To:, Cc:, and Bcc: lines of an email message to 500. This limit applies to all linked mailboxes in the organization.

```
Get-Mailbox -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'LinkedMailbox')} | Set-Mailbox
-RecipientLimits 500
```

This example changes the linked master account in the fabrikam.com account forest that is associated with a linked mailbox in an Exchange forest.

```
Set-Mailbox -Identity "Ayla Kol" -LinkedDomainController
DC1.fabrikam.com -LinkedMasterAccount "fabrikam\robinw" -
LinkedCredential:(Get-Credential fabrikam\administrator)
```

How do you know this worked?

To verify that you have successfully changed properties for a linked mailbox, do the following:

- In the EAC, select the linked mailbox and then click **Edit** to view the property or feature that you changed. Depending on the property that you changed, it might be displayed in the Details pane for the selected mailbox.
- In the Shell, use the **Get-Mailbox** cmdlet to verify the changes. One advantage of using the Shell is that you can view multiple properties for multiple linked mailboxes. In the example above where the recipient limit was changed, running the following command will verify the new value.

```
Get-Mailbox -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'LinkedMailbox')} | fl
Name,RecipientLimits
```

For the example above where the linked master account was changed, run the following command to verify the new value.

```
Get-Mailbox "Ayla Kol" | fl LinkedMasterAccount
```

Manage Distribution Groups

Exchange Server 2013 > Recipients >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-04-21*

Use the Exchange Administration Center (EAC) or the Exchange Management Shell to create a new distribution group in your Exchange organization or to mail-enable an existing group in Active Directory.

There are two types of groups that can be used to distribute messages:

- *Mail-enabled universal distribution groups* (also called *distribution groups*) can be used only to distribute messages.
- *Mail-enabled universal security groups* (also called *security groups*) can be used to distribute messages as well as to grant access permissions to resources in Active Directory. For more information, see Manage mail-enabled security groups.

It's important to note the terminology differences between Active Directory and Exchange. In Active Directory, a distribution group refers to any group that doesn't have a security context, whether it's mail-enabled or not. In contrast, in Exchange, all mail-enabled groups are referred to as distribution groups, whether they have a security context or not.

Note:
You can create or mail-enable only universal distribution groups. To convert a domain-local or a global group to a universal group, you can use the Set-Group cmdlet using the Shell. You may have mail-enabled groups that were migrated from previous versions of Exchange that are not universal groups. You can use the EAC or the Shell to manage these groups

What do you need to know before you begin?

- Estimated time to complete: 2 to 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Distribution groups" entry in the Recipients Permissions topic.

- If your organization has configured a group naming policy, it's applied only to groups created by users. When you or other administrators use the EAC to create distribution groups, the group naming policy is ignored and isn't applied to the group name. However, if you use the Shell to create or rename a distribution group, the policy is applied unless you use the *IgnoreNamingPolicy* parameter to override the group naming policy. For more information, see:
  - Create a distribution group naming policy
  - Override the distribution group naming policy
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Create a distribution group

Use the EAC to create a distribution group

1. In the EAC, navigate to **Recipients** > **Groups**.
2. Click **New +** > **Distribution group**.
3. On the **New distribution group** page, complete the following boxes:
   - *** Display name** Use this box to type the display name. This name appears in your organization's address book, on the To: line when email is sent to this group, and in the Groups list in the EAC. The display name is required and should be user-friendly so people recognize what it is. It also must be unique in the forest.
   - *** Alias** Use this box to type the name of the alias for the group. The alias can't exceed 64 characters and must be unique in the forest. When a user types the alias in the To: line of an email message, it resolves to the group's display name.
   - **Description** Use this box to describe the group so people know what the purpose of the group is. This description appears in the address book.
   - **Organizational unit** You can select an organizational unit (OU) other than the default (which is the recipient scope). If the recipient scope is set to the forest, the default value is set to the Users container in the Active Directory domain that contains the computer on which the EAC is running. If the recipient scope is set to a specific domain, the Users container in that domain is selected by default. If the recipient scope is set to a specific OU, that OU is selected by default.

To select a different OU, click **Browse**. The dialog box displays all OUs in the forest that are within the specified scope. Select the OU you want, and then click **OK**.

   - *** Owners** By default, the person who creates a group is the owner. All groups must have at least one owner. You can add owners by clicking **Add +**.
   - **Members** Use this section to add members and to specify whether approval is required for people to join or leave the group.

Group owners don't have to be members of the group. Use **Add group owners as members** to add or remove the owners as members.

To add members to the group, click **Add +**. When you've finished adding members, click **OK** to return to the **New distribution group** page.

Under **Choose whether owner approval is required to join the group**, specify whether approval is required for people to join the group. Select one of the following settings:

- **Open: Anyone can join this group without being approved by the group owners** This is the default setting.
- **Closed: Members can be added only by the group owners. All requests to join will be rejected automatically**
- **Owner Approval: All requests are manually approved or rejected by the group owners** If you select this option, the group owner or owners will receive an email message requesting approval to join the group.

Under **Choose whether the group is open to leave**, specify whether approval is required for people to leave the group. Select one of the following settings:

- **Open: Anyone can leave this group without being approved by the group owners** This is the default setting.
- **Closed: Members can be removed only by the group owners. All requests to leave will be rejected automatically**

4. When you've finished, click **Save** to create the distribution group.

Note:

By default, new distribution groups require that all senders be authenticated. This prevents external senders from sending messages to distribution groups. To configure a distribution group to accept messages from all senders, you must modify the message delivery restriction settings for that distribution group.

Use the Shell to create a distribution group

This example creates a distribution group with an alias **itadmin** and the name **IT Administrators**. The distribution group is created in the default OU, and anyone can join this group without approval by the group owners.

```
New-DistributionGroup -Name "IT Administrators" -Alias
itadmin -MemberJoinRestriction open
```

For more information about using the Shell to create distribution groups, see New-DistributionGroup.

How do you know this worked?

To verify that you've successfully created a distribution group, do one of the following:

- In the EAC, navigate to **Recipients** > **Groups**. The new distribution group is displayed in the group list. Under **Group Type**, the type is **Distribution group**.
- In the Shell, run the following command to display information about the new distribution group.

```
Get-DistributionGroup <Name> | FL
Name,RecipientTypeDetails,PrimarySmtpAddress
```

Change distribution group properties

Use the EAC to change distribution group properties

1. In the EAC, navigate to **Recipients** > **Groups**.
2. In the list of groups, click the distribution group that you want to view or change, and then click **Edit** .
3. On the group properties page, click one of the following sections to view or change properties.
   - General
   - Ownership
   - Membership
   - Membership approval
   - Delivery management
   - Message approval
   - Email options
   - MailTip
   - Group delegation

General

Use this section to view or change basic information about the group.

- *** Display name** This name appears in the address book, on the To: line when email is sent to this group, and in the Groups list. The display name is required and should be user-friendly so people recognize what it is. It also has to be unique in your domain.

If you've implemented a group naming policy, the display name has to conform to the naming format defined by the policy.

- *** Alias** This is the portion of the email address that appears to the left of the at (@) symbol. If you change the alias, the primary SMTP address for the group will also be changed, and contain the new alias. Also, the email address with the previous alias will be kept as a proxy address for the group.
- **Description** Use this box to describe the group so people know what the purpose of the group is. This description appears in the address book and in the Details pane in the EAC.
- **Hide this group from address lists** Select this check box if you don't want users to see this group in the address book. To send email to this group, a sender has to type the group's alias or email address on the To: or Cc: lines.

Tip:
Consider hiding security groups because they're typically used to assign permissions to group members and not to send email.

- **Organizational unit** This read-only box displays the organizational unit (OU) that contains the

distribution group. You have to use Active Directory Users and Computers to move the group to a different OU.

Ownership

Use this section to assign group owners. The group owner can add members to the group, approve or reject requests to join or leave the group, and approve or reject messages sent to the group. By default, the person who creates a group is the owner. All groups must have at least one owner.

You can add owners by clicking **Add +**. You can remove an owner by selecting the owner and then clicking **Remove −**.

Membership

Use this section to add or remove members. Group owners don't have to be members of the group. Under **Members**, you can add members by clicking **Add +**. You can remove a member by selecting a user in the member list and then clicking **Remove −**.

Membership approval

Use this section to specify whether approval is required for users to join or leave the group.

- **Choose whether owner approval is required to join the group** Select one of the following settings:
  - **Open: Anyone can join this group without being approved by the group owners**
  - **Closed: Members can be added only by the group owners. All requests to join will be rejected automatically**
  - **Owner Approval: All requests are approved or rejected by the group owners** If you select this option, the group owner or owners receive an email requesting approval to join the group.
- **Choose whether the group is open to leave** Select one of the following settings:
  - **Open: Anyone can leave this group without being approved by the group owners**
  - **Closed: Members can be removed only by the group owners. All requests to leave will be rejected automatically**

Delivery management

Use this section to manage who can send email to this group.

- **Only senders inside my organization** Select this option to allow only senders in your organization to send messages to the group. This means that if someone outside of your organization sends an email message to this group, it will be rejected. This is the default setting.
- **Senders inside and outside of my organization** Select this option to allow anyone to send messages to the group.

You can further limit who can send messages to the group by allowing only specific senders to send messages to this group. Click **Add +** and then select one or more recipients. If you add senders to this list, they are the only ones who can send mail to the group. Mail sent by anyone not in the list will be rejected.

To remove a person or a group from the list, select them in the list and then click **Remove −**.

Important:

If you've configured the group to allow only senders inside your organization to send messages to the group, email sent from a mail contact will be rejected, even if they are added to this list.

Message approval

Use this section to set options for moderating the group. Moderators approve or reject messages sent to the group before they reach the group members.

- **Messages sent to this group have to be approved by a moderator** This check box isn't selected by default. If you select this check box, incoming messages are reviewed by the group moderators before delivery. Group moderators can approve or reject incoming messages.
- **Group moderators** To add group moderators, click **Add +**. To remove a moderator, select the moderator, and then click **Remove −**. If you've selected "Messages sent to this group have to be approved by a moderator" and you don't select a moderator, messages to the group are sent to the group owners for approval.
- **Senders who don't require message approval** To add people or groups that can bypass moderation for this group, click **Add +**. To remove a person or a group, select the item, and then click **Remove −**.
- **Select moderation notifications** Use this section to set how users are notified about message approval.
  - **Notify all senders when their messages aren't approved** This is the default setting. Notify all senders, inside and outside your organization, when their message isn't approved.
  - **Notify senders in your organization when their messages aren't approved** When you select this option, only people or groups in your organization are notified when a message that they sent to the group isn't approved by a moderator.
  - **Don't notify anyone when a message isn't approved** When you select this option, notifications aren't sent to message senders whose messages aren't approved by the group moderators.

Email options

Use this section to view or change the email addresses associated with the group. This includes the group's primary SMTP addresses and any associated proxy addresses. The primary SMTP address (also known as the *reply address*) is displayed in bold text in the address list, with the uppercase **SMTP** value in the **Type** column.

- **Add** Click **Add +** to add a new email address for this mailbox. Select one of following address types:
  - **SMTP** This is the default address type. Click this button and then type the new SMTP address in the *** Email address** box.

Note:

To make the new address the primary SMTP address for the group, select the **Make this the reply address** check box.

  - **Custom address type** Click this button and type one of the supported non-SMTP email

address types in the * **Email address** box.

Note:
With the exception of X.400 addresses, Exchange doesn't validate custom addresses for correct formatting. You must make sure that the custom address you specify complies with the format requirements for that address type.

- **Edit** To change an email address associated with the group, select it in the list, and then click **Edit** .

Note:
To make an existing address the primary SMTP address for the group, select the **Make this the reply address** check box.

- **Remove** To delete an email address associated with the group, select it in the list, and then click **Remove** .
- **Automatically update email addresses based on the email address policy applied to this recipient** Select this check box to have the recipient's email addresses automatically updated based on changes made to email address policies in your organization. This box is selected by default.

MailTip

Use this section to add a MailTip to alert users of potential issues if they send a message to this group. A MailTip is text that's displayed in the InfoBar when this group is added to the To, Cc, or Bcc lines of a new email message. For example, you could add a MailTip to large groups to warn potential senders that their message will be sent to lots of people.

Note:
MailTips can include HTML tags, but scripts aren't allowed. The length of a custom MailTip can't exceed 175 displayed characters. HTML tags aren't counted in the limit.

Group delegation

Use this section to assign permissions to a user (called a *delegate*) to allow them to send messages as the group or send messages on behalf of the group. You can assign the following permissions:

- **Send As** This permission allows the delegate to send messages as the group. After this permission is assigned, the delegate has the option to add the group to the **From** line to indicate that the message was sent by the group.
- **Send on Behalf Of** This permission also allows a delegate to send messages on behalf of the group. After this permission is assigned, the delegate has the option to add the group in the **From** line. The message will appear to be sent by the group and will say that it was sent by the delegate on behalf of the group.

To assign permissions to delegates, click **Add** under the appropriate permission to display the **Select Recipient** page, which displays a list of all recipients in your Exchange organization that can be assigned the permission. Select the recipients you want, add them to the list, and then click **OK**. You can also search for a specific recipient by typing the recipient's name in the search box and

then clicking **Search**.

Use the Shell to change distribution group properties

Use the **Get-DistributionGroup** and **Set-DistributionGroup** cmdlets to view and change properties for distribution groups. Advantages of using the Shell are the ability to change the properties that aren't available in the EAC and to change properties for multiple groups. For information about which parameters correspond to distribution group properties, see the following topics:

- Get-DistributionGroup
- Set-DistributionGroup

Here are some examples of using the Shell to change distribution group properties.

This example changes the primary SMTP address (also called the reply address) for the Seattle Employees distribution group from employees@contoso.com to sea.employees@contoso.com. Also, the previous reply address will be kept as a proxy address.

```
Set-DistributionGroup "Seattle Employees" -EmailAddresses
SMTP:sea.employees@contoso.com,smtp:employees@contoso.com
```

This example limits the maximum message size that can be sent to all distribution groups in the organization to 10 megabytes (MB).

```
Get-DistributionGroup -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq
'MailUniversalDistributionGroup')} | Set-DistributionGroup
-MaxReceiveSize 10MB
```

This example enables moderation for the distribution group Customer Support and sets the moderator to Amy. In addition, this moderated distribution group will notify senders who send mail from within the organization if their messages aren't approved.

```
Set-DistributionGroup -Identity "Customer Support" -
ModeratedBy "Amy" -ModerationEnabled $true -
SendModerationNotifications 'Internal'
```

This example changes the user-created distribution group Dog Lovers to require the group manager to approve users' requests to join the group. In addition, by using the *BypassSecurityGroupManagerCheck* parameter, the group manager will not be notified that a change was made to the distribution group's settings.

```
Set-DistributionGroup -Identity "Dog Lovers" -
MemberJoinRestriction 'ApprovalRequired' -
BypassSecurityGroupManagerCheck
```

How do you know this worked?

To verify that you've successfully changed properties for a distribution group, do the following:

- In the EAC, select the group and then click **Edit** to view the property or feature that you changed. Depending on the property that you changed, it might be displayed in the Details pane for the selected group.
- In the Shell, use the **Get-DistributionGroup** cmdlet to verify the changes. One advantage of using the Shell is that you can view multiple properties for multiple groups. In the example above where the recipient limit was changed, run the following command to verify the new value.

```
Get-Mailbox -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'UserMailbox')} | fl
Name,RecipientLimits
```

For the example above where the message limits were changed, run this command.

```
Get-Mailbox -OrganizationalUnit "Marketing" | fl
Name,IssueWarningQuota,ProhibitSendQuota,ProhibitSendReceiv
eQuota,UseDatabaseQuotaDefaults
```

Create a distribution group naming policy

Exchange Server 2013 > Recipients > Manage Distribution Groups >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-01*

A *group naming policy* lets you standardize and manage the names of distribution groups created by users in your organization. You can require a specific prefix and suffix be added to the name for a distribution group when it's created, and you can block specific words from being used. This helps you minimize the use of inappropriate words in group names.

A group naming policy:

- Enforces a consistent naming strategy for groups created by users.
- Identifies distribution groups in the shared address book.
- Suggests the function or membership of the group.
- Identifies the type of users who are likely members of the group.
- Identifies the geographic region the group is used in.
- Blocks inappropriate words in group names.

How does a group naming policy work? When a user creates a group, they specify a name in the

Display Name field. After the group is created, Microsoft Exchange applies the group naming policy by adding any prefix or suffix that you've defined in the group naming policy. The full name is displayed in the distribution groups list in the Exchange Administration Center (EAC), the shared address book, and the To:, Cc:, and From: fields in email messages. If a user tries to use a word that you've blocked, they get an error message when they try to save the new group and are asked to remove the blocked word and save the group again.

Here are some examples of a group naming policy. In each, **<Group Name>** is a descriptive name provided by the person who creates the group. Exchange adds the prefixes and suffixes defined by the policy to the display name when the group is created.

- Text strings, with underscore characters, used for a single prefix (**DG**) and suffix (**Users**):

DG_<Group Name>_Users

- Multiple prefixes (**DG** and **Contoso**) and one suffix (**Users**), using text strings:

DG_Contoso_<Group Name>_Users

- An attribute (**Department**) used for the prefix:

Department_<Group Name>

For example, say that your school populates the Department attribute for faculty members. Here's an example of a group name created by a faculty member in the Psychology department:

Psychology_Cognitive201

In this example, the underscore character (_) is provided as the only text string in a second prefix to separate the department name from the group name.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Distribution Groups" entry in the Recipients Permissions topic.
- The maximum length for a group name is 64 characters. This includes the combined number of characters in the prefix, the group name provided by the user, and the suffix.
- The group naming policy is applied only to groups created by users. When you or other administrators use the EAC to create distribution groups, the group naming policy is ignored and not applied to the group name.
- Group names are created without spacing. We recommend that you use an underscore character (_) or some other placeholder between text strings, attributes, and the group name.
- You can use Windows PowerShell to override the group naming policy when you create and edit a distribution group. For more information, see Override the distribution group naming policy.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

Use the EAC to create a group naming policy

1. In the EAC, select **Groups** > **More ⋯** > **Configure group naming policy**.
2. Under **Group Naming Policy**, configure the prefix by selecting either **Attribute** or **Text** in the pull-down menu.
   - **Attribute** Select the attribute and then click **OK**.
   - **Text** Type the text string and click **OK**.

Notice that the text string that you typed or the attribute you selected is displayed as a hyperlink. Click the hyperlink to change the text string or attribute.

3. Click **Add** to add additional prefixes.
4. For the suffix, in the pull-down menu, select either **Attribute** or **Text**, and configure the suffix.
5. Click **Add** to add additional suffixes.

After you add a prefix or suffix, notice that a preview of the group naming policy is displayed.

6. To delete a prefix or suffix from the policy, click **Remove −**.
7. Click **Blocked Words** to add or remove blocked words.
   - To add a word to the list, type the word to block and click **Add +**.
   - To remove a word from the list, select it and click **Remove**.
   - To edit an existing blocked word, select it and click **Edit**.
8. When you are finished, click **Save**.

How do you know this worked?

To verify that you've successfully created a group naming policy, do the following:

- In the EAC, select **Groups** > **More** > **Configure group naming policy**.

On the **Group naming policy** page, the group naming policy that you defined is displayed under **Preview of policy**.

- In Windows PowerShell, run the following command to display the group naming policy.

```
Get-OrganizationConfig | FL DistributionGroupNamingPolicy
```

Override the distribution group naming policy

Exchange Server 2013 > Recipients > Manage Distribution Groups >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-13*

The group naming policy for distribution groups is applied only to groups created by users. When

you or other administrators use the Exchange Administration Center (EAC) to create distribution groups, the group naming policy is ignored and not applied to the group name.

However, if you use the Exchange Management Shell to create or rename a distribution group, the group naming policy is applied to groups created by administrators unless you use the *IgnoreNamingPolicy* parameter to override the group naming policy.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Distribution Groups" entry in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the Shell to override the group naming policy when you create a new group

To override the group naming policy, run the following command.

```
New-DistributionGroup -Name <Group Name> -
IgnoreNamingPolicy
```

For example, if the group naming policy for your organization is **DG_<Group Name>_Users**, run the following command to create a group named **All Administrators**.

```
New-DistributionGroup -Name "All Administrators" -
IgnoreNamingPolicy
```

When Microsoft Exchange creates this group, it uses **All Administrators** for both the *Name* and *DisplayName* parameters.

Use the Shell to override the group naming policy when you rename a group

To override the group naming policy when you rename an existing group with the Shell, run the following command.

```
Set-DistributionGroup -Identity <Old Group Name> -Name <New Group Name> -DisplayName <New Group Name> -IgnoreNamingPolicy
```

For example, let's say you created a group naming policy late one night and the next morning you realized you misspelled the text string in the prefix. The next morning, you see that a new group has already been created with the misspelled prefix. You can fix the group naming policy in the EAC, but you have to use the Shell to rename the group with the misspelled name. Run the following command.

```
Set-DistributionGroup -Identity "Goverment_Contracts_NWRegion" -Name "Government_ContractEstimates_NWRegion" -DisplayName "Government_ContractEstimates_NWRegion" -IgnoreNamingPolicy
```

Important:

Be sure to include the *DisplayName* parameter when you rename a group. If you don't, the old name is still displayed in the shared address book on the To:, Cc:, and From: lines in email messages.

How do you know this worked?

To verify that you've successfully created or renamed a distribution group that ignores the group naming policy, run the following commands.

```
Get-DistributionGroup <Name> | FL DisplayName

Get-OrganizationConfig | FL DistributionGroupNamingPolicy
```

If the format of the display name for the group is different than the one enforced by your organization's group naming policy, it worked.

Manage mail-enabled security groups

Exchange Server 2013 > Recipients >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-15*

A mail-enabled security group can be used to distribute messages as well as to grant access permissions to resources in Active Directory. For more information, see Recipients.

What do you need to know before you begin?

- Estimated time to complete: 2 to 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Distribution groups" entry in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Create a mail-enabled security group

Use the EAC to create a security group

1. In the EAC, navigate to **Recipients** > **Groups**.
2. Click **New +** > **Security group**.
3. On the **New security group** page, complete the following fields:
   - *** Display name** Use this box to type the display name. This name appears in the shared address book, on the To: line when email is sent to this group, and in the Groups list in the EAC. The display name is required and should be user-friendly so people recognize what it is. It also must be unique in the forest.

Note:

If a group naming policy is applied, you must follow the naming constraints enforced for your organization. For more information, see Create a distribution group naming policy. If you want to override your organization's group naming policy, see Override the distribution group naming policy.

   - *** Alias** Use this box to type the alias for the security group. The alias can't exceed 64 characters and must be unique in the forest. When a user types the alias on the To: line of an email message, it resolves to the group's display name.
   - **Description** Use this box to describe the security group so people know what the purpose of the group is.
   - **Organizational unit** You can select an organizational unit (OU) other than the default (which is the recipient scope). If the recipient scope is set to the forest, the default value is set to the Users container in the Active Directory domain that contains the computer on which the EAC is running. If the recipient scope is set to a specific domain, the Users container in that domain is

selected by default. If the recipient scope is set to a specific OU, that OU is selected by default. To select a different OU, click **Browse**. The dialog box displays all OUs in the forest that are within the specified scope. Select the desired OU, and then click **OK**.

- *** Owners** By default, the person who creates a group is the owner. All groups must have at least one owner. You can add owners by clicking **Add**.
- **Members** Use this section to add members and to specify whether approval is required for people to join or leave the group.

Group owners don't have to be members of the group. Use **Add group owners as members** to add or remove the owners as members.

To add members to the group, click **Add +**. When you've finished adding members, click **OK** to return to the **New security group** page.

Select the **Owner approval is required** check box if you want the group owners to receive user requests to join the group. If you select this option, members can only be removed by the group owners.

4. When you've finished, click **Save** to create the security group.

Note:

By default, all new mail-enabled security groups require that all senders be authenticated. This prevents external senders from sending messages to mail-enabled security groups. To configure a mail-enabled security group to accept messages from all senders, you must modify the message delivery restriction settings for that group.

Use the Shell to create a security group

This example creates a security group with an alias fsadmin and the name File Server Managers. The security group is created in the default OU, and anyone can join this group with approval by the group owners.

```
New-DistributionGroup -Name "File Server Managers" -Alias
fsadmin -Type security
```

For more information about using the Shell to create mail-enabled security groups, see New-DistributionGroup.

How do you know this worked?

To verify that you've successfully created a mail-enabled security group, do one of the following:

- In the EAC, navigate to **Recipients** > **Groups**. The new mail-enabled security group is displayed in the group list. Under **Group Type**, the type is **Security group**.
- In the Shell, run the following command to display information about the new mail-enabled security group.

```
Get-DistributionGroup <Name> | FL
Name,RecipientTypeDetails,PrimarySmtpAddress
```

Change mail-enabled security group properties

Use the EAC to change mail-enabled security group properties

1. In the EAC, navigate to **Recipients** > **Groups**.
2. In the list of groups, click the security group that you want to view or change, and then click **Edit** .
3. On the group properties page, click one of the following sections to view or change properties.
   - General
   - Ownership
   - Membership
   - Membership approval
   - Delivery management
   - Message approval
   - Email options
   - MailTip
   - Group delegation

General

Use this section to view or change basic information about the group.

- *** Display name** This name appears in the address book, on the To: line when email is sent to this group, and in the Groups list. The display name is required and should be user-friendly so people recognize what it is. It also has to be unique in your domain.
- *** Alias** This is the portion of the email address that appears to the left of the at (@) symbol. If you change the alias, the primary SMTP address for the group will also be changed, and contain the new alias. Also, the email address with the previous alias will be kept as a proxy address for the group.
- **Description** Use this box to describe the group so people know what the purpose of the group is. This description appears in the address book and in the Details pane in the EAC.
- **Hide this group from address lists** Select this check box if you don't want users to see this group in the address book. If this check box is selected, a sender has to type the group's alias or email address on the To: or Cc: lines to send mail to the group.

Tip:
Consider hiding security groups because they're typically used to assign permissions to group members and not to send email.

- **Organizational unit** This read-only box displays the organizational unit (OU) that contains the security group. You have to use Active Directory Users and Computers to move the group to a different OU.

Ownership

Use this section to assign group owners. The group owner can add members to the group, and approve or reject requests to join the group. By default, the person who creates a group is the

owner. All groups must have at least one owner.

You can add owners by clicking **Add +**. You can remove an owner by selecting the owner and then clicking **Remove −**.

Membership

Use this section to add or remove members. Group owners don't have to be members of the group. Under **Members**, you can add members by clicking **Add +**. You can remove a member by selecting a user in the member list and then clicking **Remove −**.

Membership approval

Use this section to specify whether owner approval is required for users to join the group. If you select the **Owner approval is required** check box, the group owner or owners receive an email requesting approval to join the group. As previously mentioned, only owners can remove members from the group.

Delivery management

Use this section to manage who can send email to this group.

- **Only senders inside my organization** Select this option to allow only senders in your organization to send messages to the group. This means that if someone outside of your organization sends an email message to this group, it will be rejected. This is the default setting.
- **Senders inside and outside of my organization** Select this option to allow anyone to send messages to the group.

You can further limit who can send messages to the group by allowing only specific senders to send messages to this group. Click **Add +** and then select one or more recipients. If you add senders to this list, they are the only ones who can send mail to the group. Mail sent by anyone not in the list will be rejected.

To remove a person or a group from the list, select them in the list and then click **Remove −**.

Important:
If you've configured the group to allow only senders inside your organization to send messages to the group, email sent from a mail contact will be rejected, even if they're added to this list.

Message approval

Use this section to set options for moderating the group. Moderators approve or reject messages sent to the group before they reach the group members.

- **Messages sent to this group have to be approved by a moderator** This check box isn't selected by default. If you select this check box, incoming messages will be reviewed by the group moderators before delivery. Group moderators can approve or reject incoming messages.
- **Group moderators** To add group moderators, click **Add +**. To remove a moderator, select the moderator, and then click **Remove −**. If you've selected "Messages sent to this group have to be

approved by a moderator" and you don't select a moderator, messages to the group will be sent to the group owners for approval.

- **Senders who don't require message approval** To add people or groups that can bypass moderation for this group, click **Add +**. To remove a person or a group, select the item, and then click **Remove −**.
- **Select moderation notifications** Use this section to set how users are notified about message approval.
  - **Notify all senders when their messages aren't approved** This is the default setting. Senders inside and outside your organization will be notified when their messages aren't approved.
  - **Notify senders in your organization when their messages aren't approved** When you select this option, only people or groups in your organization are notified when a message that they sent to the group isn't approved by a moderator.
  - **Don't notify anyone when a message isn't approved** When you select this option, notifications aren't sent to message senders whose messages aren't approved by the group moderators.

Email options

Use this section to view or change the email addresses associated with the group. This includes the group's primary SMTP addresses and any associated proxy addresses. The primary SMTP address (also known as the *reply address*) is displayed in bold text in the address list, with the uppercase **SMTP** value in the **Type** column.

- **Add** Click **Add +** to add a new email address for this mailbox. Select one of following address types:
  - **SMTP** This is the default address type. Click this button and then type the new SMTP address in the *** Email address** box.

Note:

To make the new address the primary SMTP address for the group, select the **Make this the reply address** check box. This check box is displayed only when the **Automatically update email addresses based on the email address policy applied to this recipient** check box isn't selected.

  - **Custom address type** Click this button and type one of the supported non-SMTP email address types in the *** Email address** box.

Note:

With the exception of X.400 addresses, Exchange doesn't validate custom addresses for correct formatting. You must make sure that the custom address you specify complies with the format requirements for that address type.

- **Edit** To change an email address associated with the group, select it in the list, and then click **Edit** ✎.

Note:

To make an existing address the primary SMTP address for the group, select the **Make this the reply address** check box. As previously mentioned, this check box is displayed only when the **Automatically update email addresses based on the email address policy applied**

to this recipient check box isn't selected.

- **Remove** To delete an email address associated with the group, select it in the list, and then click **Remove** −.
- **Automatically update email addresses based on the email address policy applied to this recipient** Select this check box to have the recipient's email addresses automatically updated based on changes made to email address policies in your organization. By default, this box is selected.

MailTip

Use this section to add a MailTip to alert users of potential issues before they send a message to this group. A MailTip is text that's displayed in the InfoBar when this group is added to the To, Cc, or Bcc lines of a new email message. For example, you could add a MailTip to large groups to warn potential senders that their message will be sent to lots of people.

Note:

MailTips can include HTML tags, but scripts aren't allowed. The length of a custom MailTip can't exceed 175 displayed characters. HTML tags aren't counted in the limit.

Group delegation

Use this section to assign permissions to a user (called a *delegate*) to allow them to send messages as the group or send messages on behalf of the group. You can assign the following permissions:

- **Send As** This permission allows the delegate to send messages as the group. After this permission is assigned, the delegate has the option to add the group to the **From** line to indicate that the message was sent by the group.
- **Send on Behalf Of** This permission also allows a delegate to send messages on behalf of the group. After this permission is assigned, the delegate has the option to add the group in the **From** line. The message will appear to be sent by the group and will say that it was sent by the delegate on behalf of the group.

To assign permissions to delegates, click **Add** under the appropriate permission to display the **Select Recipient** page, which displays a list of all recipients in your Exchange organization that can be assigned the permission. Select the recipients you want, add them to the list, and then click **OK**. You can also search for a specific recipient by typing the recipient's name in the search box and then clicking **Search** .

Use the Shell to change security group properties

Use the **Get-DistributionGroup** and **Set-DistributionGroup** cmdlets to view and change properties for security groups. Advantages of using the Shell are the ability to change the properties that aren't available in the EAC and to change properties for multiple security groups. For information about which parameters correspond to which distribution group properties, see the following topics:

- Get-DistributionGroup
- Set-DistributionGroup

Here are some examples of using the Shell to change security group properties.

This example displays a list of all security groups in the organization.

```
Get-DistributionGroup -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'MailUniversalSecurityGroup')}
```

This example changes the primary SMTP address (also called the reply address) for the Seattle Administrators security group from admins@contoso.com to seattle.admins@contoso.com. The previous reply address will be kept as a proxy address.

```
Set-DistributionGroup "Seattle Employees" -EmailAddresses
SMTP:sea.admins@contoso.com,smtp:admins@contoso.com
```

This example hides all security groups in the organization from the address book.

```
Get-DistributionGroup -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'MailUniversalSecurityGroup')} |
Set-DistributionGroup -HiddenFromAddressListsEnabled $true
```

How do you know this worked?

To verify that you've successfully changed properties for a security group, do the following:

- In the EAC, select the group and then click **Edit** to view the property or feature that you changed. Depending on the property that you changed, it might be displayed in the Details pane for the selected group.
- In the Shell, use the **Get-DistributionGroup** cmdlet to verify the changes. One advantage of using the Shell is that you can view multiple properties for multiple groups. In the example above where all security groups were hidden from the address book, run the following command to verify the new value.

```
Get-DistributionGroup -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'MailUniversalSecurityGroup')} |
 fl Name,HiddenFromAddressListsEnabled
```

Manage dynamic distribution groups

Exchange Server 2013 > Recipients >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-15*

Dynamic distribution groups are mail-enabled Active Directory group objects that are created to expedite the mass sending of email messages and other information within a Microsoft Exchange organization.

Unlike regular distribution groups that contain a defined set of members, the membership list for dynamic distribution groups is calculated each time a message is sent to the group, based on the filters and conditions that you define. When an email message is sent to a dynamic distribution group, it's delivered to all recipients in the organization that match the criteria defined for that group.

Important:

A dynamic distribution group includes any recipient in Active Directory with attribute values that match its filter. If a recipient's properties are modified to match the filter, the recipient could inadvertently become a group member and start receiving messages that are sent to the group. Well-defined, consistent account provisioning processes will reduce the chances of this issue occurring.

What do you need to know before you begin?

- Estimated time to complete: 2 to 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Dynamic distribution groups" entry in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Create a dynamic distribution group

Use the EAC to create a dynamic distribution group

1. In the EAC, navigate to **Recipients** > **Groups** > **New** > **Dynamic distribution group**.
2. On the **New dynamic distribution group** page, complete the following boxes:
   - *** Display name** Use this box to type the display name. This name appears in the shared address book, on the To: line when email is sent to this group, and in the Groups list in the EAC. The display name is required and should be user-friendly so people recognize what it is. It also must be unique in the forest.

Note:

Group naming policy isn't applied to dynamic distribution groups.

- *** Alias** Use this box to type the name of the alias for the group. The alias cannot exceed 64 characters and must be unique in the forest. When a user types the alias in the To: line of an email message, it resolves to the group's display name.
- **Description** Use this box to describe the group so people know what the purpose of the group is. This description appears in the shared address book.
- **Organizational unit** You can select an organizational unit (OU) other than the default (which is the recipient scope). If the recipient scope is set to the forest, the default value is set to the Users container in the Active Directory domain that contains the computer on which the EAC is running. If the recipient scope is set to a specific domain, the Users container in that domain is selected by default. If the recipient scope is set to a specific OU, that OU is selected by default.

To select a different OU, click **Browse**. The dialog box displays all OUs in the forest that are within the specified scope. Select the OU you want, and then click **OK**.

- **Owner** An owner for a dynamic distribution group is optional. You can add owners by clicking **Browse** and then selecting users from the list.

3. Use the **Members** section to specify the types of recipients for the group and set up rules that will determine membership. Select one of the following boxes:
   - **All recipient types** Choose this option to send messages that meet the criteria defined for this group to all recipient types.
   - **Only the following recipient types** Messages that meet the criteria defined for this group will be sent to one or more of the following recipient types:
     - **Users with Exchange mailboxes** Select this check box if you want to include users that have Exchange mailboxes. Users that have Exchange mailboxes are those that have a user domain account and a mailbox in the Exchange organization.
     - **Users with external email addresses** Select this check box if you want to include users that have external email addresses. Users that have external email accounts have user domain accounts in Active Directory, but use email accounts that are external to the organization. This enables them to be included in the global address list (GAL) and added to distribution lists.
     - **Resource mailboxes** Select this check box if you want to include Exchange resource mailboxes. Resource mailboxes allow you to administer company resources through a mailbox, such as a conference room or a company vehicle.
     - **Contacts with external email addresses** Select this check box if you want to include contacts that have external email addresses. Contacts that have external email addresses don’t have user domain accounts in Active Directory, but the external email address is available in the GAL.
     - **Mail-enabled groups** Select this check box if you want to include security groups or distribution groups that have been mail-enabled. Mail-enabled groups are similar to distribution groups. Email messages that are sent to a mail-enabled group account will be delivered to several recipients.
4. Click **Add a rule** to define the criteria for membership in this group.
5. Select one of the following recipient attributes from the drop-down list and provide a value. If the value for the selected attribute matches that value you define, the recipient receives a

message sent to this group.

Attribute	Send message to a recipient if...
Recipient container	The recipient object resides in the specified domain or OU.
State or province	The specified value matches the recipient's State or province property.
Company	The specified value matches the recipient's Company property.
Department	The specified value matches the recipient's Department property.
Custom attributeN (where N is a number from 1 to 15)	The specified value matches the recipient's CustomAttributeN property.

Important:

The values that you enter for the selected attribute must exactly match those that appear in the recipient's properties. For example, if you enter **Washington** for **State or province**, but the value for the recipient's property is **WA**, the condition will not be met. Also, text-based values that you specify aren't case-sensitive. For example, if you specify **Contoso** for the **Company** attribute, messages will be sent to a recipient if this value is **contoso**.

6. In the **Specify words or phrases** window, type the value in the text box. Click **Add** and then click **OK**.
7. To add another rule to define the criteria for membership, click **Add a rule** under the previous rule that you created.

Important:

If you add multiple rules to define membership, a recipient must meet the criteria of each rule to receive a message sent to the group. In other words, each rule is connected with the Boolean operator **AND**.

8. When you've finished, click **Save** to create the dynamic distribution group.

Note:

If you want to specify rules for attributes other than the ones available in the EAC, you must use the Shell to create a dynamic distribution group. Keep in mind that the filter and condition settings for dynamic distribution groups that have custom recipient filters can be managed only by using the Shell. For an example of how to create a dynamic distribution group with a custom query, see the next section on using the Shell to create a dynamic distribution group.

Use the Shell to create a dynamic distribution group

This example creates the dynamic distribution group "Mailbox Users DDG" that contains only mailbox users.

```
New-DynamicDistributionGroup -IncludedRecipients
MailboxUsers -Name "Mailbox Users DDG" -OrganizationalUnit
Users
```

This example creates a dynamic distribution group with a custom recipient filter. The dynamic distribution group contains all mailbox users on a server called Server1.

```
New-DynamicDistributionGroup -Name "Mailbox Users on
Server1" -OrganizationalUnit Users -RecipientFilter
{((RecipientTypeDetails -eq 'UserMailbox' -and ServerName -
eq 'Server1'))}
```

This example creates a dynamic distribution group with a custom recipient filter. The dynamic distribution group contains all mailbox users that have a value of "FullTimeEmployee" in the **CustomAttribute10** property.

```
New-DynamicDistributionGroup -Name "Full Time Employees" -
RecipientFilter {(RecipientTypeDetails -eq 'UserMailbox') -
and (CustomAttribute10 -eq 'FullTimeEmployee')}
```

For detailed syntax and parameter information, see New-DynamicDistributionGroup.

How do you know this worked?

To verify that you've successfully created a dynamic distribution group, do one of the following:

- In the EAC, navigate to **Recipients** > **Groups**. The new dynamic distribution group is displayed in the group list. Under **Group Type**, the type is **Dynamic distribution group**.
- In the Shell, run the following command to display information about the new dynamic distribution group.

```
Get-DynamicDistributionGroup | FL
Name,RecipientTypeDetails,RecipientFilter,PrimarySmtpAddres
s
```

Change dynamic distribution group properties

Use the EAC to change dynamic distribution group properties

1. In the EAC, navigate to **Recipients** > **Groups**.
2. In the list of groups, click the dynamic distribution group that you want to view or change, and then click **Edit** ✎.
3. On the group's properties page, click one of the following sections to view or change properties.
   - General
   - Ownership

- Membership
- Delivery management
- Message approval
- Email options
- MailTip
- Group delegation

General

Use this section to view or change basic information about the group.

- *** Display name** This name appears in the address book, on the To: line when email is sent to this group, and in the Groups list. The display name is required and should be user-friendly so people recognize what it is. It also has to be unique in your domain.
- *** Alias** This is the portion of the email address that appears to the left of the at (@) symbol. If you change the alias, the primary SMTP address for the group will also be changed, and contain the new alias. Also, the email address with the previous alias will be kept as a proxy address for the group.
- **Description** Use this box to describe the group so people know what the purpose of the group is. This description appears in the address book and in the Details pane in the EAC.
- **Hide this group from address lists** Select this check box if you don't want users to see this group in the address book. To send email to this group, a sender has to type the group's alias or email address on the To: or Cc: lines.
- **Organizational unit** This read-only box displays the organizational unit (OU) that contains the dynamic distribution group. You have to use Active Directory Users and Computers to move the group to a different OU.

Ownership

Use this section to assign a group owner. A dynamic distribution group can have only one owner. The group owner appears on the **Managed by** tab of the object in Active Directory Users and Computers.

You can add owners by clicking **Browse** and selecting the owner from the list. To remove the owner, click **Clear** and then click **Save**.**—**.

Membership

Use this section to change the criteria used to determine membership of the group. You can delete or change existing membership rules and add new rules. For procedures that tell you how to do this, see step 3 in the procedures for configuring membership when you use the EAC to create a new dynamic distribution group.

Delivery management

Use this section to manage who can send email to this group.

- **Only senders inside my organization** Select this option to allow only senders in your

organization to send messages to the group. This means that if someone outside your organization sends an email message to this group, it is rejected. This is the default setting.

- **Senders inside and outside of my organization** Select this option to allow anyone to send messages to the group.

You can further limit who can send messages to the group by allowing only specific senders to send messages to this group. Click **Add +** and then select one or more recipients. If you add senders to this list, they are the only ones who can send mail to the group. Mail sent by anyone not in the list will be rejected.

To remove a person or a group from the list, select them in the list and then click **Remove −**.

Important:
If you've configured the group to allow only senders inside your organization to send messages to the group, email sent from a mail contact is rejected, even if they're added to this list.

Message approval

Use this section to set options for moderating the group. Moderators approve or reject messages sent to the group before they reach the group members.

- **Messages sent to this group have to be approved by a moderator** This check box isn't selected by default. If you select this check box, incoming messages are reviewed by the group moderators before delivery. Group moderators can approve or reject incoming messages.
- **Group moderators** To add group moderators, click **Add +**. To remove a moderator, select the moderator, and then click **Remove −**. If you've selected "Messages sent to this group have to be approved by a moderator" and you don't select a moderator, messages to the group are sent to the group owners for approval.
- **Senders who don't require message approval** To add people or groups that can bypass moderation for this group, click **Add +**. To remove a person or a group, select the item, and then click **Remove −**.
- **Select moderation notifications** Use this section to set how users are notified about message approval.
  - **Notify all senders when their messages aren't approved** This is the default setting. Notify all senders, inside and outside your organization, when their message isn't approved.
  - **Notify senders in your organization only when their messages aren't approved** When you select this option, only people or groups in your organization are notified when a message that they sent to the group isn't approved by a moderator.
  - **Don't notify anyone when a message isn't approved** When you select this option, notifications aren't sent to message senders whose messages aren't approved by the group moderators.

Email options

Use this section to view or change the email addresses associated with the group. This includes the group's primary SMTP addresses and any associated proxy addresses. The primary SMTP address (also known as the *reply address*) is displayed in bold text in the address list, with the uppercase

SMTP value in the **Type** column.

- **Add** Click **Add +** to add a new email address for this mailbox. Select one of following address types:
  - **SMTP** This is the default address type. Click this button and then type the new SMTP address in the *** Email address** box.

Note:
To make the new address the primary SMTP address for the group, select the **Make this the reply address** check box.

  - **Custom address type** Click this button and type one of the supported non-SMTP email address types in the *** Email address** box.

Note:
With the exception of X.400 addresses, Exchange doesn't validate custom addresses for proper formatting. You must make sure that the custom address you specify complies with the format requirements for that address type.

- **Edit** To change an email address associated with the group, select it from the list, and then click **Edit** .

Note:
To make an existing address the primary SMTP address for the group, select the **Make this the reply address** check box.

- **Remove** To delete an email address associated with the group, select it from the list, and then click **Remove −**.
- **Automatically update email addresses based on the email address policy applied to this recipient** Select this check box to have the recipient's email addresses automatically updated based on changes made to email address policies in your organization. This box is selected by default.

MailTip

Use this section to add a MailTip to alert users of potential issues before they send a message to this group. A MailTip is text that's displayed in the InfoBar when this group is added to the To, Cc, or Bcc lines of a new email message. For example, you could add a MailTip to large groups to warn potential senders that their message will be sent to lots of people.

Note:
MailTips can include HTML tags, but scripts aren't allowed. The length of a custom MailTip can't exceed 175 displayed characters. HTML tags aren't counted in the limit.

Group delegation

Use this section to assign permissions to a user (called a *delegate*) to allow them to send messages as the group or send messages on behalf of the group. You can assign the following permissions:

- **Send As** This permission allows the delegate to send messages as the group. After this permission is assigned, the delegate has the option to add the group to the **From** line to indicate

that the message was sent by the group.

- **Send on Behalf Of** This permission also allows a delegate to send messages on behalf of the group. After this permission is assigned, the delegate has the option to add the group on the **From** line. The message will appear to be sent by the group and will say that it was sent by the delegate on behalf of the group.

To assign permissions to delegates, click **Add** under the appropriate permission to display the **Select Recipient** page, which displays a list of all recipients in your Exchange organization that can be assigned the permission. Select the recipients you want, add them to the list, and then click **OK**. You can also search for a specific recipient by typing the recipient's name in the search box and then clicking **Search**.

Use the Shell to change dynamic distribution group properties

Use the **Get-DynamicDistributionGroup** and **Set-DynamicDistributionGroup** cmdlets to view and change properties for dynamic distribution groups. Advantages of using the Shell are the ability to change the properties that aren't available in the EAC and change properties for multiple groups. For information about what parameters correspond to distribution group properties, see the following topics:

- Get-DynamicDistributionGroup
- Set-DynamicDistributionGroup

Here are some examples of using the Shell to change dynamic distribution group properties.

This example changes the following parameters for all dynamic distribution groups in the organization:

- Hide all dynamic distribution groups from the address book
- Set the maximum message size that can be sent to the group to 5MB
- Enable moderation
- Assign the administrator as the group moderator

```
Get-DynamicDistributionGroup -ResultSize unlimited | Set-
DynamicDistributionGroup -HiddenFromAddressListsEnabled
$true -MaxReceiveSize 5MB -ModerationEnabled $true -
ModeratedBy administrator
```

This example adds the proxy SMTP email address, Seattle.Employees@contoso.com, to the All Employees group.

```
Set-DynamicDistributionGroup -Identity "All Employees" -
EmailAddresses SMTP:All.Employees@contoso.com,
smtp:Seattle.Employees@contoso.com
```

How do you know this worked?

To verify that you've successfully changed properties for a dynamic distribution group, do the

following:

- In the EAC, select the group and then click **Edit** to view the property or feature that you changed. Depending on the property that you changed, it might be displayed in the Details pane for the selected group.
- In the Shell, use the **Get-DynamicDistributionGroup** cmdlet to verify the changes. One advantage of using the Shell is that you can view multiple properties for multiple groups. In the first example, you would run the following command to verify the new values.

```
Get-DynamicDistributionGroup -ResultSize unlimited | fl
Name,HiddenFromAddressListsEnabled,MaxReceiveSize,Moderatio
nEnabled,ModeratedBy
```

For the example above where the message limits were changed, run this command.

```
Get-Mailbox -OrganizationalUnit "Marketing" | fl
Name,IssueWarningQuota,ProhibitSendQuota,ProhibitSendReceiv
eQuota,UseDatabaseQuotaDefaults
```

View members of a dynamic distribution group

Exchange Server 2013 > Recipients > Manage dynamic distribution groups >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-13*

Dynamic distribution groups are distribution groups whose membership is based on specific recipient filters rather than a defined set of recipients. Microsoft Exchange provides precanned filters to make it easier to create recipient filters for dynamic distribution groups. A *precanned filter* is a commonly used filter that you can use to meet a variety of recipient-filtering criteria. You can specify the recipient types you want to include in a dynamic distribution group. Additionally, you can also specify a list of conditions that the recipients must meet. You can use the Shell to preview the list of recipients for a dynamic distribution group that uses precanned filters.

You can also use the Exchange Administration Center (EAC) to see how many recipients received the most recent message that was sent to a dynamic distribution group.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To

see what permissions you need, see the "Dynamic distribution groups" entry in the Recipients Permissions topic.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the Shell to preview the list of members of a dynamic distribution group

This example returns the list of members for the dynamic distribution group Full Time Employees. The first command stores the dynamic distribution group object in the variable $FTE. The second command uses the **Get-Recipient** cmdlet to list the recipients that match the criteria defined for the dynamic distribution group.

```
$FTE = Get-DynamicDistributionGroup "Full Time Employees"

Get-Recipient -RecipientPreviewFilter $FTE.RecipientFilter
```

For detailed syntax and parameter information, see Get-DynamicDistributionGroup and Get-Recipient.

Use the EAC to see how many recipients received a message sent to a dynamic distribution group

1. In the EAC, navigate to **Recipients** > **Groups**.
2. Select a dynamic distribution group.

In the details pane under **Membership**, the number of people who received the last message sent to the dynamic distribution group is displayed.

How do you know this worked?

To verify that you've successfully viewed the members of a dynamic distribution group, do one of the following:

- In the Shell, a list of members is returned after you run the previous command to preview a list of dynamic distribution group members. For example, if you created a new user mailbox with properties that match the recipient filter for the dynamic distribution group, this new user should

be displayed in the list of group members.

- The number of people who received the last message sent to the dynamic distribution group is displayed in the details pane in the EAC. If no one has received a message sent to this group, it's possible that a message hasn't been sent to the group or that the group doesn't have any members that meet the conditions of the recipient filter.

Manage mail contacts

Exchange Server 2013 > Recipients >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-19*

Mail contacts are mail-enabled directory service objects that contain information about people or organizations that exist outside your Exchange or Exchange Online organization. Each mail contact has an external email address. For more information about mail contacts, see Recipients.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Create a mail contact

Use the EAC to create a mail contact

1. In the EAC, navigate to **Recipients** > **Contacts**.
2. Click **New +** > **Mail contact**.
3. Complete the following boxes on the **New mail contact** page:
   - **First name** Use this box to type the contact's first name.
   - **Initials** Use this box to type the contact's initials.
   - **Last name** Use this box to type the contact's last name.

- *** Display name** Use this box to type a display name for the contact. This is the name that's listed in the contacts list in the EAC and in your organization's address book. By default, this box is populated with the names you enter in the **First name**, **Initials**, and **Last name** boxes. If you didn't use those boxes, you must still type a name in this box because it's required. The name can't exceed 64 characters.
- *** Name** Use this box to type a name for the contact. This is the name that's listed in the directory service. Like the display name, this box is populated by default with the names you enter in the **First name**, **Initials**, and **Last name** boxes. If you didn't use those boxes, you must still type a name in this box because it's required. The name can't exceed 64 characters.
- *** Alias** Use this box to type a unique alias (64 characters or less) for the contact. This box is required.
- *** External email address** Use this box to type the outside email account of the contact. This box is required. Email sent to this contact is forwarded to this email address.
- **Organizational unit** You can select an organizational unit (OU) other than the default, which is the recipient scope. If the recipient scope is set to the forest, the default value is set to the Users container in the domain that contains the computer on which the EAC is running. If the recipient scope is set to a specific domain, the Users container in that domain is selected by default. If the recipient scope is set to a specific OU, that OU is selected by default.

To select a different OU, click **Browse**. The dialog box displays all OUs in the forest that are within the specified scope. Select the OU you want, and then click **OK**.

Note:
The **Organizational unit** box is only available in Exchange Server 2013. It isn't available in Exchange Online.

4. When you've finished, click **Save**.

Use the Shell to create a mail contact

This example creates a mail contact for Debra Garcia in Exchange Server 2013.

```
New-MailContact -Name "Debra Garcia" -ExternalEmailAddress
dgarcia@tailspintoys.com -OrganizationalUnit Users
```

This example creates a mail contact for Alan Shen in Exchange Online.

```
New-MailContact -Name "Alan Shen" -ExternalEmailAddress
alans@fourthcoffee.com
```

This example mail-enables an existing contact named Karen Toh in Exchange Server 2013.

```
Enable-MailContact -Identity "Karen Toh" -
ExternalEmailAddress ktoh@tailspintoys.com
```

How do you know this worked?

To verify that you've successfully created a mail contact, do one of the following:

- In the EAC, navigate to **Recipients** > **Contacts**. The new mail contact is displayed in the contact list. Under **Contact Type**, the type is **Mail contact**.
- In the Shell, run the following command to display information about the new mail contact.

```
Get-MailContact <Name> | FL
Name,RecipientTypeDetails,ExternalEmailAddress
```

Change mail contact properties

Use the EAC to change mail contact properties

1. In the EAC, navigate to **Recipients** > **Contacts**.
2. In the list of mail contacts and mail users, click the mail contact that you want to change the properties for, and then click **Edit** ✎.
3. On the mail contact properties page, click one of the following sections to view or change properties.
   - General
   - Contact Information
   - Organization
   - Email Options (not available in Exchange Online)
   - MailTip

General

Use the **General** section to view or change basic information about the mail contact.

- **First name**, **Initials**, **Last name**
- *** Name** This is the name that's listed in Active Directory. If you change this name, it can't exceed 64 characters.
- *** Display name** This name appears in your organization's address book, on the To and From lines in email, and in the Mailbox list. This name can't contain empty spaces before or after the display name.
- *** Alias** This is the mail contact's alias. If you change it, it must be unique in the organization and must be 64 characters or less.
- *** External email address** This is mail contact's primary SMTP address and their outside email account. Email sent to this contact is forwarded to this email address.
- Click **More options** to display the OU that contains the mail contact account. You have to use Active Directory Users and Computers to move the contact to a different OU.

Contact Information

Use the **Contact Information** section to view or change the recipient's contact information, such as mailing address and telephone numbers. This information is displayed in the address book.

Organization

Use the **Organization** section to record detailed information about the mail contact's role in the organization. This information is displayed in the address book. Also, you can create a virtual organization chart that's accessible from email clients such as Outlook.

- **Title** Use this box to view or change the contact's title.
- **Department** Use this box to view or change the department in which the contact works. You can use this box to create recipient conditions for dynamic distribution groups and address lists.
- **Company** Use this box to view or change the company for which the contact works. You can also use this box to create recipient conditions for dynamic distribution groups.
- **Manager** To add a manager, click **Browse**. In **Select Manager**, select a person, and then click **OK**.
- **Direct reports** You can't modify this box. A *direct report* is a recipient who reports to a specific manager. If you've specified a manager for the recipient, that recipient appears as a direct report in the details of the manager's mailbox. For example, Toby manages Ann and Spencer, who are mail contacts, so Toby is specified in the **Manager** box in the organization properties for Ann and Spencer, and Ann and Spencer appear in the **Direct reports** box in the properties of Toby's mailbox.

Email Options

Use the **Email Options** section to add or remove proxy addresses for the mail contact or edit existing proxy addresses. The mail contact's primary SMTP address is also displayed in this section, but you can't change it. To change it, you have to change the contact's external email address in the **General** section.

Note:

The **Email Options** section is only available in Exchange Server 2013. It's not available in Exchange Online.

MailTip

Use the **MailTip** section to add a MailTip to alert users of potential issues before they send a message to this recipient. A MailTip is text that's displayed in the InfoBar when this recipient is added to the To, Cc, or Bcc lines of a new email message.

Note:

MailTips can include HTML tags, but scripts aren't allowed. The length of a custom MailTip can't exceed 175 displayed characters. HTML tags aren't counted in the limit.

Use the Shell to change mail contact properties

Properties for a mail contact are stored in both Active Directory and Exchange. In general, use the **Get-Contact** and **Set-Contact** cmdlets to view and change organization and contact information properties. Use the **Get-MailContact** and **Set-MailContact** cmdlets to view or change mail-related properties, such as email addresses, the MailTip, custom attributes, and whether the contact is hidden from address lists.

For more information, see the following topics:

- Get-Contact
- Set-Contact
- Get-MailContact
- Set-MailContact

Here are some examples of using the Shell to change mail contact properties.

This example configures the Title, Department, Company, and Manager properties for the mail contact Kai Axford.

```
Set-Contact "Kai Axford" _-Title Consultant -Department
"Public Relations" -Company Fabrikam -Manager "Karen Toh"
```

This example sets the CustomAttribute1 property to a value of PartTime for all mail contacts and hides them from the organization's address book.

```
Get-MailContact | Set-MailContact -CustomAttribute1
PartTime -HiddenFromAddressListsEnabled $true
```

This example sets the CustomAttribute15 property to a value of TemporaryEmployee for all mail contacts in the Public Relations department.

```
Get-Contact -Filter "Department -eq 'Public Relations'" |
Set-MailContact -CustomAttribute15 TemporaryEmployee
```

How do you know this worked?

To verify that you've successfully changed properties for a mail contact, do the following:

- In the EAC, select the mail contact, and then click **Edit** to view the property that you changed.
- In the Shell, use the **Get-Contact** and **Get-MailContact** cmdlets to verify the changes. One advantage of using the Shell is that you can view multiple properties for multiple mail contacts. In the example above where all mail contacts had the CustomAttribute1 property set to PartTime and were hidden from the address book, run the following command to verify the changes.

```
Get-MailContact | Fl
Name,CustomAttribute1,HiddenFromAddressListsEnabled
```

In the example above where the CustomAttribute15 was set for all mail contacts in the Public Relations department, run the following command to verify the changes.

```
Get-Contact -Filter "Department -eq 'Public Relations'" |
Get-MailContact | FL Name,CustomAttribute15
```

Bulk edit mail contacts

You can use the EAC to change selected properties for multiple mail contacts. When you select two

or more mail contacts from the contacts list in the EAC, the properties that can be bulk edited are displayed in the Details pane. When you change one of these properties, the change is applied to all selected recipients.

When you bulk edit mail contacts, you can change the following property areas:

- **Contact Information** Change shared properties such as street, postal code, and city name.
- **Organization** Change shared properties such as department name, company name, and the manager that the selected mail contacts or mail users report to.

Use the EAC to bulk edit mail contacts

1. In the EAC, navigate to **Recipients** > **Contacts**.
2. In the list of contacts, select two or more mail contacts. You can't bulk edit a combination of mail contacts and mail users.

> **Tip:**
> You can select multiple adjacent mail contacts by holding down the Shift key and clicking the first mail contact, and then clicking the last mail contact you want to edit. You can also select multiple mail contacts by holding down the Ctrl key and clicking each one that you want to edit.

3. In the Details pane, under **Bulk Edit**, click **Update** under **Contact Information** or **Organization**.
4. Make the changes on the properties page and then save your changes.

How do you know this worked?

To verify that you've successfully bulk edited mail contacts, do one of the following:

- In the EAC, select each of the mail contacts that you bulk edited, and then click **Edit** to view the properties that you changed.
- In the Shell, use the **Get-Contact** cmdlet to verify the changes. For example, say you used the bulk edit feature in the EAC to change the manager and the office for all mail contacts from a vendor company named A. Datum Corporation. To verify these changes, you could run the following command in the Shell.

```
Get-Contact -ResultSize unlimited -Filter {(Company -eq
'Adatum')} | fl Name,Office,Manager
```

Enable or disable email for a mail contact

Exchange Server 2013 > Recipients > Manage mail contacts >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-12-05*

You can disable email for an existing mail contact in your Exchange organization. When you disable email for a mail contact, it's removed from Exchange and from your organization's address book. If the mail contact is a member of a distribution group, the contact no longer receives mail sent to the group. Also, the Exchange attributes are removed from the mail-enabled contact object in Active Directory, but the contact and its non-Exchange attributes (such as contact and organization information) are retained in Active Directory.

After you disable email for a mail contact, you can mail-enable the contact again by using the **Enable-MailContact** cmdlet in the Shell. You can also use this cmdlet to mail-enable any Active Directory contact.

For additional management tasks related to mail contacts, see Manage mail contacts.

What do you need to know before you begin?

- Estimated time to complete each procedure: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mail contacts" entry in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Disable email for a mail contact

As previously stated, when you disable email for a mail contact, the Exchange attributes are removed from the corresponding Active Directory contact object, but the contact is retained. The mail contact is removed from the list of mail contacts in the EAC, but you can view and manage the corresponding Active Directory contact object by using Active Directory Users and Computers or by using the **Get-Contact** and **Set-Contact** cmdlets in the Shell.

Use the EAC to disable email for a mail contact

1. In the EAC, navigate to **Recipients** > **Contacts**.
2. In the list of contacts, click the mail contact for which you want to disable email.
3. Click **More** ··· and then click **Disable**.
4. A warning will appear asking if you're sure you want to disable the selected mail contact. Click **Yes** to disable it.

The mail contact will be removed from the contacts list.

Use the Shell to disable email for a mail contact

This example disables email for the mail contact Neil Black.

```
Disable-MailContact -Identity "Neil Black"
```

For detailed syntax and parameter information, see Disable-MailContact.

How do you know this worked?

To verify that you've successfully disabled email for a mail contact, do one of the following:

1. In the EAC, navigate to **Recipients** > **Contacts** and verify that the mail contact is no longer listed.
2. In Active Directory Users and Computers, right-click the contact, and then click **Properties**. On the **General** tab, notice that the **E-mail** box is blank. This verifies that the contact isn't mail-enabled.
3. In the Shell, run the following command.

```
Get-MailContact
```

The contact that you disabled email for won't be returned in the results because this cmdlet only returns mail-enabled contacts.

4. In the Shell, run the following command.

```
Get-Contact
```

The contact that you disabled email for is returned in the results because this cmdlet returns all Active Directory contact objects.

Use the Shell to mail-enable contacts

You can use the **Enable-MailContact** cmdlet to mail-enable existing Active Directory contacts. You can mail-enable a single contact or use a CSV file to mail-enable multiple contacts.

Use the Shell to mail-enable a single contact

This example mail-enables the contact Rene Valdes. You must provide an external email address.

```
Enable-MailContact -Identity "Rene Valdes" -
ExternalEmailAddress renev@tailspintoys.com
```

Use the Shell and a CSV file to mail-enable multiple contacts

When you're mail-enabling contacts in bulk, you first export the list of contacts that aren't mail-enabled to a CSV (comma-separated values) file, and then add the external email addresses to the CSV file by using a text editor such as Notepad, or a spreadsheet application such as Microsoft Excel. Then you use the updated CSV file in the Shell command to mail-enable the contacts listed in the CSV file.

1. Run the following command to export a list of existing contacts that aren't mail-enabled to a file

on the administrator's desktop named Contacts.csv.

```
Get-Contact | Where { $_.RecipientType -eq "Contact" } |
Out-File "C:\Users\Administrator\Desktop\Contacts.csv"
```

The resulting file will be similar to the following file.

```
Name
Walter Harp
James Alvord
Rainer Witt
Susan Burk
Ian Tien
...
```

2. Add a column heading named **EmailAddress** and then add an email address for each contact in the file. The name and external email address for each contact must be separated by a comma. The updated CSV file should look similar to the following file.

```
Name,EmailAddress
James Alvord,james@contoso.com
Susan Burk,sburk@tailspintoys.com
Walter Harp,wharp@tailspintoys.com
Ian Tien,iant@tailspintoys.com
Rainer Witt,rainerw@fourthcoffee.com
...
```

3. Run the following command to use the data in the CSV file to mail-enable the contacts listed in the file.

```
Import-CSV C:\Users\Administrator\Desktop\Contacts.csv |
ForEach-Object {Enable-MailContact -Identity $_.Name -
ExternalEmailAddress $_.EmailAddress}
```

The command results display information about the new mail-enabled contacts.

How do you know this worked?

To verify that you've successfully mail-enabled Active Directory contacts, do one of the following:

- In the EAC, navigate to **Recipients** > **Contacts**. New mail contacts are displayed in the contact list. Under **Contact Type**, the type is **Mail contact**.

Note:
You may have to click **Refresh** to display new mail contacts.

- In the Shell, run the following command to display information about new mail contacts.

```
Get-MailContact | Format-Table
Name,RecipientTypeDetails,ExternalEmailAddress
```

Manage mail users

Exchange Server 2013 > Recipients >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-08-04*

Mail users are similar to mail contacts. Both have external email addresses and both contain information about people outside your Exchange or Exchange Online organization that can be displayed in the shared address book and other address lists. However, unlike a mail contact, a mail user has logon credentials in your Exchange or Office 365 organization and can access resources. For more information, see Recipients.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Create a mail user

Use the EAC to create a mail user

1. In the EAC, navigate to **Recipients** > **Contacts** > **New** > **Mail user**.
2. On the **New mail user** page, in the *** Alias** box, type the alias for the mail user. The alias can't exceed 64 characters and must be unique in the forest. This box is required.
3. Do one of the following to specify the email address type for the mail user:
   - To specify an SMTP email address for the mail user's external email address, click **SMTP**.

Note:

Exchange validates SMTP addresses for correct formatting. If your entry is inconsistent with the SMTP format, an error message will be displayed when you click **Save** to create the mail user.

- To specify a custom address type, click the option button and then type the custom address type. For example, you can specify an X.500, GroupWise, or Lotus Notes address.

4. In the *** External email address** box, type the mail user's external email address. Email sent to this mail user is forwarded to this email address. This box is required.
5. Select one of the following options:
   - **Existing user** Select to mail-enable an existing user.

Click **Browse** to open the **Select User – Entire Forest** dialog box. This dialog box displays a list of user accounts in the organization that aren't mail-enabled or don't have mailboxes. Select the user account you want to mail-enable, and then click **OK**. If you select this option, you don't have to provide user account information because this information already exists in Active Directory.

   - **New user** Select to create a new user account in Active Directory and mail-enable the user. If you select this option, you'll have to provide the required user account information.

6. If you selected **New User** in Step 5, complete the following boxes on the **New mail user** page. Otherwise skip to Step 7.
   - **First name** Use this box to type the first name of the mail user.
   - **Initials** Use this box to type the initials of the mail user.
   - **Last name** Use this box to type the last name of the mail user.
   - *** Display name** Use this box to type a display name for the user. This is the name that's listed in the contacts list in the EAC and in your organization's address book. By default, this box is populated with the names you enter in the **First name**, **Initials**, and **Last name** boxes. If you didn't use those boxes, you must still type a name in this box because it's required. The name can't exceed 64 characters.
   - *** Name** Use this box to type a name for the mail user. This is the name that's listed in the directory service. This box is also populated with the names you enter in the **First name**, **Initials**, and **Last name** boxes. If you didn't use those boxes, you must still type a name because this box is required. This name also can't exceed 64 characters.

Note:

The **Name** box is only available in Exchange Server 2013. It isn't available in Exchange Online.

   - **Organizational unit** You can select an organizational unit (OU) other than the default (which is the recipient scope). If the recipient scope is set to the forest, the default value is set to the Users container in the domain that contains the computer on which the EAC is running. If the recipient scope is set to a specific domain, the Users container in that domain is selected by default. If the recipient scope is set to a specific OU, that OU is selected by default.

To select a different OU, click **Browse**. The dialog box displays all OUs in the forest that are within the specified scope. Select the OU you want, and then click **OK**.

Note:

The **Organizational unit** box is only available in Exchange Server 2013. It isn't available in Exchange Online.

- *** User logon name** Use this box to type the name that the mail user will use to log on to the domain. The user logon name consists of a user name on the left side of the at (@) symbol and a suffix on the right side. Typically, the suffix is the domain name the user account resides in.

Note:
In Exchange Online, this box is labeled as **User ID**.

- *** New Password** Use this box to type the password that the mail user must use to log on to the domain.

Note:
Make sure that the password you supply complies with the password length, complexity, and history requirements of the domain you're creating the user account in.

- *** Confirm password** Use this box to confirm the password that you typed in the **Password** box.
- **Require password change on next logon** Select this check box if you want mail users to reset the password when they first log on to the domain.

If you select this check box, at first logon, the new mail user will be prompted with a dialog box in which to change the password. The mail user won't be allowed to perform any tasks until the password is changed successfully.

7. When you've finished, click **Save** to create the mail user.

Use the Shell to create a mail user

This example creates a mail-enabled user account for Jeffrey Zeng in Exchange Server 2013 with the following details:

- The name and display name is Jeffrey Zeng.
- The alias is jeffreyz.
- The external email address is jzeng@tailspintoys.com.
- The first name is Jeffrey and the last name is Zeng.
- The logon name is jeffreyz@contoso.com.
- The password is Pa$$word1.
- The mail user will be created in the default OU. To specify a different OU, you can use the *OrganizationalUnit* parameter.

```
New-MailUser -Name "Jeffrey Zeng" -Alias jeffreyz -
ExternalEmailAddress jzeng@tailspintoys.com -FirstName
Jeffrey -LastName Zeng -UserPrincipalName
jeffreyz@contoso.com -Password (ConvertTo-SecureString -
String 'Pa$$word1' -AsPlainText -Force)
```

This example creates a mail-enabled user account for Rene Valdes in Exchange Online.

```
New-MailUser -Name "Rene Valdes" -Alias renev -
ExternalEmailAddress renevaldes@fineartschool.edu -
```

```
FirstName Rene -LastName Valdes -MicrosoftOnlineServicesID
renev@contoso.com -Password (ConvertTo-SecureString -String
'P@sswOrd' -AsPlainText -Force)
```

How do you know this worked?

To verify that you've successfully created a mail user, do one of the following:

- In the EAC, navigate to **Recipients** > **Contacts**. The new mail user is displayed in the list of contacts. Under **Contact Type**, the type is **Mail user**.
- In the Shell, run the following command to display information about the new mail user.

```
Get-MailUser <Name> | FL
Name,RecipientTypeDetails,ExternalEmailAddress
```

Change mail user properties

After you create a mail user, you can make changes and set additional properties by using the EAC or the Shell.

You can also change properties for multiple user mailboxes at the same time. For more information, see Bulk edit mail users.

The estimated time to complete this task will vary based on the number of properties you want to view or change.

Use the EAC to change user mailbox properties

1. In the EAC, navigate to **Recipients** > **Contacts**.
2. In the list of contacts, click the mail user that you want to change the properties for, and then click **Edit** ✎.
3. On the mail user properties page, click one of the following sections to view or change properties.
   - General
   - Contact Information
   - Organization
   - Email Addresses
   - Mail Flow Settings
   - Member Of
   - MailTip

General

Use the **General** section to view or change basic information about the mail user.

- **First name**, **Initials**, **Last name**
- *** Name** This is the name that's listed in Active Directory. If you change this name, it can't exceed 64 characters.

- *** Display name** This name appears in your organization's address book, on the To: and From: lines in email, and in the list of contacts in the EAC. This name can't contain empty spaces before or after the display name.
- *** User logon name** This is the name that the user uses to log on to the domain. In Exchange Online, this is the User ID that the user uses to sign in to Office 365.
- **Hide from address lists** Select this check box to prevent the mail user from appearing in the address book and other address lists that are defined in your Exchange organization. After you select this check box, users can still send messages to the recipient by using the email address.
- **Require password change on next logon** Select this check box if you want the user to reset their password the next time they log on to the domain.

Note:
This box isn't available in Exchange Online.

Click **More options** to view or change these additional properties:

- **Organizational unit** This read-only box displays the organizational unit (OU) that contains the mail user account. You have to use Active Directory Users and Computers to move the account to a different OU.

Note:
This box isn't available in Exchange Online.

- **Custom attributes** This section displays the custom attributes defined for the mail user. To specify custom attribute values, click **Edit** . You can specify up to 15 custom attributes for the recipient.

Contact Information

Use the **Contact Information** section to view or change the user's contact information. The information on this page is displayed in the address book. Click **More options** to display additional boxes.

Tip:
You can use the **State/Province** box to create recipient conditions for dynamic distribution groups, email address policies, or address lists.

Organization

Use the **Organization** section to record detailed information about the user's role in the organization. This information is displayed in the address book. Also, you can create a virtual organization chart that's accessible from email clients such as Outlook.

- **Title** Use this box to view or change the recipient's title.
- **Department** Use this box to view or change the department in which the user works. You can use this box to create recipient conditions for dynamic distribution groups, email address policies, or address lists.
- **Company** Use this box to view or change the company for which the user works. You can use this box to create recipient conditions for dynamic distribution groups, email address policies, or

address lists.

- **Manager** To add a manager, click **Browse**. In **Select Manager**, select a person, and then click **OK**.
- **Direct reports** You can't modify this box. A *direct report* is a user who reports to a specific manager. If you've specified a manager for the user, that user appears as a direct report in the details of the manager's mailbox. For example, Kari manages Chris and Kate, so Kari is specified in the **Manager** box for Chris and Kate, and Chris and Kate appear in the **Direct reports** box in the properties of Kari's account.

Email Addresses

Use the **Email Addresses** section to view or change the email addresses associated with the mail user. This includes the mail user's primary SMTP address, their external email address, and any associated proxy addresses. The primary SMTP address (also known as the *default reply address*) is displayed in bold text in the address list, with the uppercase **SMTP** value in the **Type** column. By default, after the mail user is created, the primary SMTP address and the external email address are the same.

- **Add** Click **Add +** to add a new email address for this mailbox. Select one of following address types:
  - **SMTP** This is the default address type. Click this button and then type the new SMTP address in the *** Email address** box.
  - **Custom address type** Click this button and type one of the supported non-SMTP email address types in the *** Email address** box.

Note:

With the exception of X.400 addresses, Exchange doesn't validate custom addresses for correct formatting. You must make sure that the custom address you specify complies with the format requirements for that address type.

- **Set the external email address** Use this box to change the mail user's external address. Email sent to this mail user is forwarded to this email address.
- **Automatically update email addresses based on the email address policy applied to this recipient** Select this check box to have the recipient's email addresses automatically updated based on changes made to email address policies in your organization. This box is selected by default.

Note:

This check box isn't available in Exchange Online.

Mail Flow Settings

Use the **Mail Flow Settings** section to view or change the following settings:

- **Message Size Restrictions** These settings control the size of messages that the mail user can send and receive. Click **View details** to view and change maximum size for sent and received messages.
  - **Sent messages** To specify a maximum size for messages sent by this user, select the

Maximum message size (KB) check box and type a value in the box. The message size must be between 0 and 2,097,151 KB. If the user sends a message larger than the specified size, the message will be returned to the user with a descriptive error message.

- **Received messages** To specify a maximum size for messages received by this user, select the **Maximum message size (KB)** check box and type a value in the box. The message size must be between 0 and 2,097,151 KB. If the user receives a message larger than the specified size, the message will be returned to the sender with a descriptive error message.

- **Message Delivery Restrictions** These settings control who can send email messages to this mail user. Click **View details** to view and change these restrictions.
  - **Accept messages from** Use this section to specify who can send messages to this user.
    - **All senders** Select this option to specify that the user can accept messages from all senders. This includes both senders in your Exchange organization and external senders. This option is selected by default. This option includes external users only if you clear the **Require that all senders are authenticated** check box. If you select this check box, messages from external users will be rejected.
    - **Only senders in the following list** Select this option to specify that the user can accept messages only from a specified set of senders in your Exchange organization. Click **Add +** to display the **Select Recipients** page, which displays a list of all recipients in your Exchange organization. Select the recipients you want, add them to the list, and then click **OK**. You can also search for a specific recipient by typing the recipient's name in the search box and then clicking **Search**.
    - **Require that all senders are authenticated** Select this option to prevent anonymous users from sending messages to the user.
  - **Reject messages from** Use this section to block people from sending messages to this user.
    - **No senders** Select this option to specify that the mailbox won't reject messages from any senders in the Exchange organization. This option is selected by default.
    - **Senders in the following list** Select this option to specify that the mailbox will reject messages from a specified set of senders in your Exchange organization. Click **Add +** to display the **Select Recipients** page, which displays a list of all recipients in your Exchange organization. Select the recipients you want, add them to the list, and then click **OK**. You can also search for a specific recipient by typing the recipient's name in the search box and then clicking **Search**.

Member Of

Use the **Member Of** section to view a list of the distribution groups or security groups to which this user belongs. You can't change membership information on this page. Note that the user may match the criteria for one or more dynamic distribution groups in your organization. However, dynamic distribution groups aren't displayed on this page because their membership is calculated each time they're used.

MailTip

Use the **MailTip** section to add a MailTip to alert users of potential issues before they send a

message to this recipient. A MailTip is text that's displayed in the InfoBar when this recipient is added to the To, Cc, or Bcc lines of a new email message.

Note:
MailTips can include HTML tags, but scripts aren't allowed. The length of a custom MailTip can't exceed 175 displayed characters. HTML tags aren't counted in the limit.

Use the Shell to change mail user properties

Properties for a mail user are stored in both Active Directory and Exchange. In general, use the **Get-User** and **Set-User** cmdlets to view and change organization and contact information properties. Use the **Get-MailUser** and **Set-MailUser** cmdlets to view or change mail-related properties, such email addresses, the MailTip, custom attributes, and whether the mail user is hidden from address lists.

Use the **Get-MailUser** and **Set-MailUser** cmdlets to view and change properties for mail users. For information, see the following topics:

- Get-User
- Set-User
- Get-MailUser
- Set-MailUser

Here are some examples of using the Shell to change mail user properties.

This example sets the external email address for Pilar Pinilla.

```
Set-MailUser "Pilar Pinilla" -ExternalEmailAddress
pilarp@tailspintoys.com
```

This example hides all mail users from the organization's address book.

```
Get-MailUser | Set-MailUser -HiddenFromAddressListsEnabled
$true
```

This example sets the Company property for all mail users to Contoso.

```
Get-User -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'mailuser')} | Set-User -Company
Contoso
```

This example sets the CustomAttribute1 property to a value of ContosoEmployee for all mail users that have a value of Contoso in the Company property.

```
Get-User -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'mailuser') -and (Company -eq
'Contoso')}| Set-MailUser -CustomAttribute1 ContosoEmployee
```

How do you know this worked?

To verify that you've successfully changed properties for mail users, do the following:

- In the EAC, select the mail user and then click **Edit** to view the property that you changed.
- In the Shell, use the **Get-User** and **Get-MailUser** cmdlets to verify the changes. One advantage of using the Shell is that you can view multiple properties for multiple mail contacts.

```
Get-MailUser | Fl Name,CustomAttribute1
```

In the example above where the Company property was set to Contoso for all mail contacts, run the following command to verify the changes:

```
Get-User -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'mailuser')} | FL Name,Company
```

In the example above where all mail users had the CustomAttribute1 property set to ContosoEmployee, run the following command to verify the changes.

```
Get-MailUser | Fl Name,CustomAttribute1
```

Bulk edit mail users

You can also use the EAC to change selected properties for multiple mail users. When you select two or more mail users from the contacts list in the EAC, the properties that can be bulk edited are displayed in the Details pane. When you change one of these properties, the change is applied to all selected recipients.

When you bulk edit mail users, you can change the following property areas:

- **Contact Information** Change shared properties such as street, postal code, and city name.
- **Organization** Change shared properties such as department name, company name, and the manager that the selected mail contacts or mail users report to.

Use the EAC to bulk edit mail users

1. In the EAC, navigate to **Recipients** > **Contacts**.
2. In the list of contacts, select two or more mail users. You can't bulk edit a combination of mail contacts and mail users.

Tip:
You can select multiple adjacent mail users by holding down the Shift key and clicking the first mail user, and then clicking the last mail user you want to edit. You can also select multiple mail users by holding down the Ctrl key and clicking each one that you want to edit.

3. In the Details pane, under **Bulk Edit**, click **Update** under **Contact Information** or **Organization**.
4. Make the changes on the properties page and then save your changes.

How do you know this worked?

To verify that you've successfully bulk edited mail users, do one of the following:

- In the EAC, select each of the mail users that you bulk edited and then click **Edit** to view the properties that you changed.
- In the Shell, use the **Get-User** cmdlet to verify the changes. For example, say you used the bulk edit feature in the EAC to change the manager and the office for all mail users from a vendor company named A. Datum Corporation. To verify these changes, you could run the following command in the Shell:

```
Get-User -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'mailuser') -and (Company -eq
'Adatum')} | fl Name,Office,Manager
```

Use directory synchronization to manage mail users in Exchange Online

This section provides information about managing email users by using directory synchronization in Exchange Online. Directory synchronization is available for hybrid customers with on-premises and cloud-hosted mailboxes, and for fully hosted Exchange Online customers whose Active Directory is on-premises.

Note:

If you use directory synchronization to manage your recipients, you can still add and manage users in the Office 365 admin center, but they will not be synchronized with your on-premises Active Directory. This is because directory synchronization only syncs recipients from your on-premises Active Directory to the cloud.

Note:

Using directory synchronization is recommended for use with the following features:

- **Outlook safe sender and blocked sender lists** When synchronized to the service, these lists will take precedence over spam filtering in the service. This lets users manage their own safe sender and blocked sender lists on a per-user or per-domain basis.
- **Directory Based Edge Blocking (DBEB)** For more information about DBEB, see **Use Directory Based Edge Blocking to Reject Messages Sent to Invalid Recipients**.
- **End user spam quarantine** In order to access the end user spam quarantine, end users must have a valid Office 365 user ID and password. Customers with on-premises mailboxes must be valid email users.
- **Transport rules** When you use directory synchronization, your existing Active Directory users and groups are automatically uploaded to the cloud, and you can then create Transport rules that target specific users and/or groups without having to manually add them via the EAC or remote Windows PowerShell. Note that dynamic distribution groups can't be synchronized via directory synchronization.

Before you begin

Get the necessary permissions and prepare for directory synchronization, as described in Prepare for directory synchronization.

To synchronize user directories

1. Activate directory synchronization, as described in Activate directory synchronization.
2. Set up your directory synchronization computer, as described in Set up your directory sync computer.
3. Synchronize your directories, as described in Use the Configuration Wizard to sync your directories.

Important:

When you finish the Windows Azure AD Sync Tool Configuration Wizard, the **MSOL_AD_SYNC** account is created in your Active Directory forest. This account is used to read and synchronize your on-premises Active Directory information. In order for directory synchronization to work correctly, make sure that TCP 443 on your local directory synchronization server is open.

4. Activate synced users, as described in Activate synced users.
5. Manage directory synchronization, as described in Manage directory synchronization.
6. Verify that Exchange Online is synchronizing correctly. In the EAC, go to **Recipients** > **Contacts** and view that the list of users was correctly synchronized from your on-premises environment.

Enable or disable email for a mail user

Exchange Server 2013 > Recipients > Manage mail users >

Applies to: *Exchange Online*

Topic Last Modified: *2012-11-14*

You can disable email for an existing mail user in your Exchange organization. When you disable email for a mail user, it's removed from Exchange and your organization's address book. If the mail user is a member of a distribution group, the user no longer receives mail sent to the group. Also, the Exchange attributes are removed from the user object in Active Directory, but the user object and its non-Exchange attributes (such as contact and organization information) are retained in Active Directory.

After you disable email for a mail user, you can mail-enable the user again by using the **Enable-MailUser** cmdlet in the Shell. You can also use this cmdlet to mail-enable any Active Directory user.

Note:

Mail users (also called *mail-enabled users*) are different than users in your organization that have a mailbox. The primary difference is that mail users represent users outside your Exchange organization that have an external email address. They don't have a mailbox in your organization. For more information about the differences between users who have mailboxes

in your organization and mail users, see Recipients.

For additional management tasks related to mail users, see Manage mail users.

What do you need to know before you begin?

- Estimated time to complete each procedure: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mail users" entry in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Disable email for a mail user

As previously stated, when you disable email for a mail user, the Exchange attributes are removed from the corresponding Active Directory mail user object, but the user is retained. The mail user is removed from the list of mail users in the EAC, but you can view and manage the corresponding Active Directory contact object by using Active Directory Users and Computers or by using the **Get-MailUser** and **Set-Set-MailUser** cmdlets in the Shell.

Use the EAC to disable email for a mail user

1. In the EAC, navigate to **Recipients** > **Contacts**.
2. In the list of contacts, click the mail user you want to disable email for.
3. Click **More** ··· and then click **Disable**.
4. A warning will appear asking if you're sure you want to disable the selected mail user. Click **Yes** to disable it.

The mail user will be removed from the contacts list.

Use the Shell to disable email for a mail user

This example disables email for the mail user Yan Li.

```
Disable-MailUser -Identity "Yan Li"
```

For detailed syntax and parameter information, see Disable-MailUser.

How do you know this worked?

To verify that you've successfully disabled email for a mail user, do one of the following:

1. In the EAC, navigate to **Recipients** > **Contacts** and verify that the mail user is no longer listed.
2. In Active Directory Users and Computers, right-click the user, and then click **Properties**. On the **General** tab, notice that the **E-mail** box is blank. This verifies that the mail user isn't mail-enabled.
3. In the Shell, run the following command.

```
Get-MailUser
```

The mail user that you disabled email for won't be returned in the results because this cmdlet only returns mail-enabled users.

4. In the Shell, run the following command.

```
Get-User
```

The mail user that you disabled email for is returned in the results because this cmdlet returns all Active Directory user objects.

Use the Shell to mail-enable users

You can use the **Enable-MailUser** cmdlet to mail-enable existing Active Directory users. You can mail-enable a single user or use a CSV file to mail-enable multiple users.

Use the Shell to mail-enable a single user

This example mail-enables the user Sanjay Shah. You must provide an external email address.

```
Enable-MailUser -Identity "Sanjay Shah" -
ExternalEmailAddress renev@tailspintoys.com
```

Use the Shell and a CSV file to mail-enable multiple users

When you're mail-enabling users in bulk, you first export the list of users that aren't mail-enabled to a CSV (comma-separated values) file, and then add the external email addresses to the CSV file by using a text editor such as Notepad, or a spreadsheet application such as Microsoft Excel. Then you use the updated CSV file in the Shell command to mail-enable the users listed in the CSV file.

1. Run the following command to export a list of existing users that aren't mail-enabled or don't have a mailbox in your organization to a file on the administrator's desktop named UsersToMailEnable.csv.

```
Get-User | Where { $_.RecipientType -eq "User" } | Out-File
"C:\Users\Administrator\Desktop\UsersToMailEnable.csv"
```

The resulting file will be similar to the following file.

```
Name              RecipientType
----              -------------
```

```
Guest           User
krbtgt          User
RMS_SERVICE     User
David Pelton    User
Kim Akers       User
Janet Schorr    User
Jeffrey Zang    User
Spencer Low     User
Toni Poe        User
...
```

2. Make the following changes to the CSV file:
   - Delete any users that you don't want to mail-enable from the CSV file. For example, you would delete the first three entries in the previous example because they're default system accounts.
   - Delete the **RecipientType** column and all the instances of `User`.
   - Add a column heading named **EmailAddress** and then add an email address for each user in the file. The name and external email address for each user must be separated by a comma.

The updated CSV file should look similar to the following file.

```
Name,EmailAddress
David Pelton,davidp@contoso.com
Kim Akers,kakers@tailspintoys.com
Janet Schorr,janet.schorr@adatum.com
Jeffrey Zang,jzang@tailspintoys.com
Spencer Low,spencerl@fouthcoffee.com
Toni Poe,tonip@contoso.com
...
```

3. Run the following command to use the data in the CSV file to mail-enable the users listed in the file.

```
Import-CSV "C:\Users\Administrator\Desktop
\UsersToMailEnable.csv" | ForEach-Object {Enable-MailUser -
Identity $_.Name -ExternalEmailAddress $_.EmailAddress}
```

The command results display information about the new mail-enabled users.

How do you know this worked?

To verify that you've successfully mail-enabled Active Directory users, do one of the following:

- In the EAC, navigate to **Recipients** > **Contacts**. New mail users are displayed in the contact list. Under **Contact Type**, the type is **Mail user**.

Note:

You may have to click **Refresh** to display new mail users.

- In the Shell, run the following command to display information about new mail users.

```
Get-MailUser | Format-Table
Name,RecipientTypeDetails,ExternalEmailAddress
```

Create and Manage Room Mailboxes

Exchange Server 2013 > Recipients >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-04-29*

Estimated time to complete: 5 minutes.

A *room mailbox* is a resource mailbox that's assigned to a physical location, such as a conference room, an auditorium, or a training room. After an administrator creates room mailboxes, users can easily reserve rooms by including room mailboxes in meeting requests. You can use the EAC or the Shell to create a room mailbox. For more details, check out Recipients.

For information about another type of resource mailbox, an equipment mailbox, see Manage equipment mailboxes.

What do you need to know before you begin?

- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Important:

If you're running Exchange 2013 in a hybrid scenario, make sure you create the room mailboxes in the appropriate place. Create your room mailboxes for your on-premises organization on-premises, and room mailboxes for Exchange Online side should be created in the cloud.

What do you want to do?

Create a room mailbox

Use the EAC to create a room mailbox

1. In the EAC, navigate to **Recipients** > **Resources**.
2. To create a room mailbox, click **New +** > **Room mailbox**. To create an equipment mailbox, click **New +** > **Equipment mailbox**.
3. Use the options on the page to specify the settings for the new resource mailbox.
   - *** Room name** Use this box to type a name for the room mailbox. This is the name that's listed in the resource mailbox list in the EAC and in your organization's address book. This name is required and it can't exceed 64 characters.

Tip:
Although there are other fields that describe the details of the room, for example, Location and Capacity, consider summarizing the most important details in the room name using a consistent naming convention. Why? So users can easily see the details when they select the room from the address book in the meeting request.

   - *** Email address** A room mailbox has an email address so it can receive booking requests. The email address consists of an alias on the left side of the @ symbol, which must be unique in the forest, and your domain name on the right. The email address is required.
   - **Organizational unit** You can select an organizational unit (OU) other than the default (which is the recipient scope). If the recipient scope is set to the forest, the default value is set to the Users container in the Active Directory domain that contains the computer on which the EAC is running. If the recipient scope is set to a specific domain, the Users container in that domain is selected by default. If the recipient scope is set to a specific OU, that OU is selected by default.

To select a different OU, click **Browse**. The dialog box displays all OUs in the forest that are within the specified scope. Select the desired OU, and then click **OK**.

   - **Location**, **Phone**, **Capacity** You can use these fields to enter details about the room. However, as explained earlier, you can include some or all of this information in the room name so users can see it.
   - **Booking requests** Use this section to configure how the room mailbox handles reservation requests.
     - **Automatically accept or decline booking requests** A valid meeting request automatically reserves the resource. If there's a scheduling conflict with an existing reservation, or if the booking request violates the scheduling limits of the resource, for example, the reservation duration is too long, the meeting request is automatically declined.
     - **Select delegates to accept or decline booking requests** The delegates are responsible for accepting or declining meeting requests that are sent to the room mailbox. If you assign more than one resource delegate, only one of them has to act on a specific meeting request.
   - **Delegates** If you selected the option requiring that booking requests are sent to delegates, use this section to select delegates. To add a delegate, click **Add**. On the **Select Delegates** page, select a user, click **Add**, and then click **OK** to return to the **New room mailbox** page.

To remove a delegate, select the user and then click **Remove**.

4. Click **More options** to configure the following fields. Otherwise, skip to Step 5 to save the new room mailbox.
   - **Alias** Use this field to create an alias that is different than the one that you used to create the email address for the room mailbox. For example, if you create a room mailbox with an email

address of ConfRoom1@contoso.com, the portion of the email address on the left side of the **@** symbol is used as the alias by default. If you want the alias to be different, type it in this field.

- **Specify the mailbox database** Use this option to specify a mailbox database instead of allowing Exchange to select a database for you. Click **Browse** to open the **Select Mailbox Database** dialog box. This dialog box lists all the mailbox databases in your Exchange organization. By default, the mailbox databases are sorted by name. You can also click the title of the corresponding column to sort the databases by server name or version. Select the mailbox database you want to use, and then click **OK**.
- **Address book policy** Use this option to specify an address book policy (ABP) for the room mailbox. ABPs contain a global address list (GAL), an offline address book (OAB), a room list, and a set of address lists. To learn more, see Address book policies.

In the drop-down list, select the policy that you want associated with this mailbox.

5. When you're finished, click **Save** to create the room mailbox.

Use the Shell to create a room mailbox

This example creates a room mailbox with the following configuration:

- The room mailbox resides on Mailbox Database 1.
- The mailbox's name is ConfRoom1. This name will also be used to create the room's email address.
- The display name in the EAC and the address book will be Conference Room 1.
- The mailbox is in the Conference Rooms organizational unit.
- The *Room* switch specifies that this mailbox will be created as a room mailbox.

```
New-Mailbox -Database "Mailbox Database 1" -Name ConfRoom1
-OrganizationalUnit "Conference Rooms" -DisplayName
"Conference Room 1" -Room
```

For detailed syntax and parameter information, see New-Mailbox.

How do you know this worked?

To verify that you've successfully created a room mailbox, do one of the following:

- In the EAC, navigate to **Recipients** > **Resources**. The new room mailbox is displayed in the mailbox list. Under **Mailbox Type**, the type is **Room**.
- In the Shell, run the following command to display information about the new room mailbox.

```
Get-Mailbox <Name> | FL
Name,RecipientTypeDetails,PrimarySmtpAddress
```

Create a room list

If you're planning to have more than a hundred rooms, or already have more than a hundred rooms

created, use a room list to help you organize your rooms. If your company has several buildings with rooms that can be booked for meetings, it might help to create room lists for each building. Room lists are specially marked distribution groups that you can use the same way you use distribution groups. However, you can only create room lists using the Exchange Management Shell.

Use the Shell to create a room list

This example creates a room list for building 32.

```
New-DistributionGroup -Name "Building 32 Conference Rooms"
-OrganizationalUnit "contoso.com/rooms" -RoomList
```

Use the Shell to add a room to a room list

This example adds confroom3223 to the building 32 room list.

```
Add-DistributionGroupMember -Identity "Building 32
Conference Rooms" -Member confroom3223@contoso.com
```

Use the Shell to convert a distribution group to a room list

You may already have created distribution groups in the past that contain your conference rooms. You don't need to recreate them; we can convert them quickly into a room list.

This example converts the distribution group, building 34 conference rooms, to a room list.

```
Set-DistributionGroup -Identity "Building 34 Conference
Rooms" -RoomList
```

Change room mailbox properties

After you create a room mailbox, you can make changes and set additional properties by using the EAC or the Shell.

Use the EAC to change room mailbox properties

1. In the EAC, navigate to **Recipients** > **Resources**.
2. In the list of resource mailboxes, click the room mailbox that you want to change the properties for, and then click **Edit** ✎.
3. On the room mailbox properties page, click one of the following sections to view or change properties.
   - General
   - Delegates
   - Booking Options
   - Contact Information
   - Email Address

- MailTip

General

Use the **General** section to view or change basic information about the resource.

- *** Room name** This name appears in the resource mailbox list in the EAC and in your organization's address book. It can't exceed 64 characters if you change it.
- *** Email address** This read-only box displays the email address for the room mailbox. You can change it in the Email Address section.
- **Capacity** Use this box to enter the maximum number of people who can safely occupy the room.

Click **More options** to view or change these additional properties:

- **Organizational unit** This read-only box displays the organizational unit (OU) that contains the account for the room mailbox. You have to use Active Directory Users and Computers to move the account to a different OU.
- **Mailbox database** This read-only box displays the name of the mailbox database that hosts the room mailbox. Use the **Migration** page in the EAC to move the mailbox to a different database.
- *** Alias** Use this box to change the alias for the room mailbox.
- **Hide from address lists** Select this check box to prevent the room mailbox from appearing in the address book and other address lists that are defined in your Exchange organization. After you select this check box, users can still send booking messages to the room mailbox by using the email address.
- **Department** Use this box to specify a department name that the room is associated with. You can use this property to create recipient conditions for dynamic distribution groups and address lists.
- **Company** Use this box to specify a company that the room is associated with, if applicable. Like the Department property, you can use this property to create recipient conditions for dynamic distribution groups and address lists.
- **Address book policy** Use this option to specify an address book policy (ABP) for the room mailbox. ABPs contain a global address list (GAL), an offline address book (OAB), a room list, and a set of address lists. To learn more, see Address book policies.

In the drop-down list, select the policy that you want associated with this mailbox.

- **Custom attributes** This section displays the custom attributes defined for the room mailbox. To specify custom attribute values, click **Edit** ✎. You can specify up to 15 custom attributes for the recipient.

Delegates

Use this section to view or change how the room mailbox handles reservation requests and to define who can accept or decline booking requests if it isn't done automatically.

- **Booking requests** Select one of the following options to handle booking requests.
  - **Accept or decline booking requests automatically** A valid meeting request automatically reserves the room. If there's a scheduling conflict with an existing reservation, or if the booking request violates the scheduling limits of the resource, for example, the reservation duration is

too long, the meeting request is automatically declined.
    - **Select delegates who can accept or decline booking requests** Resource delegates are responsible for accepting or declining meeting requests that are sent to the room mailbox. If you assign more than one resource delegate, only one of them has to act on a specific meeting request.
- **Delegates** If you selected the option requiring that booking requests be sent to delegates, the specified delegates are listed. Click **Add +** or **Remove −** to add or remove delegates from this list.

Booking Options

Use the **Booking Options** section to view or change the settings for the booking policy that defines when the room can be scheduled, how long it can be reserved, and how far in advance it can be reserved.

- **Allow repeating meetings** This setting allows or prevents repeating meetings for the room. By default, this setting is enabled, so repeating meetings are allowed.
- **Allow scheduling only during working hours** This setting accepts or declines meeting requests that aren't during the working hours defined for the room. By default, this setting is disabled, so meeting requests are allowed outside the working hours.By default, working hours are 8:00 A.M. to 5:00 P.M. Monday through Friday. You can configure the working hours of the room mailbox in the Appearance section on the Calendar page.
- **Always decline if the end date is beyond this limit** This setting controls the behavior of repeating meetings that extend beyond the date specified by the maximum booking lead time setting.
    - If you enable this setting, a repeating booking request is automatically declined if the bookings start on or before the date specified by the value in the **Maximum booking lead time** box, and they extend beyond the specified date. This is the default setting.
    - If you disable this setting, a repeating booking request is automatically accepted if booking requests start on or before the date specified by the value in the **Maximum booking lead time** box, and they extend beyond the specified date. However, the number of bookings is reduced so bookings won’t occur after the specified date.
- **Maximum booking lead time (days)** This setting specifies the maximum number of days in advance that the room can be booked. Valid input is an integer between 0 and 1080. The default value is 180 days.
- **Maximum duration (hours)** This setting specifies the maximum duration that the room can be reserved in a booking request. The default value is 24 hours.

For repeating booking requests, the maximum booking duration applies to the length of each instance of the repeating booking request.

There’s also a box on this page that you can use to write a message that will be sent to users who send booking requests to reserve the room.

Contact Information

Use the **Contact Information** section to view or change the contact information for the room. The information on this page is displayed in the address book.

Tip:
You can use the **State/Province** box to create recipient conditions for dynamic distribution groups, email address policies, or address lists.

Email Address

Use the **Email Address** section to view or change the email addresses associated with the room mailbox. This includes the mailbox's primary SMTP address and any associated proxy addresses. The primary SMTP address (also known as the *reply address*) is displayed in bold text in the address list, with the uppercase **SMTP** value in the **Type** column.

- **Add** Click **Add +** to add a new email address for this mailbox. Select one of following address types:
  - **SMTP** This is the default address type. Click this button and then type the new SMTP address in the *** Email address** box.
  - **EUM** An EUM (Exchange Unified Messaging) address is used by the Microsoft Exchange Unified Messaging service to locate UM-enabled recipients within an Exchange organization. EUM addresses consist of the extension number and the UM dial plan for the UM-enabled user. Click this button and type the extension number in the **Address/Extension** box. Then click **Browse** and select a dial plan for the mailbox.
  - **Custom address type** Click this button and type one of the supported non-SMTP email address types in the *** Email address** box.

Note:
With the exception of X.400 addresses, Exchange doesn't validate custom addresses for correct formatting. You must make sure that the custom address you specify complies with the format requirements for that address type.

Note:
When you add a new email address, you have the option to make it the primary SMTP address.

- **Automatically update email addresses based on the email address policy applied to this recipient** Select this check box to have the recipient's email addresses automatically updated based on changes made to email address policies in your organization.

MailTip

Use the **MailTip** section to add a MailTip to alert users of potential issues before they send a booking request to the room mailbox. A MailTip is text that's displayed in the InfoBar when this recipient is added to the To, Cc, or Bcc lines of a new email message.

Note:
MailTips can include HTML tags, but scripts aren't allowed. The length of a custom MailTip can't exceed 175 displayed characters. HTML tags aren't counted in the limit.

Use the Shell to change room mailbox properties

Use the following sets of cmdlets to view and change room mailbox properties:**Get-Mailbox** and **Set-Mailbox** cmdlets to view and change general properties and email addresses for room mailboxes. Use the **Get-CalendarProcessing** and **Set-CalendarProcessing** cmdlets to view and change delegates and booking options.

- **Get-User** and **Set-User** Use these cmdlets to view and set general properties such as location, department, and company names.
- **Get-Mailbox** and **Set-Mailbox** Use these cmdlets to view and set mailbox properties, such as email addresses and the mailbox database.
- **Get-CalendarProcessing** and **Set-CalendarProcessing** Use these cmdlets to view and set booking options and delegates.

For information about these cmdlets, see the following topics:

- Get-User
- Set-User
- Get-Mailbox
- Set-Mailbox
- Get-CalendarProcessing
- Set-CalendarProcessing

Here are some examples of using the Shell to change room mailbox properties.

This example changes the display name, the primary SMTP address (called the default reply address), and the room capacity. Also, the previous reply address is kept as a proxy address.

```
Set-Mailbox "Conf Room 123" -DisplayName "Conf Room 31/123
(12)" -EmailAddresses
SMTP:Rm33.123@contoso.com,smtp:rm123@contoso.com -
ResourceCapacity 12
```

This example configures room mailboxes to allow booking requests to be scheduled only during working hours and sets a maximum duration of 9 hours.

```
Get-Mailbox -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'RoomMailbox')} | Set-
CalendarProcessing -ScheduleOnlyDuringWorkHours $true -
MaximumDurationInMinutes 540
```

This example uses the **Get-User** cmdlet to find all room mailboxes that correspond to private conference rooms, and then uses the **Set-CalendarProcessing** cmdlet to send booking requests to a delegate named Robin Wood to accept or decline.

```
Get-User -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'RoomMailbox') -and (DisplayName
-like 'Private*')} | Set-CalendarProcessing -
```

```
AllBookInPolicy $false -AllRequestInPolicy $true -
ResourceDelegates "Robin Wood"
```

How do you know this worked?

To verify that you've successfully changed properties for a room mailbox, do the following:

- In the EAC, select the mailbox and then click **Edit** to view the property or feature that you changed. Depending on the property that you changed, it might be displayed in the Details pane for the selected mailbox.
- In the Shell, use the **Get-Mailbox** cmdlet to verify the changes. One advantage of using the Shell is that you can view multiple properties for multiple mailboxes. In the example above where booking requests could be scheduled only during working hours and have a maximum duration of 9 hours, run the following command to verify the new values.

```
Get-Mailbox -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'RoomMailbox')} | Get-
CalendarProcessing | fl
Identity,ScheduleOnlyDuringWorkHours,MaximumDurationInMinut
es
```

Manage equipment mailboxes

Exchange Server 2013 > Recipients >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-10-09*

An *equipment mailbox* is a resource mailbox assigned to a resource that's not location specific, such as a portable computer, projector, microphone, or a company car. After an administrator creates an equipment mailbox, users can easily reserve the piece of equipment by including the corresponding equipment mailbox in a meeting request. You can use the EAC and the Shell to create an equipment mailbox or change equipment mailbox properties. For more information, see Recipients.

For information about another type of resource mailbox, a room mailbox, see Create and Manage Room Mailboxes.

What do you need to know before you begin?

- Estimated time to complete: 2 to 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Create an equipment mailbox

Use the EAC to create an equipment mailbox

1. In the EAC, navigate to **Recipients** > **Resources**.
2. To create an equipment mailbox, click **New** > **Equipment mailbox**. To create a room mailbox, click **New** > **Room mailbox**.
3. Use the options on the page to specify the settings for the new resource mailbox.
   - *** Equipment name** Use this box to type a name for the equipment mailbox. This is the name that's listed in the resource mailbox list in the EAC and in your organization's address book. This name is required and it can't exceed 64 characters.

Tip:

Although there are other fields that describe the details of the room, for example, Capacity, consider summarizing the most important details in the equipment name using a consistent naming convention. Why? So users can easily see the details when they select the equipment from the address book in a meeting request.

   - *** Email address** An equipment mailbox has an email address so it can receive booking requests. The email address consists of an alias on the left side of the @ symbol, which must be unique in the forest, and your domain name on the right. The email address is required.
   - **Organizational unit** You can select an organizational unit (OU) other than the default (which is the recipient scope). If the recipient scope is set to the forest, the default value is set to the Users container in the Active Directory domain that contains the computer on which the EAC is running. If the recipient scope is set to a specific domain, the Users container in that domain is selected by default. If the recipient scope is set to a specific OU, that OU is selected by default.

To select a different OU, click **Browse**. The dialog box displays all OUs in the forest that are within the specified scope. Select the desired OU, and then click **OK**.

   - **Booking requests** Use this section to configure how the equipment mailbox handles

reservation requests.

- **Accept or decline booking requests automatically** A valid meeting request automatically reserves the resource. If there's a scheduling conflict with an existing reservation, or if the booking request violates the scheduling limits of the resource, for example, the reservation duration is too long, the meeting request is automatically declined.
- **Select delegates who can accept or decline booking requests** The delegates are responsible for accepting or declining meeting requests that are sent to the equipment mailbox. If you assign more than one resource delegate, only one of them has to act on a specific meeting request.

- **Delegates** If you selected the option requiring that booking requests are sent to delegates, use this section to select delegates. To add a delegate, click **Add +**. On the **Select Delegates** page, select a user, click **Add**, and then click **OK** to return to the **New equipment mailbox** page.

4. Click **More options** to configure the following fields. Otherwise, skip to Step 5 to save the new equipment mailbox.
   - **Alias** Use this field to create an alias that is different than the one that you used to create the email address for the equipment mailbox. For example, if you create an equipment mailbox with an email address of motorpool1@contoso.com, the portion of the email address on the left side of the **@** symbol is used as the alias by default. If you want the alias to be different, type it in this field.
   - **Specify the mailbox database** Use this option to specify a mailbox database instead of allowing Exchange to select a database for you. Click **Browse** to open the **Select Mailbox Database** dialog box. This dialog box lists all the mailbox databases in your Exchange organization. By default, the mailbox databases are sorted by name. You can also click the title of the corresponding column to sort the databases by server name or version. Select the mailbox database you want to use, and then click **OK**.
   - **Address book policy** Use this option to specify an address book policy (ABP) for the equipment mailbox. ABPs contain a global address list (GAL), an offline address book (OAB), a room list, and a set of address lists. To learn more, see Address book policies.

In the drop-down list, select the policy that you want associated with this mailbox.

5. When you're finished, click **Save** to create the equipment mailbox.

Use the Shell to create an equipment mailbox

This example creates an equipment mailbox with the following configuration:

- The equipment mailbox resides on Mailbox Database 1.
- The equipment's name is MotorVehicle2 and the name will display in the GAL as Motor Vehicle 2.
- The email address is MotorVehicle2@contoso.com.
- The mailbox is in the Equipment organizational unit.
- The *Equipment* parameter specifies that this mailbox will be created as an equipment mailbox.

```
New-Mailbox -Database "Mailbox Database 1" -Name
MotorVehicle2 -OrganizationalUnit Equipment -DisplayName
```

```
"Motor Vehicle 2" -Equipment
```

For detailed syntax and parameter information, see New-Mailbox.

How do you know this worked?

To verify that you've successfully created a user mailbox, do one of the following:

- In the EAC, navigate to **Recipients** > **Resources**. The new user mailbox is displayed in the mailbox list. Under **Mailbox Type**, the type is **Equipment**.
- In the Shell, run the following command to display information about the new equipment mailbox.

```
Get-Mailbox <Name> | FL
Name,RecipientTypeDetails,PrimarySmtpAddress
```

Change equipment mailbox properties

After you create an equipment mailbox, you can make changes and set additional properties by using the EAC or the Shell.

Use the EAC to change equipment mailbox properties

1. In the EAC, navigate to **Recipients** > **Resources**.
2. In the list of resource mailboxes, click the equipment mailbox that you want to change the properties for, and then click **Edit** ✎.
3. On the equipment mailbox properties page, click one of the following sections to view or change properties.
   - General
   - Delegates
   - Booking Options
   - Contact Information
   - Email Address
   - MailTip

General

Use the **General** section to view or change basic information about the resource.

- *** Equipment name** This name appears in the resource mailbox list in the EAC and in your organization's address book. It can't exceed 64 characters if you change it.
- *** Email address** This read-only box displays the email address for the equipment mailbox. You can change it in the Email Address section.
- **Capacity** Use this box to enter the maximum number of people who can use this resource, if applicable, For example, if the equipment mailbox corresponds to a compact car, you could enter **4**.

Click **More options** to view or change these additional properties:

- **Organizational unit** This read-only box displays the organizational unit (OU) that contains the account for the equipment mailbox. You have to use Active Directory Users and Computers to move the account to a different OU.
- **Mailbox database** This read-only box displays the name of the mailbox database that hosts the equipment mailbox. Use the **Migration** page in the EAC to move the mailbox to a different database.
- *** Alias** Use this box to change the alias for the equipment mailbox.
- **Hide from address lists** Select this check box to prevent equipment mailbox from appearing in the address book and other address lists that are defined in your Exchange organization. After you select this check box, users can still send booking messages to the equipment mailbox by using the email address.
- **Department** Use this box to specify a department name that the resource is associated with. You can use this property to create recipient conditions for dynamic distribution groups and address lists.
- **Company** Use this box to specify a company that the resource is associated with. Like the Department property, you can use this property to create recipient conditions for dynamic distribution groups and address lists.
- **Address book policy** Use this option to specify an address book policy (ABP) for the resource. ABPs contain a global address list (GAL), an offline address book (OAB), a room list, and a set of address lists. To learn more, see Address book policies.

In the drop-down list, select the policy that you want associated with this mailbox.

- **Custom attributes** This section displays the custom attributes defined for the equipment mailbox. To specify custom attribute values, click **Edit** ✎. You can specify up to 15 custom attributes for the recipient.

Delegates

Use this section to view or change how the equipment mailbox handles reservation requests and to define who can accept or decline booking requests if it isn't done automatically.

- **Booking requests** Select one of the following options to handle booking requests.
  - **Accept or decline booking requests automatically** A valid meeting request automatically reserves the resource. If there's a scheduling conflict with an existing reservation, or if the booking request violates the scheduling limits of the resource, for example, the reservation duration is too long, the meeting request is automatically declined.
  - **Select delegates who can accept or decline booking requests** Resource delegates are responsible for accepting or declining meeting requests that are sent to the equipment mailbox. If you assign more than one resource delegate, only one of them has to act on a specific meeting request.
- **Delegates** If you selected the option requiring that booking requests be sent to delegates, the specified delegates are listed. Click **Add +** or **Remove −** to add or remove delegates from this list.

Booking Options

Use the **Booking Options** section to view or change the settings for the booking policy that defines when the resource can be scheduled, how long it can be reserved, and how far in advance it can be reserved.

- **Allow repeating meetings** This setting allows or prevents repeating meetings for the resource. By default, this setting is enabled, so repeating meetings are allowed.
- **Allow scheduling only during working hours** This setting accepts or declines meeting requests that aren't during the working hours defined for the resource. By default, this setting is disabled, so meeting requests are allowed outside the working hours.By default, working hours are 8:00 A.M. to 5:00 P.M. Monday through Friday. You can configure the working hours of the equipment mailbox in the Appearance section on the Calendar page.
- **Always decline if the end date is beyond this limit** This setting controls the behavior of repeating meetings that extend beyond the date specified by the maximum booking lead time setting.
  - If you enable this setting, a repeating booking request is automatically declined if the bookings start on or before the date specified by the value in the **Maximum booking lead time** box, and they extend beyond the specified date. This is the default setting.
  - If you disable this setting, a repeating booking request is automatically accepted if the booking requests start on or before the date specified by the value in the **Maximum booking lead time** box, and they extend beyond the specified date. However, the number of bookings is reduced so bookings won't occur after the specified date.
- **Maximum booking lead time (days)** This setting specifies the maximum number of days in advance that the resource can be booked. Valid input is an integer between 0 and 1080. The default value is 180 days.
- **Maximum duration (hours)** This setting specifies the maximum duration that the resource can be reserved in a booking request. The default value is 24 hours.

For repeating booking requests, the maximum booking duration applies to the length of each instance of the repeating booking request.

There is also a box on this page that you can use to write a message that will be sent to users who send meeting requests to reserve the resource.

Contact Information

Use the **Contact Information** section to view or change the contact information for the resource. The information on this page is displayed in the address book.

Tip:
You can use the **State/Province** box to create recipient conditions for dynamic distribution groups, email address policies, or address lists.

Email Address

Use the **Email Address** section to view or change the email addresses associated with the equipment mailbox. This includes the mailbox's primary SMTP address and any associated proxy addresses. The primary SMTP address (also known as the *reply address*) is displayed in bold text in

the address list, with the uppercase **SMTP** value in the **Type** column.

- **Add** Click **Add +** to add a new email address for this mailbox. Select one of following address types:
  - **SMTP** This is the default address type. Click this button and then type the new SMTP address in the *** Email address** box.
  - **EUM** An EUM (Exchange Unified Messaging) address is used by the Microsoft Exchange Unified Messaging service to locate UM-enabled recipients within an Exchange organization. EUM addresses consist of the extension number and the UM dial plan for the UM-enabled user. Click this button and type the extension number in the **Address/Extension** box. Then click **Browse** and select a dial plan for the mailbox.
  - **Custom address type** Click this button and type one of the supported non-SMTP email address types in the *** Email address** box.

Note:
With the exception of X.400 addresses, Exchange doesn't validate custom addresses for correct formatting. You must make sure that the custom address you specify complies with the format requirements for that address type.

Note:
When you add a new email address, you have the option to make it the primary SMTP address.

- **Automatically update email addresses based on the email address policy applied to this recipient** Select this check box to have the recipient's email addresses automatically updated based on changes made to email address policies in your organization.

MailTip

Use the **MailTip** section to add a MailTip to alert users of potential issues before they send a booking request to the equipment mailbox. A MailTip is text that's displayed in the InfoBar when this recipient is added to the To, Cc, or Bcc lines of a new email message.

Note:
MailTips can include HTML tags, but scripts aren't allowed. The length of a custom MailTip can't exceed 175 displayed characters. HTML tags aren't counted in the limit.

Use the Shell to change equipment mailbox properties

Use the following sets of cmdlets to view and change equipment mailbox properties:**Get-Mailbox** and **Set-Mailbox** cmdlets to view and change general properties and email addresses for equipment mailboxes. Use the **Get-CalendarProcessing** and **Set-CalendarProcessing** cmdlets to view and change delegates and booking options.

- **Get-User** and **Set-User** Use these cmdlets to view and set general properties such as department and company names.
- **Get-Mailbox** and **Set-Mailbox** Use these cmdlets to view and set mailbox properties, such as email addresses and the mailbox database.
- **Get-CalendarProcessing** and **Set-CalendarProcessing** Use these cmdlets to view and set booking options and delegates.

For information about these cmdlets, see the following topics:

- Get-User
- Set-User
- Get-Mailbox
- Set-Mailbox
- Get-CalendarProcessing
- Set-CalendarProcessing

Here are some examples of using the Shell to change equipment mailbox properties.

This example changes the display name and primary SMTP address (called the default reply address) for the MotorPool 1 equipment mailbox. The previous reply address is kept as a proxy address.

```
Set-Mailbox "MotorPool 1" -DisplayName "Motor Pool 1 -
Compact" -EmailAddresses
SMTP:MP1.compact@contoso.com,smtp:MP.1@contoso.com
```

This example configures equipment mailboxes to allow booking requests to be scheduled only during working hours.

```
Get-Mailbox -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'EquipmentMailbox')} | Set-
CalendarProcessing -ScheduleOnlyDuringWorkHours $true
```

This example uses the **Get-User** cmdlet to find all equipment mailboxes in the Audio Visual department, and then uses the **Set-CalendarProcessing** cmdlet to send booking requests to a delegate named Ann Beebe to accept or decline.

```
Get-User -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'EquipmentMailbox') -and
(Department -eq 'Audio Visual')} | Set-CalendarProcessing -
AllBookInPolicy $false -AllRequestInPolicy $true -
ResourceDelegates "Ann Beebe"
```

How do you know this worked?

To verify that you've successfully changed properties for an equipment mailbox, do the following:

- In the EAC, select the mailbox and then click **Edit** ✎ to view the property or feature that you changed. Depending on the property that you changed, it might be displayed in the Details pane for the selected mailbox.
- In the Shell, use the **Get-Mailbox** cmdlet to verify the changes. One advantage of using the Shell is that you can view multiple properties for multiple mailboxes. In the example above where booking requests could be scheduled only during working hours, run the following command to

verify the new value.

```
Get-Mailbox -ResultSize unlimited -Filter
{(RecipientTypeDetails -eq 'EquipmentMailbox')} | Get-
CalendarProcessing | fl
Identity,ScheduleOnlyDuringWorkHours
```

Disconnected mailboxes

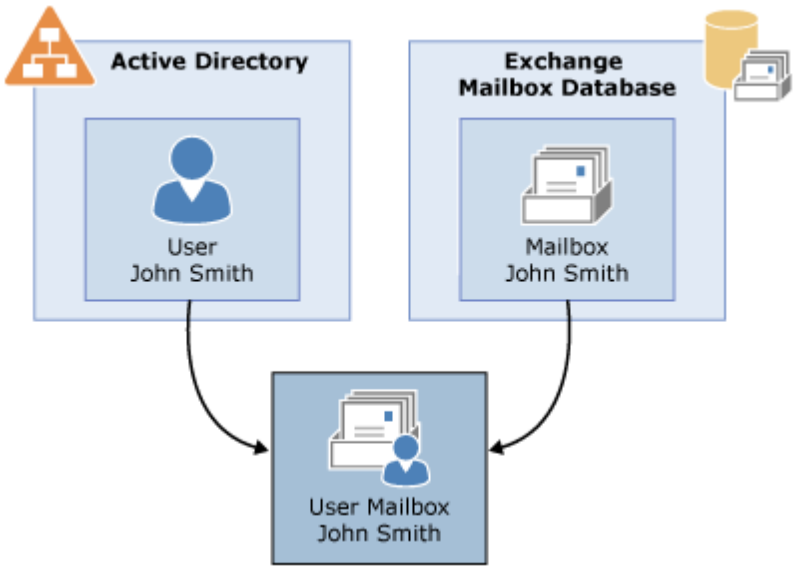
Exchange Server 2013 > Recipients >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-08-25*

Each Microsoft Exchange mailbox consists of an Active Directory user account and the mailbox data stored in the Exchange mailbox database. All configuration data for a mailbox is stored in the Exchange attributes of the Active Directory user object. The mailbox database contains the mail data that's in the mailbox associated with the user account. The following figure shows the components of a mailbox.

Mailbox components



A *disconnected mailbox* is a mailbox object in the mailbox database that isn't associated with an Active Directory user account. There are two types of disconnected mailboxes:

- **Disabled mailboxes** When a mailbox is disabled or deleted in the Exchange Administration Center (EAC) or using the **Disable-Mailbox** or **Remove-Mailbox** cmdlet in the Exchange Management Shell, Exchange retains the deleted mailbox in the mailbox database, and switches the mailbox to a disabled state. This is why mailboxes that are either disabled or deleted are referred to as *disabled mailboxes*. The difference is that when you disable a mailbox, the Exchange attributes are removed from the corresponding Active Directory user account, but the user

account is retained. When you delete a mailbox, both the Exchange attributes and the Active Directory user account are deleted.

Disabled and deleted mailboxes are retained in the mailbox database until the deleted mailbox retention period expires, which is 30 days by default. After the retention period expires, the mailbox is permanently deleted (also called *purged*). If a mailbox is deleted using the **Remove-Mailbox** cmdlet, it's also retained for the duration of the retention period.

Important:
If a mailbox is deleted using the **Remove-Mailbox** cmdlet and either the *Permanent* or *StoreMailboxIdentity* parameter, it will be immediately deleted from the mailbox database.

To identify the disabled mailboxes in your organization, run the following command in the Shell.

```
Get-MailboxDatabase | Get-MailboxStatistics | Where
{ $_.DisconnectReason -eq "Disabled" } | ft
DisplayName,Database,DisconnectDate
```

- **Soft-deleted mailboxes** When a mailbox is moved to a different mailbox database, Exchange doesn't fully delete the mailbox from the source mailbox database when the move is complete. Instead, the mailbox in the source mailbox database is switched to a *soft-deleted* state. Like disabled mailboxes, soft-deleted mailboxes are retained in the source database either until the deleted mailbox retention period expires or until the **Remove-StoreMailbox** cmdlet is used to purge the mailbox.

Run the following command to identify soft-deleted mailboxes in your organization.

```
Get-MailboxDatabase | Get-MailboxStatistics | Where
{ $_.DisconnectReason -eq "SoftDeleted" } | ft
DisplayName,Database,DisconnectDate
```

Contents

Working with disabled mailboxes

You can perform several operations on a disabled mailbox before it's purged from the mailbox database:

- Reconnect it to the same user account.
- Connect it to a different user account that isn't mail-enabled, which means the user account doesn't have a mailbox.

- Restore it to a user account that has an existing mailbox. For example, if a user whose mailbox was deleted has a new mailbox, you can restore the user's disabled mailbox to their new mailbox.
- Permanently delete it from the Exchange mailbox database.

Connecting or restoring a disabled mailbox

Here are scenarios in which you may want to connect or restore a disabled mailbox before the mailbox retention period expires or before it's permanently deleted:

- You disabled a mailbox and now want to reconnect the mailbox to the same Active Directory user account.
- You deleted a mailbox by using the EAC or the Remove-Mailbox cmdlet and now want to reconnect the mailbox to a different Active Directory user account.
- You deleted a mailbox and now want to restore the mailbox to an existing mailbox. For example, if a user whose mailbox was deleted has a new mailbox, you can restore the user's disabled mailbox to their new mailbox.
- You want to convert a user mailbox to a linked mailbox associated with a user account that's external to the forest in which your Exchange organization exists. The resource forest scenario is an example of when you would want to associate a mailbox with an external account. In this scenario, user objects in the Exchange forest have mailboxes, but the user objects are disabled for logon. You must associate a mailbox in the Exchange forest with a user account in the external account forest.

There are two ways you can reconnect or restore a disabled mailbox. The first method is to use the EAC or the **Connect-Mailbox** cmdlet to connect a disabled mailbox to a user account. For procedures to reconnect disabled mailboxes, see Connect a disabled mailbox.

The second method uses the **New-MailboxRestoreRequest** cmdlet to merge the contents of the disabled mailbox with an existing mailbox. This cmdlet uses the Mailbox Replication Service (MRS) to restore the mailbox. For procedures to restore disabled mailboxes, see Connect or restore a deleted mailbox.

Permanently deleting a disabled mailbox

As stated previously, Exchange retains disabled mailboxes in the mailbox database based on the deleted mailbox retention settings configured for that mailbox database. After the specified retention period, a disabled mailbox is purged from the Exchange mailbox database. You can also permanently delete a disabled mailbox and all its message content from the mailbox database by using the **Remove-StoreMailbox** cmdlet. After a disabled mailbox is automatically purged or permanently deleted by an administrator, the data loss is permanent and the mailbox can't be recovered.

For more information, see Permanently delete a mailbox.

Return to top

Working with disabled archive mailboxes

Archive mailboxes become disconnected when they're disabled. Similar to a disabled primary mailbox, a disconnected archive mailbox can be connected by using the **Connect-Mailbox** cmdlet with the *Archive* parameter.

The primary mailbox and the archive mailbox share the same legacy distinguished name (DN), so you must connect the archive mailbox to the same user mailbox that it was previously connected to. You can't connect the archive mailbox to a different user mailbox.

You can perform two operations on a disconnected archive mailbox:

- **Connect it to an existing primary mailbox** Like a disconnected primary mailbox, a disconnected archive mailbox is retained in the mailbox database until the deleted mailbox retention period expires, which is 30 days by default. During this time, you can recover the archive mailbox by reconnecting it to the same user account that it was connected to before it was disabled.

Note:

If you disable an archive mailbox for a user mailbox and then enable an archive mailbox for that same user, that user mailbox will get a new archive mailbox. While you can use the **Connect-Mailbox** cmdlet to connect a primary mailbox to a user, you must use the **Enable-Mailbox** cmdlet to connect a disabled archive mailbox to an existing mailbox.

For more information, see Manage In-Place Archives.

- **Permanently delete it from the Exchange mailbox database** Exchange retains disconnected archive mailboxes based on the deleted mailbox retention settings configured for the mailbox database. The default retention period is 30 days. After the specified mailbox retention period, a disconnected archive mailbox is purged from the Exchange mailbox database.

Like a disabled primary mailbox, you can permanently delete a disabled archive mailbox at any time by using the **Remove-StoreMailbox** cmdlet. For more information, see Permanently delete a mailbox.

Return to top

Working with soft-deleted mailboxes

A soft-deleted mailbox is created when a mailbox is moved from one Exchange mailbox database to any other mailbox database. Exchange doesn't fully delete the mailbox from the source database after a move in case an error occurs during the move that causes the mailbox on the destination database to fail. You can always restore the source mailbox and try again. Exchange will retain the soft-deleted mailbox for the duration of the mailbox retention period.

You can perform two operations on a soft-deleted mailbox:

- Restore it to an existing mailbox.
- Permanently delete it from the Exchange mailbox database.

The procedures for restoring and permanently deleting a soft-deleted mailbox are similar to those for a disabled mailbox. For more information, see the following topics:

- Restore a soft-deleted mailbox
- Permanently delete a mailbox

Return to top

Summary of working with disconnected mailboxes

The following table summarizes the information about disconnected mailboxes, including how the mailbox was disconnected, what happens to the corresponding Active Directory user account when a mailbox is disconnected, and the options and tools you have to connect or restore disconnected mailboxes.

How mailbox was disabled	Value of *DisconnectReason* property	Is Active Directory user account retained?	Connect or restore options	Tools
• The EAC: **Recipients** > **Mailboxes** > **Disable** • The Shell: **Disable-Mailbox** cmdlet	Disabled	Yes	Connect to same user account	• The EAC: **Recipients** > **Mailboxes** > **Connect a Mailbox** • The Shell: **Connect-Mailbox** cmdlet
• The EAC: **Recipients** > **Mailboxes** > **Delete** • The Shell: **Remove-Mailbox** cmdlet	Disabled	No	• Connect to a different user account • Restore to a different mailbox	• The EAC: **Recipients** > **Mailboxes** > **Connect a Mailbox** • The Shell: **Connect-Mailbox** cmdlet • **Enable-Mailbox** • The Shell: **New-MailboxRestore** cmdlet

Moved to a different mailbox database	SoftDeleted	Yes	• Connect to a different user account • Restore to a different mailbox	• The EAC: **Recipients** > **Mailboxes** > **Connect a Mailbox** • The Shell: **Connect-Mailbox** cmdlet • **Enable-Mailbox** • The Shell: **New-MailboxRestore** cmdlet

Disable or delete a mailbox

Topic Last Modified: *2014-08-11*

You can use the EAC or the Shell to disable or delete a mailbox. When a mailbox is disabled or deleted, Exchange retains the mailbox in the mailbox database and switches the mailbox to a disabled state. Disabled and deleted mailboxes are retained in the mailbox database until the deleted mailbox retention period expires, which is 30 days by default. After the retention period expires, the mailbox is permanently deleted or *purged*.

Note:
Disabled or deleted mailboxes are referred to as *disconnected mailboxes*.

The primary difference between deleting and disabling a mailbox is that when you disable a mailbox, the Exchange attributes are removed from the corresponding Active Directory user account, but the user account is retained. When you delete a mailbox, both the Exchange attributes and the Active Directory user account are deleted. This difference also determines your options to reconnect or restore disabled and deleted mailboxes.

The following table shows which types of Exchange mailboxes you can disable and delete.

Mailbox type	Disable?	Delete?
Archive mailbox	Yes	No *
Linked mailbox	Yes	Yes
Resource mailbox (Room or Equipment)	No	Yes
Shared mailbox	Yes	Yes
User mailbox	Yes	Yes

* If an archive mailbox is enabled, it will be deleted when the primary mailbox is deleted. For information about disabling archive mailboxes, see Manage In-Place Archives.

If an administrator deletes a user account that has a mailbox, the Exchange Information store will eventually detect that the mailbox is no longer connected to a user account and mark that mailbox

for deletion, even if the mailbox is on hold. If you want to retain the mailbox you must do the following:

1. Instead of deleting the user account, disable the user account.
2. Change the properties of the mailbox to restrict its use and access to the mailbox. For example, set send and receive quotas equal to 1, block who can send messages to the mailbox, and restrict who can access the mailbox.
3. Retain the mailbox until all data has been expunged, or until hold is no longer required.

For additional management tasks related to disconnected mailboxes, see the following topics:

- Disconnected mailboxes
- Connect a disabled mailbox
- Connect or restore a deleted mailbox
- Permanently delete a mailbox

What do you need to know before you begin?

- Estimated time to complete each procedure: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Disable a mailbox

As previously stated, when you disable a mailbox, the Exchange attributes are removed from the corresponding Active Directory user account, but the user account is retained.

Use the EAC to disable a mailbox

The following procedure shows how to disable a user mailbox. Use the same procedure to disable other mailbox types after navigating to the appropriate page in the EAC.

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of user mailboxes, click the mailbox that you want to disable.
3. Click **More** ··· and then click **Disable**.
4. A warning appears asking if you're sure you want to disable the mailbox. Click **Yes** to disable the mailbox.

The mailbox is removed from the mailbox list.

Use the Shell to disable a mailbox

Use the following command to disable user mailboxes, linked mailboxes, resource mailboxes, and shared mailboxes.

```
Disable-Mailbox <identity>
```

When you run this command, a message is displayed that asks you to confirm that you want to disable the mailbox.

Here are some examples of commands for disabling mailboxes.

```
Disable-Mailbox danj

Disable-Mailbox "Conf Room 31/1234 (12)"

Disable-Mailbox sharedmbx@contoso.com
```

How do you know this worked?

To verify that you've successfully disabled a mailbox, do one of the following:

- In the EAC, click **Recipients**, navigate to the appropriate page for the mailbox type that you disabled, and then verify that the mailbox is no longer listed.
- In Active Directory Users and Computers, right-click the user account whose mailbox you disabled, and then click **Properties**. On the **General** tab, notice that the **E-mail** field is blank. This verifies that the mailbox is disabled, but the user account still exists.
- In the Shell, run the following command.

```
Get-MailboxDatabase | Get-MailboxStatistics | Where
{ $_.DisplayName -eq "<display name>" } | fl
DisconnectReason,DisconnectDate
```

The `Disabled` value in the *DisconnectReason* property indicates that the mailbox is disabled.

Note:
When you delete a mailbox, the value in the *DisconnectReason* property is also `Disabled`. However, the corresponding Active Directory user account is deleted.

- In the Shell, run the following command.

```
Get-User <identity>
```

Note that that value for the *RecipientType* property is `User`, instead of `UserMailbox`, which is the value for users with enabled mailboxes. This also verifies that the mailbox is disabled, but the user account is retained.

Delete a mailbox

As previously stated, when you delete a mailbox, both the Exchange attributes and the Active Directory user account are deleted. The mailbox (and the archive mailbox, if it's enabled) will be permanently deleted from the mailbox database after the mailbox retention period expires.

Use the EAC to delete a mailbox

The following procedure shows how to delete a user mailbox. Use the same procedure to delete other mailbox types after navigating to the appropriate page in the EAC.

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of user mailboxes, click the mailbox that you want to delete, and then click **Delete** 🗑.
3. A warning appears asking if you're sure you want to delete the mailbox. Click **Yes** to delete the mailbox.

The mailbox is removed from the mailbox list.

Use the Shell to delete a mailbox

Use the following command to delete user mailboxes, linked mailboxes, resource mailboxes, and shared mailboxes.

```
Remove-Mailbox <identity>
```

When you run this command, a message is displayed that asks you to confirm that you want to remove the mailbox and the corresponding Active Directory user account.

Here are some examples of commands for deleting mailboxes.

```
Remove-Mailbox pilarp@contoso.com

Remove-Mailbox "Fleet Van (16)"

Remove-Mailbox corpprint
```

How do you know this worked?

To verify that you've successfully deleted a mailbox, do one of the following sets of verification procedures.

1. In the EAC, click **Recipients** and then navigate to the appropriate page for the mailbox type that you deleted, and verify that the mailbox is no longer listed.
2. In Active Directory Users and Computers, verify that the corresponding user account is no longer listed.

Or

1. Run the following command to verify that the mailbox has been deleted.

```
Get-MailboxDatabase | Get-MailboxStatistics | Where
{ $_.DisplayName -eq "<display name>" } | fl
DisconnectReason,DisconnectDate
```

The `Disabled` value in the *DisconnectReason* property indicates that the mailbox has been deleted.

Note:
When you disable a mailbox, the value in the *DisconnectReason* property is also `Disabled`. However, the corresponding Active Directory user account is retained.

2. Run the following command to verify that Active Directory user account has been deleted.

```
Get-User <identity>
```

The command will return an error stating that user couldn't be found, verifying that the account was deleted.

Connect a disabled mailbox

Exchange Server 2013 > Recipients > Disconnected mailboxes >

Applies to: *Exchange Online*

Topic Last Modified: *2012-11-13*

You can use the EAC or the Shell to connect a disabled mailbox to an Active Directory user account. When you disable a mailbox, Exchange retains the mailbox in the mailbox database and switches the mailbox to a disabled state. The Exchange attributes are also removed from the corresponding Active Directory user account, but the user account is retained. The mailbox is retained until the deleted mailbox retention period expires, which is 30 days by default, and then it's permanently deleted (or *purged*) from the mailbox database.

Until a disabled mailbox is permanently deleted from the Exchange mailbox database, you can use the EAC or the Shell to reconnect it to the original Active Directory user account.

To learn more about disconnected mailboxes and perform other related management tasks, see the following topics:

- Disconnected mailboxes
- Disable or delete a mailbox
- Connect or restore a deleted mailbox
- Permanently delete a mailbox

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To

see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.

- Run the **Get-User** cmdlet in the Shell to verify that the Active Directory user account that you want to connect the disabled mailbox to exists and that it isn't already associated with another mailbox. To connect a disabled mailbox to a user account, the account must exist and the value for the *RecipientType* property has to be `User`, which indicates that the account isn't already mailbox-enabled.

For on-premises Exchange organizations, you can also verify this information in Active Directory Users and Computers.

- Run the following command to verify that the disabled mailbox that you want to connect a user account to exists in the mailbox database and isn't a soft-deleted mailbox.

```
Get-MailboxDatabase | Get-MailboxStatistics | Where
{ $_.DisplayName -eq "<display name>" } | fl
DisplayName,Database,DisconnectReason
```

To be able to connect a disabled mailbox, the mailbox has to exist in the mailbox database and the value for the *DisconnectReason* property has to be `Disabled`. If the mailbox has been purged from the database, the command won't return any results.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to connect a disabled mailbox

The following procedure shows how to connect a disabled user mailbox. You can also reconnect disabled linked mailboxes and disabled shared mailboxes to the corresponding user account.

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. Click **More** ···, and then click **Connect a mailbox**.

A list of mailboxes that are disconnected on the selected Exchange server in your Exchange organization will be displayed.

Note:

This list of disconnected mailboxes includes disabled mailboxes, deleted mailboxes, and soft-deleted mailboxes.

3. Click the disabled mailbox that you want to reconnect, and then click **Connect**.
4. In the window that asks if you're sure that you want to reconnect the mailbox, click **Yes**.

Exchange will reconnect the disabled mailbox to the corresponding user account.

Use the Shell to connect a disabled mailbox

Use the **Connect-Mailbox** cmdlet in the Shell to connect a user account to a disabled mailbox. You have to specify the type of mailbox that you're connecting. The following examples show the syntax for reconnecting user, linked, and shared mailboxes.

This example connects a user mailbox. The *Identity* parameter specifies the disconnected mailbox in the Exchange database. The *User* parameter specifies the Active Directory user account to reconnect the mailbox to.

```
Connect-Mailbox -Identity "Jeffrey Zeng" -Database MBXDB01
-User "Jeffrey Zeng"
```

This example connects a linked mailbox. The *Identity* parameter specifies the disconnected mailbox in the Exchange database. The *LinkedMasterAccount* parameter specifies the Active Directory user account in the account forest that you want to reconnect the mailbox to. The *Alias* parameter specifies the alias, which is the portion of the email address on the left side of the at (@) symbol, for the reconnected mailbox.

```
Connect-Mailbox -Identity "Kai Axford" -Database MBXDB02 -
LinkedDomainController FabrikamDC01 -LinkedMasterAccount
kai.axford@fabrikam.com -Alias kaia
```

This example connects a shared mailbox.

```
Connect-Mailbox -Identity "Corporate Shared Mailbox" -
Database "Mailbox Database 03" -User "Corporate Shared
Mailbox" -Alias corpshared -Shared
```

Note:

If you don't include the *Alias* parameter when you run the **Connect-Mailbox** cmdlet, the value specified in the *User* or *LinkedMasterAccount* parameter is used to create the email address alias for the reconnected mailbox.

For detailed syntax and parameter information, see Connect-Mailbox.

How do you know this worked?

To verify that you've successfully connected a disabled mailbox to a user account, do one of the following:

- In the EAC, click **Recipients**, navigate to the appropriate page for the mailbox type that you reconnected, click **Refresh**, and verify that the mailbox is listed.
- In Active Directory Users and Computers, right-click the user account whose mailbox you disabled, and then click **Properties**. On the **General** tab, notice that the **E-mail** box is populated

with the email address for the reconnected mailbox.
- In the Shell, run the following command.

```
Get-User <identity>
```

The **UserMailbox** value for the *RecipientType* property indicates that the user account and the mailbox are connected. You can also run the **Get-Mailbox** cmdlet to verify that the mailbox exists.

Connect or restore a deleted mailbox

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-12*

You can use the EAC or the Shell to connect a deleted mailbox to an Active Directory user account. When you delete a mailbox, Exchange retains the mailbox in the mailbox database and switches the mailbox to a disabled state. The associated Active Directory user account is also deleted. The mailbox is retained until the deleted mailbox retention period expires, which is 30 days by default, and then it's permanently deleted (or *purged*) from the mailbox database.

Until a deleted mailbox is permanently deleted from the Exchange mailbox database, you can use the EAC or the Shell to connect it to an Active Directory user account. You can also use the Shell to restore the contents of the deleted mailbox to an existing mailbox.

To learn more about disconnected mailboxes and perform other related management tasks, see the following topics:
- Disconnected mailboxes
- Disable or delete a mailbox
- Connect a disabled mailbox
- Permanently delete a mailbox

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.
- Create a new user account in Active Directory to connect the deleted mailbox to. Or use the **Get-User** cmdlet in the Shell to verify that the Active Directory user account that you want to connect the deleted mailbox to exists and that it isn't already associated with another mailbox. To connect a deleted mailbox to a user account, the account must exist and the value for the *RecipientType* property has to be `User`, which indicates that the account isn't already mailbox-

enabled.

For on-premises Exchange organizations, you can also verify this information in Active Directory Users and Computers.

Important:

When you connect deleted linked mailboxes, resource mailboxes, or shared mailboxes, the Active Directory user account that you're connecting the mailbox to must be disabled.

- To verify that the deleted mailbox that you want to connect a user account to exists in the mailbox database and isn't a soft-deleted mailbox, run the following command.

```
Get-MailboxDatabase | Get-MailboxStatistics | Where
{ $_.DisplayName -eq "<display name>" } | fl
DisplayName,Database,DisconnectReason
```

The deleted mailbox has to exist in the mailbox database and the value for the *DisconnectReason* property has to be `Disabled`. If the mailbox has been purged from the database, the command won't return any results.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.
- Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Connect a deleted mailbox

When you connect a deleted mailbox, you associate the mailbox with a user account that isn't mail-enabled, which means that it doesn't have an existing mailbox. To connect a deleted mailbox to a user account that has a mailbox, you have to restore the deleted mailbox. For more information, see Restore a deleted mailbox later in this topic.

Use the EAC to connect a deleted mailbox

The following procedure shows how to connect a deleted user mailbox to a user account. You can also use this procedure to connect linked mailboxes, resource mailboxes, and shared mailboxes that have been deleted to a user account.

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. Click **More** ···, and then click **Connect a mailbox**.

A list of mailboxes that are disconnected on the selected Exchange server in your Exchange organization will be displayed.

Note:

This list of disconnected mailboxes includes disabled mailboxes, deleted mailboxes, and soft-deleted mailboxes.

3. Click the deleted mailbox that you want to connect a user to, and then click **Connect**.
4. In the window that asks if you're sure that you want to connect the mailbox, click **Yes**.

A list of user accounts that aren't mail-enabled is displayed.

5. Click the user that you want to connect the deleted mailbox to, and then click **OK**.

Exchange will connect the deleted mailbox to the user account that you selected.

Use the Shell to connect a deleted mailbox

Use the **Connect-Mailbox** cmdlet in the Shell to connect a deleted mailbox to a user account that isn't mail enabled. You have to specify the type of mailbox that you're connecting. The following examples show the syntax for reconnecting user, linked, room, equipment, and shared mailboxes. In all examples, the optional *Alias* parameter is used to specify the email alias, which is the portion of the email address on the left side of the at (@) symbol. If you don't include the *Alias* parameter, the value specified in the *User* or *LinkedMasterAccount* parameter is used to create the alias for the email address for the reconnected mailbox.

Note:

As previously stated, when you connect linked, resource, or shared mailboxes, the Active Directory user account that you're linking the mailbox to must be disabled.

This example connects a user mailbox. The *Identity* parameter specifies the display name of the deleted mailbox retained in the mailbox database named MBXDB01. The *User* parameter specifies the Active Directory user account to connect the mailbox to.

```
Connect-Mailbox -Identity "Paul Cannon" -Database MBXDB01 -
User "Robin Wood" -Alias robinw
```

Note:

You can also use the values for the `LegacyDN` or `MailboxGuid` properties to identify the deleted mailbox.

This example connects a linked mailbox. The *Identity* parameter specifies the deleted mailbox on the mailbox database named MBXDB02. The *LinkedMasterAccount* parameter specifies the Active Directory user account in the account forest that you want to connect the mailbox to. The *LinkedDomainController* parameter specifies a domain controller in the account forest.

```
Connect-Mailbox -Identity "Temp User" -Database MBXDB02 -
LinkedDomainController FabrikamDC01 -LinkedMasterAccount
danpark@fabrikam.com -Alias dpark
```

This example connects a room mailbox.

```
Connect-Mailbox -Identity "rm2121" -Database
"MBXResourceDB" -User "Conference Room 2121" -Alias
ConfRm2121 -Room
```

This example connects an equipment mailbox.

```
Connect-Mailbox -Identity "MotorPool01" -Database
"MBXResourceDB" -User "Van01 (12 passengers)" -Alias van01
-Equipment
```

This example connects a shared mailbox.

```
Connect-Mailbox -Identity "Printer Support" -Database
MBXDB01 -User "Corp Printer Support" -Alias corpprint -
Shared
```

Note:

You can also use the `LegacyDN` or `MailboxGuid` values to identify the deleted mailbox.

For detailed syntax and parameter information, see Connect-Mailbox.

How do you know this worked?

To verify that you've successfully connected a deleted mailbox to a user account, do one of the following:

- In the EAC, click **Recipients**, navigate to the appropriate page for the mailbox type that you connected, click **Refresh**, and verify that the mailbox is listed.
- In Active Directory Users and Computers, right-click the user account that you connected to the mailbox, and then click **Properties**. On the **General** tab, notice that the **E-mail** box is populated with the email address for the connected mailbox.
- In the Shell, run the following command.

```
Get-User <identity>
```

The **UserMailbox** value for the *RecipientType* property indicates that the user account and the mailbox are connected. You can also run the **Get-Mailbox <identity>** command to verify that the mailbox was connected.

Restore a deleted mailbox

You can use the Shell to restore a deleted mailbox to an existing mailbox using the **New-MailboxRestoreRequest** cmdlet. When you restore a deleted mailbox, its contents are copied to an existing mailbox, which is referred to as the *target mailbox*. After a deleted mailbox is restored, it's still retained in the mailbox database until it's permanently deleted by an administrator or purged after the deleted mailbox retention period expires.

After a mailbox restore request is successfully completed, it's retained for 30 days, by default, before it's removed. You can remove it sooner by using the **Remove-StoreMailbox** cmdlet.

Note:

You can't use the EAC to restore a deleted mailbox.

Use the Shell to restore a deleted mailbox

To create a mailbox restore request, you have to use the display name, legacy distinguished name (DN), or mailbox GUID of the deleted mailbox. Use the **Get-MailboxStatistics** cmdlet to display the values of the `DisplayName`, `MailboxGuid`, and `LegacyDN` properties for the deleted mailbox that you want to restore. For example, run the following command to return this information for all disabled and deleted mailboxes in your organization.

```
Get-MailboxDatabase | Get-MailboxStatistics | Where {$_.DisconnectReason -eq "Disabled"} | fl DisplayName,MailboxGuid,LegacyDN,Database
```

This example restores the deleted mailbox, which is identified by the *SourceStoreMailbox* parameter and is located on the MBXDB01 mailbox database, to the target mailbox Debra Garcia. The *AllowLegacyDNMismatch* parameter is used so the source mailbox can be restored to a different mailbox, one that doesn't have the same legacy DN value.

```
New-MailboxRestoreRequest -SourceStoreMailbox e4890ee7-79a2-4f94-9569-91e61eac372b -SourceDatabase MBXDB01 -TargetMailbox "Debra Garcia" -AllowLegacyDNMismatch
```

This example restores Pilar Pinilla's deleted archive mailbox to her current archive mailbox. The *AllowLegacyDNMismatch* parameter isn't necessary because a primary mailbox and its corresponding archive mailbox have the same legacy DN.

```
New-MailboxRestoreRequest -SourceStoreMailbox "Personal Archive - Pilar Pinilla" -SourceDatabase "MDB01" -TargetMailbox pilarp@contoso.com -TargetIsArchive
```

For detailed syntax and parameter information, see New-MailboxRestoreRequest.

How do you know this worked?

To verify that you've successfully restored a deleted mailbox to the target mailbox, run the **Get-MailboxRestoreRequest** cmdlet to display information about the restore request. If the restore request was successfully created, the *Status* property will have a value of `Queued`, `InProgress`, or `Completed`. After the restore request is completed, the contents from the deleted mailbox will appear in the target mailbox.

For more information, see:

- Manage mailbox restore requests
- Get-MailboxRestoreRequest
- Get-MailboxRestoreRequestStatistics

Restore a soft-deleted mailbox

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-29*

Use the Shell to connect a soft-deleted mailbox to an Active Directory user account. A mailbox becomes *soft-deleted* in the source mailbox database when it's moved to a different mailbox database. Exchange doesn't fully delete the mailbox from the source mailbox database when the move is complete. Instead, the mailbox in the source mailbox database is switched to a soft-deleted state. This lets you restore the source mailbox in case errors occur during the move that cause a failure or corruption of the mailbox on the destination database. If this happens, you can restore the source mailbox and try the move again.

A soft-deleted mailbox is retained in the source database until the deleted mailbox retention period expires or until the **Remove-StoreMailbox** cmdlet is used to purge the soft-deleted mailbox. Until a soft-deleted mailbox is permanently deleted from the Exchange mailbox database, you can use the Shell to restore the contents of the soft-deleted mailbox to an existing mailbox or an archive mailbox.

To learn more about soft-deleted mailboxes and perform other related management tasks, see the following topics:

- Disconnected mailboxes
- Connect or restore a deleted mailbox
- Manage mailbox restore requests
- Permanently delete a mailbox

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.
- The procedures in this topic can only be performed in the Shell. You can't use the EAC to restore soft-deleted mailboxes.
- Run the following command to verify that the soft-deleted mailbox that you want to connect a user account still exists in the mailbox database and is not a disabled mailbox.

```
Get-MailboxDatabase | Get-MailboxStatistics | Where
{ $_.DisplayName -eq "<display name>" } | fl
DisplayName,DisconnectReason,DisconnectDate
```

The soft-deleted mailbox has to exist in the mailbox database and the value for the *DisconnectReason* property has to be `SoftDeleted`. If the mailbox has been purged from the database, the command won't return any results.

Alternatively, run the following command to display all soft-deleted mailboxes in your organization.

```
Get-MailboxDatabase | Get-MailboxStatistics | Where
{ $_.DisconnectReason -eq "SoftDeleted" } | fl
DisplayName,DisconnectReason,DisconnectDate
```

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.
- Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

Use the Shell to restore a soft-deleted mailbox

You can use the Shell to restore a soft-deleted mailbox to an existing mailbox by using the **New-MailboxRestoreRequest** cmdlet. When you restore a soft-deleted mailbox, its contents are copied to an existing mailbox, which is called the *target mailbox*. After a mailbox restore request is successfully completed, the request is retained for 30 days, by default, before it's removed. You can remove it sooner by using the **Remove-MailboxRestoreRequest** cmdlet.

After a soft-deleted mailbox is restored, the mailbox is retained in the mailbox database until it's permanently deleted by an administrator or purged when the deleted mailbox retention period expires.

To create a mailbox restore request, you have to use the display name, mailbox GUID, or legacy distinguished name (DN) of the soft-deleted mailbox. Use the **Get-MailboxStatistics** cmdlet to display the values of the **DisplayName**, **MailboxGuid**, and **LegacyDN** properties for the soft-deleted mailbox that you want to restore. For example, run the following command to return this information for all disabled and soft-deleted mailboxes in your organization.

```
Get-MailboxDatabase | Get-MailboxStatistics | Where
{$_.DisconnectReason -eq "SoftDeleted"} | fl
DisplayName,MailboxGuid,LegacyDN,Database
```

This example restores a soft-deleted mailbox, which is identified by the display name in the *SourceStoreMailbox* parameter and is located on the MBXDB01 mailbox database, to the target mailbox named Debra Garcia. The *AllowLegacyDNMismatch* parameter is used so the source mailbox can be restored to a mailbox that doesn't have the same legacy DN value as the soft-deleted mailbox.

```
New-MailboxRestoreRequest -SourceStoreMailbox "Debra
```

```
Garcia" -SourceDatabase MBXDB01 -TargetMailbox "Debra
Garcia" -AllowLegacyDNMismatch
```

This example restores Pilar Pinilla's soft-deleted archive mailbox, which is identified by the mailbox GUID, to her current archive mailbox. The *AllowLegacyDNMismatch* parameter isn't necessary because a primary mailbox and its corresponding archive mailbox have the same legacy DN.

```
New-MailboxRestoreRequest -SourceStoreMailbox dc35895a-
a628-4bba-9aa9-650f5cdb9ae7 -SourceDatabase MBXDB02 -
TargetMailbox pilarp@contoso.com -TargetIsArchive
```

For detailed syntax and parameter information, see New-MailboxRestoreRequest.

How do you know this worked?

To verify that you've successfully restored a soft-deleted mailbox to the target mailbox, run the **Get-MailboxRestoreRequest** cmdlet or the **Get-MailboxRestoreRequestStatistics** cmdlet to display information about the restore request. If the restore request was successfully created, the *Status* property will have a value of **Queued**, **InProgress**, or **Completed**. After the restore request is completed, the contents from the soft-deleted mailbox will appear in the target mailbox.

For more information, see:

- Manage mailbox restore requests
- Get-MailboxRestoreRequest
- Get-MailboxRestoreRequestStatistics

Manage mailbox restore requests

Exchange Server 2013 > Recipients > Disconnected mailboxes >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-05-30*

Mailbox restore requests are used to restore disconnected mailboxes. A disconnected mailbox is a mailbox in an Exchange mailbox database that isn't associated with an Active Directory user account. Mailboxes become disconnected when they're disabled, deleted, or moved to another database. For more information, see Disconnected mailboxes.

Disconnected mailboxes remain in the mailbox database for the duration specified in the deleted mailbox retention settings for the mailbox database. By default, disconnected mailboxes are retained for 30 days. During this retention period, the contents of a deleted mailbox can be restored (copied) to an existing mailbox. This topic describes how to use the Shell to manage mailbox restore requests.

For additional management tasks related to disconnected mailboxes, see the following topics:

Disable or delete a mailbox

Connect a disabled mailbox

Connect or restore a deleted mailbox

Restore a soft-deleted mailbox

Permanently delete a mailbox

What do you need to know before you begin?

- Estimated time to complete each procedure: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mailbox restore request" entry in the Recipients Permissions topic.
- The procedures in this topic can only be performed in the Shell. You can't use the EAC to manage mailbox restore requests.
- To display the value of the *Identity* property for all mailbox restore requests, run the following command.

```
Get-MailboxRestoreRequest | Format-Table Identity
```

You can use this identity value to specify a specific mailbox restore request when you're performing the procedures in this topic.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the Shell to view restore request properties

You can view the properties of a mailbox restore request, which provide you with basic information about the status of a mailbox restore request.

To display a list and the value of the *Identity* property for all mailbox restore requests, run the following command.

```
Get-MailboxRestoreRequest | Format-Table Identity
```

You can use the identity to get information about specific mailbox restore requests.

This example returns the status of the restore request "Pilar Pinilla \MailboxRestore" using the *Identity* parameter.

```
Get-MailboxRestoreRequest -Identity "Pilar Pinilla \MailboxRestore"
```

This example returns all information for the second restore request for the Pilar Pinilla target mailbox.

```
Get-MailboxRestoreRequest -Identity "Pilar Pinilla \MailboxRestore1" | Format-List
```

This example returns the status of restore requests being restored from the source database MBD01.

```
Get-MailboxRestoreRequest -SourceDatabase MBD01
```

This example returns all restore requests that are currently in progress.

```
Get-MailboxRestoreRequest -Status InProgress
```

Other useful status states include `Queued`, `Completed`, `Suspended`, and `Failed`.

This example returns all restore requests that have been suspended.

```
Get-MailboxRestoreRequest -Suspend $true
```

For detailed syntax and parameter information, see Get-MailboxRestoreRequest.

Get-MailboxRestoreRequest Output

By default, the **Get-MailboxRestoreRequest** cmdlet returns the name of the request, the target mailbox to which data is being restored, and the status of the request. The following table lists useful information returned if you pipe the cmdlet to the **Format-List** cmdlet.

Value	Description
`SourceDatabase`	Specifies the database that contains the disconnected mailbox that's being restored.
`TargetMailbox`	Specifies the mailbox into which data is being restored.
`Name`	Specifies the name of the request.
`RequestQueue`	Specifies the database on which the Microsoft

	Exchange Mailbox Replication service (MRS) stores the detailed status of the request.
`Status`	Specifies the status of the request.
`Suspend`	Specifies whether the request is suspended. A mailbox restore can be suspended when it's created using the **New-MailboxRestoreRequest** cmdlet with the *Suspend* parameter. It can also be suspended if the mailbox restore operation fails or by an administrator using the **Suspend-MailboxRestoreRequest** cmdlet.
`Identity`	Specifies the identity of the request. This identity is a combination of the target mailbox name and the request name.

How do you know this worked?

Run the **Get-MailboxRestoreRequest** cmdlet to verify that you can view properties for mailbox restore requests. If the cmdlet returns an error, verify that you're using the correct syntax and identity. In some cases, the cmdlet may be successful and not return any results. For example, if you've submitted a mailbox restore request and run the command `Get-MailboxRestoreRequest -Status InProgress` and no results are returned, then none of the restore requests are currently running.

Use the Shell to view restore request statistics

You can view the statistics of a mailbox restore request, which provide you with detailed information that can be used for troubleshooting purposes.

This example returns the default statistics for the restore request danp\MailboxRestore1. By default, the information returned includes name, mailbox, status, and percentage complete.

```
Get-MailboxRestoreRequestStatistics -Identity danp
\MailboxRestore1
```

This example returns the statistics for Dan Park's mailbox and exports the report to a .csv file.

```
Get-MailboxRestoreRequestStatistics -Identity "Dan Park
```

```
\MailboxRestore" | Export-CSV \\SERVER01
\RestoreRequest_Reports\DanPark_Restorestats.csv
```

This example returns additional information about the restore request for Pilar Pinilla's mailbox using the *IncludeReport* parameter and piping the results to the **Format-List** cmdlet.

```
Get-MailboxRestoreRequestStatistics -Identity "Pilar
Pinilla\MailboxRestore" -IncludeReport | Format-List
```

This example returns additional information for all restore requests that have a status of `Failed` using the *IncludeReport* parameter, and then saves the information to the file AllRestoreReports.txt in the location where the command is being run.

```
Get-MailboxRestoreRequest -Status Failed | Get-
MailboxRestoreRequestStatistics -IncludeReport | Format-
List > AllRestoreReports.txt
```

For detailed syntax and parameter information, see Get-MailboxRestoreRequestStatistics and Get-MailboxRestoreRequest.

Get-MailboxRestoreRequestStatistics Output

By default, the Get-MailboxRestoreRequestStatistics cmdlet returns the name of the request, the status of the request, the alias of the target mailbox, and the percentage completed. The following table lists other useful information returned if you pipeline the cmdlet to the **Format-List** cmdlet.

Value	Description
`Name`	Specifies the name of the request.
`Status`	Specifies the status of the request.
`StatusDetail`	Specifies more details about the request status. For example, if the `Status` value returns `InProgress`, the `StatusDetail` value would return the specific stages for the `InProgress` status, such as `CreatingFolderHierarchy` and `CopyingMessages`.
`SyncStage`	Specifies how far along the request is through the restore process.
`Suspend`	Specifies whether the restore request is suspended. This value is `true` in the following

	scenarios: • MRS stopped or is in the process of stopping the request due to a failure. • An administrator suspended the request.
`SourceExchangeGuid`	Specifies the GUID of the source mailbox from which data is being restored.
`SourceRootFolder`	Specifies the name of the root folder in the source mailbox hierarchy from which data is being restored. If this value is blank, data is restored from the folder Top of Information Store.
`SourceDatabase`	Specifies the name of the database on which the source mailbox is located.
`MailboxRestoreFlags`	Specifies that the mailbox being restored is either `Disabled` or `Soft-Deleted`.
`TargetAlias`	Specifies the alias of the target mailbox.
`TargetIsArchive`	Specifies whether the mailbox is being restored into an archive.
`TargetExchangeGuid`	Specifies the GUID of the target mailbox.
`TargetRootFolder`	Specifies the name of the root folder in the target mailbox hierarchy to which data is being restored. If this value is blank, data is restored to the folder Top of Information Store.
`TargetDatabase`	Specifies the name of the database on which the target mailbox is located.
`TargetMailboxIdentity`	Specifies the identity of the target mailbox.
`IncludeFolders`	Specifies the list of folders to include during the

	restore. If this value is blank, no folders were specified when the request was created, and all folders will be restored to the mailbox (unless the *ExcludeFolders* parameter is used to exclude specific folders).
`ExcludeFolders`	Specifies the list of folders to exclude during the restore. If this value is blank, no folders were specified when the request was created, and all folders will be restored to the mailbox (unless the *IncludeFolders* parameter is used to include specific folders).
`ExcludeDumpster`	Specifies whether the Recoverable Items folder was excluded when the request was created.
`ConflictResolutionOption`	Specifies the action for MRS to take if there are matching messages in the target and source folders.
`AssociatedMessagesCopyOption`	Specifies whether the associated messages are copied when the request is processed. Associated messages are special messages that contain hidden data with information about rules, views, and forms.
`BadItemLimit`	Specifies the number of bad items that MRS will skip if the request encounters corrupted messages.
`BadItemsEncountered`	Specifies the number of corrupted messages encountered by the command. If the *BadItemsEncountered* value is greater than the *BadItemLimit* value, the request fails.
`QueuedTimeStamp`	Specifies the date and time at which the request

	was initiated to MRS.
`StartTimeStamp`	Specifies the date and time at which MRS started processing the restore request.
`LastUpdateTimeStamp`	Specifies the date and time at which the last change was made to the request. The change may have been made by an administrator or by MRS.
`SuspendTimeStamp`	Specifies the date and time at which the request was suspended.
`OverallDuration`	Specifies the amount of time it took to complete the request. If the request is in a `Failed` state, this value specifies the amount of time between the request being initiated and the request failing. If the request isn't complete, this value specifies the amount of time between the request being initiated and the **Get-MailboxRestoreRequestStatistics** cmdlet being run.
`TotalSuspendedDuration`	Specifies the amount of time the request was in the `Suspended` state.
`TotalFailedDuration`	Specifies the amount of time the request was in the `Failed` state.
`TotalQueuedDuration`	Specifies the amount of time the request was in the `Queued` state.
`TotalInProgressDuration`	Specifies the amount of time the request was in the `In Progress` state.
`TotalStalledDueToHADuration`	Specifies the amount of time the request was stalled due to high availability.

`MRSServerName`	Specifies the name of the Client Access server that processed the request.
`EstimatedTransferSize`	Specifies the total file size that was restored or the file size that MRS expects to restore if the request is in the `In Progress` state.
`EstimatedTransferItemCount`	Specifies the number of items that were restored or the number of items that MRS expects to restore if the request is in the `In Progress` state.
`BytesTransferredPerMinute`	Specifies the average number of bytes that have been transferred per minute.
`ItemsTransferred`	Specifies the number of items that have been transferred.
`PercentComplete`	Specifies the percentage of the request that has been completed.
`CompletedRequestAgeLimit`	Specifies how long a completed restore request will be retained before it's deleted. The default is 30 days.
`PositionInQueue`	If the request hasn't started, this value specifies the request's position in the queue.
`FailureCode`	If there is a failure, this value specifies the failure code.
`FailureType`	If there is a failure, this value specifies the failure type.
`FailureSide`	If there is a failure, this value specifies whether the failure occurred on the target mailbox or the source mailbox.
`Message`	If there is a failure, this value specifies the failure

	message. This value can also specify the suspend comment.
`FailureTimestamp`	If the request failed, this value specifies the date and time at which the request failed.
`FailureContext`	If the request failed, this value specifies information about the action being performed at the time of failure.
`ValidationMessage`	If the request isn't valid, this value specifies the reason.
`RequestQueue`	Specifies the database on which MRS stores the detailed status of the request.
`Identity`	Specifies the identity of the request.
`Report`	If you used the *IncludeReport* parameter, this value specifies information that can be used to troubleshoot the request.

How do you know this worked?

Run the **Get-MailboxRestoreRequestStatistics** cmdlet to verify that you can view the statistics for mailbox restore requests. If the cmdlet returns an error, verify that you're using the correct identity for the restore request.

Use the Shell to change restore request properties

If a mailbox restore request fails, you can use the **Set-MailboxRestoreRequest** cmdlet to change the request's properties to try to recover from the failure.

This example specifies that the restore request MailboxRestore1 for Debra Garcia's mailbox skips 10 corrupted mailbox items.

```
Set-MailboxRestoreRequest -Identity "Debra Garcia
\MailboxRestore1" -BadItemLimit 10
```

This example specifies that the restore request MailboxRestore1 for Florence Flipo's mailbox skips 100 corrupted items. Because the *BadItemLimit* value is greater than 50, the *AcceptLargeDataLoss* parameter must be specified.

```
Set-MailboxRestoreRequest -Identity "Florence Flipo
\MailboxRestore1" -BadItemLimit 100 -AcceptLargeDataLoss
```

For detailed syntax and parameter information, see Set-MailboxRestoreRequest.

How do you know this worked?

To verify that you've successfully changed the properties of a restore request, run the **Get-MailboxRestoreRequestStatistics** cmdlet to display the revised properties for the restore request. If the restore request was successfully created, the *Status* property will have a value of `Queued`, `InProgress`, or `Completed`. After the restore request is completed, the contents of the soft-deleted mailbox will appear in the target mailbox.

For detailed syntax and parameter information, see Get-MailboxRestoreRequestStatistics.

Use the Shell to suspend a restore request

You can suspend a restore request any time after the request was created but before the request reaches the status of `Completed`. See Use the Shell to resume a restore request later in this topic for the command syntax to resume the restore request using the Resume-MailboxRestoreRequest cmdlet.

This example suspends the restore request MailboxRestore1 for Pilar Pinilla's mailbox.

```
Suspend-MailboxRestoreRequest -Identity "Pilar Pinilla
\MailboxRestore1"
```

This example suspends all restore requests in progress by first retrieving all requests that have a status of `InProgress`, and then piping the output to the **Suspend-MailboxRestoreRequest** cmdlet and including the suspend comment "Resume after FY13Q2 Maintenance."

```
Get-MailboxRestoreRequest -Status InProgress | Suspend-
MailboxRestoreRequest -SuspendComment "Resume after FY13Q2
Maintenance"
```

For detailed syntax and parameter information, see Suspend-MailboxRestoreRequest.

How do you know this worked?

To verify that you've successfully suspended a mailbox restore request, run the following command.

```
Get-MailboxRestoreRequest <identity> | Format-List
Suspend,Status
```

If the value of the *Suspend* property equals `True`, the restore request was successfully suspended. Also, a value of `Suspended` for the *Status* property indicates that the restore request was suspended.

Use the Shell to resume a restore request

Use the **Resume-MailboxRestoreRequest** cmdlet to resume a restore request that failed or was suspended.

This example resumes the restore request Pilar Pinilla\MailboxRestore1.

```
Resume-MailboxRestoreRequest -Identity "Pilar Pinilla
\MailboxRestore1"
```

This example resumes all restore requests that have a status of Failed.

```
Get-MailboxRestoreRequest -Status Failed | Resume-
MailboxRestoreRequest
```

For detailed syntax and parameter information, see Resume-MailboxRestoreRequest.

How do you know this worked?

To verify that a restore request has resumed, run the following command.

```
Get-MailboxRestoreRequest <identity> | Format-List
Suspend,Status
```

If the value of the *Suspend* property equals `False`, the restore request successfully resumed. Also, a value of `InProgress` for the *Status* property indicates that the restore request resumed.

Use the Shell to remove a restore request

You can use the **Remove-MailboxRestoreRequest** cmdlet to remove mailbox restore requests. If you remove a restore request after mailbox data begins being copied to the target mailbox, the mailbox data that's copied remains in the target mailbox.

Note:
As previously stated, completed restore requests are retained for 30 days by default before they're automatically deleted.

This example removes the restore request Pilar Pinilla\MailboxRestore1.

```
Remove-MailboxRestoreRequest -Identity "Pilar Pinilla
\MailboxRestore1"
```

This example removes all restore requests that have the status of Completed.

```
Get-MailboxRestoreRequest -Status Completed | Remove-
MailboxRestoreRequest
```

This example cancels the restore request by using the *RequestGuid* parameter for a request stored on MBXDB01. The parameter set that requires the *RequestGuid* and *RequestQueue* parameters is used only for Microsoft Replication Service debugging purposes. You should use this parameter set only if instructed by Microsoft Customer Service and Support.

```
Remove-MailboxRestoreRequest -RequestQueue MBXDB01 -
RequestGuid 25e0eaf2-6cc2-4353-b83e-5cb7b72d441f
```

For detailed syntax and parameter information, see Remove-MailboxRestoreRequest.

How do you know this worked?

To verify that you've successfully removed a mailbox restore request, run the following command.

```
Get-MailboxRestoreRequest -Identity <identity of removed
restore request>
```

The command will return an error stating that the restore request doesn't exist.

You can also run the **Get-MailboxRestoreRequest** cmdlet. If a restore request was successfully removed, it won't be included in the results.

Permanently delete a mailbox

Exchange Server 2013 > Recipients > Disconnected mailboxes >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-16*

When you permanently delete active mailboxes and disconnected mailboxes, all mailbox contents are purged from the Exchange mailbox database, and the data loss is permanent. When you permanently delete an active mailbox, the associated Active Directory user account is also deleted.

An alternative to permanently deleting a mailbox is to disconnect it. After you disconnect a mailbox, by default, it's retained in the mailbox database for 30 days. This gives you the opportunity to reconnect or restore a mailbox before it's purged from the database.

To learn more about disconnected mailboxes and perform other related management tasks, see the following topics:

- Disconnected mailboxes
- Disable or delete a mailbox
- Connect a disabled mailbox
- Connect or restore a deleted mailbox

Note:

You can't use the EAC to permanently delete an active mailbox or a disconnected mailbox.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Permanently delete an active mailbox

Use the Shell to permanently delete an active mailbox

Run the following command to permanently delete an active mailbox and the associated Active Directory user account.

```
Remove-Mailbox -Identity <identity> -Permanent $true
```

Note:

If you don't include the *Permanent* parameter, the deleted mailbox is retained in the mailbox database for 30 days, by default, before it's permanently deleted.

For detailed syntax and parameter information, see Remove-Mailbox.

How do you know this worked?

To verify that you've permanently deleted an active mailbox, do the following:

1. Verify that the mailbox is no longer listed in the EAC.
2. Verify that the associated user account is no longer listed in Active Directory Users and Computers.
3. Run the following command to verify that the mailbox was successfully purged from the Exchange mailbox database.

```
Get-MailboxDatabase | Get-MailboxStatistics | Where
{ $_.DisplayName -eq "<display name>" }
```

If you successfully purged the mailbox, the command won't return any results. If the mailbox wasn't

purged, the command will return information about the mailbox.

Permanently delete a disconnected mailbox

Use the Shell to permanently delete a disconnected mailbox

There are two types of disconnected mailboxes: disabled and soft-deleted. You must specify one of these types when running the cmdlet to permanently delete the mailbox. If the type you specify doesn't match the actual type of the disconnected mailbox, the command fails.

Run the following command to determine whether a disconnected mailbox is disabled or soft-deleted.

```
Get-MailboxDatabase | Get-MailboxStatistics | Where
{ $_.DisplayName -eq "<display name>" } | fl
DisplayName,MailboxGuid,Database,DisconnectReason
```

The value for the *DisconnectReason* property for disconnected mailboxes will be either `Disabled` or `SoftDeleted`.

You can run the following command to display the type for all disconnected mailboxes in your organization.

```
Get-MailboxDatabase | Get-MailboxStatistics | Where
{ $_.DisconnectReason -ne $null } | fl
DisplayName,MailboxGuid,Database,DisconnectReason
```

⚠Warning:

When you use the **Remove-StoreMailbox** cmdlet to permanently delete a disconnected mailbox, all its contents are purged from the mailbox database and the data loss is permanent.

This example permanently deletes the disabled mailbox with the GUID 2ab32ce3-fae1-4402-9489-c67e3ae173d3 from mailbox database MBD01.

```
Remove-StoreMailbox -Database MBD01 -Identity "2ab32ce3-
fae1-4402-9489-c67e3ae173d3" -MailboxState Disabled
```

This example permanently deletes the soft-deleted mailbox for Dan Jump from mailbox database MBD01.

```
Remove-StoreMailbox -Database MBD01 -Identity "Dan Jump" -
MailboxState SoftDeleted
```

This example permanently deletes all soft-deleted mailboxes from mailbox database MBD01.

```
Get-MailboxStatistics -Database MBD01 | where
```

```
{$_.DisconnectReason -eq "SoftDeleted"} | ForEach {Remove-
StoreMailbox -Database $_.Database -Identity $_.MailboxGuid
-MailboxState SoftDeleted}
```

For detailed syntax and parameter information, see Remove-StoreMailbox and Get-MailboxStatistics.

How do you know this worked?

To verify that you've permanently deleted a disconnected mailbox and that it was successfully purged from the Exchange mailbox database, run the following command.

```
Get-MailboxDatabase | Get-MailboxStatistics | Where
{ $_.DisplayName -eq "<display name>" }
```

If you successfully purged the mailbox, the command won't return any results. If the mailbox wasn't purged, the command will return information about the mailbox.

Custom attributes

Exchange Server 2013 > Recipients >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-17*

Microsoft Exchange Server 2013 includes 15 extension attributes. You can use these attributes to add information about a recipient, such as an employee ID, organizational unit (OU), or some other custom value for which there isn't an existing attribute. These custom attributes are labeled in Active Directory as **ms-Exch-Extension-Attribute1** through **ms-Exch-Extension-Attribute15**. In the Exchange Management Shell, the corresponding parameters are *CustomAttribute1* through *CustomAttribute15*. These attributes aren't used by any Exchange components. They can be used to store Active Directory data without having to extend the Active Directory schema.

In Exchange Server 2003 and earlier, if you wanted to store this information in Active Directory, you had to create an attribute by extending the Active Directory schema. Schema extension requires planning, procuring object identifiers (OIDs) for new attributes, and testing the extension process in a test environment before you implement it in a production environment. In Exchange 2013, schema extensions can't be used in recipient filters used by address lists, e-mail address policies, and dynamic distribution groups.

Contents

Advantages of custom attributes

Some of the advantages of using custom attributes include:

- You avoid extending the Active Directory schema.
- The attributes are created by Exchange Setup.
- You can use the Exchange Administration Center (EAC) or the Exchange Management Shell to manage the attributes. You don't need to build custom controls or write scripts to populate and display these attributes.
- The attributes are filterable properties that can be used in the *Filter* parameter with recipient cmdlets such as **Get-Mailbox**. They can also be used in the EAC and the Shell to create filters for e-mail address policies, address lists, and dynamic distribution groups.

Multivalued custom attributes

In Exchange 2010 Service Pack 2 (SP2), five multivalued custom attributes were added to Exchange to allow you to store additional information for mail recipients if the traditional custom attributes didn't meet your needs. The *ExtensionCustomAttribute1* to *ExtensionCustomAttribute5* parameters can hold up to 1,300 values each. You can specify multiple values as a comma-delimited list. The following cmdlets support these new parameters:

- Set-DistributionGroup
- Set-DynamicDistributionGroup
- Set-Mailbox
- Set-MailContact
- Set-MailPublicFolder
- Set-RemoteMailbox

For more information about multivalued properties, see Modifying multivalued properties.

Custom attribute examples

In many Exchange deployments, creating an e-mail address policy for all recipients in an OU is a common scenario. The OU isn't a filterable property that can be used in the *RecipientFilter* parameter of an e-mail address policy or an address list.

Note:
Dynamic distribution groups have an additional parameter that you can use to restrict it to recipients in a particular OU or container.

If the recipients in that OU don't share any common properties that you can filter by, such as

department or location, you can populate one of the custom attributes with a common value, as shown in this example.

```
Get-Mailbox -OrganizationalUnit Sales | Set-Mailbox
CustomAttribute1 "SalesOU"
```

Now you can create an e-mail address policy for all recipients that have the *CustomAttribute1* property that equals SalesOU, as shown in this example.

```
New-EmailAddressPolicy -Name "Sales" -RecipientFilter
{ CustomAttribute1 -eq "SalesOU"} -
EnabledEmailAddressTemplates "SMTP:%s%2g@sales.contoso.com"
```

Custom attribute example using the ConditionalCustomAttributes parameter

When creating dynamic distribution groups, email address policies, or address lists, you don't need to use the *RecipeintFilter* parameter to specify custom attributes. You can use the *ConditionalCustomAttribute1* to *ConditionalCustomAttribute15* parameters instead.

This example creates a dynamic distribution group based on the recipients whose *CustomAttribute1* is set to SalesOU.

```
New-DynamicDistributionGroup -Name "Sales Users and
Contacts" -IncludedRecipients "MailboxUsers,MailContacts" -
ConditionalCustomAttribute1 "SalesOU"
```

Note:

You must use the *IncludedRecipients* parameter if you use a *Conditional* parameter. In addition, you can't use *Conditional* parameters if you use the *RecipientFilter* parameter. If you want to include additional filters to create your dynamic distribution group, email address policies, or address lists, you should use the *RecipientFilter* parameter.

Custom attribute example using ExtensionCustomAttributes parameter

In this example, the mailbox for Kweku will have *ExtensionCustomAttribute1* updated to reflect that he's enrolled in the following educational classes: MATH307, ECON202, and ENGL300.

```
Set-Mailbox -Identity Kweku -ExtensionCustomAttribute1
MATH307,ECON202,ENGL300
```

Next, a dynamic distribution group for all students enrolled MATH307 is created by using the *RecipientFilter* parameter where *ExtensionCustomAttribute1* is equal to MATH307. When using the *ExtentionCustomAttributes* parameters, you can use the `-eq` operator instead of the `-like` operator.

```
New-DynamicDistributionGroup -Name Students_MATH307 -
RecipientFilter {ExtensionCustomAttribute1 -eq "MATH307"}
```

In this example, Kweku's *ExtensionCustomAttribute1* values are updated to reflect that he's added the class ENGL210 and removed the class ECON202.

```
Set-Mailbox -Identity Kweku -ExtensionCustomAttribute1
@{Add="ENGL210"; Remove="ECON202"}
```

Filters in recipient Shell commands

Exchange Server 2013 > Recipients >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-12-05*

You can use several Exchange Management Shell commands to filter a set of recipients. You can create the following types of filters in an Exchange command:

- Precanned filters
- Custom filters using the *RecipientFilter* parameter
- Custom filters using the *Filter* parameter
- Custom filters using the *ContentFilter* parameter

In Microsoft Exchange Server 2003 and earlier versions, LDAP filtering syntax is used to create custom address lists, global address lists (GALs), email address policies, and distribution groups. In later versions of Exchange, the OPATH filtering syntax replaces the LDAP filtering syntax.

Contents

Precanned filters

A *precanned filter* is a commonly used Exchange filter that you can use to meet a variety of recipient-filtering criteria for creating dynamic distribution groups, email address policies, address lists, or GALs. With precanned filters, you can use either the Exchange Management Shell or the Exchange Administration Center (EAC). Using precanned filters, you can do the following:

- Determine the scope of recipients.
- Add conditional filtering based on properties such as company, department, and state or region.
- Add custom attributes for recipients. For more information, see Custom attributes.

The following parameters are considered precanned filters:

- *IncludedRecipients*
- *ConditionalCompany*
- *ConditionalDepartment*
- *ConditionalStateOrProvince*
- *ConditionalCustomAttribute1*–15.

Precanned filters are available for the following cmdlets:

- New-DynamicDistributionGroup
- Set-DynamicDistributionGroup
- New-EmailAddressPolicy
- Set-EmailAddressPolicy
- New-AddressList
- Set-AddressList
- New-GlobalAddressList
- Set-GlobalAddressList

Example

This example describes using precanned filters in the Shell to create a dynamic distribution group. The syntax in this example is similar but not identical to the syntax you would use to create an email address policy, address list, or GAL. When creating a precanned filter, you should ask the following questions:

- From which organizational unit (OU) do you want to include recipients? (This question corresponds to the *RecipientContainer* parameter.)

Note:

Selecting the OU for this purpose applies only when creating dynamic distribution groups, and not when creating email address policies, address lists, or GALs.

- What type of recipients do you want to include? (This question corresponds to the *IncludedRecipients* parameter.)
- What additional conditions do you want to include in the filter? (This question corresponds to the *ConditionalCompany*, *ConditionalDepartment*, *ConditionalStateOrProvince*, and

ConditionalCustomAttribute parameters.)

This example creates the dynamic distribution group Contoso Finance for user mailboxes in the OU Contoso.com/Users and specifies the condition to include only recipients who have the **Department** attribute defined as Finance and the **Company** attribute defined as Contoso.

```
New-DynamicDistributionGroup -Name "Contoso Finance" -
OrganizationalUnit Contoso.com/Users -RecipientContainer
Contoso.com/Users -IncludedRecipients MailboxUsers -
ConditionalDepartment "Finance" -ConditionalCompany
"Contoso"
```

This example displays the properties of this new dynamic distribution group.

```
Get-DynamicDistributionGroup -Identity "Contoso Finance" |
Format-List Recipient*,Included*
```

Return to top

Custom filters using the RecipientFilter parameter

If precanned filters don't meet your needs for creating or modifying dynamic distribution groups, email address policies, and address lists, you can create a custom filter by using the *RecipientFilter* parameter.

The recipient filter parameter is available for the following cmdlets:

- New-DynamicDistributionGroup
- Set-DynamicDistributionGroup
- New-EmailAddressPolicy
- Set-EmailAddressPolicy
- New-AddressList
- Set-AddressList
- New-GlobalAddressList
- Set-GlobalAddressList

For more information about the filterable properties you can use with the *RecipientFilter* parameter, see Filterable properties for the -RecipientFilter parameter.

Example

The following example uses the *RecipientFilter* parameter to create a dynamic distribution group. The syntax in this example is similar but not identical to the syntax you use to create an email address policy, address list, or GAL.

This example uses custom filters to create a dynamic distribution group for user mailboxes that

have the **Company** attribute defined as Contoso and the **Office** attribute defined as North Building.

```
New-DynamicDistributionGroup -Name AllContosoNorth -
OrganizationalUnit contoso.com/Users -RecipientFilter
{ ((RecipientType -eq 'UserMailbox') -and (Company -eq
'Contoso') -and (Office -eq 'North Building')) }
```

Return to top

Custom filters using the Filter parameter

You can use the *Filter* parameter to filter the results of a command to specify which objects to retrieve. For example, instead of retrieving all users or groups, you can specify a set of users or groups by using a filter string. This type of filter doesn't modify any configuration or attributes of objects. It only modifies the set of objects that the command returns.

Using the *Filter* parameter to modify command results is known as *server-side filtering*. Server-side filtering submits the command and the filter to the server for processing. The Shell also supports client-side filtering, in which the command retrieves all objects from the server and then applies the filter in the local console window. To perform client-side filtering, use the **Where-Object** cmdlet. For more information about server-side and client-side filtering, see "How to Filter Data" in Working with command output.

To find the filterable properties for cmdlets that have the *Filter* parameter, you can run the **Get** command against an object and format the output by pipelining the **Format-List** parameter. Most of the returned values will be available for use in the *Filter* parameter. The following example returns a detailed list for the mailbox Ayla.

```
Get-Mailbox -Identity Ayla | Format-List
```

The *Filter* parameter is available for the following cmdlets:

- Get-ActiveSyncDevice
- Get-ActiveSyncDeviceClass
- Get-CASMailbox
- Get-Contact
- Get-DistributionGroup
- Get-DynamicDistributionGroup
- Get-Group
- Get-Mailbox
- Get-MailboxStatistics
- Get-MailContact
- Get-MailPublicFolder
- Get-MailUser
- Get-Message

- Get-MobileDevice
- Get-Queue
- Get-QueueDigest
- Get-Recipient
- Get-RemoteMailbox
- Get-RoleGroup
- Get-SecurityPrincipal
- Get-StoreUsageStatistics
- Get-ThrottlingPolicyAssociation
- Get-UMMailbox
- Get-User
- Get-UserPhoto
- Remove-Message
- Resume-Message
- Resume-Queue
- Retry-Queue
- Suspend-Message
- Suspend-Queue

For more information about the filterable properties you can use with the *Filter* parameter, see Filterable properties for the -Filter parameter.

Example

This example uses the *Filter* parameter to return information about users whose title contains the word "manager".

```
Get-User -Filter {Title -like 'Manager*'}
```

Return to top

Custom filters using the ContentFilter parameter

You can use the *ContentFilter* parameter to select specific message content to export when using the New-MailboxExportRequest cmdlet. If the command finds a message that contains the match to the content filter, it exports the message to a .pst file.

Example

This example creates an export request that searches Ayla's mailbox for messages where the body contains the phrase "company prospectus". If that phrase is found, the command exports all messages with that phrase to a .pst file.

```
New-MailboxExportRequest -Mailbox Ayla -ContentFilter {Body
-like "company prospectus*"}
```

For more information about the filterable properties you can use with the *ContentFilter* parameter, see Filterable properties for the -ContentFilter parameter.

Return to top

Additional OPATH syntax information

When creating your own custom filters, be aware of the following:

- Use braces { } around the entire OPATH syntax string with the *Filter* or *RecipientFilter* parameter.
- Include the hyphen before all operators. The most common operators include:
  - **-and**
  - **-or**
  - **-not**
  - **-eq** (equals)
  - **-ne** (not equal)
  - **-lt** (less than)
  - **-gt** (greater than)
  - **-like** (string comparison)
  - **-notlike** (string comparison)
- Many of the properties for the *RecipientFilter* and *Filter* parameters accept wildcard characters. If you use a wildcard character, use the **like** operator instead of the **eq** operator. The **like** operator is used to find pattern matches in rich types, such as strings, whereas the **eq** operator is used to find an exact match.
- Run the following commands to get information about operators you can use:
  - `Help about_logical_operator`
  - `Help about_comparison_operator`
- You can use most properties of recipient types to create filter strings. For information about filterable properties you can use with a specific cmdlet, see the cmdlet reference topics in Exchange Management Shell.

Recipient filter documentation

The following table contains links to topics that will help you learn more about the filterable properties that you can use with Exchange recipient commands.

Topic	Description
Filterable properties for the -RecipientFilter parameter	Learn more about the filterable properties for the *RecipientFilter* parameter.

Filterable properties for the -Filter parameter	Learn more about the filterable properties for the *Filter* parameter.
Filterable properties for the -ContentFilter parameter	Learn more about using the *ContentFilter* parameter when using the **New-MailboxExportRequest** cmdlet.

Filterable properties for the -RecipientFilter parameter

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-11-05*

This topic lists the filterable properties for the *-RecipientFilter* parameter in Microsoft Exchange 2013. The *-RecipientFilter* parameter allows you to define the criteria to create custom dynamic distribution groups, email address policies, address lists, or global address lists (GALs).

The following two tables in this topic outline the common filterable properties and the advanced filterable properties. Other properties, including any customer schema extensions, cannot be used in the *-RecipientFilter* parameter.

The *-RecipientFilter* parameter is used in the following cmdlets:

- New-DynamicDistributionGroup
- Set-DynamicDistributionGroup
- New-EmailAddressPolicy
- Set-EmailAddressPolicy
- New-AddressList
- Set-AddressList
- New-GlobalAddressList
- Set-GlobalAddressList

In many instances, a filterable property accepts the distinguished name (DN) or the globally unique identifier (GUID) of an object instead of the object's name. To locate the DN or the GUID of the object that you want to use in a recipient filter, use the corresponding **Get-** cmdlet.

For example, to locate the DN or GUID for a Microsoft Exchange ActiveSync mailbox policy named NewActiveSyncPolicy, run the following command:

```
Get-ActiveSyncMailboxPolicy -Identity NewActiveSyncPolicy |
format-list DistinguishedName,GUID
```

You can then copy the DN or GUID and paste it into your recipient filter. For example, to use the DN to create a dynamic distribution group based on the Exchange ActiveSync mailbox policy, run the following command:

```
New-DynamicDistributionGroup -Name NewDDG -RecipientFilter
{(ActiveSyncMailboxPolicy -eq 'CN=Default,CN=Mobile Mailbox
Policies,CN=First Organization,CN=Microsoft
Exchange,CN=Services,CN=Configuration,DC=IELRVS-
dom,DC=extest,DC=Contoso,DC=com')}
```

Common filterable properties

The following table contains the common filterable properties for the *-RecipientFilter* parameter. This table lists the name of the property, the Lightweight Directory Access Protocol (LDAP) display name, a description of the property, and the possible values that the property can take. You can use the LDAP display name to convert your Microsoft Exchange Server 2003 or earlier LDAP filters into Exchange Server 2007 OPath filters. For more information about converting LDAP filters to Exchange OPath filters, see the Microsoft Exchange Team Blog article, Need help converting your LDAP filters to OPATH.

Note:
The content of each blog and its URL are subject to change without notice. The content within each blog is provided "AS IS" with no warranties, and confers no rights. Use of included script samples or code is subject to the terms specified in the Microsoft Terms of Use.

Note:
Not all filterable properties have an LDAP display name. The properties that do not have an LDAP display name are not Active Directory directory service properties. They are properties that are calculated by Exchange.

Note:
Many of the properties for the *-RecipientFilter* parameter accept wildcard characters. If you use a wildcard character, use the *-like* operator instead of the *-eq* operator. The *-like* operator is used to find pattern matches in rich types, such as strings, whereas the *-eq* operator is used to find an exact match.

Property name	LDAP display name	Description	Value
ActiveSyncMailboxPolicy	*msExchMobileMailboxPolicyLink*	This property contains the name of the Exchange ActiveSync	DN

		mailbox policy for the mailbox.	
Alias	*mailNickname*	This property contains the alias (the generic name used to identify a mail account) of the recipient.	• String • Wildcard character accepted
AssistantName	*msExchAssistantName*	This property contains the assistant name of the recipient.	• String • Wildcard character accepted
C	*C*	This property contains the two-letter country/region designation from International Organization for Standardization (ISO) 3166.	• ISO 3166 **Note:** For a complete list of the ISO 3166 standard values, see International Organization for Standardization. **Note:** The third-party Web site information in this topic is provided to help you find the technical information you need. The URLs are subject to change without notice.
City	*l*	This property contains the city name of the recipient.	• String • Wildcard character accepted
Co	*Co*	This property contains the country/region name in which the recipient resides.	• Country/Region • You can locate valid *Co* values on the **Address and Phone** tab in the recipient's properties.
Company	*company*	This property contains	• String

		the company of the recipient.	• Wildcard character accepted
CountryCode	*CountryCode*	This property contains the numeric country/ region designation from ISO 3166.	• ISO 3166 **Note:** For a complete list of the ISO 3166 standard values, see International Organization for Standardization. **Note:** The third-party Web site information in this topic is provided to help you find the technical information you need. The URLs are subject to change without notice.
CountryOrRegion	Not applicable	This property contains the country or region in which the recipient resides.	• Country/Region • You can locate valid *CountryOrRegion* values on the **Address and Phone** tab in the recipient's properties.
CustomAttribute1	*extensionAttribute1*	This property contains a custom attribute that you can add to a recipient.	• String • Wildcard character accepted
CustomAttribute2	*extensionAttribute2*	This property contains a custom attribute that you can add to a recipient.	• String • Wildcard character accepted
CustomAttribute3	*extensionAttribute3*	This property contains a custom attribute that you can add to a	• String • Wildcard character accepted

		recipient.	
CustomAttribute4	*extensionAttribute4*	This property contains a custom attribute that you can add to a recipient.	• String • Wildcard character accepted
CustomAttribute5	*extensionAttribute5*	This property contains a custom attribute that you can add to a recipient.	• String • Wildcard character accepted
CustomAttribute6	*extensionAttribute6*	This property contains a custom attribute that you can add to a recipient.	• String • Wildcard character accepted
CustomAttribute7	*extensionAttribute7*	This property contains a custom attribute that you can add to a recipient.	• String • Wildcard character accepted
CustomAttribute8	*extensionAttribute8*	This property contains a custom attribute that you can add to a recipient.	• String • Wildcard character accepted
CustomAttribute9	*extensionAttribute9*	This property contains a custom attribute that you can add to a recipient.	• String • Wildcard character accepted
CustomAttribute10	*extensionAttribute10*	This property contains a custom attribute that you can add to a recipient.	• String • Wildcard character accepted

CustomAttribute11	*extensionAttribute11*	This property contains a custom attribute that you can add to a recipient.	• String • Wildcard character accepted
CustomAttribute12	*extensionAttribute12*	This property contains a custom attribute that you can add to a recipient.	• String • Wildcard character accepted
CustomAttribute13	*extensionAttribute13*	This property contains a custom attribute that you can add to a recipient.	• String • Wildcard character accepted
CustomAttribute14	*extensionAttribute14*	This property contains a custom attribute that you can add to a recipient.	• String • Wildcard character accepted
CustomAttribute15	*extensionAttribute15*	This property contains a custom attribute that you can add to a recipient.	• String • Wildcard character accepted
Database	*homeMDB*	This property contains the mailbox database.	• Mailbox database • Identity • DN
Department	*department*	This property contains the department of the recipient.	• String • Wildcard character accepted
DisplayName	*displayName*	This property contains the ambiguous name resolution (ANR) search for the display	• String • Wildcard character accepted

		name of the recipient.	
EmailAddresses	*proxyAddresses*	This property contains the email addresses of this recipient. All Exchange 2007 email address types are valid. Separate multiple values by using commas.	• Email address • Wildcard character accepted
EmailAddressPolicyEnabled	Not applicable	This property contains the control for applying email address policies to this recipient.	• Boolean • $true or $false
ExternalEmailAddress	*targetAddress*	This property contains the external email address. Email messages sent to the mail-enabled user are sent to this external address.	• Email address • Wildcard character accepted
ExternalOofOptions	*msExchExternalOOFOptions*	This property contains the option for sending an out-of-office message to external senders.	• InternalOnly • External
FirstName	*givenName*	This property contains the ANR search for the first name of the recipient.	• String • Wildcard character accepted

HiddenFromAddressListsEnabled	*msExchHideFromAddressLists*	This property specifies whether the recipient is visible in the address list.	• Boolean • $true or $false
IsLinked	Not applicable	This property specifies whether a folder is linked to a master folder.	• Boolean • $true or $false
IsMailboxEnabled	Not applicable	This property specifies whether a mailbox is mailbox-enabled.	• Boolean • $true or $false
IsResource	Not applicable	This property specifies whether a mailbox is a resource mailbox.	• Boolean • $true or $false
IsShared	Not applicable	This property specifies whether a resource mailbox is shared.	• Boolean • $true or $false
IssueWarningQuota	*mDBStorageQuota*	This property contains the mailbox size at which a warning message is sent to the user.	Unlimited or integer
LanguagesRaw	*msExchUserCulture*	This property contains the language preference for this mailbox.	• ISO 639-ISO 3166 **Note:** An acceptable value for this parameter is a combination of an ISO 639 two-letter lowercase culture code that is associated with a language and an ISO 3166 two-letter uppercase subculture

			code that is associated with a country or region. For example, United States English is represented as `en-us`. To learn more about culture codes and for a full list of acceptable values, see CultureInfo Class in the MSDN Library.
LastName	*sn*	This property contains the ANR search for the last name of the recipient.	• String • Wildcard character accepted
ManagedFolderMailboxPolicy	*msExchMailboxTemplateLink*	This property contains the managed folder mailbox policy that controls messaging records management (MRM).	• Name • GUID • DN
Manager	*manager*	This property contains the manager of the recipient.	• String • Wildcard character accepted
MaxReceiveSize	*delivContLength*	This property contains the maximum size of messages that this recipient can receive.	Unlimited or integer
MaxSendSize	*submissionContLength*	This property contains the maximum size of messages that this recipient can send.	Unlimited or integer

MobileFeaturesEnabled	*msExchOmaAdminWirelessEnable*	This property specifies whether a mailbox has mobile features enabled.	• Boolean • $true or $false
Name	*name*	This property contains the name of the recipient.	String
Office	*physicalDeliveryOfficeName*	This property contains the office of the recipient.	String
OfflineAddressBook	*msExchUseOAB*	This property contains the offline address book (OAB) that is associated with this recipient.	• Name • GUID • DN
PostalCode	*postalCode*	This property contains the postal code of the recipient.	String
ProhibitSendQuota	*mDBOverQuotaLimit*	This property contains the mailbox size at which the user associated with this mailbox can no longer send messages.	Unlimited or integer
ProhibitSendReceiveQuota	*mDBOverHardQuotaLimit*	This property contains the mailbox size at which the user associated with this mailbox can no longer send or receive	Unlimited or integer

		messages	
RecipientLimits	*msExchRecipLimit*	This property contains the maximum number of recipients per message to which this mailbox can send.	Unlimited or integer
RecipientType	Not applicable	This property specifies the recipient type.	• UserMailbox • MailUser • MailContact • MailUniversalDistributionGroup • MailUniversalSecurityGroup • MailNonUniversalGroup • DynamicDistributionGroup • PublicFolder
RecipientTypeDetails	Not applicable	This property specifies the recipient subtype.	• ConferenceRoomMailbox • EquipmentMailbox • LegacyMailbox • LinkedMailbox • UserMailbox • MailContact • DynamicDistributionGroup • MailForestContact • MailNonUniversalGroup • MailUniversalDistributionGroup • MailUniversalSecurityGroup

			• MailUser • PublicFolder • SharedMailbox
SamAccountName	*SamAccountName*	This property contains the logon name that is used to support client computers and servers running older versions of Microsoft Windows operating systems.	• String • Wildcard character accepted
ServerName	Not applicable	This property contains the name of the server where the recipient resides.	Server name
StateOrProvince	*st*	This property contains the state or province information that is defined for this recipient.	• String • Wildcard character accepted
StreetAddress	*streetAddress*	This property contains the street address that is defined for this recipient.	String
Title	*title*	This property contains the title of the recipient.	String
UMEnabled	Not applicable	This property specifies whether Unified Messaging (UM) is	• Boolean • $true or $false

		enabled for this mailbox.	
UseDatabaseQuotaDefaults	*mDBUseDefaults*	This property specifies whether the mailbox uses the quota attributes for the mailbox database in which this mailbox resides. The quota attributes are: ProhibitSendQuota, ProhibitSendReceiveQuota, IssueWarningQuota, and RulesQuota.	• ProhibitSendQuota • ProhibitSendReceiveQuota • IssueWarningQuota • RulesQuota
UserPrincipalName	*userPrincipalName*	This property contains the user principal name (UPN) for this recipient. The UPN is the logon name for the user and consists of a user name and a suffix. Typically, the suffix is the domain name where the user account resides. For example, `kim@contoso.com`.	• User logon name • User principal name • Wildcard character accepted

Advanced filterable properties

The following table lists filterable properties that are not commonly used. They are included in this topic for reference purposes.

Name	LDAP name
AcceptMessagesOnlyFrom	*authOrig*
AcceptMessagesOnlyFromDLMembers	*dLMemSubmitPerms*
ActiveSyncAllowedDeviceIDs	*msExchMobileAllowedDeviceIds*
ActiveSyncDebugLogging	*msExchMobileDebugLogging*
ActiveSyncEnabled	Not applicable
AddressListMembership	*showInAddressBook*
AllowUMCallsFromNonUsers	*msExchUMListInDirectorySearch*
CallAnsweringAudioCodec	*msExchUMAudioCodec*
Certificate	*userCertificate*
CommonName	*cn*
DeletedItemFlags	*deletedItemFlags*
DeliverToMailboxAndForward	*deliverAndRedirect*
Description	*description*
DistinguishedName	*distinguishedName*
ElcExpirationSuspensionEndDate	*msExchELCExpirySuspensionEnd*
ElcExpirationSuspensionStartDate	*msExchELCExpirySuspensionStart*
ElcMailboxFlags	*msExchELCMailboxFlags*
ExchangeGuid	*msExchMailboxGuid*
ExchangeSecurityDescriptor	*msExchMailboxSecurityDescriptor*
ExchangeVersion	*msExchVersion*
ExpansionServer	*msExchExpansionServerName*

ExternalOofOptions	*msExchExternalOOFOptions*
Fax	*facsimileTelephoneNumber*
ForwardingAddress	*altRecipient*
GrantSendOnBehalfTo	*publicDelegates*
GroupType	*groupType*
Guid	*objectGuid*
HasActiveSyncDevicePartnership	Not applicable
HiddenGroupMembershipEnabled	*hideDLMembership*
HomeMTA	*homeMTA*
HomePhone	*homePhone*
Id	*distinguishedName*
ImapEnabled	Not applicable
IncludedRecipients	Not applicable
Initials	*initials*
InternetEncoding	*internetEncoding*
LdapRecipientFilter	*msExchDynamicDLFilter*
LegacyExchangeDN	*legacyExchangeDN*
LinkedMasterAccount	Not applicable
LocaleID	*localeID*
MailboxFolderSet	*msExchMailboxFolderSet*
ManagedBy	*managedBy*
MAPIEnabled	Not applicable

MapiRecipient	*mAPIRecipient*
MasterAccountSid	*msExchMasterAccountSid*

Filterable properties for the -Filter parameter

Exchange Server 2013 > Recipients > Filters in recipient Shell commands >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-01-07*

This topic lists the filterable properties for the *-Filter* parameter in Microsoft Exchange 2013.

Use the *-Filter* parameter to return the objects from a **Get-** command in a filtered list. For example, if you want the **Get-Contact** cmdlet to return a subset of all of the contacts in your Microsoft Exchange organization, you would use the *-Filter* parameter. The subset of objects that is returned is based on specific properties.

The *-Filter* parameter is used in the following cmdlets:

- Get-CASMailbox
- Get-Contact
- Get-DistributionGroup
- Get-DynamicDistributionGroup
- Get-Group
- Get-Mailbox
- Get-MailContact
- Get-MailboxStatistics
- Get-MailPublicFolder
- Get-MailUser
- Get-Recipient
- Get-RemoteMailbox
- Get-UMMailbox
- Get-User

Common filterable properties

The following table contains the common filterable properties for the *-Filter* parameter. This table lists the name of the property, the Lightweight Directory Access Protocol (LDAP) display name, a description of the property, the possible values that the property can take, and each of the cmdlets that accept this property for the *-Filter* parameter. You can use the LDAP display name to convert your Exchange Server 2003 or earlier LDAP filters into Exchange Opath filters. For more information about converting LDAP filters to Opath filters, see the Microsoft Exchange Team Blog article, Need help converting your LDAP filters to OPATH.

Note:

The content of each blog and its URL are subject to change without notice. The content within each blog is provided "AS IS" with no warranties, and confers no rights. Use of included script samples or code is subject to the terms specified in the Microsoft Terms of Use.

Note:

Not all filterable properties have an LDAP display name. The properties that do not have an LDAP display name are not Active Directory directory service properties. They are properties that are calculated by Exchange.

Note:

Many of the properties for the *-Filter* parameter accept wildcard characters. If you use a wildcard character, use the *-like* operator instead of the *-eq* operator. The *-like* operator is used to find pattern matches in rich types, such as strings, whereas the *-eq* operator is used to find an exact match.

Property name	LDAP display name	Description	Value	Cmdlets that accept this property

AcceptMessagesOnlyFrom	*authOrig*	This property contains the mailbox users and mail-enabled contacts that can send email messages to this distribution group.	• Distinguished name (DN) • Canonical name • Globally unique identifier (GUID) • Name • Display name • Alias • Exchange DN • Primary Simple Mail Transfer Protocol (SMTP) address	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-RemoteMailbox
AcceptMessagesOnlyFromDLMembers	*dLMemSubmitPerms*	This property contains the distribution groups that are allowed to send email messages to this distribution group.	• DN • Canonical name • GUID • Name • Display name • Alias • Exchange DN • Primary SMTP address	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-RemoteMailbox
ActiveSyncAllowedDeviceIDs	*msExchMobileAllowedDeviceIds*	This property contains a list of device IDs that are allowed to synchronize with	Device IDs	Get-CASMailbox

		the mailbox.		
ActiveSyncDebugLogging	*msExchMobileDebugLogging*	This property specifies whether error logging is enabled for mobile devices.	• String • Wildcard character accepted	Get-CASMailbox
ActiveSyncEnabled	Not applicable	This property specifies whether Exchange ActiveSync is enabled for the mailbox	• Boolean • $true or $false	Get-CASMailbox
ActiveSyncMailboxPolicy	*msExchMobileMailboxPolicyLink*	This property contains the name of the Exchange ActiveSync mailbox policy for the mailbox.	• String • Wildcard character accepted	Get-CASMailbox Get-Recipient
AddressListMembership	*showInAddressBook*	This property contains the address lists and global address list (GAL) to which the recipient is a member.	DN	Get-Recipient
Alias	*mailNickname*	This property contains the alias (the generic name used to identify a	• String • Wildcard character accepted	Get-DistributionGroup Get-DynamicDistributi

		mail account) of the recipient. The alias can be a combination of characters separated by a period with no intervening spaces.		onGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox
AllowUMCallsFromNonUsers	*msExchUMListInDirectorySearch*	This property specifies whether to exclude the mailbox from directory searches.	• 0 or None • 1 or SearchEnabled	Get-Contact Get-UMMailbox Get-User
AssistantName	*msExchAssistantName*	This property contains the assistant name of the user or contact.	• String • Wildcard character accepted	Get-Contact Get-User
CallAnsweringAudioCodec	*msExchUMAudioCodec*	This property contains the audio codec to use for call answering messages. The default for the user's mailbox is the audio codec that is configured	• 0 or G711 • 1 or Wma • 2 or Gsm	Get-UMMailbox

		on the Unified Messaging (UM) dial plan.		
City	*L*	This property contains the city name of the recipient.	• String • Wildcard character accepted	Get-Contact Get-Recipient Get-User
Company	*Company*	This property contains the company name of the recipient.	• String • Wildcard character accepted	Get-Contact Get-Recipient Get-User
CountryOrRegion	Not applicable	This property contains the country or region in which the recipient resides.	• Country/Region • You can locate valid *CountryOrRegion* values on the **Address and Phone** tab in the recipient's properties.	Get-Contact Get-Recipient Get-User
CustomAttribute1	*extensionAttribute1*	This property contains a custom attribute that you can add to a mailbox, mail contact, mail user, mail-enabled public folder, dynamic distribution group, or	• String • Wildcard character accepted	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser

		distribution group.		Get-Recipient Get-RemoteMailbox
CustomAttribute2	*extensionAttribute2*	This property contains a custom attribute that you can add to a mailbox, mail contact, mail user, mail-enabled public folder, dynamic distribution group, or distribution group.	• String • Wildcard character accepted	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox
CustomAttribute3	*extensionAttribute3*	This property contains a custom attribute that you can add to a mailbox, mail contact, mail user, mail-enabled public folder, dynamic distribution group, or distribution group.	• String • Wildcard character accepted	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-

				RemoteMailbox
CustomAttribute4	*extensionAttribute4*	This property contains a custom attribute that you can add to a mailbox, mail contact, mail user, mail-enabled public folder, dynamic distribution group, or distribution group.	• String • Wildcard character accepted	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox
CustomAttribute5	*extensionAttribute5*	This property contains a custom attribute that you can add to a mailbox, mail contact, mail user, mail-enabled public folder, dynamic distribution group, or distribution group.	• String • Wildcard character accepted	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox
CustomAttribute6	*extensionAttribut*	This property	• String	Get-

	e6	contains a custom attribute that you can add to a mailbox, mail contact, mail user, mail-enabled public folder, dynamic distribution group, or distribution group.	• Wildcard character accepted	DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox
CustomAttribute7	*extensionAttribute7*	This property contains a custom attribute that you can add to a mailbox, mail contact, mail user, mail-enabled public folder, dynamic distribution group, or distribution group.	• String • Wildcard character accepted	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox
CustomAttribute8	*extensionAttribute8*	This property contains a custom attribute that you	• String • Wildcard character accepted	Get-DistributionGroup Get-

		can add to a mailbox, mail contact, mail user, mail-enabled public folder, dynamic distribution group, or distribution group.		DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox
CustomAttribute9	*extensionAttribute9*	This property contains a custom attribute that you can add to a mailbox, mail contact, mail user, mail-enabled public folder, dynamic distribution group, or distribution group.	• String • Wildcard character accepted	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox
CustomAttribute10	*extensionAttribute10*	This property contains a custom attribute that you can add to a mailbox, mail	• String • Wildcard character accepted	Get-DistributionGroup Get-DynamicDistributionGroup

		contact, mail user, mail-enabled public folder, dynamic distribution group, or distribution group.		Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox
CustomAttribute11	*extensionAttribute11*	This property contains a custom attribute that you can add to a mailbox, mail contact, mail user, mail-enabled public folder, dynamic distribution group, or distribution group.	• String • Wildcard character accepted	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox
CustomAttribute12	*extensionAttribute12*	This property contains a custom attribute that you can add to a mailbox, mail contact, mail user, mail-enabled public folder,	• String • Wildcard character accepted	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact

		dynamic distribution group, or distribution group.		Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox
CustomAttribute13	*extensionAttribute13*	This property contains a custom attribute that you can add to a mailbox, mail contact, mail user, mail-enabled public folder, dynamic distribution group, or distribution group.	• String • Wildcard character accepted	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox
CustomAttribute14	*extensionAttribute14*	This property contains a custom attribute that you can add to a mailbox, mail contact, mail user, mail-enabled public folder, dynamic distribution	• String • Wildcard character accepted	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder

		group, or distribution group.		Get-MailUser Get-Recipient Get-RemoteMailbox
CustomAttribute15	*extensionAttribute15*	This property contains a custom attribute that you can add to a mailbox, mail contact, mail user, mail-enabled public folder, dynamic distribution group, or distribution group.	• String • Wildcard character accepted	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox
Database	*homeMDB*	This property contains the mailbox database.	DN	Get-Mailbox Get-Recipient
Department	*department*	This property contains the department of the user or contact.	• String • Wildcard character accepted	Get-Contact Get-Recipient Get-User
DisplayName	*displayName*	This property contains the ambiguous name resolution (ANR)	• String • Wildcard character accepted	Get-CASMailbox Get-Contact Get-DistributionGroup

		search for the display name of the recipient.		Get-DynamicDistributionGroup Get-Group Get-Mailbox Get-MailboxStatistics Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox Get-UMMailbox Get-User
DistinguishedName	*distinguishedName*	This property contains the DN of the recipients for which you are filtering.	DN	Get-CASMailbox Get-Contact Get-DistributionGroup Get-DynamicDistributionGroup Get-Group Get-Mailbox Get-MailContact Get-MailPublicFolder

				Get-MailUser Get-Recipient Get-RemoteMailbox Get-UMMailbox Get-User
EmailAddresses	*proxyAddresses*	This property contains the email addresses of this recipient. All Exchange 2007 email address types are valid. Separate multiple values with commas.	• Email address • Wildcard character accepted	Get-CASMailbox Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox Get-UMMailbox
EmailAddressPolicyEnabled	Not applicable	This property contains the control for applying email address policies to this recipient.	• Boolean • $true or $false	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact

				Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox
ExchangeGuid	*msExchMailboxGuid*	This property contains the GUID for the identity of the mailbox.	GUID	Get-Mailbox
ExchangeVersion	*msExchVersion*	This property contains the earliest version of Exchange that you can use to manage the returned object.	String	Get-CASMailbox Get-Contact Get-DistributionGroup Get-DynamicDistributionGroup Get-Group Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox Get-UMMailbox Get-User

ExpansionServer	*msExchExpansionServerName*	This property contains the name of the Exchange server on which to expand the distribution group or dynamic distribution group.	Server name	Get-DistributionGroup Get-DynamicDistributionGroup Get-Recipient
ExternalEmailAddress	*targetAddress*	This property contains the external email address. Email messages sent to the mail-enabled user are sent to this external address.	• Email address • Wildcard character accepted	Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox
ExternalOofOptions	*msExchExternalOOFOptions*	This property contains the option for sending an out-of-office message to external senders.	• InternalOnly • External	Get-Mailbox
Fax	*facsimileTelephoneNumber*	This property contains the fax number of the user or contact.	• String • Wildcard character accepted	Get-Contact Get-User
FirstName	*givenName*	This property	• String	Get-Contact

		contains the ANR search for the first name of the recipient.	• Wildcard character accepted	Get-Recipient Get-User
ForwardingAddress	*altRecipient*	This property contains the forwarding address to which messages are sent.	Existing SMTP address	Get-Mailbox Get-MailPublicFolder
GrantSendOnBehalfTo	*publicDelegates*	This property contains the DN of other mailboxes that can send messages on behalf of this recipient.	DN	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-RemoteMailbox
GroupType	*groupType*	This property contains the group type in Active Directory.	• DomainLocal • SecurityEnabled • Global • Universal • BuiltinLocal	Get-DistributionGroup Get-Group
Guid	*objectGuid*	This property contains the GUID for the identity of	GUID	Get-CASMailbox Get-Contact Get-

		the Active Directory object.		DistributionGroup Get-DynamicDistributionGroup Get-Group Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox Get-UMMailbox Get-User
HiddenFromAddressListsEnabled	*msExchHideFromAddressLists*	This property specifies whether the user is visible in the address list.	• Boolean • $true or $false	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox

HomePhone	*homePhone*	This property contains the home phone number of the user or contact.	• String • Wildcard character accepted	Get-Contact Get-User
IncludedRecipients	Not applicable	This property contains the recipient types that are used to build the dynamic distribution group.	• AllRecipients • MailboxUsers • Resources • MailContacts • MailGroups • Mail Users • None	Get-DynamicDistributionGroup
Initials	*initials*	This property contains the initials for the name of the user or contact.	• String • Wildcard character accepted	Get-Contact Get-User
IsLinked	Not applicable	This property specifies whether a folder is linked to a master folder.	• Boolean • $true or $false	Get-Mailbox
IsMailboxEnabled	Not applicable	This property specifies whether a mailbox is mailbox-enabled.	• Boolean • $true or $false	Get-Mailbox
IsResource	Not applicable	This property specifies whether a mailbox is a resource mailbox.	• Boolean • $true or $false	Get-Mailbox

IsShared	Not applicable	This property specifies whether a resource mailbox is shared.	• Boolean • $true or $false	Get-Mailbox
IssueWarningQuota	*mDBStorageQuota*	This property contains the mailbox size at which a warning message is sent to the user.	Unlimited or integer	Get-Mailbox
LanguagesRaw	*msExchUserCulture*	This property contains the language preference for this mailbox.	An acceptable value for this parameter is a combination of an International Organization for Standardization (ISO) 639 two-letter lowercase culture code that is associated with a language and an ISO 3166 two-letter uppercase subculture code that is associated with a country or region. For example, United States English is represented as `en-us`. To learn more about culture codes and for	Get-Mailbox

			a full list of acceptable values, see CultureInfo Class in the MSDN Library.	
LastName	*sn*	This property contains the ANR search for the last name of the recipient.	• String • Wildcard character accepted	Get-Contact Get-Recipient Get-User
LinkedMasterAccount	Not applicable	If this mailbox is a linked mailbox, this property contains the master account in the forest in which the user account resides.	• GUID • DN • Domain\Account • User principal name (UPN) • LegacyExchangeDN • SmtpAddress • Alias	Get-CASMailbox Get-Mailbox Get-UMMailbox
ManagedBy	*managedBy*	This property contains the DN of the user or contact that manages this group.	DN	Get-DistributionGroup Get-DynamicDistributionGroup Get-Group Get-Recipient
ManagedFolderMailboxPolicy	*msExchMailboxTemplateLink*	This property contains the managed folder mailbox policy that controls messaging	• Name • GUID • DN	Get-Mailbox Get-Recipient

		records management (MRM) for the mailbox.		
Manager	*manager*	This property contains the manager of the recipient.	• String • Wildcard character accepted	Get-Contact Get-Recipient Get-User
MaxBlockedSenders	*msExchMaxBlockedSenders*	This property contains the maximum number of senders that can be included in the Blocked Senders list.	Integer	Get-Mailbox
MaxReceiveSize	*delivContLength*	This property contains the maximum size of messages that this recipient can receive.	Unlimited or integer	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-RemoteMailbox
MaxSafeSenders	*msExchMaxSafeS*	This property	Integer	Get-Mailbox

	enders	contains the maximum number of senders that can be included in the Safe Senders list.		
MaxSendSize	*submissionContLength*	This property contains the maximum size of messages that this recipient can send.	Unlimited or integer	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-RemoteMailbox
MemberOfGroup	*memberOf*	This property contains the groups of which the recipient is a member.	String	Get-CASMailbox Get-Contact Get-DistributionGroup Get-DynamicDistributionGroup Get-Group Get-Mailbox Get-MailContact Get-MailUser

				Get-MailPublicFolder Get-Recipient Get-RemoteMailbox Get-UMMailbox Get-User
MobilePhone	*mobile*	This property contains the mobile phone number of the user or contact.	• String • Wildcard character accepted	Get-Contact Get-User
Name	*name*	This property contains the name of the recipient.	String	Get-CASMailbox Get-Contact Get-DistributionGroup Get-DynamicDistributionGroup Get-Group Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox

				Get-UMMailbox Get-User
Notes	*info*	This property contains specific comments about the recipient.	• String • Wildcard character accepted	Get-Contact Get-DynamicDistributionGroup Get-Group Get-Recipient Get-User
Office	*physicalDeliveryOfficeName*	This property contains the office of the recipient.	String	Get-Contact Get-Mailbox Get-Recipient Get-User
OfflineAddressBook	*msExchUseOAB*	This property contains the offline address book (OAB) that is associated with this mailbox.	• Name • GUID • DN	Get-Mailbox
OperatorNumber	*msExchUMOperatorNumber*	This property contains the string of digits for the personal operator.	• String • Wildcard character accepted	Get-UMMailbox
OtherFax	*otherFacsimileTelephoneNumber*	This property contains the additional fax number of the	• String • Wildcard character accepted	Get-Contact Get-User

		user or contact.		
OtherHomePhone	*otherHomePhone*	This property contains the additional home phone number of the user or contact.	• String • Wildcard character accepted	Get-Contact Get-User
OtherTelephone	*otherTelephone*	This property contains the additional telephone number of the user or contact.	• String • Wildcard character accepted	Get-Contact Get-User
Pager	*pager*	This property contains the pager number of the user or contact.	• String • Wildcard character accepted	Get-Contact Get-User
Phone	*telephoneNumber*	This property contains the phone number of the recipient.	• String • Wildcard character accepted	Get-Contact Get-Recipient Get-User
PhoneticDisplayName	*msDS-PhoneticDisplayName*	This property contains a phonetic pronunciation of the *DisplayName* property. UM uses this property for automatic	• String • Wildcard character accepted	Get-Contact Get-DynamicDistributionGroup Get-Group Get-MailPublicFolder

		speech recognition.		Get-User
PoliciesExcluded	*msExchPoliciesExcluded*	This property contains the GUIDs of any policies that are excluded.	GUID	Get-Recipient
PostalCode	*postalCode*	This property contains the postal code of the user or contact.	• String • Wildcard character accepted	Get-Contact Get-Recipient Get-User
PostOfficeBox	*postOfficeBox*	This property contains the post office box number of the user or contact.	• String • Wildcard character accepted	Get-Contact Get-User
PrimarySmtpAddress	Not applicable	This property contains the primary SMTP address, which is the email address that external users will see when they receive a message from this recipient.	SMTP address	Get-CASMailbox Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-

				RemoteMailbox Get-UMMailbox
ProhibitSendQuota	*mDBOverQuotaLimit*	This property contains the mailbox size at which the user associated with this mailbox can no longer send messages.	Unlimited or integer	Get-Mailbox
ProhibitSendReceiveQuota	*mDBOverHardQuotaLimit*	This property contains the mailbox size at which the user associated with this mailbox can no longer send or receive messages.	Unlimited or integer	Get-Mailbox
PublicFolderContacts	*pFContacts*	This property contains the contacts for the public folder.	Multiple DNs	Get-MailPublicFolder
PublicFolderType	*msExchPFTreeType*	This property specifies the public folder type.	• GeneralPurpose • MAPI • Network News Transfer Protocol (NNTP) • NotSpecified	Get-MailPublicFolder
RecipientFilter	*msExchQueryFilter*	This property contains the recipient filter	String	Get-DynamicDistributionGroup

		that has been applied.		
RecipientLimits	*msExchRecipLimit*	This property contains the maximum number of recipients per message to which this mailbox can send.	Unlimited or integer	Get-Mailbox Get-MailContact Get-MailUser Get-RemoteMailbox
RecipientType	Not applicable	This property specifies the recipient type.	• UserMailbox • MailUser • MailContact • MailUniversalDistributionGroup • MailUniversalSecurityGroup • MailNonUniversalGroup • DynamicDistributionGroup • PublicFolder	Get-Contact Get-DistributionGroup Get-DynamicDistributionGroup Get-Group Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox Get-User
RecipientTypeDetails	Not applicable	This property specifies the recipient subtype.	• ConferenceRoomMailbox • EquipmentMailbox	Get-Contact Get-DistributionGroup

			• LegacyMailbox • LinkedMailbox • UserMailbox • MailContact • DynamicDistributionGroup • MailForestContact • MailNonUniversalGroup • MailUniversalDistributionGroup • MailUniversalSecurityGroup • MailUser • PublicFolder • SharedMailbox	Get-DynamicDistributionGroup Get-Group Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox Get-User
RejectMessagesFrom	*unauthOrig*	This property contains the recipients from whom messages will be rejected by this recipient.	• DN • Canonical name • GUID • Name • Display name • Alias • Exchange DN • Primary SMTP address	Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-RemoteMailbox
RejectMessagesFromDLMembers	*dLMemRejectPerms*	This property specifies the distribution	• DN • Canonical name • GUID	Get-DistributionGroup Get-

		groups from which this recipient will reject messages.	• Name • Display name • Alias • Exchange DN • Primary SMTP address	DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-RemoteMailbox
ResourceCapacity	*msExchResourceCapacity*	This property contains the capacity of this resource mailbox.	Non-negative integer	Get-Mailbox
ResourceCustom	Not applicable	This property contains custom properties for this resource mailbox.	Custom property defined by **Set-ResourceConfig**	Get-Mailbox
RetainDeletedItemsFor	*garbageCollPeriod*	This property contains the length of time to keep deleted items.	Time span: *dd.hh:mm:ss* where *dd* = days, *hh* = hours, *mm* = minutes, and *ss* = seconds	Get-Mailbox
RulesQuota	*msExchMDBRulesQuota*	This property contains the limit for the size of rules for this mailbox.	String	Get-Mailbox
SamAccountNam	*SamAccountNam*	This property	String	Get-CASMailbox

e	*e*	contains the logon name that is used to support client computers and servers running older versions of Microsoft Windows operating systems.		Get-DistributionGroup Get-Group Get-Mailbox Get-MailUser Get-Recipient Get-RemoteMailbox Get-UMMailbox Get-User
SendOofMessageToOriginatorEnabled	*oOFReplyToOriginator*	This property specifies whether out-of-office messages from distribution group members are sent to the message sender.	• Boolean • $true or $false	Get-DistributionGroup Get-DynamicDistributionGroup
ServerName	Not applicable	This property contains the name of the server on which the object resides	Server name	Get-CASMailbox Get-Mailbox Get-MailboxStatistics Get-Recipient Get-UMMailbox
SimpleDisplayName	*displayNamePrintable*	This property contains an alternative display name of	• String • Wildcard character accepted	Get-Contact Get-DistributionGroup Get-

		the object when only a limited set of characters is permitted.		DynamicDistributionGroup Get-Group Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-RemoteMailbox Get-User
StateOrProvince	*st*	This property contains the state or province information that is defined for this recipient.	• String • Wildcard character accepted	Get-Contact Get-Recipient Get-User
StreetAddress	*streetAddress*	This property contains the street address that is defined for the user or contact.	String	Get-Contact Get-User
TelephoneAssistant	*telephoneAssistant*	This property contains the telephone number of the contact's assistant.	• String • Wildcard character accepted	Get-Contact Get-User

Title	*title*	This property contains the title of the recipient.	String	Get-Contact Get-Recipient Get-User
UMDtmfMap	*msExchUMDtmfMap*	This property contains a user-defined dual tone multi-frequency (DTMF) map for the UM-enabled user. DTMF is also referred to as *touch-tone*.	• String • Wildcard character accepted	Get-Contact Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-RemoteMailbox Get-UMMailbox Get-User
UMEnabled	Not applicable	This property specifies whether UM is enabled for this mailbox.	• Boolean • $true or $false	Get-Mailbox Get-Recipient Get-UMMailbox
UMMailboxPolicy	*msExchUMTemplateLink*	This property contains the UM mailbox policy for the mailbox. You use UM mailbox policies to set UM	String	Get-Recipient Get-UMMailbox

		settings for UM-enabled users, such as personal identification number (PIN) policies and dialing restrictions.		
UMRecipientDialPlanId	*msExchUMRecipientDialPlanLink*	This property contains the dial plan identifier for the mailbox, user, or contact.	DN	Get-Contact Get-UMMailbox Get-User
UseDatabaseQuotaDefaults	*mDBUseDefaults*	This property specifies whether the mailbox uses the quota attributes for the mailbox database in which this mailbox resides. The quota attributes are: ProhibitSendQuota, ProhibitSendReceiveQuota, IssueWarningQuota, and RulesQuota.	• Boolean • $true or $false	Get-Mailbox
UserPrincipalNa	*userPrincipalNam*	This property	• User logon name • User principal	Get-Mailbox

me	*e*	contains the UPN for this recipient. The UPN is the logon name for the user and consists of a user name and a suffix. Typically, the suffix is the domain name in which the user account resides.	name • Wildcard character accepted	Get-MailUser Get-Recipient Get-RemoteMailbox Get-User
WhenChanged	*WhenChanged*	This property contains the date and time stamp when the object was last changed.	Date-time stamp	Get-CASMailbox Get-Contact Get-DistributionGroup Get-DynamicDistributionGroup Get-Group Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-Recipient Get-RemoteMailbox Get-UMMailbox

				Get-User
WhenCreated	*whenCreated*	This property contains the date and time stamp when the object was created. Filterable properties for the -ContentFilter parameter

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-11-19*

This topic lists the filterable properties for the *ContentFilter* parameter. The *ContentFilter* parameter is used to export messages to a .pst file that match the filter. The *ContentFilter* parameter is used in the New-MailboxExportRequest cmdlet.

Filterable properties

Many of the properties for the *ContentFilter* parameter accept wildcard characters. If you use a wildcard character, use the **-like** operator instead of the **-eq** operator. The **-like** operator is used to find pattern matches in rich types, such as strings, whereas the **-eq** operator is used to find an exact match.

The following table contains a list of the filterable properties for the *ContentFilter* parameter. This table lists the name of the property, a description, the acceptable values, and a syntax example. For more information about OPATH filters, see Filters in recipient Shell commands.

Property	Description	Values	Example syntax
All	This property returns all messages that have a particular string in any of the indexed properties. For example, use this property if you want to	String Wildcard	`-ContentFilter {A`

	export all messages that have "Ayla" as the recipient, the sender, or have the name mentioned in the message body.		
Attachment	This property returns messages that have the specified string in the content of an attachment or in the attachment's file name.	String Wildcard	`-ContentFilter {A`
BCC	This property returns sent messages that have the specified recipient in the Bcc field.	Display name Alias SMTP address LegacyDN Wildcard	`-ContentFilter {(`
Body	This property returns messages that have the specified string within the message body.	String Wildcard	`-ContentFilter {B`
Category	This property returns messages that have a matching category. Categories are set by users or Inbox rules.	String Wildcard	`-ContentFilter {C`
CC	This property returns sent messages that have the specified	Display name Alias SMTP address	`-ContentFilter {(`

	recipient in the Cc field.	LegacyDN Wildcard	
Expires	This property returns messages that have a specified expiration time stamp.	Date-Time stamp	`-ContentFilter {`
HasAttachment	This property returns messages with or without attachments.	Boolean `$true` or `$false`	`-ContentFilter {`
Importance	This property returns messages that have a specified importance level.	0 or "Low" 1 or "Normal" 2 or "High"	`-ContentFilter {` `-ContentFilter {`
IsFlagged	This property returns messages that have been flagged by the user or Inbox rule.	Boolean `$true` or `$false`	`-ContentFilter {`
IsRead	This property returns messages that have been read or not read by the user.	Boolean `$true` or `$false`	`-ContentFilter {`
MessageKind	This property returns messages that are of the specified type.	Calendar Contact Doc Email Fax InstantMessage Journal	`-ContentFilter {` `-ContentFilter {`

		Note Post RSSFeed Task Voicemail	
MessageLocale	This property returns messages that are of the specified locale.	CultureInfo	`-ContentFilter {M` `-ContentFilter {M`
Participants	This property returns messages that have the specified recipient in the To, Bcc, or Cc fields.	Display name Alias SMTP address LegacyDN Wildcard	`-ContentFilter {(`
PolicyTag	This property returns messages that have a policy tag. The Exchange store persists policy tags as GUIDs. Therefore, the string can contain either an explicit GUID value, which is then searched by the PR_POLICY_TAG, or a wildcard string. If the supplied value isn't a GUID, the command uses Active Directory information	String Wildcard	`-ContentFilter {P`

	to resolve names to GUIDs.		
Received	This property returns messages that were received with the specified Received time stamp.	Date-Time stamp	`-ContentFilter {R` `{(Received -lt '(`
Sender	This property returns messages that were received from the specified sender.	Display name Alias SMTP address LegacyDN Wildcard	`ContentFilter {Se`
Sent	This property returns messages that were sent by with the specified Sent time stamp.	Date-Time stamp	`-ContentFilter {S` `-ContentFilter {(`
Size	This property returns messages that are of a specific size.	B (bytes) KB (kilobytes) MB (megabytes)	`-ContentFilter {S`
Subject	This property returns messages that have the specified string within the subject of the message.	String Wildcard	`-ContentFilter {S`
To	This property returns sent messages that have the specified	Display name Alias SMTP address	`-ContentFilter {T`

	recipient in the To field.	LegacyDN Wildcard	

Manage Permissions for Recipients

Exchange Server 2013 > Recipients >

Applies to: *Exchange Online*

Topic Last Modified: *2014-06-02*

You can use the EAC or the Shell to assign permissions to users or groups (called *delegates*) that allow them to open or send messages from other mailboxes. Permissions can be assigned to user mailboxes, linked mailboxes, resource mailboxes, and shared mailboxes. You can also assign permissions to distribution groups, dynamic distribution groups, and mail-enabled security groups to allow delegates to send messages on behalf of the group. You can assign delegates the following permissions to access mailboxes or send messages on behalf of mailboxes or groups:

- **Full Access** This permission allows a delegate to open a user's mailbox and access the contents of the mailbox. However, assigning the Full Access permission doesn't allow the delegate to send mail from the mailbox. You have to assign the delegate the Send As or the Send on Behalf permission to send mail.

The Full Access permission isn't available when configuring permissions for groups.

Note:

If you assign the Full Access permission to access a mailbox that is hidden from address lists, the delegate won't be able to open the mailbox.

- **Send As** This permission allows delegates to use the mailbox to send messages. After this permission is assigned to a delegate, any message that the delegate sends from the mailbox will appear to have been sent by the mailbox owner. However, this permission doesn't allow a delegate to sign in to the user's mailbox. It only allows users to open the mailbox. If this permission is assigned to a group, a message sent by the delegate will appear to have been sent by the group.
- **Send on Behalf** This permission also allows a delegate to use the mailbox to send messages. After this permission is assigned to a delegate, the **From** address in any message sent by the delegate indicates that the message was sent by the delegate on behalf of the mailbox owner.

The Send on Behalf permission isn't available when configuring permissions for shared mailboxes.

What do you need to know before you begin?

- Estimated time to complete each procedure: 2 minutes.
- Procedures in this topic require specific permissions. See each procedure for its permissions

information.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Assign permissions to a mailbox

As previously stated, you can assign delegates permissions to user mailboxes, linked mailboxes, resource mailboxes, and shared mailboxes. You can also use the Shell to assign delegates permissions to access a discovery mailbox.

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Permissions and delegation" entry in the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.

Use the EAC to assign permissions

The following procedure shows how to assign permissions to a user mailbox. You follow a similar procedure to assign permissions to resource or shared mailboxes by navigating to the **Resources** or **Shared** page in the EAC and selecting the mailbox to assign the permissions to.

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of mailboxes, click the mailbox that you want to assign permissions for, and then click **Edit** .
3. On the mailbox properties page, click **Mailbox Delegation**.
4. To assign permissions to delegates, click **Add +** under the appropriate permission to display a page that lists all recipients in your Exchange organization that can be assigned the permission. Select the recipients you want, add them to the list, and then click **OK**. You can also search for a specific recipient by typing the recipient's name in the search box and then clicking **Search** .

To remove a permission for a recipient, under the appropriate permission, select the recipient and then click **Remove −**.

5. Click **Save** to save your changes.

Use the EAC to bulk assign permissions

Use the following steps to bulk assign permissions.

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. Select the mailboxes that you wish to assign permissions to.
3. Click or tap **More options** in the right pane, and under **Mailbox Delegation** choose, **Add**.
4. On the **bulk add delegation** page, click or tap **Add +** under the appropriate permission to display a page that lists all recipients in your Exchange organization that can be assigned the

permission. Select the recipients you want, add them to the list, and then click **OK**.

To remove a permission for recipients, under the appropriate permission, select the recipients and then click **Remove** −.

Use the EAC to assign a user permission to send email from another user's mailbox

The following procedure shows how to assign a user permission to send email from another user's mailbox.

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of mailboxes, click the mailbox that you want to assign send as permissions for, and then click **Edit** ✎.
3. On the mailbox properties page, click **Mailbox Delegation**.
4. To assign permissions to delegates, click **Add** + under **Send As** or **Send on Behalf** to display a page that lists all recipients in your Exchange organization that can be assigned the permission. Select the recipients you want, add them to the list, and then click **OK**. You can also search for a specific recipient by typing the recipient's name in the search box and then clicking **Search** 🔍.

The **Send As** permission allows the delegate to send email from this mailbox.

The **Send on Behalf** permission allows the delegate to send email on behalf of this mailbox. The **From** line in any message sent by a delegate indicates that the message was sent by the delegate on behalf of the mailbox owner.

Note:
If the user also needs to be able to open and view the content of that mailbox, you must also assign the user the **Full Access** permission.

5. Click **Save** to save your changes.

Use the EAC to assign a user permission to send email from a group

The following procedure shows how to assign a user permission to send email from a group.

1. In the EAC, navigate to **Recipients** > **Groups**.
2. In the list of groups, click the group that you want to assign send as permissions for, and then click **Edit** ✎.
3. On the group properties page, click **Group Delegation**.
4. To assign permissions to delegates, click **Add** + under **Send As** or **Send on Behalf** to display a page that lists all recipients in your Exchange organization that can be assigned the permission. Select the recipients you want, add them to the list, and then click **OK**. You can also search for a specific recipient by typing the recipient's name in the search box and then clicking **Search** 🔍.

The **Send As** permission allows the delegate to send email from this group.

The **Send on Behalf** permission allows the delegate to send email on behalf of this group. The **From** line in any message sent by a delegate indicates that the message was sent by the delegate on behalf of the group.

5. Click **Save** to save your changes.

Use the EAC to assign full access permissions

The following procedure shows how to assign full access permissions to a user mailbox.

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of mailboxes, click the mailbox that you want to assign full access permissions for, and then click **Edit** .
3. On the mailbox properties page, click **Mailbox Delegation**.
4. To assign permissions to delegates, click **Add +** under **Full Access** to display a page that lists all recipients in your Exchange organization that can be assigned the permission. Select the recipients you want, add them to the list, and then click **OK**. You can also search for a specific recipient by typing the recipient's name in the search box and then clicking **Search** .

The **Full Access** permission allows a delegate to open a user's mailbox and access the contents of the mailbox.

Note:
Assigning the **Full Access** permission doesn't allow the delegate to send mail from the mailbox. You have to assign the delegate the **Send As** or the **Send on Behalf** permission to send mail.

5. Click **Save** to save your changes.

Use the Shell to assign permissions

The following sections show how to use the Shell to manage Full Access, Send As, and Send on Behalf permissions for mailboxes.

Manage the Full Access permission

The following examples show how to use the **Add-MailboxPermission** and **Remove-MailboxPermission** cmdlets to manage Full Access permissions.

This example assigns the delegate Raymond Sam the Full Access permission to the mailbox of Terry Adams.

```
Add-MailboxPermission -Identity "Terry Adams" -User
raymonds -AccessRights FullAccess -InheritanceType all
```

This example assigns Esther Valle the Full Access permission to the organization's default discovery search mailbox.

```
Add-MailboxPermission -Identity
"DiscoverySearchMailbox{D919BA05-46A6-415f-80AD-
7E09334BB852}" -User estherv -AccessRights FullAccess -
InheritanceType all
```

This example assigns members of the Helpdesk distribution group the Full Access permission to the Helpdesk Tickets shared mailbox.

```
Add-MailboxPermission "HelpdeskTickets" -User helpdesk -
```

```
AccessRights FullAccess -InheritanceType all
```

This example removes Jim Hance's Full Access permission to Ayla Kol's mailbox.

```
Remove-MailboxPermission -Identity ayla -User "Jim Hance" -
AccessRights FullAccess -Inheritance
```

For detailed syntax and parameter information, see the following topics:

- Add-MailboxPermission
- Remove-MailboxPermission

Manage the Send As permission

The following examples show how to manage Send As permissions in Exchange Server 2013 and in Exchange Online. In Exchange 2013, you have to use the **Add-ADPermission** and **Remove-ADPermission** cmdlets; in Exchange Online, you have to use the **Add-RecipientPermission** and **Remove-RecipientPermission** cmdlets. In both cases, you use the *Identity* parameter to specify the name of the mailbox on which the Send As permission should be added or removed and the *User* or *Trustee* parameter to specify the delegate (for example, a user or group) that will be assigned or unassigned the Send As permission.

Tip:
Use the **Get-Recipient** cmdlet to retrieve the *Name* property for the mailbox and the delegate. Use these values to assign the Send As permission.

Exchange Server 2013

This example assigns the Send As permission to the Helpdesk group on the shared mailbox Helpdesk Support Team.

```
Add-ADPermission -Identity helpdesksupport -User
helpdeskgroup -ExtendedRights "Send As"
```

This example removes the Send As permission for the user Pilar Pinilla on the mailbox of James Alvord.

```
Remove-ADPermission -Identity "James Alvord" -User pilarp -
ExtendedRights "Send As"
```

For detailed syntax and parameter information, see:

- Add-ADPermission
- Remove-ADPermission

Exchange Online

This example assigns the Send As permission to the Printer Support group on the shared mailbox named Contoso Printer Support.

```
Add-RecipientPermission -Identity "Contoso Printer Support"
-Trustee "Printer Support" -AccessRights SendAs
```

This example removes the Send As permission for the user Karen Toh on the mailbox for Yan Li.

```
Remove-RecipientPermission -Identity "Yan Li" -Trustee
"Karen Toh" -ExtendedRights SendAs
```

For detailed syntax and parameter information, see:

- **Add-RecipientPermission**
- **Remove-RecipientPermission**

Manage the Send on Behalf permission

The following examples show how to use the **Set-Mailbox** cmdlet to manage Send on Behalf permissions.

This example assigns the delegate Holly Holt the Send on Behalf permission to the mailbox of Sean Chai.

```
Set-Mailbox -Identity seanc@contoso.com -
GrantSendOnBehalfTo hollyh
```

This example removes the Send on Behalf permission on the Contoso Executives shared mailbox that was assigned to the Temporary Executive Assistants group.

```
Set-Mailbox "Contoso Executives" -GrantSendOnBehalfTo
@{remove="tempassistants@contoso.com"}
```

For detailed syntax and parameter information, see Set-Mailbox.

How do you know this worked?

To verify that you've successfully assigned permissions to a mailbox or a shared mailbox, do one of the following:

- In the EAC:
  1. Navigate to **Recipients** > **Mailbox** or **Shared**, click the mailbox, and then click **Edit** ✎.
  2. On the mailbox properties page, click **Mailbox Delegation**.
  3. If you assigned permissions to a recipient, verify that the user or group is listed under the appropriate permission. If you removed permissions, verify that the recipient isn't listed under the appropriate permission.

Or

- In the Shell, run one of the following commands, depending on the permission you managed.
  - **Full Access**

```
Get-MailboxPermission -Identity <mailbox>
```

To verify whether a specific delegate is assigned the Full Access permission to a mailbox, run the following command.

```
Get-MailboxPermission -Identity <mailbox> -User <delegate>
```

- **Send As**

In Exchange Server 2013, run the following command.

```
Get-ADPermission -Identity <name of mailbox> -User
<delegate>
```

In Exchange Online, run the following command.

```
Get-RecipientPermission -Identity <mailbox> -Trustee
<delegate>
```

- **Send on Behalf**

```
Get-Mailbox -Identity <mailbox> | FL GrantSendOnBehalfTo
```

Assign permissions to a group

As previously stated, you can assign the Send As and Send on Behalf permissions to distribution groups, dynamic distribution groups, and mail-enabled security groups to allow delegates to send messages as the group or on behalf of the group.

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Distribution groups" and "Dynamic distribution groups" entries in the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.

Use the EAC to assign permissions

1. In the EAC, navigate to **Recipients** > **Groups**.
2. In the list of groups, click the group that you want to assign permissions for, and then click **Edit** .
3. On the group properties page, click **Group Delegation**.
4. To assign permissions to delegates, click **Add +** under the appropriate permission to display a page that displays a list of all recipients in your Exchange organization that can be assigned the permission. Select the recipients you want, add them to the list, and then click **OK**. You can also search for a specific recipient by typing the recipient's name in the search box and then clicking **Search** .

To remove permission for a recipient, under the appropriate permission, select the recipient and then click **Remove −**.

5. Click **Save** to save your changes.

Use the Shell to assign permissions

The following sections show how to use the Shell to manage Send As and Send on Behalf permissions for groups.

Manage the Send As permission

The following examples show how to manage Send As permissions for groups in Exchange Server 2013 and in Exchange Online. In Exchange 2013, you have to use the **Add-ADPermission** and **Remove-ADPermission** cmdlets. In Exchange Online, you have to use the **Add-RecipientPermission** and **Remove-RecipientPermission** cmdlets. In both cases, you use the *Identity* parameter to specify the name of the group on which the Send As permission should be added or removed and the *User* or *Trustee* parameter to specify the delegate (for example, a user or group) that will be assigned or unassigned the Send As permission.

Tip:

Use the **Get-Recipient** cmdlet to retrieve the *Name* property for the group and the delegate. Use these values to assign the Send As permission.

Exchange Server 2013

This example assigns the Send As permission to the Sales Admins group for the group named Contoso Sales Info. This allows members of the sales admin group to send messages as the Contoso Sales Information group.

```
Add-ADPermission -Identity "Contoso Sales Info" -User
"Sales Admins" -ExtendedRights "Send As"
```

This example removes the Send As permission for the user Alan Shen on the group Corporate IT Admins.

```
Remove-ADPermission -Identity "Corporate IT Admins" -User
contoso\alans -ExtendedRights "Send As"
```

For detailed syntax and parameter information, see:

- Add-ADPermission
- Remove-ADPermission

Exchange Online

This example assigns the Send As permission to the Contoso Admins group on the dynamic distribution group named Emergency Broadcast Messages.

```
Add-RecipientPermission -Identity
emergencybroadcast@contoso.com -Trustee "Contoso Admins" -
AccessRights SendAs
```

This example removes the Send As permission for the user Walter Harp on the Printer Resources security group.

```
Remove-RecipientPermission -Identity "Printer Resources" -
Trustee walterh@contoso.com ExtendedRights SendAs
```

For detailed syntax and parameter information, see:

- **Add-RecipientPermission**
- **Remove-RecipientPermission**

Manage the Send on Behalf permission

The following examples show how to use the **Set-DistributionGroup** and **Set-DynamicDistributionGroup** cmdlets to manage Send on Behalf permissions for groups.

This example assigns the delegate Sara Davis the Send on Behalf permission to the Printer Support distribution group.

```
Set-DistributionGroup -Identity printersupport@contoso.com
-GrantSendOnBehalfTo sarad
```

This example assigns the delegate Administrator the Send on Behalf permission to the All Employees dynamic distribution group.

```
Set-DynamicDistributionGroup -Identity "All Employees" -
GrantSendOnBehalfTo administrator
```

This example removes the Send on Behalf permission on the All Employees dynamic distribution group that was assigned to the administrator.

```
Set-DynamicDistributionGroup "All Employees" -
GrantSendOnBehalfTo @{remove="administrator"}
```

For detailed syntax and parameter information, see:

- Set-DistributionGroup
- Set-DynamicDistributionGroup

How do you know this worked?

To verify that you've successfully assigned permissions to a group, do one of the following:

- In the EAC:
  1. Navigate to **Recipients** > **Groups**, click the group, and then click **Edit** ✎.
  2. On the group properties page, click **Group Delegation**.
  3. If you assigned permissions to a recipient, verify that the user or group is listed under the appropriate permission. If you removed permissions, verify that the recipient isn't listed under the appropriate permission.

Or

- In the Shell, run one of the following commands depending on the permission you managed.
  - **Send As**

In Exchange Server 2013, run the following command.

```
Get-ADPermission -Identity <name of group> -User <delegate>
```

In Exchange Online, run the following command.

```
Get-RecipientPermission -Identity <group> -Trustee
<delegate>
```

  - **Send on Behalf**

```
Get-DistributionGroup -Identity <group> | FL
GrantSendOnBehalfTo
```

Or

```
Get-DynamicDistributionGroup -Identity <group> | FL
GrantSendOnBehalfTo
```

Unsupported characters for Exchange 2013 object names

Exchange Server 2013 > Recipients >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-04-22*

This article describes characters that you can't use in object or component names in Exchange 2013. When you create names for objects or components in Exchange 2013, the names can't contain unsupported characters, even though you may be able to create an object using an unsupported character. Also, if you try to import or connect to objects whose names contain unsupported characters, you may receive an error message or experience unexpected behavior.

Unsupported characters

The following table lists characters that aren't supported for use in the names of Exchange-related objects or components. The table also lists the scenario in which problems may occur if unsupported characters are used. Note that there is a maximum length of 64 characters for each

object listed in the table.

Exchange object or component	Exchange scenario	Unsupported characters
Email domain name	Simple Mail Transfer Protocol (SMTP) connector	~ ` ! @ # $ % ^ & * ( ) + = { } | [ ] \ : " ; < > , . ? /
Host name of connector address space	Mail flow	. . (two periods)
Host name for Exchange servers	SMTP	_ (underscore)
Organization or site name	Running the Setup program or moving mailboxes	~ ` ! @ # $ % ^ & * ( ) _ + = { } | [ ] \ : " ; ' < > , . ? /
Organization internal directory name	Directory	~ ` ! @ # $ % ^ & * ( ) _ + = { } | [ ] \ : " ; ' < > , . ? /
Public folder tree name	Viewing and creating the public folder	: ;
Recipient name	SMTP	' "
Recipient policy SMTP address	Viewing the public folder hierarchy	~ ` ! @ # $ % ^ & * ( ) + = { } | [ ] \ : " ; < > , . ? /
Recipient policy SMTP address host name	Mail flow	. . (two periods)
Site internal directory name	Viewing the public folder hierarchy	? ( ) *
Smart host name	SMTP	Leading or trailing spaces

Automatic mailbox distribution

Exchange Server 2013 > Recipients >

Applies to: *Exchange Server 2010 Service Pack 2 (SP2)*

Topic Last Modified: *2013-08-13*

When you create or move a mailbox, or mail-enable an existing user, that mailbox needs to be stored in a mailbox database. In Microsoft Exchange Server 2013, you have the option of letting Exchange choose the database for you using automatic mailbox distribution.

With automatic mailbox distribution, Exchange looks at the mailbox databases in your organization, excludes databases that aren't suitable using criteria discussed later in this topic, and then randomly chooses a database where the mailbox should be located. This process randomly distributes mailboxes across all of the suitable mailbox databases in your organization.

Automatic distribution is used when you don't specify the *Database* parameter on the **New-Mailbox** and **Enable-Mailbox** cmdlets or the *TargetDatabase* parameter on the **New-MoveRequest** cmdlet.

Note:

Automatic mailbox distribution is performed only when a mailbox is created on an Exchange 2013 server, moved to an Exchange 2013 server, or when a user is mail-enabled. The **New-Mailbox**, **New-MoveRequest**, and **Enable-Mailbox** cmdlets must be run from a server running Exchange 2013. Exchange doesn't redistribute mailboxes to distribute load across databases automatically based on server load.

The following process is used to find a suitable mailbox database where a new or moved mailbox should be located:

1. Exchange retrieves a list of all mailbox databases in the Exchange 2013 organization.
2. Any mailbox database that's marked for exclusion from the distribution process is removed from the available list of databases. You can control which databases are excluded. For more information, see Exclude Databases from Automatic Distribution later in this topic.
3. Any mailbox database that's outside of the database management scopes applied to the administrator performing the operation is removed from the list of available databases. For more information, see Database Scopes later in this topic.
4. Any mailbox database that's outside of the local Active Directory site where the operation is being performed is removed from the list of available databases.
5. From the remaining list of mailbox databases, Exchange chooses a database randomly. If the database is online and healthy, the database is used by Exchange. If it's offline or not healthy, another database is chosen at random. If no online or healthy databases are found, the operation fails with an error.

The process of selecting a mailbox database is performed by the Mailbox Resources Management Agent cmdlet extension agent. The `Mailbox Resources Management Agent` is one of several cmdlet extension agents that extend the functionality of running cmdlets. For more information about cmdlet extension agents, see Cmdlet extension agents.

If you never want mailboxes to be distributed automatically, you can disable the `Mailbox Resources Management Agent`. When you disable the agent, the change is applied to the entire Exchange

organization. For more information about how to disable cmdlet extension agents, see Manage cmdlet extension agents.

Exclude Databases from Automatic Distribution

By default, all online and healthy mailbox databases on Exchange 2013 servers in the local Active Directory site can be chosen by automatic mailbox distribution to store a new or moved mailbox. However, you might want to exclude some databases from the distribution process for various reasons. For example, you may designate a mailbox database as a journaling database in which only mailboxes you manually specify should be located. Or you might want to temporarily remove a database from rotation to perform scheduled maintenance. Exchange 2013 gives you the option to either permanently or temporarily exclude databases from the exclusion process using the *IsExcludedFromProvisioning* parameter that can be set using the **Set-MailboxDatabase** cmdlet.

Note:

Two other parameters, *IsSuspendedFromProvisioning* and *IsExcludedFromInitialProvisioning*, are also available on the **Set-MailboxDatabase** cmdlet. These parameters will be removed in a future release of Exchange and their use isn't supported.

The *IsExcludedFromProvisioning* parameter has have two valid values, `$True` and `$False`. When you set this property to `$True`, the mailbox database is excluded from the automatic distribution process. When you set it to `$False`, the mailbox database is included in the automatic distribution process. The default value is `$False`.

To exclude a mailbox database from automatic distribution, use the following command:

```
Set-MailboxDatabase <database name> -
IsExcludedFromProvisioning $True
```

When a mailbox database is excluded from automatic distribution, the only way to create a mailbox in, or move a mailbox to, the database is to use the *Database* parameter on the **New-Mailbox** and **Enable-Mailbox** cmdlets or the *TargetDatabase* parameter on the **New-MoveRequest** cmdlet.

Database Scopes

Database management scopes are an additional level of control over the automatic mailbox distribution process that are available in Exchange 2013. If a mailbox database is online and healthy, it's in the local Active Directory site, and it isn't excluded from the automatic distribution process, Exchange 2013 checks to see if the mailbox database is included in the database scope applied to the administrator running the cmdlet. If it's included in the database scope, it's included in the list of databases available to that administrator.

Database scopes are part of the Role Based Access Control (RBAC) permissions model. For more

information about RBAC and database scopes, see the following topics:

- Understanding Role Based Access Control
- Understanding management role scopes

Database scopes can be useful if you have many mailbox databases in your local Active Directory site that are available to automatic distribution, but you want to limit which databases can be used by certain sets of administrators. For example, your Exchange 2013 servers may serve several agencies but you only want to allow each agency to create or move mailboxes to mailbox databases that are allocated to them.

By default, all administrators in an Exchange 2013 organization can see all of the mailbox databases in the organization. To limit the databases that they can see, and therefore limit the databases they can potentially create mailboxes in or move mailboxes to, you must do the following:

1. Create a custom database management scope using the **New-ManagementScope** cmdlet that includes only the mailbox databases you want the administrator to use.
2. Associate the new database scope with a management role assignment in one of the following ways:
   - Add the new database scope to an existing management role assignment using the *CustomConfigWriteScope* parameter on the **Set-ManagementRoleAssignment** cmdlet. The database scope is now applied to the management role group, universal security group (USG), or user assigned the role assignment.
   - Create a management role assignment using the **New-ManagementRoleAssignment** cmdlet and use the *CustomConfigWriteScope* parameter to specify the new database scope. You can create a role assignment between a management role and a role group, USG, or user.
3. If you created a role assignment to a role group or USG, add users to the role group or USG so that the role assignment and database scope are applied to the users.
4. If applicable, remove the user (or users who are members of role groups or USGs you created in the preceding steps) you assigned the new role assignment to from any other role groups or USGs that might be assigned a database scope that contains databases you don't want them to access.
5. Verify that the administrators have access only to the databases they should have access to.

After you complete these steps, the administrators that are assigned role assignments with the database scopes you created will only be able to create mailboxes in or move mailboxes to the databases you specified.

For more information about how to use database scopes to limit which mailbox databases are available to administrators, see Control automatic mailbox distribution using database scopes.

Collaboration

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-12-07*

Exchange 2013 provides the following rich features that can help your end users easily collaborate in email:

- Site mailboxes
- Public folders
- Shared mailboxes
- Distribution groups

Each of these features has a different user experience and feature set and should be used based on what the user needs to accomplish and what your organization can provide. For example, site mailboxes provide great documentation collaboration features. However site mailboxes rely on SharePoint Server 2013, so if you aren't planning on deploying SharePoint, you should use public folders to share documents.

This topic compares these collaboration features to help you decide which features to offer your users.

Site mailboxes

A site mailboxe is functionally comprised of a SharePoint 2013 site membership (owners and members), shared storage through an Exchange 2013 mailbox for email messages, and a SharePoint 2013 site to store and share. Essentially, site mailboxes bring Exchange email and SharePoint documents together. For users, a site mailbox serves as a central filing cabinet for the project, providing a place to file project email and documents that can be accessed and edited only by site members. In addition, site mailboxes have a specified lifecycle and are optimized to be used for projects that have set start and end dates. To fully implement site mailboxes, end users must use Outlook 2013.

To learn more, see Site mailboxes.

Public folders

Public folders are designed for shared access and provide an easy and effective way to collect, organize, and share information with other people in your workgroup or organization.

Public folders organize content in a deep hierarchy that's easy to browse. Users discover interesting and relevant content by browsing through branches of the hierarchy that are relevant to them. Users always see the full hierarchy in their Outlook folder view. Public folders are a great technology for distribution group archiving. A public folder can be mail-enabled and added as a member of the distribution group. Email sent to the distribution group is automatically added to the public folder for later reference. Public folders also provide simple document sharing and don't require SharePoint Server 2013 to be installed in your organization. Finally, end users can use public folders

with the following supported Outlook clients: Outlook 2007, Outlook 2010, and Outlook 2013.

To learn more, see Public folders.

Shared mailboxes

A shared mailbox is a mailbox that multiple designated users can access to read and send email messages and to share a common calendar. Shared mailboxes can provide a generic email address (such as info@contoso.com or sales@contoso.com) that customers can use to inquire about your company. If the shared mailbox has the Send As permission assigned when a delegated user responds to the email message, it can appear as though the mailbox (for example, sales@contoso.com) is responding, not the actual user.

To learn more, see Shared mailboxes.

Groups

Groups (also called distribution groups) are a collection of two or more recipients that appears in the shared address book. When an email message is sent to a group, it's received by all members of the group. Distribution groups can be organized by a particular discussion subject (such as "Dog Lovers") or by users who share a common work structure that requires them to communicate frequently.

To learn more, see Recipients.

Which one to use?

The following table gives you a quick glance at each of the collaboration features to help you decide which one to use.

Site mailboxes	Public folders	Shared mailboxes	Groups	
Type of group	Users who work together as a team on a specific project with definitive start and end dates.	With the proper permissions, everyone in your organization can access and search public folders. Public folders are ideal for maintaining history	Delegates working on behalf of a virtual identity, and they can respond to email as that shared mailbox identity. Example: support@tailspintoys.com	Users who need to send email to a group of recipients with a common interest or characteristic.

		or distribution group conversations.		
Ideal group size	Small	Large	Small	Large
Access	Site mailbox owners and members.	Accessible by anyone in your organization.	Users can be granted Full Access and/or Send As permissions. If granted Full Access permissions, users must also add the shared mailbox to their Outlook profile to access the shared mailbox.	For distribution groups, members, must be manually added. For dynamic distribution groups, members are added based on filtering criteria.
Shared calendar?	No	Yes	Yes	No
Email arrives in user's personal Inbox?	No. Email arrives in the site mailbox.	No. Email arrives in the public folder.	No. Email arrives in the Inbox of the shared mailbox.	Yes. Email arrives in the Inbox of a distribution group member.
Supported clients	• Outlook 2013 • SharePoint 2013	• Outlook 2013 • Outlook 2010 • Outlook 2007	• Outlook 2013 • Outlook Web App • Outlook 2010 • Outlook 2007	• Outlook 2013 • Outlook Web App • Outlook 2010 • Outlook 2007

Site mailboxes

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-13*

Email and documents are traditionally kept in two unique and separate data repositories. Most organizations collaborate using both mediums. The challenge is that both email and documents are accessed using different clients. This usually results in a reduction in user productivity and a degraded user experience.

The *site mailbox* is a new concept in Microsoft Exchange 2013 that attempts to solve this problem. Site mailboxes improve collaboration and user productivity by allowing access to both Microsoft SharePoint 2013 documents and Exchange email using the same client interface. A site mailbox is functionally comprised of SharePoint 2013 site membership (owners and members), shared storage through an Exchange 2013 mailbox for email messages and a SharePoint 2013 site for documents, and a management interface that addresses provisioning and lifecycle needs.

Site mailboxes require Exchange 2013 and SharePoint Server 2013 integration and configuration. For more information about how to configure your Exchange 2013 organization to work with your SharePoint Server 2013 organization, see the following topics:

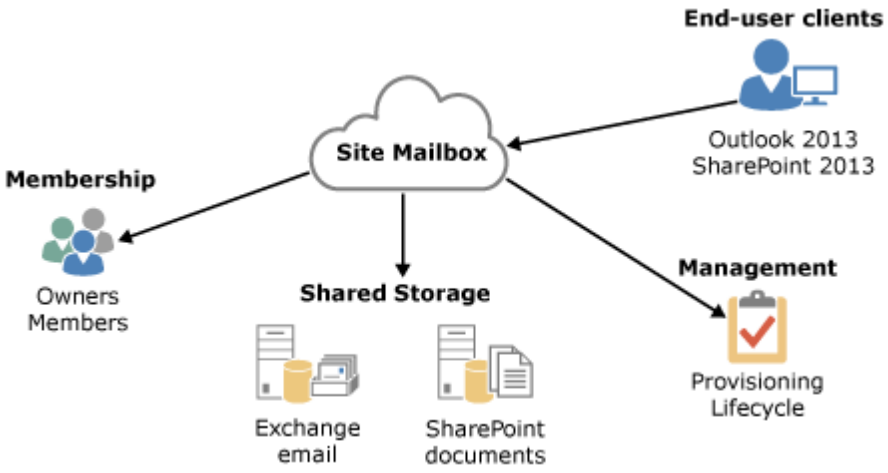
- Configure site mailboxes in SharePoint Server 2013.
- Integration with SharePoint and Lync

For more information about collaboration features in Exchange Server 2013, see Collaboration.

Contents

How do site mailboxes work?

When one project member files mail or documents using the site mailbox, any project member can then access the content. Site mailboxes are surfaced in Outlook 2013 and give users easy access to the email and documents for the projects they care about. Additionally, the same set of content can be accessed directly from the SharePoint site itself. With site mailboxes, the content is kept where it belongs. Exchange stores the email, providing users with the same message view for email conversations that they use every day for their own mailboxes. Meanwhile, SharePoint stores the documents, bringing document coauthoring and versioning to the table. Exchange synchronizes just enough metadata from SharePoint to create the document view in Outlook (e.g. document title, last modified date, last modified author, size).



Site mailbox provisioning policies

Site mailbox quotas can be set by using the **SiteMailboxProvisioningPolicy** cmdlets in the Exchange Management Shell. The Site mailbox provisioning policies only apply to the email that is sent to and from the site mailbox and the size of the site mailbox on the Exchange server. The document repository settings are configured in SharePoint. Although you can create multiple site mailbox provisioning policies using the **New-SiteMailboxProvisioningPolicy** cmdlet, only the default provisioning policy will be applied to all site mailboxes. You can't apply multiple policies within your organization. The provisioning policies allow you to set the following quotas:

Quota	Description	Default setting
IssueWarningQuota	The *IssueWarningQuota* parameter specifies the site mailbox size that triggers a warning message to the site mailbox	4.5 GB
MaxReceiveSize	The *MaxReceiveSize* parameter specifies the maximum size of email messages that can be received by the site mailbox.	36 MB
ProhibitSendReceiveQuota	The *ProhibitSendReceiveQuota* parameter specifies the size at which the site mailbox can no longer send or receive messages.	5 GB

For more information about how to configure site mailbox provisioning policies, see Manage site mailbox provisioning policies.

Return to top

Lifecycle policy and retention

The lifecycle of a site mailbox is managed through a SharePoint. It is through SharePoint that you should perform all site mailbox tasks such as creating and removing site mailboxes. In addition, you can create a SharePoint Lifecycle policy to manage the lifecycle of a site mailbox. For example, you can create a lifecycle policy in SharePoint that automatically closes all site mailboxes after 6 months. If the user still requires the use of the site mailbox, the user can reactivate the site mailbox through SharePoint. We recommend that you use the Lifecycle application is in the farm. Manually deleting active site mailboxes from Exchange will result in orphaned site mailboxes. .

When the lifecycle application in SharePoint closes a site mailbox, the site mailbox is retained for the period stated in the lifecycle policy in the closed state. The mailbox can then be reactivated by an end-user or by an administrator from SharePoint. After the retention period, the Exchange site mailbox that is housed in the mailbox database will have its name prepended with **MDEL:** to indicate that it has been marked for deletion. You will need to manually remove these site mailboxes from the mailbox database in order to free storage space and the alias. If you don't have the SharePoint Lifecycle Policy enabled, you'll lose the ability to determine which site mailboxes are marked for deletion. Until the site mailbox has been removed by an administrator, the content of the mailbox is still recoverable.

You can use the following command to search for and remove site mailboxes that have been marked for deletion.

```
Get-Mailbox MDEL:* | ?{$_.RecipientTypeDetails -eq
"TeamMailbox"} | Remove-Mailbox -Confirm:$false
```

Site mailboxes don't support retention at the item-level. Retention works on a project-level for site mailboxes, so when the entire site mailbox is deleted, the retained items will be deleted.

Compliance

Using the eDiscovery Console in SharePoint, site mailboxes can be part of the In-Place eDiscovery scope as you can do keyword searches against user mailboxes or site mailboxes. In addition, you can put a site mailbox on legal hold. For more info, see In-Place eDiscovery.

Return to top

Backup and restore

Backup and Restore for the Exchange site mailboxes housed on the mailbox server will use the same backup and restore method that you use for all Exchange mailboxes. For more information,

see Database availability groups.

For SharePoint documents, you should backup and restore into the same place. If you restore your SharePoint content to same URLs, then the site mailbox will continue to work and no additional configuration is needed. If you restore to a different URL, then you'll need to run **Set-SiteMailbox** cmdlet to update the *SharePointURL* property. We recommend that you don't restore SharePoint to a new forest.

Manage site mailbox provisioning policies

Exchange Server 2013 > Collaboration > Site mailboxes >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-21*

Site mailbox provisioning policies apply only to email that's sent to and from the site mailbox and to the size of the site mailbox on the Exchange server.

To learn more about site mailboxes, see Site mailboxes.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the"Site mailboxes" entry in the Sharing and collaboration permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.
- Although you can create multiple site mailbox provisioning policies, only the default provisioning policy will be applied to all site mailboxes. You can't apply multiple policies within your organization.
- You can't use the Exchange Administration Center (EAC) to perform this procedure. You must use the Shell.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Create a site mailbox provisioning policy

This example creates the default provisioning policy SM_ProvisioningPolicy with the following settings:

- The warning quota for the site mailboxes is 9 GB.
- The site mailboxes are prohibited from receiving messages when the mailbox size reaches 10 GB.
- The maximum size of email messages that can be sent to site mailboxes is 50 MB.

```
New-SiteMailboxProvisioningPolicy -Name
SM_ProvisioningPolicy -IsDefault -IssueWarningQuota 9GB -
ProhibitSendReceiveQuota 10GB -MaxReceiveSize 50MB
```

View the settings of a site mailbox provisioning policy

This example returns detailed information about all site mailbox provisioning policies in your organization.

```
Get-SiteMailboxProvisioningPolicy | Format-List
```

This example returns all policies in your organization, but only displays the `IsDefault` information to identify which policy is the default policy.

```
Get-SiteMailboxProvisioningPolicy | Format-List IsDefault
```

Make changes to an existing site mailbox provisioning policy

This example changes the site mailbox provisioning policy named Default to allow the maximum size of email messages that can be received by the site mailbox to 25 MB. (When you install Exchange, a provisioning policy is created with the name **Default**.)

```
Set-SiteMailboxProvisioningPolicy -Identity Default -
MaxReceiveSize 25MB
```

This example changes the warning quota to 9.5 GB and the prohibit send and receive quota to 10 GB.

```
Set-SiteMailboxProvisioningPolicy -Identity Default -
IssueWarningQuota 9GB -ProhibitSendReceiveQuota 10GB
```

Configure a site mailbox name prefix

When a new site mailbox is created, by default its email address will have a prefix. The email address prefix allows you to easily search for and query site mailboxes and may help users recognize them as well. If you choose, you can disable the prefix, or change the prefix for your tenant in Office 365 or for a given forest in an on-premises deployment. With the default prefix behavior, if your site mailbox is created in Office 365, the default prefix is **SMO-**. Alternatively, if your site mailbox is created in your on-premises deployment, the prefix is **SM-**. The default behavior differs between these premises so that hybrid customers will not experience conflicts if site mailboxes are created in both locations and are then synced cross-premises.

This example disables the prefix naming by setting the *DefaultAliasPrefixEnabled* parameter to $false.

```
Set-SiteMailboxProvisioningPolicy -Identity Default -
DefaultAliasPrefixEnabled $false -AliasPrefix $null
```

This example changes the default provisioning policy and sets the *AliasPrefix* to FOREST01.

Note:

For deployments with multiple forests, it is recommended that a different prefix is used in each forest in order to prevent conflicts when objects are synced across forests, in the event that site mailboxes have been created with the same name in two or more forests.

```
Set-SiteMailboxProvisioningPolicy -Identity Default -
AliasPrefix FOREST01 -DefaultAliasPrefixEnabled $false
```

Note:

In the case of a hybrid deployment where you have Exchange on-premises and in Office 365, all cloud-based site mailboxes are created with the prefix **SMO-**. The prefixes are different in Office 365 and Exchange on-premises so that hybrid customers will not experience conflicts if site mailboxes are created in both locations and are then synced cross-premises.The AliasPrefix parameter takes precedence over the DefaultAliasPrefixEnabled parameter; therefore, if the *AliasPrefix* parameter is set to a valid, non-null string, each new site mailbox will have that string prepended to the alias.

Delete a site mailbox provisioning policy

This example deletes the default site mailbox policy that was created during Exchange Setup.

```
Remove-SiteMailboxProvisioningPolicy -Identity Default
```

Important:

You must first create and designate another default policy before you can remove the policy named **Default**.

For detailed syntax and parameter information, see the following topics:

New-SiteMailboxProvisioningPolicy

Get-SiteMailboxProvisioningPolicy

Set-SiteMailboxProvisioningPolicy

Remove-SiteMailboxProvisioningPolicy

Public folders

Exchange Server 2013 > Collaboration >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-08-18*

Public folders are designed for shared access and provide an easy and effective way to collect, organize, and share information with other people in your workgroup or organization. Public folders help organize content in a deep hierarchy that's easy to browse. Users will see the full hierarchy in Outlook, which makes it easy for them to browse for the content they're interested in.

Note:
Public folders are available in the following Outlook clients: Outlook Web App for Exchange 2013, Outlook 2007, Outlook 2010, Outlook 2013, and Outlook for Mac.

Public folders can also be used as an archiving method for distribution groups. When you mail-enable a public folder and add it as a member of the distribution group, email sent to the group is automatically added to the public folder for later reference.

Public folders aren't designed for the following purposes:

- **Data archiving** Users who have mailbox limits sometimes use public folders instead of mailboxes to archive data. This practice isn't recommended because it affects storage in public folders and undermines the goal of mailbox limits. Instead, we recommend that you use In-Place Archiving as your archiving solution.
- **Document sharing and collaboration** Public folders don't provide versioning or other document management features, such as controlled check-in and check-out functionality and automatic notifications of content changes. Instead, we recommend that you use SharePoint as your documentation sharing solution.

To learn more about public folders and other collaboration methods in Exchange 2013, see Collaboration.

To browse some frequently asked questions about public folders in Exchange 2013, see FAQ: Public folders.

For more information about the limits and quotas for public folders, see Limits for public folders.

For a list of public folder management tasks, see Public folder procedures.

Looking for the Exchange Online version of this topic? See **Public folders in Office 365 and Exchange Online**.

Contents

Public folder architecture

In Exchange 2013, public folders were re-engineered using mailbox infrastructure to take advantage of the existing high availability and storage technologies of the mailbox database. Public folder architecture uses specially designed mailboxes to store both the public folder hierarchy and the content. This also means that there's no longer a public folder database. High availability for the public folder mailboxes is provided by a database availability group (DAG). To learn more about DAGs, see Database availability groups.

The main architectural components of public folders are the public folder mailboxes, which can reside in one or more mailbox databases.

Public folder mailboxes

There are two types of public folder mailboxes: the *primary hierarchy mailbox* and *secondary hierarchy mailboxes*. Both types of mailboxes can contain content:

- **Primary hierarchy mailbox** The primary hierarchy mailbox is the one writable copy of the public folder hierarchy. The public folder hierarchy is copied to all other public folder mailboxes, but these will be read-only copies.
- **Secondary hierarchy mailboxes** Secondary hierarchy mailboxes contain public folder content as well and a read-only copy of the public folder hierarchy.

There are two ways you can manage public folder mailboxes:

- In the Exchange admin center (EAC), navigate to **Public folders** > **Public folder mailboxes**.
- In the Exchange Management Shell, use the ***-Mailbox** set of cmdlets. The following parameters

have been added to the New-Mailbox cmdlet to support public folder mailboxes:

- *PublicFolder* This parameter is used with the **New-Mailbox** cmdlet to create a public folder mailbox. When you create a public folder mailbox, a new mailbox is created with the mailbox type of `PublicFolder`. For more information, see Create a public folder mailbox.
- *HoldForMigration* This parameter is used only if you are migrating public folders from a previous version to Exchange 2013. For more information, see Migrate Public folders from previous versions later in this topic.
- *IsHierarchyReady* This parameter indicates whether the public folder mailbox is ready to serve the public folder hierarchy to users. It's set to `$True` only after the entire hierarchy has been synced to the public folder mailbox. If the parameter is set to $False, users won't use it to access the hierarchy. However, if you set the *DefaultPublicFolderMailbox* property on a user mailbox to a specific public folder mailbox, the user will still access the specified public folder mailbox even if the *IsHierarchyReady* parameter is set to `$False`.
- *IsExcludedFromServingHierarchy* This parameter prevents users from accessing the public folder hierarchy on the specified public folder mailbox. For load-balancing purposes, users are equally distributed across public folder mailboxes by default. When this parameter is set on a public folder mailbox, that mailbox isn't included in this automatic load balancing and won't be accessed by users to retrieve the public folder hierarchy. However, if you set the *DefaultPublicFolderMailbox* property on a user mailbox to a specific public folder mailbox, the user will still access the specified public folder mailbox even if the *IsExcludedFromServingHierarchy* parameter is set for that public folder mailbox.

A secondary hierarchy mailbox will serve only public folder hierarchy information to users if it's specified explicitly on the users' mailboxes using the *DefaultPublicFolderMailbox* property, or if the following conditions are met:

- The *IsHierarchyReady* property on the public folder mailbox is set to `$True`.
- The *IsExcludedFromServingHierarchy* on the public folder mailbox is set to `$False`.

Public folder hierarchy

The public folder hierarchy contains the folders' properties and organizational information, including tree structure. Each public folder mailbox contains a copy of the public folder hierarchy. There's only one writeable copy of the hierarchy, which is in the primary public folder mailbox. For a specific folder, the hierarchy information is used to identify the following:

- Permissions on the folder
- The folder's position in the public folder tree, including its parent and child folders

Note:
The hierarchy doesn't store information about email addresses for mail-enabled public folders. The email addresses are stored on the directory object in Active Directory.

Hierarchy synchronization

The public folder hierarchy synchronization process uses Incremental Change Synchronization (ICS), which provides a mechanism to monitor and synchronize changes to an Exchange store hierarchy or

content. The changes include creating, modifying, and deleting folders and messages. When users are connected to and using content mailboxes, synchronization occurs every 15 minutes. If no users are connected to content mailbox, synchronization will be triggered less often (every 24 hours).If a write operation such as a creating a folder is performed on the primary hierarchy, synchronization is triggered immediately (synchronously) to the content mailbox.

Important:
Because there's only one writeable copy of the hierarchy, folder creation is proxied to the hierarchy mailbox by the content mailbox users are connected to.

In a large organization, when you create a new public folder mailbox, the hierarchy must synchronize to that public folder before users can connect to it. Otherwise, users may see an incomplete public folder structure when connecting with Outlook. To allow time for this synchronization to occur without users attempting to connect to the new public folder mailbox, set the *IsExcludedFromServingHierarchy* parameter on the **New-Mailbox** cmdlet when creating the public folder mailbox. This parameter prevents users from connecting to the newly created public folder mailbox. When synchronization is complete, run the Set-Mailbox cmdlet with the *IsExcludedFromServingHierarchy* parameter set to `false`, indicating that the public folder mailbox is ready to be connected to. You can use also the Get-PublicFolderMailboxDiagnostics cmdlet to view the sync status by the *SyncInfo* and the *AssistantInfo* properties.

For more information, see Create a public folder.

Public folder content

Public folder content can include email messages, posts, documents, and eForms. The content is stored in the public folder mailbox but isn't replicated across multiple public folders mailboxes. All users access the same public folder mailbox for the same set of content. Although a full text search of public folder content is available, public folder content isn't searchable across public folders and the content isn't indexed by Exchange Search.

Considerations

Although there are many advantages to using Exchange 2013 public folders, there are some things to consider before implementing them in your organization:

- It's very important that you carefully plan you public folder deployment. Because there's only one replica of any particular public folder, planning is critical to avoid severe delays in accessing the folders. For example, you can plan to separate heavily used public folders across multiple public folder mailboxes for load balancing purposes.
- Exchange 2013 no longer supports public folder databases. Therefore, there's no coexistence with legacy public folders. As a result, Exchange 2013 is unable to read from the hierarchy stored in a public folder database on Exchange 2010 or Exchange 2007 servers.
- Outlook Web App is supported, but with limitations. You can add and remove favorite public

folders and perform item-level operations such as creating, editing, deleting posts, and replying to posts. However, you can't create or delete public folders from Outlook Web App.

- Although a full text search of public folder content is available, public folder content isn't searchable across public folders and the content isn't indexed by Exchange Search.
- You must use Outlook 2007 or later to access public folders on Exchange 2013 servers.
- Retention policies aren't supported for public folder mailboxes.

Migrate public folders from previous versions

If you already have Exchange 2010 SP3 or Exchange 2007 SP3 RU10 public folders in your organization prior to installing Exchange 2013, you must migrate those public folders to Exchange 2013. To do this, use the **PublicFolderMigrationRequst** cmdlets. For more information, see Migrate public folders to Exchange 2013 from previous versions. If your organization is moving to Exchange Online, you can migrate your public folders to the cloud and upgrade them at the same time. For details, see Migrate legacy public folders to Office 365 and Exchange Online.

Due to the changes in how public folders are stored, legacy Exchange mailboxes are unable to access the public folder hierarchy on Exchange 2013 servers or on Exchange Online. However, user mailboxes on Exchange 2013 servers or Exchange Online can connect to legacy public folders. Exchange 2013 public folders and legacy public folders can't exist in your Exchange organization simultaneously. This effectively means that there's no coexistence between versions. Migrating public folders to Exchange Server 2013 or Exchange Online is currently a one-time cutover process.

For this reason, it's recommended that prior to migrating your public folders, you should first migrate your legacy mailboxes to Exchange 2013 or Exchange Online. For more information about migrating mailboxes, see Mailbox moves in Exchange 2013, **Migrate all mailboxes to Exchange Online with a cutover migration**, and **Migrate mailboxes to Exchange Online with a staged migration**

Public folder moves

You can move public folders to a different public folder mailbox, and you can move public folder mailboxes to different mailbox databases. To move public folders to different public folder mailboxes, use the **PublicFolderMoveRequest** set of cmdlets. Subfolders under the public folder that's being moved won't be moved by default. If you want to move a branch of public folders, you can use the `Move-PublicFolderBranch.ps1` script that's installed by default with Exchange 2013. For more information, see Move a public folder to a different public folder mailbox.

In addition to moving public folders, you can move public folder mailboxes to different mailbox databases by using the **MoveRequest** set of cmdlets. This is the same set of cmdlets that are used for moving regular mailboxes. For more information, see Move a public folder mailbox to a different mailbox database.

PublicFolderMoveRequest cmdlets and the **MoveRequest** cmdlets use the Mailbox Replication

Service to move public folders asynchronously. That means that the cmdlet doesn't do the actual work and, during most of the move, the public folder and public folder mailboxes will still be available to users. Because the Mailbox Replication Service performs mailbox moves, import and export requests, and public folder move requests, it's important to consider throttling and workload management.

Public folder quotas

When created, public folder mailboxes automatically inherit the size limits of the mailbox database defaults. As a result, to accurately evaluate the current storage quota status when using the Get-Mailbox cmdlet, you must review at the *UseDatabaseQuotaDefaults* property in addition to the *ProhibitSendQuota*, *ProhibitSendReceiveQuota*, and *IssueWarningQuota* properties. If the *UseDatabaseQuotaDefaults* property is set to `true`, the per-mailbox settings are ignored and the mailbox database limits are used. If this property is set to `true` and the *ProhibitSendQuota*, *ProhibitSendReceiveQuota*, and *IssueWarningQuota* properties are set to `unlimited`, the mailbox size isn't really unlimited. Instead, you must use the **Get-MailboxDatabase** cmdlet and review the mailbox database storage limits to find out what the limits for the mailbox are. If the *UseDatabaseQuotaDefaults* property is set to `false`, the per-mailbox settings are used. In Exchange 2013, the default mailbox database quota limits are as follows:

- *Issue warning quota*: 1.9 GB
- *Prohibit send quota*: 2 GB
- *Prohibit receive quota*: 2.3 GB

To find the mailbox database quotas, run the Get-MailboxDatabase cmdlet.

To set the quotas on a public folder mailbox, use the Set-OrganizationConfig cmdlet.

Disaster recovery

Exchange 2013 public folders are built on mailbox infrastructure and use the same mechanisms for availability and redundancy. Every public folder mailbox can have multiple redundant copies with automatic failover, just like regular mailboxes. To learn more, see High availability and site resilience.

In addition to the overall disaster recovery scenario, you can also restore public folders in the following situations:

- **Soft-deleted public folder restore** The public folder was deleted but is still within the retention period.
- **Soft-deleted public folder mailbox restore** The public folder mailbox was deleted and is still within the mailbox retention period.
- **Public folder mailbox restore from a recovery database** You can recover an individual public folder mailbox from backup when the deleted mailbox retention period has elapsed. You then extract data from the restored mailbox and copy it to a target folder or merge it with another

mailbox.

In all of these situations, the public folder or public folder mailbox is recoverable by using the **MailboxRestoreRequest** cmdlets.

For more information, see Restore public folders and public folder mailboxes from failed moves.

FAQ: Public folders

Exchange Server 2013 > Collaboration > Public folders >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-08-18*

This topic provides you with a list of frequently asked questions regarding public folders in Exchange Server 2013. To learn more about public folders, see Public folders.

Have questions about public folders that aren't answered here? Send us an email at Ex2013HelpFeedback@microsoft.com.

Are public folders going away?

No. Public folders are great for Outlook integration, simple sharing scenarios, and for allowing large audiences to access the same data.

Which clients support public folders?

Outlook 2007, Outlook 2010, and Outlook 2013, and Outlook 2011 for Mac users can access public folders. However, users whose mailboxes are on Exchange 2013 servers won't be able to connect to Exchange 2007 or Exchange 2010 public folders from clients that use Exchange Web Services (EWS), such as Outlook for Mac. We recommend that you migrate legacy public folders to Exchange 2013 in order to maintain access for those users.

Are there any limitations in the using the clients?

Outlook Web App is supported, but with some limitations. You can add and remove favorite public folders (if they are Mail or Post public folders) and perform item level operations, such as creating, editing, deleting posts, and replying to posts. But, you can't do the following in Outlook Web App:

- Create or delete public folders
- Drag-and-drop content
- Access public folders located on servers running previous versions of Exchange

In a hybrid scenario, Outlook Web App and Outlook 2011 for Mac aren't supported for cross-premises public folders. Users must be in the same location as the public folders to access them with Outlook 2011 for Mac or Outlook Web App.

How can I store a very large hierarchy in a public folder mailbox?

For more information about public folder storage limits, see Limits for public folders.

How can I view the hierarchy public folder mailbox?

Run the following command:

```
Get-OrganizationConfig | Format-List
RootPublicFolderMailbox
```

For detailed syntax and parameter information, see Get-OrganizationConfig.

How can I create content mailboxes for public folders using Exchange Management Shell cmdlets?

Run the following command to create the first master hierarchy public folder mailbox and the secondary hierarchy mailboxes.

```
New-Mailbox -PublicFolder -Name <name of public folder>
```

For more detail, see Create a public folder.

In previous versions of Exchange, for each mailbox database there was an option to specify its public folder database. How will this work in Exchange 2013?

There is no database-level setting in Exchange 2013. Exchange 2013 has a mailbox-level ability to specify the public folder mailbox, but by default Exchange auto-calculates the per-user hierarchy mailbox.

How are public folder metric tools being used in Exchange 2013?

In Exchange 2013, you can use Get-PublicFolderStatistics and Get-PublicFolderItemStatistics cmdlets to get public folder metrics data. This is the same solution that we had in Exchange 2010, so nothing has changed here. Public folders don't require additional reporting add-ons.

Can public folders distinguish between internal versus third-party access to public folders?

In Exchange 2013, public folder permissions are managed by using Role Based Access Control (RBAC). Access control lists (ACLs) aren't used in Exchange 2013. You can use Get-PublicFolderStatistics and Get-PublicFolderItemStatistics cmdlets to keep track of accounts that are performing administrative tasks and then audit access accordingly. To learn more about RBAC, see Understanding Role Based Access Control.

Does mailbox audit logging work against public folders?

No. Not at this time.

What are the limits on public folders? What are the recommendations?

For more information about public folder limits, see Limits for public folders.

What are the recommendations for splitting public folder mailboxes? Should they stay on the same database?

In previous versions of Exchange, you could split public folders across public folder databases. You can decide whether to split the content of a public folder mailbox to a mailbox on the same mailbox database or a different database. Typically, a split is recommended to be on a separate database, because you want to balance storage and I\O.

Can you set retention policies on public folders?

Just like in previous versions of Exchange, you can set retention limits on items. For details, see Step 1 of Set up public folders in a new organization.

Can you specify which users can use a specific public folder mailbox?

In Exchange 2007 and Exchange 2010, you could specify which users had access to specific public folders. In Exchange 2013, you can set the default public folder mailbox per user. To do so, run the Set-Mailbox cmdlet with the *DefaultPublicFolderMailbox* parameter.

```
Set-Mailbox -Identity kweku@contoso.com -
DefaultPublicFolderMailbox "PF_Administration"
```

If the master hierarchy goes down, what's the user impact?

If the master hierarchy public folder mailbox goes down, users can view but not write to public folders. To help prevent the hierarchy from going down, we recommend that you include your public folders in a database availability group (DAG). To learn about DAGs, see Database availability groups.

Can you change which public folder mailbox is the master hierarchy mailbox?

No. If you try to change the master hierarchy mailbox, you'll receive an error.

Do public folders have full text searching capabilities?

Yes, full text search is available for public folders in Exchange 2013. However, you can't search across multiple public folders.

FAQs about public folder migration

This section contains frequently asked questions about public folder migration. For more information, see Migrate public folders to Exchange 2013 from previous versions.

After migration, what happens to the hierarchy on the source Exchange 2010 servers?

During the finalization stage in migration, a lock is placed on the source server to make it inaccessible to user. This lock remains in place to prevent users from accessing the source public folders after migration completes. Although you can release this lock, we don't recommend doing so because the changes can't be synced to Exchange 2013.

When you migrate public folders, what happens to existing public folder rules?

Public folder rules are migrated along with the data and are kept as public folder rules. They aren't converted to mailbox rules.

What happens if hierarchy changes are performed on the source after the initial .csv file was generated? How would these reflect on the destination?

The .csv file is used to determine the mapping between the source hierarchy and the destination mailbox. It contains only the top-level folders. Child folders under the top-level folders are automatically migrated. Therefore, if a new child folder is added, it's migrated during the process. If a new top-level folder is created, it will be created in the mailbox that contains the writable copy of the hierarchy.

During migration to Exchange 2013 public folders, if there's a long window of time between suspension and finalization, how can I force a delta sync so that users can access public folders during the final sync?

You can force a delta sync to occur before finalization (prior to locking the source) by running the following Shell command:

```
Resume-PublicFolderMigrationRequest \PublicFolderMigration
```

For detailed syntax and parameter information, see Resume-PublicFolderMigrationRequest.

For the migration of a geo-distributed hierarchy, how can I

make sure that the public folders are created in the location nearest to the target users?

As part of the migration process, a .csv file is generated (using the `publicfoldertomailboxmapgenerator.ps1` script). This file contains the folder-to-mailbox mapping for the new hierarchy. You can use this .csv file to create public folder mailboxes in the appropriate geographic location and modify the file to place the required folders in the appropriate mailbox so they are near the target users.

The input .csv file can be generated by running the script `AggregatePFData.ps1`, located in the directory <*Exchange Installation Directory*>\V15\Scripts. Run the script as follows:

```
.\AggregatePFData.ps1 | Select-Object -property
@{Name="FolderName"; Expression = {$_.Identity}},
@{Name="FolderSize"; Expression =
{$_.TotalItemSize.Value.ToBytes()}} | Export-CSV -Path
<Path followed by the name of the CSV>
```

Do existing public folder permissions migrate?

Yes, permissions automatically migrate at the folder level with the data. You don't have to perform this step separately.

Limits for public folders

Exchange Server 2013 > Collaboration > Public folders >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-08-25*

In Exchange Server 2013, we moved public folders from a traditional database architecture to a mailbox architecture. This shift allows public folders to benefit from things such as the resiliency of a Database Availability Group (DAG) and other mailbox enhancements made over the years. However, there are new limits and performance concerns that should be taken into account. In this document we provide some high level guidance for configuration options you have that could affect public folder performance and connectivity.

Limits

The following table lists the limits for public folders in on-premises Exchange Server 2013. Unless the limits are specifically stated as recommended, the values listed here are the supported limits for public folders.

Important:
Looking for Exchange Online limits for Office 365? See Exchange Online Limits.

Item	Limits	Notes
Total number of public folder mailboxes	100	Although you can create more than 100 public folder mailboxes, it isn't supported. Create a public folder mailbox
Total public folders in hierarchy	100,000	Although you can create more than 100,000 public folders, it isn't supported. Create a public folder
Sub-folders under the parent folder	1,000	While you can create more than 1,000 sub-folders under a parent folder, we don't recommend that you do so. *FolderHierarchyChildrenCountReceiveQuota* parameter on the Set-Mailbox cmdlet.
Folder depth	300	The folder depth is the number levels of nested folders that can exist in one branch of a public folder tree. *FolderHierarchyDepthRecieveQuota* parameter on the Set-Mailbox cmdlet.
Maximum messages per public folder	1 million	*MailboxMessagesPerFolderCountRecieveQuota* parameter on the Set-Mailbox cmdlet.

Maximum individual public folder size	10 GB	This limit doesn't include subfolders beneath a single folder. Configure storage quotas for a mailbox
Public folder mailbox size	100 GB	Configure storage quotas for a mailbox
Number of user logons per public folder mailbox	2,000 concurrent user logons	We recommend that you configure your hierarchy so that you have no more than 2,000 users per public folder mailbox. For example, if you have 20,000 users, you should have 10 public folder mailboxes.
Moved item retention	14 days recommended	Use the *DefaultPublicFolderMovedItemRetention* parameter on the **Set-OrganizationConfig** cmdlet.
Age limit	We recommend that you set this as the same default that you use for regular mailboxes.	These settings can be set at the following levels: • **Organizational level:** *DefaultPublicFolderAgeLimit* parameter on the **Set-OrganizationConfig** cmdlet. • **Mailbox level:** *AgeLimit* parameter on the **Set-Mailbox** cmdlet. • **Folder level:** *AgeLimit* parameter on the **Set-PublicFolder** cmdlet.

Deleted item retention	We recommend that you set this as the same default that you use for regular mailboxes.	These settings can be set at the following levels: • **Organizational level:** *DefaultPublicFolderMovedItemRetention* parameter on the **Set-OrganizationConfig** cmdlet. • **Mailbox level:** *RetainDeletedItemsFor* on the **Set-Mailbox** cmdlet. • **Folder level:** *RetainDeleteItemsFor* parameter on the **Set-PublicFolder** cmdlet.

Public folder procedures

Exchange Server 2013 > Collaboration > Public folders >

Topic Last Modified: *2013-06-03*

Set up public folders in a new organization

Migrate public folders to Exchange 2013 from previous versions

Migrate legacy public folders to Office 365 and Exchange Online

Configure legacy on-premises public folders for a hybrid deployment

Create a public folder mailbox

Create a public folder

Mail-enable or mail-disable a public folder

Update the public folder hierarchy

Remove a public folder

Move a public folder mailbox to a different mailbox database

Move a public folder to a different public folder mailbox

Restore public folders and public folder mailboxes from failed moves

View statistics for public folders and public folder items

Set up public folders in a new organization

Collaboration > Public folders > Public folder procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-02-24*

This topic shows you how to get public folders configured and running in a new organization or in an organization that has never previously had public folders.

Note:

For more information about the storage quotas and limits for public folders, see the following topics:

- For public folders in Office 365, see Exchange Online Limits.
- For public folders in on-premises Exchange Server 2013, see Limits for public folders.

For additional management tasks related to public folders in Exchange Server 2013, see Public folder procedures.

For additional management tasks related to public folders in Exchange Online, see **Public folder procedures in Office 365 and Exchange Online**.

What do you need to know before you begin?

- Estimated time to complete this task: 30 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Public folders" entry in the Sharing and collaboration permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

How do you do this?

Step 1: Create the primary public folder mailbox

The primary public folder mailbox contains a writeable copy of the public folder hierarchy plus content and is the first public folder mailbox that you create for your organization. Subsequent public folder mailboxes will be secondary public folder mailboxes, which will contain a read-only copy of the hierarchy plus content.

For detailed steps, see Create a public folder mailbox.

Step 2: Create your first public folder

For detailed steps, see Create a public folder.

Step 3: Assign permissions to the public folder

After you create the public folder, you'll need to assign the **Owner** permissions level so that at least one user can access the public folder from the client and create subfolders. Any public folders created after this one will inherit the permissions of the parent public folder.

1. In the Exchange admin center (EAC), navigate to **Public folders** > **Public folders**.
2. In the list view, select the public folder.
3. In the details pane, under **Folder permissions**, click **Manage**.
4. In **Public Folder Permissions**, click **Add +**.
5. Click **Browse** to select a user.
6. In the **Permission level** list, select a level. At least one user should be an **Owner**.
7. Click **Save**.
8. You can add multiple users by clicking **Add +** and assigning the appropriate permissions using the steps above. You can also customize the permission level by selecting or clearing the check boxes. When you edit a predefined permission level such as **Owner**, the permission level will change to **Custom**.

For information about how to use the Shell to assign permissions to a public folder, see Add-PublicFolderClientPermission.

Step 4 (Optional): Mail-enable the public folder

If you want users to send mail to the public folder, you can mail-enable it. This step is optional. If you don't mail-enable the public folder, users can post messages to the public folder by dragging items into it from within Outlook.

1. In the EAC, navigate to **Public folders** > **Public folders**.
2. In the list view, select the public folder you want to mail-enable.
3. In the details pane, under **Mail settings – Disabled**, click **Enable**.

A warning displays asking if you are sure you want to enable mail for the public folder. Click **Yes**.

The public folder will be mail-enabled and the name of the public folder will become the alias of the public folder. If you have multiple recipients with that name, the public folder's alias will be appended with a number. For example, if you have a distribution group named SalesTeam and you create a public folder named SalesTeam and then mail-enable it, the alias of that public folder will be SalesTeam1.

For information about how to use the Shell to mail-enable a public folder, see Enable-MailPublicFolder.

Migrate public folders to Exchange 2013 from previous versions

Collaboration > Public folders > Public folder procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-03-24*

This topic describes how to migrate your public folders from Exchange Server 2010 SP3 or Exchange 2007 SP3 RU10 to Microsoft Exchange Server 2013 within the same forest.

Note:
This topic refers to the Exchange 2010 SP3 and Exchange 2007 SP3 RU10 servers as the *legacy Exchange server*.

You'll perform the migration by using the ***PublicFolderMigrationRequest** cmdlets (which use the Microsoft Exchange Mailbox Replication service to perform the migration tasks), in addition to the following PowerShell scripts:

- `Export-PublicFolderStatistics.ps1` This script creates the folder name-to-folder size mapping file.
- `Export-PublicFolderStatistics.psd1` This support file is used by the `Export-PublicFolderStatistics.ps1` script and should be downloaded to the same location.
- `PublicFolderToMailboxMapGenerator.ps1` This script creates the public folder-to-mailbox mapping file.
- `PublicFolderToMailboxMapGenerator.strings.psd1` This support file is used by the `PublicFolderToMailboxMapGenerator.ps1` script and should be downloaded to the same location.

Step 1: Download the migration scripts provides details about where to download these scripts.

For additional management tasks related to public folders, see Public folder procedures.

For details about how to migrate public folders to Exchange Online, see Migrate legacy public folders to Office 365 and Exchange Online.

What versions of Exchange are supported for migrating public folders to Exchange 2013?

Exchange supports moving your public folders from the following legacy versions of Exchange Server:

- Exchange Server 2010 SP3
- Exchange Server 2007 SP3 RU10

You can't migrate public folders directly from Exchange 2003. If you're running Exchange 2003 in your organization, you must move all public folder databases and replicas to Exchange 2007 SP3 RU10 or later. No public folder replicas can remain on Exchange 2003.

What do you need to know before you begin?

- You must be assigned the following permissions before you can perform this procedure:
  - In Exchange 2013, you must be a member of the Organization Management role group. For details, see Manage role groups.
  - In Exchange 2010, you must be a member of the Organization Management or Server Management role groups. For details, see Add Members to a Role Group.
  - In Exchange 2007, you need to be assigned the Exchange Organization Administrator role or the Exchange Server Administrator role. In addition, you must be assigned the Public Folder Administrator role and local Administrators group for the target server. For details, see How to Add a User or Group to an Administrator Role.
- Before you migrate, you should consider the Limits for public folders.
- Before you begin, we recommend that you read this topic in its entirety as downtime is required for some steps.
- Before you migrate your public folders, we recommend that you first move all user mailboxes to Exchange 2013. For details, see Mailbox moves in Exchange 2013.
- The Exchange 2010 server must be running SP3 or later.
- The Exchange 2007 server must be running SP3 RU10 or later.
- On the Exchange 2007 server, upgrade to Windows PowerShell 2.0 and WinRM 2.0 for Windows Server 2008 x64 Edition.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

How do you do this?

Step 1: Download the migration scripts

1. Download all four of the Microsoft Exchange 2013 public folder migration scripts.
2. Save the scripts to the local computer on which you'll be running PowerShell from. For example, C:\PFScripts.

Step 2: Prepare for the migration

Perform the following prerequisite steps before you begin the migration.

Prerequisite steps on the legacy Exchange server

1. For verification purposes at the end of migration, we recommend that you first run the following Shell commands on the legacy Exchange server to take snapshots of your current public folder deployment.
   a. Run the following command to take a snapshot of the original source folder structure.

```
Get-PublicFolder -Recurse | Export-CliXML C:\PFMigration
\Legacy_PFStructure.xml
```

   b. Run the following command to take a snapshot of public folder statistics such as item count, size, and owner.

```
Get-PublicFolderStatistics | Export-CliXML C:\PFMigration
\Legacy_PFStatistics.xml
```

   c. Run the following command to take a snapshot of the permissions.

```
Get-PublicFolder -Recurse | Get-
PublicFolderClientPermission | Select-Object Identity,User
-ExpandProperty AccessRights | Export-CliXML C:\PFMigration
\Legacy_PFPerms.xml
```

Save the information from the preceding commands for comparison at the end of the migration.

2. If the name of a public folder contains a backslash ****, the public folders will be created in the parent public folder when migration occurs. Before you migrate, we recommend that you rename any public folders that have a backslash in the name.
   a. In Exchange 2010, to locate public folders that have a backslash in the name, run the following command:

```
Get-PublicFolderStatistics -ResultSize Unlimited | Where
{$_.Name -like "*\*"} | Format-List Name, Identity
```

   b. In Exchange 2007, to locate public folders that have a backslash in the name, run the following

command:

```
Get-PublicFolderDatabase | ForEach {Get-
PublicFolderStatistics -Server $_.Server | Where {$_.Name -
like "*\*"}}
```

c. If any public folders are returned, you can rename them by running the following command:

```
Set-PublicFolder -Identity <public folder identity> -Name
<new public folder name>
```

3. Make sure there isn't a previous record of a successful migration. If there is, you'll need to set that value to `$false`. If the value is set to `$true` the migration request will fail.

The following example checks the public folder migration status.

```
Get-OrganizationConfig | Format-List
PublicFoldersLockedforMigration,
PublicFolderMigrationComplete
```

If the status of the *PublicFoldersLockedforMigration* or *PublicFolderMigrationComplete* properties is `$true`, run the following command to set the value to `$false`.

```
Set-OrganizationConfig -
PublicFoldersLockedforMigration:$false -
PublicFolderMigrationComplete:$false
```

⚠**Warning:**
After resetting these properties, you must wait for Exchange to detect the new settings. This may take several minutes. .

For detailed syntax and parameter information, see the following topics:

- Get-PublicFolder
- Get-PublicFolderStatistics
- Get-PublicFolderDatabase
- Set-PublicFolder
- Get-PublicFolderClientPermission
- Get-OrganizationConfig
- Set-OrganizationConfig

Prerequisite steps on the Exchange 2013 server

1. Make sure there are no existing public folder migration requests. If there are, clear them. This step is a prerequisite and isn't required in all cases. It's only required if you think there may be an existing migration request in the pipeline. In any case, the following command below won't affect the new migration. The following example removes any existing public folder migration requests.

```
Get-PublicFolderMigrationRequest | Remove-
PublicFolderMigrationRequest -Confirm:$false
```

2. To make sure there are no existing public folders on the Exchange 2013 servers, run the following commands.

```
Get-Mailbox -PublicFolder
Get-PublicFolder
```

If the above commands return any public folders, use the following commands to remove the public folders.

```
Get-Mailbox -PublicFolder |
Where{$_.IsRootPublicFolderMailbox -eq $false} | Remove-
Mailbox -PublicFolder -Force -Confirm:$false
Get-Mailbox -PublicFolder | Remove-Mailbox -PublicFolder -
Force -Confirm:$false
```

For detailed syntax and parameter information, see the following topics:

- Get-PublicFolderMigrationRequest
- Remove-PublicFolderMigrationRequest
- Get-Mailbox
- Get-PublicFolder
- Get-MailPublicFolder
- Disable-MailPublicFolder
- Remove-PublicFolder
- Remove-Mailbox

Step 3: Generate the .csv files

1. On the legacy Exchange server, run the `Export-PublicFolderStatistics.ps1` script to create the folder name-to-folder size mapping file. The file will contain two columns: **FolderName** and **FolderSize**. The values for the **FolderSize** column will be in displayed bytes. For example, **\PublicFolder01,10000**.

```
.\Export-PublicFolderStatistics.ps1 <Folder to size map
path> <FQDN of source server>
```

   - *FQDN of source server* equals the fully qualified domain name of the Mailbox server where the public folder hierarchy is hosted.
   - *Folder to size map path* equals the file name and path on a network shared folder where you want the .csv file saved. You'll need to access this file from the Exchange 2013 server. If you specify only the file name, the file will be generated in its current location.
2. Run the `PublicFolderToMailboxMapGenerator.ps1` script to create the public folder-to-mailbox mapping file. This file is used to create the correct number of public folder mailboxes on the

Exchange 2013 Mailbox server.

Note:
If the name of a public folder contains a backslash ****, the public folders will be created in the parent public folder. We recommend that you review the .csv file and edit any names that contain the backslash.

```
.\PublicFolderToMailboxMapGenerator.ps1 <Maximum mailbox size in bytes> <Folder to size map path> <Folder to mailbox map path>
```

- *Maximum mailbox size in bytes* equals the maximum size you want to set for the new public folder mailboxes.

Note:
When specifying this setting, be sure to allow for expansion so the public folder mailbox has room to grow.

- *Folder to size map path* equals the file path of the .csv file you created when running the **Export-PublicFolderStatistics.ps1** script.
- *Folder To mailbox map path* equals the file name and path of the folder-to-mailbox .csv file that you'll create with this step. If you specify only the file name, the file will be generated in its current location.

Step 4: Create the public folder mailboxes on the Exchange 2013 server

Warning:
The name of the public folder mailboxes that you create must match the name of the **TargetMailbox** in the mapping file. You can edit the **TargetMailbox** names in the mapping file to match your organization's naming conventions.

1. Run the following command to create the first public folder mailbox on the Exchange 2013 Mailbox server. Public folder mailboxes contain the hierarchy information for a public folder, whereas the public folder contains the actual content. The first public folder mailbox that you create will be the master hierarchy mailbox. You need to create the first public folder mailbox in *HoldForMigration* mode.

```
New-Mailbox -PublicFolder <Name> -HoldForMigration:$true
```

2. Run the following command to create additional public folder mailboxes as needed based on the .csv file generated from the `PublicFoldertoMailboxMapGenerator.ps1` script. For example, if you open the .csv file, the public folders are named Mailbox1, Mailbox2, etc. If your last public folder is named Mailbox13, you'll need to create 13 public folder mailboxes.

If you need to create several public folder mailboxes, you can write a script to help automate the process. This example creates 25 public folder mailboxes.

```
$numberOfMailboxes = 25;
for($index =1 ; $index -le $numberOfMailboxes ; $index++)
{
    $PFMailboxName = "Mailbox"+$index;
 if($index -eq 1) {New-Mailbox -PublicFolder $PFMailboxName
-HoldForMigration:$true -
IsExcludedFromServingHiearchy:$true;}
else
{New-Mailbox -PublicFolder $PFMailboxName -
IsExcludedFromServingHierarchy:$true}
}
```

For detailed syntax and parameter information, see New-Mailbox.

Step 5: Start the migration request

The steps for migrating Exchange 2007 public folders are different from the steps for migrating Exchange 2010 public folders. Make sure that you follow the correct procedure.

Migrate Exchange 2007 public folders

1. Legacy system public folders such as OWAScratchPad and the schema-root folder subtree in Exchange 2007 won't be recognized by Exchange 2013 and will be treated as bad items. This will cause the migration to fail. As part of the migration request, you must specify a value for the BadItemLimit parameter. This value will vary depending on the number of public folder databases you have. The following commands will determine how many public folder databases you have and compute the BadItemLimit for the migration request.

```
$PublicFolderDatabasesInOrg = @(Get-PublicFolderDatabase)

$BadItemLimitCount = 5 + ($PublicFolderDatabasesInOrg.Count
-1)
```

2. From the Exchange 2013 Mailbox server, run the following command:

```
New-PublicFolderMigrationRequest -SourceDatabase (Get-
PublicFolderDatabase -Server <Source server name>) -CSVData
(Get-Content <Folder to mailbox map path> -Encoding Byte) -
BadItemLimit $BadItemLimitCount
```

3. To verify that the migration started successfully, run the following command.

```
Get-PublicFolderMigrationRequest | Get-
```

```
PublicFolderMigrationRequestStatistics -IncludeReport |
Format-List
```

You'll know that the command started successfully when the migration request reaches a status of *Queued* or *InProgress*. Depending on how much data is contained in the public folders, this command can take a long time to complete. If migration isn't being throttled due to the load on the destination server, the typical data copy rate can be 2 GB to 3 GB per hour.

4. You can periodically run the preceding command to check the status of the migration request. When the status reaches *AutoSuspended*, you can move to Step 6: Lock down the public folders on the legacy Exchange server for final migration (downtime required).

Migrate Exchange 2010 public folders

1. From the Exchange 2013 Mailbox server, run the following command:

```
New-PublicFolderMigrationRequest -SourceDatabase (Get-
PublicFolderDatabase -Server <Source server name>) -CSVData
(Get-Content <Folder to mailbox map path> -Encoding Byte)
```

2. To verify that the migration started successfully, run the following command.

```
Get-PublicFolderMigrationRequest | Get-
PublicFolderMigrationRequestStatistics -IncludeReport |
Format-List
```

You'll know that the command started successfully when the migration request reaches a status of *Queued* or *InProgress*. Depending on how much data is contained in the public folders, this command can take a long time to complete. If migration isn't being throttled due to the load on the destination server, the typical data copy rate can be 2 GB to 3 GB per hour.

3. You can periodically run the preceding command to check the status of the migration request. When the status reaches *AutoSuspended*, you can move to Step 6: Lock down the public folders on the legacy Exchange server for final migration (downtime required).

For detailed syntax and parameter information, see the following topics:

- New-PublicFolderMigrationRequest
- Get-PublicFolderDatabase
- Get-PublicFolderMigrationRequest
- Get-PublicFolderMigrationRequestStatistics

Step 6: Lock down the public folders on the legacy Exchange server for final migration (downtime required)

⚠**Warning:**
The amount of downtime required depends on how much new content was generated since the migration reached the *AutoSuspended* state. If a long time has passed between the

migration request reaching an *AutoSuspended* state and when you can finalization the migration, we recommend that you run the following command so you can synchronize the changes made since the original synchronization. This will reduce the amount of downtime required to finalize the migration.

```
Resume-PublicFolderMigrationRequest \PublicFolderMigration
```

Until this point in the migration, users have been able to access public folders. The next steps will log users off from the public folders and lock the folders while the migration completes its final synchronization. Users won't be able to access public folders during this process. Also, any mail sent to mail-enabled public folders will be queued and won't be delivered until the public folder migration is complete.

On the legacy Exchange server, run the following command to lock the legacy public folders for finalization.

```
Set-OrganizationConfig -
PublicFoldersLockedForMigration:$true
```

For detailed syntax and parameter information, see Set-OrganizationConfig.

If your organization has multiple public folder databases, you'll need to wait until public folder replication is complete to confirm that all public folder databases have picked up the `PublicFoldersLockedForMigration` flag and any pending changes users recently made to folders have converged across the organization. This may take several hours.

Step 7: Finalize the public folder migration (downtime required)

By default, when you run the **Set-PublicFolderMigrationRequest** cmdlet, it won't complete until you remove the *PreventCompletion* flag and resume the migration request.

```
Set-PublicFolderMigrationRequest -Identity
\PublicFolderMigration -PreventCompletion:$false
Resume-PublicFolderMigrationRequest -Identity
\PublicFolderMigration
```

For detailed syntax and parameter information, see Set-PublicFolderMigrationRequest and Resume-PublicFolderMigrationRequest.

Step 8: Test and unlock the public folder migration

After you finalize the public folder migration, you should run the following test to make sure that the migration was successful. This allows you to test the migrated public folder hierarchy before you switch to using Exchange 2013 public folders.

1. Run the following command to assign some test mailboxes to use any newly migrated public folder mailbox as the default public folder mailbox.

```
Set-Mailbox -Identity <Test User> -
DefaultPublicFolderMailbox <Public Folder Mailbox Identity>
```

2. Log on to Outlook 2007 or later with the test user identified in the previous step, and then perform the following public folder tests:
   a. View the hierarchy.
   b. Check permissions.
   c. Create and delete public folders.
   d. Post content to and delete content from a public folder.
3. If you run into any issues, see Roll back the migration later in this topic. If the public folder content and hierarchy is acceptable and functions as expected, run the following command to unlock the public folders for all other users.

```
Get-Mailbox -PublicFolder | Set-Mailbox -PublicFolder -
IsExcludedFromServingHierarchy $false
```

4. On the legacy Exchange server, run the following command to indicate that the public folder migration is complete:

```
Set-OrganizationConfig -PublicFolderMigrationComplete:$true
```

How do I know this worked?

In Step 2: Prepare for the migration, you were instructed to take snapshots of the public folder structure, statistics, and permissions before the migration began. The following steps will help verify that your public folder migration was successful by taking the same snapshots after the migration is complete. You can then compare the data in both files to verify success.

1. Run the following command to take a snapshot of the original source folder structure.

```
Get-PublicFolder -Recurse | Export-CliXML C:\PFMigration
\New_PFStructure.xml
```

2. Run the following command to take a snapshot of the public folder statistics such as item count, size, and owner.

```
Get-PublicFolderStatistics | Export-CliXML C:\PFMigration
\New_PFStatistics.xml
```

3. Run the following command to take a snapshot of the permissions.

```
Get-PublicFolder -Recurse | Get-
PublicFolderClientPermission | Select-Object Identity,User
```

```
-ExpandProperty AccessRights | Export-CliXML C:\PFMigration
\New_PFPerms.xml
```

Remove public folder databases from the legacy Exchange servers

After the migration is complete, and you have verified that your Exchange 2013 public folders are working as expected, you should remove the public folder databases on the legacy Exchange servers.

- For details about how to remove public folder databases from Exchange 2007 servers, see Removing Public Folder Databases.
- For details about how to remove public folder databases from Exchange 2010 servers, see Remove Public Folder Databases.

Roll back the migration

If you run into issues with the migration and need to reactivate your legacy Exchange public folders, perform the following steps:

⚠**Warning:**
After the migration is complete, any email to mail-enabled public folders, any change in public folder permissions or hierarchy, or content posted to public folders that occurred after the migration to Exchange 2013 will be lost. As a result, if you roll back the migration, you may lose public folder data or changes made on Exchange 2013 servers. To save this content, export the public folder content to a .pst file before you perform this procedure, and then import the .pst file after your rollback to the legacy public folders.

1. On the legacy Exchange server, run the following command to unlock the legacy Exchange public folders. This process may take several hours.

```
Set-OrganizationConfig -
PublicFoldersLockedForMigration:$False
```

2. On the Exchange 2013 server, run the following command to delete the public folder mailboxes.

```
Get-Mailbox -PublicFolder |
Where{$_.IsRootPublicFolderMailbox -eq $false} | Remove-
Mailbox -PublicFolder -Force -Confirm:$false
Get-Mailbox -PublicFolder | Remove-Mailbox -PublicFolder -
Force -Confirm:$false
```

3. On the legacy Exchange server, run the following command to set the `PublicFolderMigrationComplete` flag to `$false`.

```
Set-OrganizationConfig -
PublicFolderMigrationComplete:$False
```

Migrate legacy public folders to Office 365 and Exchange Online

Collaboration > Public folders > Public folder procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-07-25*

This topic describes how to migrate your public folders in a cutover or staged migration from Exchange Server 2010 Service Pack 3 (SP3) or Exchange 2007 SP3 RU10 to Office 365 or Exchange Online. For more information about migrating legacy public folders to Exchange Server 2013, see Migrate public folders to Exchange 2013 from previous versions.

Note:

This topic refers to the Exchange 2010 SP3 and Exchange 2007 SP3 RU10 servers as the *legacy Exchange server*. Also, the steps in this topic apply to both Exchange Online and Office 365. The terms may be used interchangeably in this topic.

We recommend that you don't use Outlook's PST export feature to migrate public folders to Office 365 or Exchange Online. Office 365 and Exchange online public folder mailbox growth is managed using an auto-split feature that splits the public folder mailbox when it exceeds size quotas. Auto-split can't handle the sudden growth of public folder mailboxes when you use PST export to migrate your public folders and you may have to wait for up to two weeks for auto-split to move the data from the primary mailbox. We recommend that you use the cmdlet-based instructions in this document to migrate public folders to Office 365 and Exchange Online. However, if you elect to migrate public folders using PST export, see the section Migrate Public Folders using PST files later in this topic.

You'll perform the migration by using the ***PublicFolderMigrationRequest** cmdlets, in addition to the following PowerShell scripts:

- `Export-PublicFolderStatistics.ps1` This script creates the folder name-to-folder size mapping file. You'll run this script on the legacy Exchange server.
- `Export-PublicFolderStatistics.psd1` This support file is used by the `Export-PublicFolderStatistics.ps1` script and should be downloaded to the same location.
- `PublicFolderToMailboxMapGenerator.ps1` This script creates the public folder-to-mailbox mapping file by using the output from the `Export-PublicFolderStatistics.ps1` script. You'll run

this script on the legacy Exchange server.

- `PublicFolderToMailboxMapGenerator.strings.psd1` This support file is used by the `PublicFolderToMailboxMapGenerator.ps1` script and should be downloaded to the same location.
- `Export-MailPublicFoldersForMigration.ps1` This script exports the mail-enabled public folder objects from the on-premises organization's Active Directory into a .csv file. You'll run this script on the legacy Exchange server.
- `Import-MailPublicFoldersForMigration.ps1` This script uses the .csv file generated by the `Export-MailPublicFoldersForMigration.ps1` script to import the mail-enabled public folder objects into Office 365 or Exchange Online. You'll run this script in Office 365.
- `MailPublicFolder.strings.psd1` This is a support file used by the Import and Export scripts and should be copied to the same location as the preceding scripts.

Step 1: Download the migration scripts provides details about where to download these scripts.

For additional management tasks related to public folders, see Public folder procedures.

What versions of Exchange are supported for migrating public folders to Office 365 and Exchange Online?

Exchange supports moving your public folders to Office 365 and Exchange Online from the following legacy versions of Exchange Server:

- Exchange 2010 SP3 or later
- Exchange 2007 SP3 RU10 or later

You can't migrate public folders directly from Exchange 2003. If you're running Exchange 2003 in your organization, you must move all public folder databases and replicas to Exchange 2007 SP3 RU10 or later. No public folder replicas can remain on Exchange 2003.

What do you need to know before you begin?

- In Office 365 and Exchange Online, you must be a member of the Organization Management role group. This role group is different from the permissions assigned to you when you subscribe to Office 365 or Exchange Online. For details about how to enable the Organization Management role group, see Manage role groups.
- In Exchange 2010, you must be a member of the Organization Management or Server Management RBAC role groups. For details, see Add Members to a Role Group.
- In Exchange 2007, you need to be assigned the Exchange Organization Administrator role or the Exchange Server Administrator role. In addition, you must be assigned the Public Folder Administrator role and local Administrators group for the target server. For details, see How to

Add a User or Group to an Administrator Role.

- On the Exchange 2007 server, upgrade to Windows PowerShell 2.0 and WinRM 2.0 for Windows Server 2008 x64 Edition.
- Before migration, if any public folder in your organization is greater than 2 GB, we recommend either deleting content from that folder or splitting it up into multiple public folders. If either of these options isn't feasible, we recommend that you do not move your public folders to Office 365 and Exchange Online.
- In Office 365 and Exchange Online, the default limit is 50 public folder mailboxes. Office 365 will allow you to automatically upgrade to 100 public folder mailboxes if you exceed this amount. If you need to exceed 100 public folder mailboxes, contact Office 365 support to request additional public folder mailboxes and your request will be evaluated.
- Before you migrate your public folders, we recommend that you first move all user mailboxes to Office 365 and Exchange Online. For details, see **Mailbox Migration to Exchange Online**.
- Outlook Anywhere must be enabled on the legacy Exchange server. For details about enabling Outlook Anywhere on Exchange 2010 servers, see Enable Outlook Anywhere. For details about enabling Outlook Anywhere on Exchange 2007 servers, see How to Enable Outlook Anywhere.
- You can't use the Exchange admin center (EAC) or the Exchange Management Console (EMC) to perform this procedure. On the legacy Exchange servers, you must use the Exchange Management Shell. For Exchange Online, you must use Exchange Online PowerShell. For more information, see **Connect to Exchange Online using remote PowerShell**.
- Before you begin, we recommend that you read this topic in its entirety as downtime is required for some steps.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

How do you do this?

Step 1: Download the migration scripts

1. Download all four of the Microsoft Exchange 2013 public folder migration scripts.
2. Save the scripts to the local computer on which you'll be running PowerShell. For example, C:\PFScripts.
3. Download the following scripts from Microsoft Exchange 2013 Public Folders Directory Sync Support Scripts:
   a. `Export-MailPublicFoldersForMigration.ps1`
   b. `Import-MailPublicFoldersForMigration.ps1`
   c. `MailPublicFolder.strings.psd1`
4. Save the scripts to the same location you did for step 2. For example, C:\PFScripts.

Step 2: Prepare for the migration

Perform the following prerequisite steps before you begin the migration.

Prerequisite steps on the legacy Exchange server

1. On the legacy Exchange server, make sure that routing to the mail-enabled public folders that will exist in Office 365 or Exchange Online continues to work until all DNS caches over the Internet are updated to point to the Office 365 or Exchange Online DNS where your organization now resides. To do this, run the following command to configure an accepted domain with a well-known name that will properly route email messages to the Office 365 or Exchange Online domain.

```
New-AcceptedDomain -Name
"PublicFolderDestination_78c0b207_5ad2_4fee_8cb9_f373175b3f
99" -DomainName contoso.onmicrosoft.com -DomainType
InternalRelay
```

2. If the name of a public folder contains a backslash ****, the public folders will be created in the parent public folder when migration occurs. Before you migrate, we recommend that you rename any public folders that have a backslash in the name.
   a. In Exchange 2010, to locate public folders that have a backslash in the name, run the following command:

```
Get-PublicFolderStatistics -ResultSize Unlimited | Where
{$_.Name -like "*\*"} | Format-List Name, Identity
```

   b. In Exchange 2007, to locate public folders that have a backslash in the name, run the following command:

```
Get-PublicFolderDatabase | ForEach {Get-
PublicFolderStatistics -Server $_.Server | Where {$_.Name -
like "*\*"}}
```

   c. If any public folders are returned, you can rename them by running the following command:

```
Set-PublicFolder -Identity <public folder identity> -Name
<new public folder name>
```

3. Make sure there isn't a previous record of a successful migration. If there is, you'll need to set that value to `$false`. If the value is set to `$true`, the migration request will fail.
   a. The following example checks the public folder migration status.

```
Get-OrganizationConfig | Format-List
PublicFoldersLockedforMigration,
PublicFolderMigrationComplete
```

b. If the status of the *PublicFoldersLockedforMigration* or *PublicFolderMigrationComplete* properties is `$true`, run the following command to set the value to `$false`.

```
Set-OrganizationConfig -
PublicFoldersLockedforMigration:$false -
PublicFolderMigrationComplete:$false
```

⚠**Warning:**
After resetting these properties, you must wait for Exchange to detect the new settings. This may take up to two hours to complete.

4. For verification purposes at the end of migration, we recommend that you first run the following Shell commands on the legacy Exchange server to take snapshots of your current public folder deployment.
   a. Run the following command to take a snapshot of the original source folder structure.

```
Get-PublicFolder -Recurse | Export-CliXML C:\PFMigration
\Legacy_PFStructure.xml
```

   b. Run the following command to take a snapshot of public folder statistics such as item count, size, and owner.

```
Get-PublicFolderStatistics -ResultSize Unlimited | Export-
CliXML C:\PFMigration\Legacy_PFStatistics.xml
```

   c. Run the following command to take a snapshot of the permissions.

```
Get-PublicFolder -Recurse | Get-
PublicFolderClientPermission | Select-Object Identity,User
-ExpandProperty AccessRights | Export-CliXML C:\PFMigration
\Legacy_PFPerms.xml
```

Save the information from the preceding commands for comparison at the end of the migration.

For detailed syntax and parameter information, see the following topics:

- New-AcceptedDomain
- Get-PublicFolder
- Get-PublicFolderDatabase
- Set-PublicFolder
- Get-PublicFolderStatistics
- Get-PublicFolderClientPermission
- Get-OrganizationConfig
- Set-OrganizationConfig

Prerequisite steps in Office 365 or Exchange Online

1. Make sure there are no existing public folder migration requests. If there are, clear them. This step is a prerequisite and isn't required in all cases. It's only required if you think there may be an

existing migration request in the pipeline. In any case, the following command won't affect the new migration. The following example removes any existing public folder migration requests.

Important:

Before removing the migration request, it is important to understand why there was an existing one. You can run the following command to determine when a previous request was made and diagnose any problems that may have occurred. You may need to communicate with other administrators in your organization to determine why the change was made.

```
Get-PublicFolderMigrationRequest | Get-PublicFolderMigrationRequestStatistics -IncludeReport | Format-List
```

```
Get-PublicFolderMigrationRequest | Remove-PublicFolderMigrationRequest -Confirm:$false
```

2. Make sure no public folders or public folder mailboxes exist in Office 365.

Important:

If you do see public folders in Office 365 or Exchange Online, it is important to determine why they are there and who in your organization started a public folder hierarchy before removing the public folders and public folder mailboxes.

a. In Office 365 or Exchange Online PowerShell, run the following command to see if any public folders mailboxes exist.

```
Get-Mailbox -PublicFolder
```

b. If the command didn't return any public folder mailboxes, continue to Step 3: Generate the CSV files. If the command returned any public folders mailboxes, run the following command to see if any public folders exist:

```
Get-PublicFolder
```

c. If you have any public folders in Office 365 or Exchange Online, run the following PowerShell command to remove them.

```
Get-MailPublicFolder | where {$_.EntryId -ne $null}|
Disable-MailPublicFolder -Confirm:$false
Get-PublicFolder -GetChildren \ | Remove-PublicFolder -
Recurse -Confirm:$false
```

d. After the public folders are remvoved, run the following commands to remove all public folder mailboxes.

```
$hierarchyMailboxGuid = $(Get-
OrganizationConfig).RootPublicFolderMailbox.HierarchyMailbo
xGuid
Get-Mailbox -PublicFolder:$true | Where-Object
{$_.ExchangeGuid -ne $hierarchyMailboxGuid} | Remove-
```

```
Mailbox -PublicFolder -Confirm:$false
Get-Mailbox -PublicFolder:$true | Where-Object
{$_.ExchangeGuid -eq $hierarchyMailboxGuid} | Remove-
Mailbox -PublicFolder -Confirm:$false
```

For detailed syntax and parameter information, see the following topics:

- Get-PublicFolderMigrationRequest
- Remove-PublicFolderMigrationRequest
- Get-Mailbox
- Get-PublicFolder
- Get-MailPublicFolder
- Disable-MailPublicFolder
- Remove-PublicFolder
- Remove-Mailbox

Step 3: Generate the .csv files

1. On the legacy Exchange server, run the `Export-PublicFolderStatistics.ps1` script to create the folder name-to-folder size mapping file. This script must always be run by a local administrator. The file will contain two columns: **FolderName** and **FolderSize**. The values for the **FolderSize** column will be displayed in bytes. For example, **\PublicFolder01,10000**.

```
.\Export-PublicFolderStatistics.ps1  <Folder to size map
path> <FQDN of source server>
```

   - *FQDN of source server* equals the fully qualified domain name of the Mailbox server where the public folder hierarchy is hosted.
   - *Folder to size map path* equals the file name and path on a network shared folder where you want the .csv file saved. Later in this topic, you'll need to use the Exchange Online PowerShell to access this file. If you specify only the file name, the file will be generated in the current PowerShell directory on the local computer.
2. Run the `PublicFolderToMailboxMapGenerator.ps1` script to create the public folder-to-mailbox mapping file. This file is used to calculate the correct number of public folder mailboxes in Exchange Online.

```
.\PublicFolderToMailboxMapGenerator.ps1 <Maximum mailbox
size in bytes> <Folder to size map path> <Folder to mailbox
map path>
```

   - *Maximum mailbox size in bytes* equals the maximum size you want to set for the new public folder mailboxes. In Exchange Online, the maximum size of public folder mailboxes is 50 GB. We recommend that you set this setting to 15 GB so that each public folder mailbox has room for growth. If you have one single public folder that exceeds 2 GB, that public folder won't get added to the .csv file. The following are some options for how you can fix this issue:

- Before you run the script, delete public folder content to reduce the size to 2 GB or less.
- Before you run the script, split the public folder into multiple public folders that are each 2 GB or less.
- If the public folder is greater than 2 GB but no more than 30 GB, you can manually add it to the .csv file after you've run the script. The public folder will be created in Exchange Online.

Note:
If the public folder is greater than 30 GB and deleting content or splitting it into multiple public folders isn't feasible, we recommend that you don't move your public folders to Exchange Online.

- *Folder to size map path* equals the file path of the .csv file you created when running the `Export-PublicFolderStatistics.ps1` script.
- *Folder to mailbox map path* equals the file name and path of the folder-to-mailbox .csv file that you'll create with this step. If you specify only the file name, the file will be generated in the current PowerShell directory on the local computer.

Step 4: Create the public folder mailboxes in Exchange Online

Warning:
The names of the public folder mailboxes that you create must match the name of the **TargetMailbox** in the mapping file. You can edit the **TargetMailbox** names in the mapping file to match your organization's naming conventions.

1. Run the following command to create the primary public folder mailbox in Exchange Online. The first public folder mailbox that you create will be the primary hierarchy mailbox. You must create the first public folder mailbox in *HoldForMigration* mode. In addition, Exchange will automatically exclude the public folder mailboxes from the serving hierarchy so that the public folders won't be available to Exchange Online users.

```
New-Mailbox -PublicFolder <Name> -HoldForMigration:$true
```

2. Run the following command to create additional public folder mailboxes as needed based on the .csv file generated from the `PublicFoldertoMailboxMapGenerator.ps1` script. For example, if you open the .csv file, the public folders are named Mailbox1, Mailbox2, etc. If your last public folder is named Mailbox13, you'll need to create 13 public folder mailboxes. The maximum number of public folder mailboxes that you can create is 50.

If you need to create several public folder mailboxes, you can write a script to help automate the process. This example creates 15 public folder mailboxes.

```
$numberOfMailboxes = 15;
for($index =1 ; $index -le $numberOfMailboxes ; $index++)
{
```

```
    $PFMailboxName = "Mailbox"+$index;
 if($index -eq 1) {New-Mailbox -PublicFolder $PFMailboxName
-HoldForMigration:$true}
else
{New-Mailbox -PublicFolder $PFMailboxName}
}
```

For detailed syntax and parameter information, see New-Mailbox.

Step 5: Start the migration request

1. On the legacy Exchange server, run the following command to create the .xml file that will export the set of mail-enabled public folders from Active Directory.

```
.\Export-MailPublicFoldersForMigration.ps1
<mail_publicfolders.xml>
```

2. On the legacy Exchange server, get the following information that's needed to run the migration request:
   a. Find the `LegacyExchangeDN` of the user's account who is a member of the Public Folder Administrator role. This will be the same user whose credentials you need in step 3 of this procedure.

```
Get-Mailbox <PublicFolder_Administrator_Account> | Select-
Object LegacyExchangeDN
```

   b. Find the FQDN of any Mailbox server that has a public folder database.

```
Get-ExchangeServer <public folder server> | Select-Object -
Expand ExchangeLegacyDN
```

   c. Find the FQDN of the Outlook Anywhere host name. If you have multiple instances of Outlook Anywhere, we recommend that you select the instance that is either closest to the migration endpoint or the one that is closest to the public folder replicas in the legacy Exchange organization. The following command will find all instances of Outlook Anywhere:

```
Get-OutlookAnywhere | Format-Table
Identity,ExternalHostName
```

3. In Office 365 PowerShell, run the following commands to pass the information that you was returned in the previous step to variables that will then be used in the migration request.
   a. Pass the credential of a user who has administrative permissions on the legacy Exchange server into the variable `$source_credential`. The migration request that's run in Exchange Online will use this credential to gain access to your legacy Exchange servers to copy the content over.

```
$source_credential = Get-Credential <source_domain
\PublicFolder_Administrator_Account>
```

b. Use the `ExchangeLegacyDN` of the migration user on the legacy Exchange server that you found in step 2a and pass it into the variable `$source_remoteMailboxLegacyDN`.

```
$source_remoteMailboxLegacyDN = "<paste the value here>"
```

c. Use the `ExchangeLegacyDN` of the public folder server that you found in step 2b above and pass it into the variable `$source_remotePublicFolderServerLegacyFQDN`.

```
$source_remotePublicFolderServerLegacyFQDN = "<paste the
value here>"
```

d. Use the External Host Name of Outlook Anywhere that you found in step 2c above and pass it into the variable `$source_OutlookAnywhereExternalHostName`.

```
$source_OutlookAnywhereExternalHostName = "<paste the value
here>"
```

4. In Exchange Online PowerShell, run the following command to import the migration .xml file.

```
.\Import-MailPublicFoldersForMigration.ps1
<mail_publicfolders.xml>
```

5. Finally, in Exchange Online PowerShell, run the following command to start the migration request.

Note:

The authentication method in the following shell example needs to match your Outlook Anywhere settings, otherwise the command will fail.

```
New-PublicFolderMigrationRequest -OutlookAnywhereHostName:
$source_OutlookAnywhereExternalHostName -CSVData (Get-
Content <folder_mapping.csv> -Encoding Byte) -
RemoteCredential: $source_credential -
RemoteMailboxLegacyDN: $source_remoteMailboxLegacyDN -
RemoteMailboxServerLegacyDN:
$source_remotePublicFolderServerLegacyFQDN -
AuthenticationMethod Basic
```

Where the *<folder_mapping.csv>* file is the file that was generated in Step 3: Generate the .csv files.

6. To verify that the migration started successfully, in Exchange Online PowerShell, run the following command.

```
Get-PublicFolderMigrationRequest | Get-
```

```
PublicFolderMigrationRequestStatistics -IncludeReport |
Format-List
```

You'll know that the command started successfully when the migration request reaches a status of *Queued* or *InProgress*. Depending on how much data is contained in the public folders, this command can take a long time to complete. If migration isn't being throttled due to the load on the destination server or network performance, the typical data copy rate can be 2 GB to 3 GB per hour. The actual data speeds may vary depending on server configuration and network latency of the on-premises organization.

7. You can periodically run the preceding command to check the status of the migration request. When the status reaches *AutoSuspended*, you can move to Step 6: Lock down the public folders on the legacy Exchange server for final migration (downtime required).

For detailed syntax and parameter information, see the following topics:

- Get-Mailbox
- Get-ExchangeServer
- Get-OutlookAnywhere
- New-PublicFolderMigrationRequest
- Get-PublicFolderDatabase
- Get-PublicFolderMigrationRequest
- Get-PublicFolderMigrationRequestStatistics

Step 6: Lock down the public folders on the legacy Exchange server for final migration (downtime required)

⚠Warning:

The amount of downtime required depends on how much new content was generated since the migration reached the *AutoSuspended* state. If a long time has passed between the migration request reaching an *AutoSuspended* state and when you can finalize the migration, we recommend that you run the **Resume-PublicFolderMigrationRequest** cmdlet from Exchange Online PowerShell so you can synchronize the changes made since the original synchronization. This will reduce the amount of downtime required to finalize the migration.

```
Resume-PublicFolderMigrationRequest \PublicFolderMigration
```

Until this point in the migration, users have been able to access public folders. The next steps will log users off from the legacy public folders and lock the folders while the migration completes its final synchronization. Users won't be able to access public folders during this process. Also, any mail sent to mail-enabled public folders will be queued and won't be delivered until the public folder migration is complete.

On the legacy Exchange server, run the following command to lock the legacy public folders for finalization.

```
Set-OrganizationConfig -
```

```
PublicFoldersLockedForMigration:$true
```

For detailed syntax and parameter information, see Set-OrganizationConfig.

If your organization has multiple public folder databases, you'll need to wait until public folder replication is complete to confirm that all public folder databases have picked up the `PublicFoldersLockedForMigration` flag and any pending changes users recently made to folders have converged across the organization. This may take several hours.

Step 7: Finalize the public folder migration (downtime required)

By default, when you run the **Set-PublicFolderMigrationRequest** cmdlet in the Office 365 or Exchange Online PowerShell, it won't complete until you remove the *PreventCompletion* flag and resume the migration request.

```
Set-PublicFolderMigrationRequest -Identity
\PublicFolderMigration -PreventCompletion:$false
Resume-PublicFolderMigrationRequest -Identity
\PublicFolderMigration
```

For detailed syntax and parameter information, see the following topics:

Set-PublicFolderMigrationRequest

Resume-PublicFolderMigrationRequest

Set-OrganizationConfig

Step 8: Test and unlock the public folder migration

After you finalize the public folder migration, you should run the following test to make sure that the migration was successful. This allows you to test the migrated public folder hierarchy before you switch to using Office 365 or Exchange Online public folders.

1. In Office 365 or Exchange Online PowerShell, assign some test mailboxes to use any newly migrated public folder mailbox as the default public folder mailbox.

```
Set-Mailbox -Identity <Test User> -
DefaultPublicFolderMailbox <Public Folder Mailbox Identity>
```

2. Log on to Outlook 2007 or later with the test user identified in the previous step, and then perform the following public folder tests:
   - View the hierarchy.
   - Check permissions.
   - Create and delete public folders.

- Post content to and delete content from a public folder.

3. If you run into any issues, see Roll back the migration later in this topic. If the public folder content and hierarchy is acceptable and functions as expected, run the following Exchange Online PowerShell command to unlock the public folders for all other users.

```
Get-Mailbox -PublicFolder | Set-Mailbox -PublicFolder -IsExcludedFromServingHierarchy $false
```

Important:
Don't use the *IsExcludedFromServingHierarchy* parameter after initial migration validation is complete as this parameter is used by the automated storage management service for Exchange Online.

4. On the legacy Exchange server, run the following command to indicate that the public folder migration is complete:

```
Set-OrganizationConfig -PublicFolderMigrationComplete:$true
```

For detailed syntax and parameter information, see the following topics:

Set-Mailbox

Get-Mailbox

Set-OrganizationConfig

How do I know this worked?

In Step 2: Prepare for the migration, you were instructed to take snapshots of the public folder structure, statistics, and permissions before the migration began. The following steps will help verify that your public folder migration was successful by taking the same snapshots after the migration is complete. You can then compare the data in both files to verify success.

1. In Exchange Online PowerShell, run the following command to take a snapshot of the new folder structure.

```
Get-PublicFolder -Recurse | Export-CliXML  C:\PFMigration\Cloud_PFStructure.xml
```

2. In Exchange Online PowerShell, run the following command to take a snapshot of the public folder statistics such as item count, size, and owner.

```
Get-PublicFolderStatistics -ResultSize Unlimited | Export-CliXML  C:\PFMigration\Cloud_PFStatistics.xml
```

3. In Exchange Online PowerShell, run the following command to take a snapshot of the permissions.

```
Get-PublicFolder -Recurse | Get-
PublicFolderClientPermission | Select-Object Identity,User
-ExpandProperty AccessRights | Export-CliXML  C:
\PFMigration\Cloud_PFPerms.xml
```

Remove public folder databases from the legacy Exchange servers

After the migration is complete, and you have verified that your Exchange Online public folders are working as expected, you should remove the public folder databases on the legacy Exchange servers.

- For details about how to remove public folder databases from Exchange 2007 servers, see Removing Public Folder Databases.
- For details about how to remove public folder databases from Exchange 2010 servers, see Remove Public Folder Databases.

Roll back the migration

If you run into issues with the migration and need to reactivate your legacy Exchange public folders, perform the following steps.

⚠**Warning:**
If you roll your migration back to the legacy Exchange servers, you will lose any email that was sent to mail-enabled public folders or content that was posted to public folders after the migration. To save this content, you must export the public folder content to a .pst file and then import it to the legacy public folders when the rollback is complete.

1. On the legacy Exchange server, run the following command to unlock the legacy Exchange public folders. This process may take several hours.

```
Set-OrganizationConfig -
PublicFoldersLockedForMigration:$False
```

2. In Exchange Online PowerShell, run the following commands to remove all Exchange Online public folders.

```
$hierarchyMailboxGuid = $(Get-
OrganizationConfig).RootPublicFolderMailbox.HierarchyMailbo
xGuid
Get-Mailbox -PublicFolder:$true | Where-Object
{$_.ExchangeGuid -ne $hierarchyMailboxGuid} | Remove-
Mailbox -PublicFolder -Confirm:$false -Force
```

```
Get-Mailbox -PublicFolder:$true | Where-Object
{$_.ExchangeGuid -eq $hierarchyMailboxGuid} | Remove-
Mailbox -PublicFolder -Confirm:$false -Force
```

3. On the legacy Exchange server, run the following command to set the `PublicFolderMigrationComplete` flag to `$false`.

```
Set-OrganizationConfig -
PublicFolderMigrationComplete:$False
```

Migrate Public Folders to Office 365 by using Outlook PST export

We recommend that you don't use Outlook's PST export feature to migrate public folders to Office 365 or Exchange Online if your on-premises public folder hierarchy is greater than 30 GB. Office 365 online public folder mailbox growth is managed using an auto-split feature that splits the public folder mailbox when it exceeds size quotas. Auto-split can't handle the sudden growth of public folder mailboxes when you use PST export to migrate your public folders and you may have to wait for up to two weeks for auto-split to move the data from the primary mailbox. In addition, consider the following before using Outlook PST to export public folders to Office 365 or Exchange Online:

- Public folder permissions will be lost during this process. Capture the current permissions before migration and manually add them back once the migration is completed.
- If you use complex permissions or have many folders to migrate, we recommend that you use the cmdlet method for migration.
- Any item and folder changes made to the source public folders during the PST export migration will be lost. Therefore, we recommend that you use the cmdlet method if this export and import process will take a long time to complete.

If you still want to migrate your public folders by using PST files, follow these steps to ensure a successful migration.

1. Use the instructions in Step 1: Download the migration scripts to download the migration scripts. You only need to download the `PublicFolderToMailboxMapGenerator.ps1` file.
2. Follow step 2 of Step 3: Generate the .csv files to create the public folder-to-mailbox mapping file. This file is used to calculate the correct number of public folder mailboxes in Exchange Online.
3. Create the public folder mailboxes that you'll need based on the mapping file. For more information, see Create a public folder mailbox.
4. Use the **New-PublicFolder** cmdlet to create the top-most public folder in each of the public folder mailboxes by using the *Mailbox* parameter.
5. Export and import the PST files using Outlook.
6. Set the permissions on the public folders using the EAC. For more information, follow Step 3: Assign permissions to the public folder in the Set up public folders in a new organization topic.

Warning:

If you've already started a PST migration and have run into an issue where the primary mailbox is full, you have two options for recovering the PST migration:

1. Wait for the auto-split to move the data from the primary mailbox. This may take up to two weeks. However, all the public folders in a completely filled public folder mailbox won't be able to receive new content until the auto-split completes.
2. Create a public folder mailbox and then use the **New-PublicFolder** cmdlet with the *Mailbox* parameter to create the remaining public folders in the secondary public folder mailbox. This example creates a new public folder named PF201 in the secondary public folder mailbox.

```
New-PublicFolder -Name PF201 -Mailbox SecondaryPFMbx
```

Configure legacy on-premises public folders for a hybrid deployment

Collaboration > Public folders > Public folder procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-08-26*

In a hybrid deployment, your users can be in Exchange Online, on-premises, or both and your public folders are either in Exchange Online or on-premises. Public folders can only reside in one place, so you must decide whether your public folders will be in Exchange Online or on-premises. They can't be in both locations. Public folder mailboxes are synchronized to Exchange Online by the Directory Synchronization service. However, mail-enabled public folders aren't synchronized across premises.

This topic describes how to synchronize mail-enabled public folders when your users are in Exchange Online and your Exchange 2010 SP3 or Exchange 2007 SP3 RU10 public folders are on-premises.

Note:

This topic refers to the Exchange 2010 SP3 and Exchange 2007 SP3 RU10 servers as the *legacy Exchange server*.

You will sync your mail-enabled public folders using the following scripts, which are initiated by a Windows task that runs in the on-premises environment:

1. `Export-MailPublicFoldersForMigration.ps1` This script exports the mail-enabled public folder objects from the on-premises organization's Active Directory into a .XML file. You'll run this script on the legacy Exchange server.

2. `Import-MailPublicFoldersForMigration.ps1` This script uses the .XML file generated by the `Export-MailPublicFoldersForMigration.ps1` script to import the mail-enabled public folder objects into Exchange Online. You'll run this script in Exchange Online.
3. `MailPublicFolder.strings.psd1` This is a support file used by the Import and Export scripts and should be copied to the same location as the preceding scripts.

When you complete this procedure your on-premises and Exchange Online users will be able to access the same on-premises public folder infrastructure.

What hybrid versions of Exchange will work with public folders?

The following table describes the version and location combinations of user mailboxes and public folders that are supported. "Hybrid not applicable" is still a supported scenario, but is not considered a hybrid scenario since both the public folders and the users are residing in the same location.

	On-Premises Exchange 2007 or Exchange 2010 User Mailbox	**On-Premises Exchange 2013 User Mailbox**	**Exchange Online User Mailbox**
On-Premises Exchange 2007 or Exchange 2010 Public Folders	Hybrid not applicable	Hybrid not applicable	Supported
On-Premises Exchange 2013 Public Folders	Hybrid not applicable	Hybrid not applicable	Supported
Exchange Online Public Folders	Not supported	Supported	Hybrid not applicable

A hybrid configuration with Exchange 2003 public folders is not supported. If you're running Exchange 2003 in your organization, you must move all public folder databases and replicas to Exchange 2007 SP3 RU10 or later. No public folder replicas can remain on Exchange 2003.

What do you need to know before you begin?

1. These instructions assume that you have used the Hybrid Configuration Wizard to configure and synchronize your on-premises and Exchange Online environments and that the DNS records used for most users' AutoDiscover references an on-premises end-point. For more information, see

Hybrid Configuration wizard.

2. These instructions assume that Outlook Anywhere is enabled and functional on the on-premises legacy Exchange server(s). For information on how to enable Outlook Anywhere, see Outlook Anywhere.
3. Implementing legacy public folder coexistence for a hybrid deployment of Exchange with Office 365 may require you to fix conflicts during the import procedure. Conflicts can happen due to non-routable email address assigned to mail enabled public folders, conflicts with other users and groups in Office 365, and other attributes.
4. These instructions assume your Exchange Online organization has been upgraded to a version that supports public folders.
5. In Exchange Online, you must be a member of the Organization Management role group. This role group is different from the permissions assigned to you when you subscribe to Exchange Online. For details about how to enable the Organization Management role group, see Manage role groups.
6. In Exchange 2010, you must be a member of the Organization Management or Server Management RBAC role groups. For details, see Add Members to a Role Group
7. In Exchange 2007, you need to be assigned the Exchange Organization Administrator role or the Exchange Server Administrator role. In addition, you must be assigned the Public Folder Administrator role and local Administrators group for the target server. For details, see How to Add a User or Group to an Administrator Role
8. If you have Exchange Server 2007 running on Windows Server 2008 x64, then you must upgrade to Windows PowerShell 2.0 and WinRM 2.0 for Windows Server 2008 x64 Edition. If you have Exchange Server 2007 running on Windows Server 2003 x64, then you must upgrade to Windows PowerShell 2.0. For more information, see Update for Windows Server 2003 x64 Edition..
9. In order to access public folders cross-premises, users must upgrade their Outlook clients to the November 2012 Outlook public update or later.
    a. To download the November 2012 Outlook update for Outlook 2010, see Update for Microsoft Outlook 2010 (KB2687623) 32-Bit Edition.
    b. To download the November 2012 Outlook Update for Outlook 2007, see Update for Microsoft Office Outlook 2007 (KB2687404).
10. Outlook 2011 for Mac is not supported for cross-premises public folders. Users must be in the same location as the public folders to access them with Outlook 2011 for Mac. In addition, users whose mailboxes are in Exchange Online won't be able to access on-premises public folders using Outlook Web App.

Step 1: Make remote public folders discoverable

1. If your public folders are on Exchange 2010 or later servers, then you need to install the Client Access Server role on all mailbox servers that have a public folder database. This allows the Microsoft Exchange RpcClientAccess service to be running, which allows for all clients to access public folders. The client access role isn't required for Exchange 2007 public folder servers, and this step isn't necessary. For more information, see Install Exchange Server 2010. This step isn't necessary for Exchange 2007 public folders.

Note:

This server doesn't have to be part of the Client Access load balancing. For more information, see Understanding Load Balancing in Exchange 2010.

2. Create an empty mailbox database on each public folder server.

For Exchange 2010, run the following command. This command excludes the mailbox database from the mailbox provisioning load balancer. This prevents new mailboxes from automatically being added to this database.

```
New-MailboxDatabase -Server <PFServerName_with_CASRole> -
Name <NewMDBforPFs> -IsExcludedFromProvisioning $true
```

For Exchange 2007, run the following command:

```
New-MailboxDatabase -StorageGroup "<PFServerName>
\StorageGroup>" -Name <NewMDBforPFs>
```

Note:

We recommend that the only mailbox that you add to this database is the proxy mailbox that you'll create in step 3. No other mailboxes should be created on this mailbox database.

3. Create a proxy mailbox within the new mailbox database and hide the mailbox from the address book. The SMTP of this mailbox will be returned by AutoDiscover as the *DefaultPublicFolderMailbox* SMTP, so that by resolving this SMTP the client can reach the legacy exchange server for public folder access.

```
New-Mailbox -Name <PFMailbox1> -Database <NewMDBforPFs>

Set-Mailbox -Identity <PFMailbox1> -
HiddenFromAddressListsEnabled $true
```

4. For Exchange 2010, enable AutoDiscover to return the proxy public folder mailboxes. This step isn't necessary for Exchange 2007.

```
Set-MailboxDatabase <NewMDBforPFs> -RPCClientAccessServer
<PFServerName_with_CASRole>
```

5. Repeat the preceding steps for every public folder server in your organization.

Step 2: Download the scripts

1. Download the following files from Microsoft Exchange 2013 Public Folders Directory Sync Support Scripts:
   - `Export-MailPublicFoldersForMigration.ps1`
   - `Import-MailPublicFoldersForMigration.ps1`
   - `MailPublicFolder.strings.psd1`

2. Save the files to the local computer on which you'll be running PowerShell. For example, C:\PFScripts.

Step 3: Configure directory synchronization

The Directory Synchronization service doesn't synchronize mail-enabled public folders. Running the following two scripts will synchronize the mail-enabled public folders across premises.

1. On the legacy Exchange server, run the following command to create the .XML file that will export the set of mail-enabled public folders from Active Directory.

```
.\Export-MailPublicFoldersForMigration.ps1
<mail_publicfolders.xml>
```

Where `mail_publicfolders.xml` is the file name and path to a network shared folder that can be accessed from Exchange Online.

2. In Exchange Online PowerShell, run the following command to import the migration .XML file.

```
.\Import-MailPublicFoldersForMigration.ps1
<mail_publicfolders.xml>
```

Note:

We recommend that you run these scripts daily to synchronize your mail-enabled public folders.

Step 4: Configure Exchange Online users to access on-premises public folders

The final step in this procedure is to configure the Exchange online organization and to allow access to the legacy on-premises public folders.

Enable the exchange online organization to access the on-premises public folders. You will point to all of the proxy public folder mailboxes that you created in Step 1: Make remote public folders discoverable.

```
Set-OrganizationConfig -PublicFoldersEnabled Remote -
RemotePublicFolderMailboxes
PFMailbox1,PFMailbox2,PFMailbox3
```

Note:

You must wait until ActiveDirectory synchronization has completed to see the changes. This process can take up to 3 hours to complete. If you don't want to wait for the recurring synchronizations that occur every three hours, you can force directory synchronization at any time. For detailed steps to do force directory synchronization, see Force directory

synchronization.

How do I know this worked?

1. Log on to Outlook for a user who is in Exchange Online and perform the following public folder tests:
   - View the hierarchy.
   - Check permissions
   - Create and delete public folders.
   - Post content to and delete content from a public folder.

Configure legacy public folders where user mailboxes are on Exchange 2013 servers

Collaboration > Public folders > Public folder procedures >

Topic Last Modified: *2014-05-23*

In Exchange Server 2013, you'll need to perform this task to make sure that users can access public folders if you have Exchange 2013 users accessing Exchange 2010 or earlier public folders (also known as legacy public folders).

What do you need to know before you begin?

Users whose mailboxes are on Exchange Server 2013 won't be able to access legacy public folders from Outlook Web App or Outlook for Mac.

Step 1: Make the Exchange 2010 public folders discoverable

1. If your public folders are on Exchange 2010 or later servers, then you need to install the Client Access Server role on all mailbox servers that have a public folder database. This allows the Microsoft Exchange RpcClientAccess service to be running, which allows for all clients to access public folders. The client access role isn't required for Exchange 2007 public folder servers, and this step isn't necessary. For more information, see Install Exchange Server 2010.

Note:

This server doesn't have to be part of the Client Access load balancing. For more information, see Understanding Load Balancing in Exchange 2010.

2. Create an empty mailbox database on each public folder server.

For Exchange 2010, run the following command. This command excludes the mailbox database from the mailbox provisioning load balancer. This prevents new mailboxes from automatically being added to this database.

```
New-MailboxDatabase -Server <PFServerName_with_CASRole> -
Name <NewMDBforPFs> -IsExcludedFromProvisioning $true
```

For Exchange 2007, run the following command:

```
New-MailboxDatabase -StorageGroup "<PFServerName>
\StorageGroup>" -Name <NewMDBforPFs>
```

Note:

We recommend that the only mailbox that you add to this database is the proxy mailbox that you'll create in step 3. No other mailboxes should be created on this mailbox database.

3. Create a proxy mailbox within the new mailbox database and hide the mailbox from the address book. The SMTP of this mailbox will be returned by AutoDiscover as the *DefaultPublicFolderMailbox* SMTP, so that by resolving this SMTP the client can reach the legacy exchange server for public folder access.

```
New-Mailbox -Name <PFMailbox1> -Database <NewMDBforPFs>

Set-Mailbox -Identity <PFMailbox1> -
HiddenFromAddressListsEnabled $true
```

4. For Exchange 2010, enable AutoDiscover to return the proxy public folder mailboxes. This step isn't necessary for Exchange 2007.

```
Set-MailboxDatabase <NewMDBforPFs> -RPCClientAccessServer
<PFServerName_with_CASRole>
```

5. Repeat the preceding steps for every public folder server in your organization.

Step 2: Configure user mailboxes to access the legacy public folders

The final step in this procedure is to configure the user mailboxes to allow access to the legacy on-premises public folders.

Enable the Exchange Server 2013 on-premises users to access the legacy public folders. You will point to all of the proxy public folder mailboxes that you created in Step 1: Make the Exchange

2010 public folders discoverable. Run the following command from an Exchange 2013 server with the CU5 or higher update.

```
Set-OrganizationConfig -PublicFoldersEnabled Remote -
RemotePublicFolderMailboxes
ProxyMailbox1,ProxyMailbox2,ProxyMailbox3
```

Note:

You must wait until ActiveDirectory synchronization has completed to see the changes. This process may take several hours.

How do I know this worked?

Log on to Outlook for a user whose mailbox is on an Exchange Server 2013 CU5 or higher server and perform the following public folder tests:

1. Make sure that the Outlook client is running.
2. Hold down the CTRL key, and then right-click on the Outlook icon in the notification area on the right side of the Windows task bar.
3. Select **Test E-Mail Auto Configuration...**
4. Make sure the Text E-mail Auto Configuration tool returns the following information in the XML tab:
   - <PublicFolderInformation>
   - <SmtpAddress><SMTP Address for public folder mailbox</SmtpAddress>
   - </PublicFolderInformation>
5. In the Outlook client, peform the following tasks:
   - View the public folder hierarchy.
   - Check permissions.
   - Create and delete public folders.
   - Post content to and delete content from a public folder.

Create a public folder mailbox

Collaboration > Public folders > Public folder procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-02-24*

Before you can create a public folder, you must first create a public folder mailbox. Public folder mailboxes contain the hierarchy information plus the content for public folders. The first public folder mailbox you create will be the primary hierarchy mailbox, which contains the only writable copy of the hierarchy. Any additional public folder mailboxes you create will be secondary

mailboxes, which contain a read-only copy of the hierarchy.

Note:

For more information about the storage quotas and limits for public folders, see the following topics:

- For public folders in Office 365, see Exchange Online Limits.
- For public folders in on-premises Exchange Server 2013, see Limits for public folders.

For additional management tasks related to public folders in Exchange 2013, see Public folder procedures.

For additional management tasks related to public folders in Exchange Online, see **Public folder procedures in Office 365 and Exchange Online**.

What do you need to know before you begin?

- Estimated time to complete: less than 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Public folders" entry in the Sharing and collaboration permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

What do you want to do?

Use the EAC to create a public folder mailbox

1. Navigate to **Public folders** > **Public folder mailboxes**, and then click **Add +**.
2. In **Public Folder Mailbox**, provide a name for the public folder mailbox.
3. Click **Save**.

Use the Shell to create a public folder mailbox

This example creates the primary public folder mailbox.

```
New-Mailbox -PublicFolder -Name MasterHierarchy
```

This example creates a secondary public folder mailbox. The only difference between creating the primary hierarchy mailbox and a secondary hierarchy mailbox is that the primary mailbox is the first one created in the organization. You can create additional public folder mailboxes for load balancing purposes.

```
New-Mailbox -PublicFolder -Name Istanbul
```

For detailed syntax and parameter information, see New-Mailbox.

How do you know this worked?

To verify that you have successfully created the primary public folder mailbox, run the following Shell command:

```
Get-OrganizationConfig | Format-List
RootPublicFolderMailbox
```

For detailed syntax and parameter information, see Get-OrganizationConfig.

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Create a public folder

Collaboration > Public folders > Public folder procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-02-24*

Public folders are designed for shared access and provide an easy and effective way to collect, organize, and share information with other people in your workgroup or organization.

By default, a public folder inherits the settings of its parent folder, including the permissions settings.

Note:

For more information about the storage quotas and limits for public folders, see the following topics:

- For public folders in Office 365, see Exchange Online Limits.
- For public folders in on-premises Exchange Server 2013, see Limits for public folders.

For additional management tasks related to managing public folders, see Public folder procedures.

For additional management tasks related to public folders, see **Public folder procedures in Office 365 and Exchange Online**.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Public folders" entry in the Sharing and collaboration permissions topic.
- You can't create a public folder unless you've first created a public folder mailbox. For more

information about how to create a public folder mailbox, see Create a public folder mailbox.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

What do you want to do?

Use the EAC to create a public folder

When using the EAC to create a public folder, you'll only be able to set the name and the path of the public folder. To configure additional settings, you'll need to edit the public folder after it's created.

1. Navigate to **Public folders** > **Public folders**.
2. If you want to create this public folder as a child of an existing public folder, click the existing public folder in the list view. If you want to create a top-level public folder, skip this step.
3. Click **Add +**.
4. In **Public Folder**, type the name of the public folder.

Important:
Don't use a backslash (\) in the name when creating a public folder.

5. In the **Path** box, verify the path to the public folder. If this isn't the desired path, click **Cancel** and follow Step 2 of this procedure.
6. Click **Save**.

Use the Shell to create a public folder

This example creates a public folder named Reports in the path Marketing\2013.

```
New-PublicFolder -Name Reports -Path \Marketing\2013
```

Important:
Don't use a backslash (\) in the name when creating a public folder.

For detailed syntax and parameter information, see New-PublicFolder.

How do you know this worked?

To verify that you've successfully created a public folder, do the following:

- In the EAC, click **Refresh** to refresh the list of public folders. Your new public folder should be displayed in the list.
- In the Shell, run any of the following commands:

```
Get-PublicFolder -Identity \Marketing\2013\Reports |
Format-List
```

```
Get-PublicFolder -Identity \Marketing\2013 -GetChildren

Get-PublicFolder -Recurse
```

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Mail-enable or mail-disable a public folder

Collaboration > Public folders > Public folder procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-08-18*

Public folders are designed for shared access and provide an easy and effective way to collect, organize, and share information with other people in your workgroup or organization. Mail-enabling a public folder allows users to post to the public folder by sending an email message to it. When a public folder is mail-enabled additional settings become available for the public folder in the Exchange admin center (EAC), such as email addresses and mail quotas. In the Shell, before a public folder is mail-enabled, you use the **Set-PublicFolder** cmdlet to manage all of its settings. After the public folder is mail-enabled, you use the **Set-PublicFolder** and the **Set-MailPublicFolder** cmdlets to manage the settings.

If you want users on the Internet to send mail to a mail-enabled public folder, you need to set addition permissions using the **Add-PublicFolderClientPermission** cmdlet.

For additional management tasks related to managing public folders, see Public folder procedures.

For additional management tasks related to public folders, see **Public folder procedures in Office 365 and Exchange Online**.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes
- To ensure that users on the Internet can send e-mail messages to a mail-enabled public folder, the public folder needs to have at least the *CreateItems* access right granted to the Anonymous account. If you want to learn how to do this, check out Allow anonymous users to send email to a mail-enabled public folder.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Public folders" entry in the Sharing and collaboration

permissions topic.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to mail-enable or mail-disable a public folder

1. Navigate to **Public folders** > **Public folders**.
2. In the list view, select the public folder that you want to mail-enable or mail-disable.
3. In the details pane, under **Mail settings**, click **Enable** or **Disable**.
4. A warning box displays asking if you are sure you want to enable or disable email for the public folder. Click **Yes** to continue.

If you want external users to send mail to this public folder, make sure you follow the steps in Allow anonymous users to send email to a mail-enabled public folder.

Use the Shell to mail-enable a public folder

This example mail-enables the public folder Help Desk.

```
Enable-MailPublicFolder -Identity "\Help Desk"
```

This example mail-enables the public folder Reports under the Marketing public folder, but hides the folder from address lists.

```
Enable-MailPublicFolder -Identity "\Marketing\Reports" -
HiddenFromAddressListsEnabled $True
```

If you want external users to send mail to this public folder, make sure you follow the steps in Allow anonymous users to send email to a mail-enabled public folder.

For detailed syntax and parameter information, see Enable-MailPublicFolder.

Use the Shell to mail-disable a public folder

This example mail-disables the public folder Marketing\Reports.

```
Disable-MailPublicFolder -Identity "\Marketing\Reports"
```

For detailed syntax and parameter information, see Disable-MailPublicFolder.

Allow anonymous users to send email to a mail-enabled public folder

You can use either Outlook or the Shell to set permissions on a public folder's Anonymous account. You can't use the EAC to set permissions on the Anonymous account.

Use Outlook to set permissions for the Anonymous account

1. Open Outlook using an account that's been granted Owner permissions on the email-enabled public folder you want anonymous users to send mail to.
2. Navigate to **Public folders - <user's name>**.
3. Navigate to the public folder you want to change.
4. Right-click on the public folder, click **Properties** and then select the **Permissions** tab.
5. Select the **Anonymous** account, select **Create items** under **Write**, and then click **OK**.

Use the Shell to set permissions for the Anonymous account

This example sets the `CreateItems` permission for the Anonymous account on the "Customer Feedback" mail-enabled public folder.

```
Add-PublicFolderClientPermission "\Customer Feedback" -
AccessRights CreateItems -User Anonymous
```

For detailed syntax and parameter information, see Add-PublicFolderClientPermission.

Update the public folder hierarchy

Collaboration > Public folders > Public folder procedures >

Applies to: *Exchange Online*

Topic Last Modified: *2014-04-03*

You only need to update the public folder hierarchy if you want to manually invoke the hierarchy synchronizer and the mailbox assistant. Both these are invoked at least once every 24 hours for each public folder mailbox in the organization. The hierarchy synchronizer is invoked every 15 minutes if any users are logged on to a secondary mailbox through Microsoft Outlook or a Microsoft Exchange Web Services client.

For additional management tasks related to public folders in Exchange Online, see **Public folder procedures in Office 365 and Exchange Online**.

For additional management tasks related to public folders in Exchange Server 2013, see Public folder procedures.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Public folders" entry in the Sharing and collaboration permissions topic.
- You can't perform this procedure in the EAC. You must use the Shell.
- We recommend that when you run this command with the *InvokeSynchronizer* parameter, you use the *SuppressStatus* parameter. If you don't use this parameter in the command, the output will display status messages every 3 seconds for up to one minute. Until the minute passes, you can't use that instance of the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Update the public folder hierarchy

This example updates the public folder hierarchy on the public folder mailbox PF_marketing and suppresses the command's output.

```
Update-PublicFolderMailbox -Identity PF_marketing -
InvokeSynchronizer -SuppressStatus
```

This example updates all public folder mailboxes and suppresses the command's output.

```
Get-Mailbox -PublicFolder | Update-PublicFolderMailbox
InvokeSynchronizer -SuppressStatus
```

Remove a public folder

Collaboration > Public folders > Public folder procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-13*

You may need to remove public folders that are no longer being used in your organization. To help determine which public folders should be removed, see View statistics for public folders and public folder items.

For additional management tasks related to managing public folders, see Public folder procedures.

For additional management tasks related to public folders, see **Public folder procedures in Office 365 and Exchange Online**.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Public folders" entry in the Sharing and collaboration permissions topic.
- You can't delete a mail-enabled public folder. Before you can delete it, you must first disable email for the public folder. For more information, see Mail-enable or mail-disable a public folder.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to remove a public folder

1. Navigate to **Public folders** > **Public folders**.
2. In the list view, select the public folder you want to delete, and then click **Delete** .
3. A warning box displays asking if you're sure you want to delete the public folder. Click **Yes** to continue.

Use the Shell to delete a public folder

This example deletes the public folder Help Desk\Resolved. This command assumes that the Resolved public folder doesn't have any subfolders.

```
Remove-PublicFolder -Identity "\Help Desk\Resolved"
```

This example tests the previous command without making any modifications.

```
Remove-PublicFolder -Identity "\HelpDesk\Resolved" -WhatIf
```

This example removes the public folder Marketing and all its subfolders because the command runs recursively.

```
Remove-PublicFolder -Identity "\Marketing" -Recurse:$True
```

For detailed syntax and parameter information, see Remove-PublicFolder.

Move a public folder mailbox to a different mailbox database

Collaboration > Public folders > Public folder procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-13*

You may need to move a public folder mailbox to a different mailbox database for load balancing purposes or for moving resources closer to their geographical location. Similar to moving a regular mailbox, you use the **MoveRequest** cmdlets to move a public folder mailbox. For more information about moving mailboxes, see Mailbox moves in Exchange 2013.

For additional management tasks related to public folders, see Public folder procedures.

What do you need to know before you begin?

- Estimated time to complete depends on the size of the public folder mailbox.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mailbox move and migration permissions" section in the Recipients Permissions topic.
- You can't perform this procedure in the EAC. You can only perform this procedure in the Shell.
- Depending on the size of the public folder mailbox, the move may take several hours to complete. During that time, users won't be able to access the public folders. Users also won't have access to public folders for a brief period while the folder is in the "Completion in Progress" state.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Create a move request

The **New-MoveRequest** cmdlet queues the public folder mailbox into the Microsoft Exchange Mailbox Replication service queue. When the Microsoft Exchange Mailbox Replication service is

available, it will pick up the move request and begin moving the public folder mailbox. It will complete the entire request from beginning to end.

This example begins the move request for the public folder mailbox PF_SanFrancisco to the mailbox database MBX_DB01.

```
New-MoveRequest -Identity "PF_SanFrancisco" -TargetDatabase MBX_DB01
```

For detailed syntax and parameter information, see New-MoveRequest.

Create a move request to complete at a later time

During the final stage of the move request, when it's the `CompletionInProgress` phase, users will be locked out the public folder mailbox. If needed, you can suspend the move request before it reaches that phase and resume it at a time when users won't be impacted.

This example begins the move request for the public folder mailbox PF_SanFrancisco to the mailbox database MBX_DB01, and suspends it when the move request is ready to complete.

```
New-MoveRequest -Identity "PF_SanFrancisco" -TargetDatabase MBX_DB01 -SuspendWhenReadyToComplete
```

For detailed syntax and parameter information, see New-MoveRequest.

This example retrieves the status of the ongoing mailbox move for the public folder mailbox PF_SanFrancisco.

```
Get-MoveRequest -Identity "PF_SanFrancisco"
```

For detailed syntax and parameter information, see Get-MoveRequest.

When the move request reaches the status of Suspended, you can resume the request. This example resumes the move request for the public folder mailbox PF_SanFrancisco.

```
Resume-MoveRequest -Identity "PF_SanFrancisco"
```

For detailed syntax and parameter information, see Resume-MoveRequest.

How do you know this worked?

To verify that the move request was successfully created, run the following command:

```
Get-MoveRequestStatistics -Identity PF_SanFrancisco | Format-List Status
```

A status of `Completed` indicates that the move request was successful.

If the move was unsuccessful, you may need to restore the public folder. For more information, see Restore public folders and public folder mailboxes from failed moves.

Move a public folder to a different public folder mailbox

Collaboration > Public folders > Public folder procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-13*

If the content of a public folder mailbox begins to exceed your mailbox quotas, you may need to move public folders to a different public folder mailbox. There are a couple ways to do this. To move one or more public folders that don't contain subfolders, you can use the **PublicFolderMoveRequest** cmdlets. If you need to move an entire public folder branch (which includes the parent public folder and all subfolders), you can use the `Move-PublicFolderBranch.ps1` script that's available when you install Exchange 2013.

For additional management tasks related to public folders see Public folder procedures.

What do you need to know before you begin?

- Estimated time to complete this task depends on the size of the public folder.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the"Public folders" entry in the Sharing and collaboration permissions topic.
- You can't use the EAC to perform these procedures. You must use the Shell.
- If the folder you're moving has subfolders, those subfolders won't be moved by default. If you want to move a public folder and all its subfolders, use the **Move-PublicFolderBranch.ps1** script.
- Moving public folders only moves the physical contents of the public folder; it doesn't change the logical hierarchy.
- Depending on the size of the public folder and the amount of content it contains, the move may take several hours to complete. During that time, users will be able to access the public folders. However, users won't be able to access the public folders for a brief period while the folder is in the "Completion in Progress" state.
- You can perform only one public folder move request at a time. You must use the **Remove-PublicFolderMoveRequest** cmdlet to remove the request after it's complete.
- To check the status of an ongoing public folder move request, run the Get-PublicFolderMoveRequest cmdlet.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Move a single public folder

This example starts the move request for the public folder \CustomerEnagagements from the public folder mailbox DeveloperReports to DeveloperReports01

```
New-PublicFolderMoveRequest -Folders \DeveloperReports
\CustomerEngagements -TargetMailbox DeveloperReports01
```

For detailed syntax and parameter information, see New-PublicFolderMoveRequest.

Move multiple public folders

This example begins the move request for public folders under the \Dev public folder branch to the target public folder mailbox DeveloperReports01. This example doesn't move the public folder \Dev.

```
New-PublicFolderMoveRequest -Folders \Dev
\CustomerEngagements,\Dev\RequestsforChange,\Dev\Usability
-TargetMailbox DeveloperReports01
```

For detailed syntax and parameter information, see New-PublicFolderMoveRequest.

Move a branch of public folders

This example uses the `Move-PublicFolderBranch.ps1` script to move a branch of public folders. This starts the move request for the public folder \Dev and all its subfolders to the public folder mailbox DeveloperReports01. The script is located in the scripts folder and must be run from that location.

```
CD $env:ExchangeInstallPath\scripts
.\Move-PublicFolderBranch.ps1 -FolderRoot \Dev -
TargetPublicFolderMailbox DeveloperReports01
```

How do you know this worked?

To verify that the public folder move request was successful, run the following command:

```
Get-PublicFolderMoveRequest | Format-List Status
```

A status of `Completed` indicates that the move request was successful.

If the move request was unsuccessful, you may need to restore the public folder or its contents. For more information, see Restore public folders and public folder mailboxes from failed moves.

Restore public folders and public folder mailboxes from failed moves

Collaboration > Public folders > Public folder procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-13*

If a move request for a public folder or public folder mailbox fails, you can restore the folder or mailbox as long as the following conditions apply:

- **Failed public folder move** A soft-deleted copy of the public folder still exists in the source public folder mailbox and is still within the retention period.
- **Failed public folder mailbox move** A soft-deleted copy of the public folder mailbox still exists in the source mailbox database and is still within the mailbox retention period.

If the mailbox retention period has elapsed, you can recover an individual public folder mailbox from backup. You then extract data from the restored mailbox and copy it to a target folder or merge it with another mailbox. For more information, see Restore data using a recovery database.

For additional management tasks related to public folders, see Public folder procedures.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mailbox restore request" entry in the Recipients Permissions topic.
- You can't use the EAC to perform this procedure. You must use the Shell.
- To create a restore request, you must provide the values for the *DisplayName*, *LegacyDN*, or *MailboxGUID* parameters for the soft-deleted public folder mailbox.
- By default, dumpster folders will be restored along with regular folders. This can be prevented by using the *ExcludeDumpster* parameter.
- Restoring public folder mailboxes differs from restoring regular mailboxes in that folders won't

be created if they don't exist in the target mailbox. Missing folders will be displayed in a warning message at the end of restore request.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Restore a soft-deleted public folder

This example restores the public folder \Dev\CustomerEnagagements to the target public folder mailbox Development01.

```
New-MailboxRestoreRequest -SourceStoreMailbox Development -
SourceDatabase MBX_DB01 -TargetMailbox Development01 -
AllowLegacyDNMismatch -IncludeFolders \Dev
\CustomerEngagements
```

For detailed syntax and parameter information, see New-MailboxRestoreRequest.

Restore a soft-deleted public folder mailbox

This example restores the public folder mailbox PF_Singapore to the new public folder mailbox PF_Singapore_Restore.

```
New-MailboxRestoreRequest -SourceStoreMailbox PF_Singapore
-SourceDatabase MBX_DB01 -TargetMailbox
PF_Singapore_Restore -AllowLegacyDNMismatch
```

For detailed syntax and parameter information, see New-MailboxRestoreRequest.

View statistics for public folders and public folder items

Collaboration > Public folders > Public folder procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-14*

This topic explains how to retrieve statistics about a public folder, such as the display name, creation time, last user modified time, last user access, and item size. You can use this information to make decisions about deleting or retaining public folders.

Note:
In the Exchange admin center (EAC), you can view some of the quota and usage information for public folders by navigating to **Public Folders** > **Edit** > **Mailbox usage**. However, this information is incomplete, and we recommend that you use the Shell to view public folder statistics.

For additional management tasks related to managing public folders, see Public folder procedures.

For additional management tasks related to public folders, see **Public folder procedures in Office 365 and Exchange Online**.

What do you need to know before you begin?

- Estimated time to complete: 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Public folders" entry in the Sharing and collaboration permissions topic.
- You can't use the EAC to retrieve public folder statistics.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to retrieve public folder statistics

This example returns the statistics for the public folder Marketing with a piped command to format the list.

```
Get-PublicFolderStatistics -Identity \Marketing | Format-List
```

Note:
The value for the *Identity* parameter must include the path to the public folder. For example, if the public folder Marketing existed under the parent folder Business, you would provide the following value: `\Business\Marketing`

For detailed syntax and parameter information, see Get-PublicFolderStatistics.

Use the Shell to view statistics for public folder items

You can view the following information about items within a public folder:

- Type of item
- Subject
- Last user modification time
- Last user access time
- Creation time
- Attachments
- Message size

You can use this information to make decisions about what actions to take for your public folders, such as which public folders to delete. For example, you may want to delete a public folder if the items haven't been accessed for over two years, or you may want to convert a public folder that's being used as a document repository to another client access application.

This example returns default statistics for all items in the public folder Pamphlets under the path \Marketing\2013. Default information includes item identity, creation time, and subject.

```
Get-PublicFolderItemStatistics -Identity "\Marketing\2013
\Pamphlets"
```

This example returns additional information about the items within the public folder Pamphlets, such as subject, last modification time, creation time, attachments, message size, and the type of item. It also includes a piped command to format the list.

```
Get-PublicFolderItemStatistics -Identity "\Marketing\2010
\Pamphlets" | Format-List
```

For detailed syntax and parameter information, see Get-PublicFolderItemStatistics.

Use the Shell to export the output of the Get-PublicFolderItemStatistics cmdlet to a .csv file

This example exports the output of the cmdlet to the PFItemStats.csv file that includes the following information for all items within the public folder \Marketing\Reports:

- Subject of the message (`Subject`)
- Date and time that the item was last modified (`LastModificationTime`)
- Whether the item has attachments (`HasAttachments`)
- Type of item (`ItemType`)
- Size of the item (`MessageSize`)

```
Get-PublicFolderItemStatistics -Identity "\Marketing
\Reports" | Select
Subject,LastModificationTime,HasAttachments,ItemType,Messag
eSize | Export-CSV C:\PFItemStats.csv
```

For detailed syntax and parameter information, see Get-PublicFolderItemStatistics.

Shared mailboxes

Exchange Server 2013 > Collaboration >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-13*

A shared mailbox is a mailbox that multiple users can use to read and send email messages. Shared mailboxes can also be used to provide a common calendar, allowing multiple users to schedule and view vacation time or work shifts.

Why set up a shared mailbox?

- Provides a generic email address (for example, info@contoso.com or sales@contoso.com), that customers can use to inquire about your company.
- Allows departments that provide centralized services to employees (for example, help desk, human resources, or printing services), to respond to employee questions.
- Allows multiple users to monitor and reply to email sent to an email address (for example, an address used specifically by the help desk).

What are shared mailboxes?

A shared mailbox is a type of user mailbox that doesn't have its own user name and password. As a result, users can't log into it them directly. To access a shared mailbox, users must first be granted Send As or Full Access permissions to the mailbox. Once that's done, users sign into their own mailboxes and then access the shared mailbox by adding it to their Outlook profile. In Exchange 2003 and earlier, shared mailboxes were just a regular mailbox to which an administrator could grant delegate access. Beginning in Exchange 2007, shared mailboxes became their own recipient type:

- **RecipientType:** UserMailbox
- **RecipientTypeDetails:** SharedMailbox

In previous version of Exchange, creating a shared mailbox was a multi-step process in which you had to use the Exchange Management Shell to complete some of the tasks. In Exchange 2013, you can use the Exchange admin center (EAC) to create a shared mailbox in one step. For details, see

Create a shared mailbox. In fact, the EAC has a feature area devoted entirely to shared mailboxes. Just navigate to **Recipients** > **Shared mailboxes** to view all the management tasks for shared mailboxes.

You can use the following permissions with a shared mailbox.

- **Full Access** The Full Access permission lets a user log into the shared mailbox and act as the owner of that mailbox. While logged in, the user can create calendar items; read, view, delete, and change email messages; create tasks and calendar contacts. However, a user with Full Access permission can't send email from the shared mailbox unless they also have Send As or Send on Behalf permission.
- **Send As** The Send As permission lets a user impersonate the shared mailbox when sending mail. For example, if Kweku logs into the shared mailbox Marketing Department and sends an email, it will look like the Marketing Department sent the email.
- **Send on Behalf** The Send on Behalf permission lets a user send email on behalf of the shared mailbox. For example, if John logs into the shared mailbox Reception Building 32 and sends an email, it look like the mail was sent by "John on behalf of Reception Building 32". You can't use the EAC to grant Send on Behalf permissions, you must use Set-Mailbox cmdlet with the *GrantSendonBehalf* parameter.

Converting shared mailboxes

In previous versions of Exchange, you could use a regular mailbox as a delegated mailbox. If you have delegated mailboxes, you can use the Shell to convert those delegate mailboxes to shared mailboxes. For details, see Convert a Mailbox.

Create a shared mailbox

Exchange Server 2013 > Collaboration > Shared mailboxes >

Applies to: *Office 365 Enterprise, Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-10-19*

Estimated time to complete: 5 minutes

Shared mailboxes makes it easy for a group of people in your company to monitor and send email from a common account, such as info@contoso.com or support@contoso.com. When a person in the group replies to a message sent to the shared mailbox, the email looks like it was sent by the shared mailbox, not from the individual user. You can read Open and use a shared mailbox to see some examples on how people are using shared mailboxes.

To learn more about shared mailboxes, see Shared mailboxes.

Important:

Creating a shared mailbox is now a one-step process using the Exchange admin center. Looking for how to create a shared mailbox in other versions of Exchange? Check out these topics:

- **Office 365 Small Business Admin** Create and use shared mailboxes.
- **Exchange 2010** Allow Mailbox Access.
- **Exchange 2007** How to Allow Mailbox Access.

Use the EAC to create a shared mailbox

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "User mailboxes" entry in the Recipients Permissions topic.

1. Go to **Recipients** > **Shared** > **Add +**.
2. Fill-in the required fields:
   - **Display name**
   - **Email address**
3. To grant Full Access or Send As permissions, click **Add +**, and then select the users you want to grant permissions to. You can use the **CTRL** key to select multiple users. Confused about which permission to use? See Which permission should you use? later in this topic.

Note:

The Full Access permission allows a user to open the mailbox as well as create and modify items in it. The Send As permission allows anyone other than the mailbox owner to send email from this shared mailbox. Both permissions are required for successful shared mailbox operation.

4. Click **Save** to save your changes and create the shared mailbox.

Use the EAC to edit shared mailbox delegation

1. Go to **Recipients** > **Shared** > **Edit** .
2. Click **Mailbox delegation**
3. To grant or remove Full Access and Send As permissions, click **Add +** or **Remove –** and then select the users you want to grant permissions to.

Note:

The Full Access permission allows a user to open the mailbox as well as create and modify items in it. The Send As permission allows anyone other than the mailbox owner to send email from this shared mailbox. Both permissions are required for successful shared mailbox operation.

4. Click **Save** to save your changes.

Use the Shell to create a shared mailbox

This example creates the shared mailbox Sales Department and grants Full Access and Send on Behalf permissions for the security group MarketingSG. Users who are members of the security

group will be granted the permissions to the mailbox.

Note:
This example assumes that you've already created the security group MarketingSG and that security group is mail-enabled. See Manage mail-enabled security groups.

```
New-Mailbox -Shared -Name "Sales Department" -DisplayName
"Sales Department" -Alias Sales | Set-Mailbox -
GrantSendOnBehalfTo MarketingSG | Add-MailboxPermission -
User MarketingSG -AccessRights FullAccess -InheritanceType
All
```

For detailed syntax and parameter information, see New-Mailbox.

Which permissions should you use?

You can use the following permissions with a shared mailbox.

- **Full Access** The Full Access permission lets a user log into the shared mailbox and act as the owner of that mailbox. While logged in, the user can create calendar items; read, view, delete, and change email messages; create tasks and calendar contacts. However, a user with Full Access permission can't send email from the shared mailbox unless they also have Send As or Send on Behalf permission.
- **Send As** The Send As permission lets a user impersonate the shared mailbox when sending mail. For example, if Kweku logs into the shared mailbox Marketing Department and sends an email, it will look like the Marketing Department sent the email.
- **Send on Behalf** The Send on Behalf permission lets a user send email on behalf of the shared mailbox. For example, if John logs into the shared mailbox Reception Building 32 and sends an email, it look like the mail was sent by "John on behalf of Reception Building 32". You can't use the EAC to grant Send on Behalf permissions, you must use Set-Mailbox cmdlet with the *GrantSendonBehalf* parameter.

More information

For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Email addresses and address books

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-03-26*

Recipients (which include users, resources, contacts, and groups) are any mail-enabled object in Active Directory to which Microsoft Exchange can deliver or route messages. For a recipient to send or receive email messages, the recipient must have an email address. Address books are the method by which users find each other in order to send email. There are many different methods for organizing address books. See Key terminology for detailed descriptions of address book features in Exchange Server 2013.

Key terminology

The following terms define the core components associated with email addresses and address books in Exchange 2013.

address book policies

Address book policies (ABPs) allow you to segment users into specific groups to provide customized views of your organization's global address list (GAL). When creating an ABP, you assign a GAL, an offline address book (OAB), a room list, and one or more address lists to the policy. You can then assign the ABP to mailbox users, providing them with access to a customized GAL in Outlook and Outlook Web App. The goal is to provide a simpler mechanism to accomplish GAL segmentation for on-premises organizations that require multiple GALs.

address lists

An address list is a subset of a GAL. Each address list is a collection of one or more types of mail-enabled recipients (for example, users, contacts, groups, public folders, conferencing, and other resources). You can use address lists to organize recipients and resources, making it easier for users to find the recipients and resources they need. Address lists are updated dynamically. Therefore, when new recipients are added to your organization, they're automatically added to the appropriate address lists.

email address policies

Email address policies generate the primary and secondary email addresses for your recipients so they can receive and send email. By default, Exchange contains an email address policy for every mail-enabled user.

hierarchical address books

The hierarchical address book (HAB) enables end users to look for recipients in their address book using an organizational hierarchy, such as seniority or management structure. Normally, users are limited to the default GAL and its associated recipient properties and the structure of the GAL often

doesn't accurately reflect the management or seniority relationships for recipients in your organization. Being able to customize an HAB that maps to your organization's unique business structure provides your users with an efficient method for locating internal recipients.

offline address books

An offline address book (OAB) is a copy of a collection of address lists that has been downloaded so that a Microsoft Outlook user can access the information it contains while disconnected from the server.

Email address and address book documentation

The following table contains links to topics that will help you learn about and manage email addresses and address books in Exchange 2013.

Topic	Description
Address lists	Learn more about address lists and GALs as methods for organizing your recipients for easy end user access.
Address book policies	Learn more about how to separate your address lists and GALs into separate virtual organizations.
Details templates	Learn more about customizing the address cards in Outlook.
Email address policies	Learn more about proxy email addresses to make recipients more discoverable.
Hierarchical address books	Learn more about how to customize the GAL and address lists to meet your organization’s unique business structure.
Offline address books	Learn more about providing users with offline access to your organization’s address lists.

Address book policies

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-19*

Global address list (GAL) segmentation (also known as *GAL segregation*) is the process whereby administrators can segment users into specific populations to provide customized views of their organization's GAL. Address book policies (ABPs) allow you to segment users into specific groups to provide customized views of your organization's global address list (GAL). When creating an ABP, you assign a GAL, an offline address book (OAB), a room list, and one or more address lists to the policy. You can then assign the ABP to mailbox users, providing them with access to a customized GAL in Outlook and Outlook Web App. The goal is to provide a simpler mechanism to accomplish GAL segmentation for on-premises organizations that require multiple GALs. .

Note:

ABPs are intended to optimize the GAL and address lists for each group of users, not make it difficult for them to see each other or to communicate with other users in your organization. ABPs create only a virtual separation of users from a directory perspective, not a legal separation.

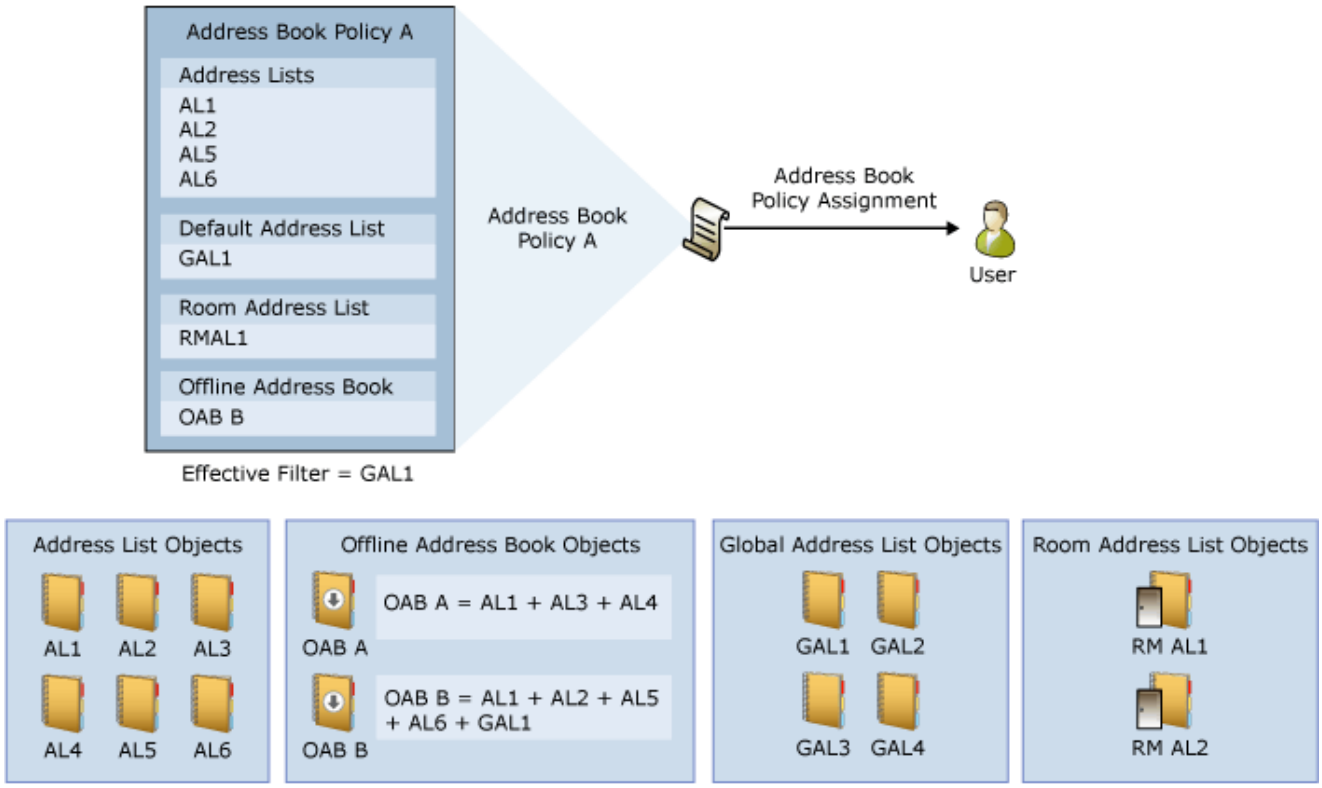
Contents

How ABPs Work

ABPs contain the following lists:

- One GAL
- One OAB
- One room list (for booking purposes)
- One or more address lists

In the following figure, Address Book Policy A consists of a subset of the various address objects that exist in the organization (shown in the bottom half of the figure). The resulting scope of an ABP is equal to that of the GAL contained in the policy, in this case GAL1. When the ABP is created and assigned to a user, the address objects in the ABP become the scope of the objects the user is able to view.



You can use the following methods to assign ABPs to individual mailbox users:

New or existing mailbox?	Shell
New	New-Mailbox cmdlet with the *AddressBookPolicy* parameter
Existing	Set-Mailbox cmdlet with the *AddressBookPolicy* parameter

ABPs take effect when a user's client application connects to a Client Access server in Exchange 2013. If you change the ABP, the updated ABP doesn't take effect until the user restarts or reconnects their client or until you restart the RPC Client Access servers on the Exchange 2013 Mailbox server.

Address Book Policy Routing Agent

In an Exchange organization that doesn't use ABPs, the following things occur when an email is created in Outlook or Outlook Web App and sent to another recipient in your Exchange organization:

1. The email address resolves. For example, if you type **kweku@contoso.com** in the **To** field, the SMTP email address would resolve to the user's display name **Kweku Ako-Adjei**.
2. You can view the other person's contact card. After the name resolves, you can double-click the user's name and view their contact information, such as office and phone number.

If you're using ABPs, and you don't want users in separate virtual organizations to view each other's potentially private information, you can turn on the Address Book Policy Routing agent. The ABP Routing agent is a Transport agent that controls how recipients are resolved in your organization.

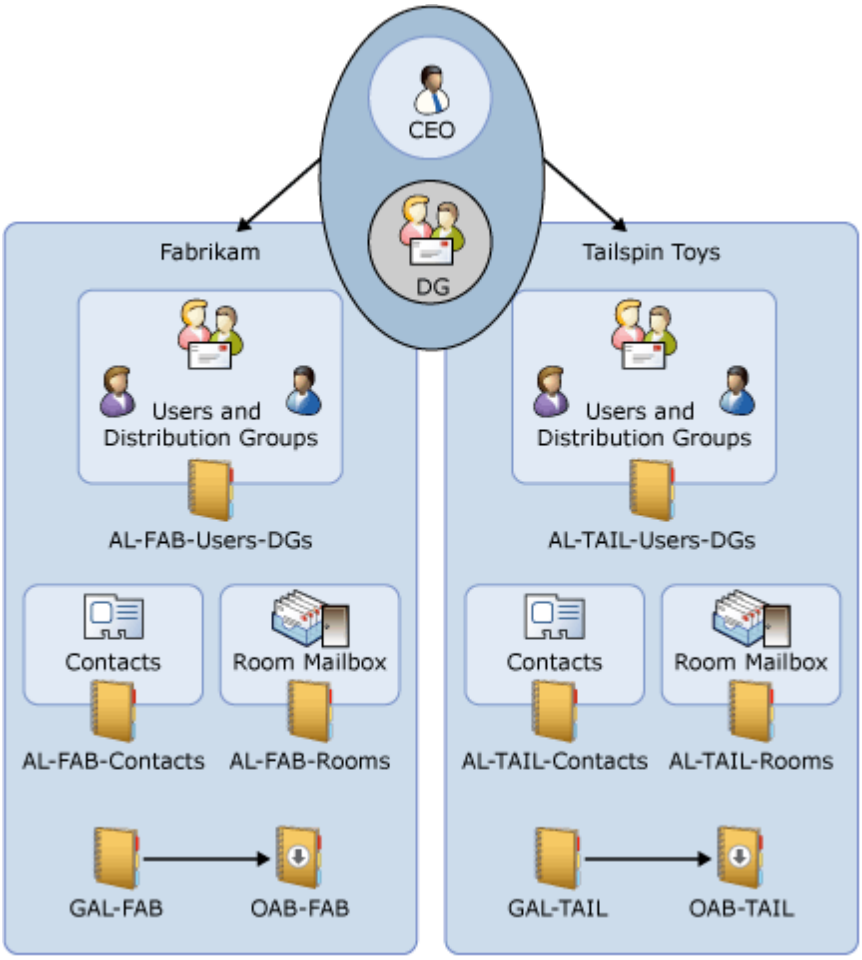
When the ABP Routing agent is installed and configured, users that are assigned to different GALs appear as external recipients in that they can't view external recipients' contact cards.

For details about how to turn on the ABP Routing agent in Exchange Online, see **Turn on address book policy routing**.

For details about how to turn on the ABP Routing agent in Exchange Server, see Install and configure the Address Book Policy Routing agent.

ABP Example

In the following diagram, Fabrikam and Tailspin Toys share the same Exchange organization and the same CEO. The CEO is the only employee common to both companies.



This configuration contains three ABPs:

- One contains Fabrikam employees and the CEO
- One contains Tailspin Toys employees and the CEO
- One contains only the CEO

The ABPs adhere to the following rules:

- The users in Tailspin Toys can only see Tailspin Toys employees and the CEO when they browse the GAL.
- The users in Fabrikam can only see Fabrikam employees and the CEO when they browse the GAL.
- The CEO can see all Fabrikam and Tailspin Toys employees when browsing the GAL.

- Users who view the CEO's group membership can see only groups that belong to the user's company. They won't see groups that exist in the other company.

Entourage, Outlook for Mac, and ABPs

ABPs won't function for Entourage users or Outlook for Mac users who are connected to their corporate network. When inside the corporate network, Entourage and Outlook for Mac clients connect directly to the global catalog server and query Active Directory directly instead of using the Client Access server. However, Outlook for Mac 2011 clients that connect from the Internet can use an OAB or Exchange Web Services (EWS). As a result, these clients can search the GAL based on the assigned ABP. To learn more about administering Outlook for Mac 2011, see Planning for Outlook for Mac 2011

Scenario: Deploying address book policies

Address book policy procedures in Exchange Online

Scenario: Deploying address book policies

Exchange Server 2013 > Email addresses and address books > Address book policies >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-12*

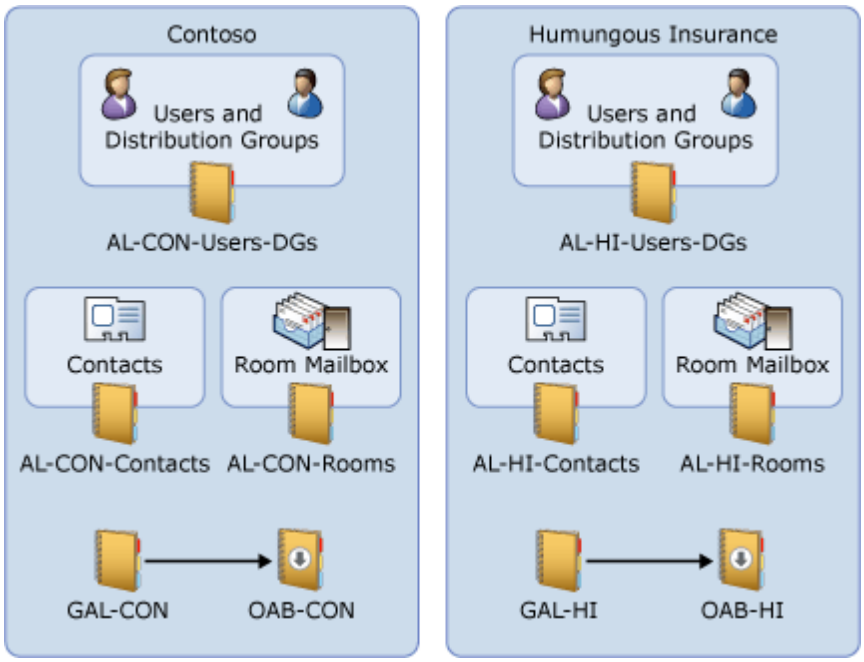
Deployment Scenarios

The following three scenarios describe possible deployment solutions for three different organization types. Although there are many more scenarios, the most popular ones are covered here. The address lists and global address lists (GALs) in these scenarios were created based on filters, such as Custom Attributes, that grouped the objects logically.

Scenario 1: Two separate companies - one Exchange organization

This scenario is applicable to government agencies, divisions, or departments that share

infrastructure, but no reporting chain and have no common employees. In addition, the divisions don't have any special security or privacy concerns. In this scenario, two address book policies (ABPs) are created where employees can only see members of the same organization when the view the GAL or look at membership of other distribution groups. In addition, no users will be members of distribution groups that span the entire organization.



The Contoso and Humungous Insurance ABPs were created using the following address lists, global address lists, room lists, and OABs, which were created using a recipient filter that grouped the objects with a filter such as Custom Attribute. Because the two companies are separate without any interaction between the two, there aren't any address lists in common.

	Contoso	Humungous Insurance
Address Lists	AL_CON_Groups AL_CON_Users AL_CON_Contacts	AL_HI_Groups AL_HI_Users AL_HI_Contacts
Global address list	GAL_CON	GAL_HI
Room address list	AL_CON_Rooms	AL_HI_Rooms
Offline address book (OAB)	OAB_CON	OAB_HI

Scenario 2: Two companies sharing a CEO

In this scenario, Fabrikam and Tailspin Toys share the same Exchange organization and the same CEO. The CEO is the only common person between the two companies. This scenario requires three ABPs that have the following characteristics:

- The users in Tailspin Toys can only see Tailspin Toys users when they browse the GAL.
- The users in Fabrikam can only see Fabrikam users when they browse the GAL.
- In each company, there is a SeniorLeaders distribution group that includes the senior leaders of that company and the CEO.
- Users who look at the CEO's group membership will only see groups that belong to the user's company. They won't see groups not in their own company.
- Three ABPs are created: **Fab**, **Tail**, and **CEO**.

	Fabrikam	Tailspin Toys	CEO
Address lists	AL_FAB_Users_DGs AL_FAB_Contacts	AL_TAIL_Users_DGs AL_TAIL_Contacts	AL_FAB_Users_DGs AL_FAB_Contacts AL_TAIL_Users_DGs AL_TAIL_Contacts
Global address list	GAL_FAB	GAL_TAIL	Default GAL
Room address list	AL_FAB_Rooms	AL_TAIL_Rooms	Default All Rooms
Offline address book (OAB)	OAB_FAB	OAB_TAIL	Default OAB

When the CEO is added to the distribution groups in each organization and falls within the scope of each company's ABP, then the CEO becomes visible to each company. The CEO can create distribution groups that span both companies and will be visible within each company's GAL, but members of the distribution group will only be able to view the members of the group that are within their own organization.

Scenario 3: Education

This scenario is applicable to schools or universities where a division of class rooms is necessary to ensure the privacy of the students. The Education scenario has the following characteristics:

- Students in each class can only see other students in their class, their teacher, and the principal.
- Teachers can only students in their own classrooms.
- Teachers can see all other teachers and the principal.
- Distribution groups are created for each class's parents and the faculty.

	Students_ClassA	Teachers_ClassA	Principal
Address Lists	AL_ClassAAL_Principal	AL_ClassAAL_AllTeachersAL_AllGroupsAL_Principal	AL_ClassA AL_ClassB AL_AllTeachers AL_AllStudents AL_AllGroups
Global address list	GAL_StudentsClassA	GAL_TeachersClassA	GAL_Everyone
Room address list	AL_BlankRoom	AL_BlankRoom	Default All Rooms
Offline address book (OAB)	OAB_StudentsClassA	OAB_TeachersClassA	Default OAB

Considerations and best practices

Consider the following when using ABPs in your organization:

- For ABPs to work correctly, the user mailbox to which you apply the ABP must be on an Exchange 2010 SP3 or an Exchange 2013 server.
- Don’t run the Exchange 2010 Client Access server role on the global catalog server. Doing so results in Active Directory being used for Name Service Provider Interface (NSPI) instead of the Microsoft Exchange Address Book service. You can run Exchange 2013 server roles on a global catalog server and have ABPs work correctly, however we don’t recommend installing Exchange on a domain controller.
- You can't use hierarchical address books (HABs) and ABPs simultaneously. To learn more, see Hierarchical address books.
- Any user assigned an ABP should exist in their own GAL.
- If you allow client applications to access Active Directory directly through LDAP, they will bypass the logic built into ABPs. Because Outlook for Mac 2011 and Entourage 2008 use direct LDAP queries to access Active Directory, those client applications won’t function properly with ABPs if a domain controller or global catalog server is specified or provided to them by the Autodiscover service. Outlook for Mac 2011 can use EWS or a local OAB to access directory information. However, if Outlook for Mac 2011 can directly access an LDAP service, it will attempt to do so.
- The GAL used in an ABP must, at a minimum, contain all of the address lists, including the room address list, defined and specified in an ABP. Don’t create a GAL that contains fewer objects than any of the address lists in the same ABP.
- We recommend creating distribution groups that don't cross virtual organization boundaries. Creating distribution groups that contain members of multiple virtual organizations results in the following issues:
  - If group members request delivery or read receipts when sending mail to the distribution group, they’ll be able to see the email addresses of the group members in other virtual organizations
  - If an encrypted message is sent to the distribution group and some group members don’t have valid digital IDs, the sender will receive a warning message that includes the total number of members who don’t have valid IDs and a list of their email addresses. However, if some of those members without valid digital IDs are in a different organization than the sender, the warning message will include the correct count but won’t include the email addresses of the members in the other organization. As a result, the total count won’t match the list of member addresses.

For example, let’s say a distribution group contains five members total from two organizations, Agency A and Agency B. Three group members are from Agency A, and one of those members has as invalid digital ID. The other two members are from Agency B, and both of them have invalid digital IDs. If a member from Agency A sends an encrypted message to the distribution group, that member will receive a warning message stating that there are a total of three recipients without valid digital IDs. However, only the email address for the recipient from Agency A will be listed in

the warning message.

  - ABP's don't apply to the **Get-Group** cmdlets. Therefore, any user or process that is able to run **Get-Group** will see all members of any group they have access to.

We recommend that you modify the group management settings of the OWA Options so users can't use Outlook Web App to manage groups. To prevent users from using OWA Options to manage groups, exclude the users from the MyDistributionGroupMembership RBAC role. For details, see MyDistributionGroupMembership role.

  - If you allow users to use Outlook or Outlook Web App to manage groups, the group owners must have full visibility to the group membership list.

- All ABPs must contain a room address list. However, if your organization doesn't use room address lists, you can create a default empty room address list.
- Deploying ABPs doesn't prevent users in one virtual organization from sending email to users in another virtual organization. If you want to prevent users from sending email across organizations, we recommend that you create a transport rule. For example, to create a transport rule that prevents Contoso users from receiving messages from Fabrikam users, but still allows Fabrikam's senior leadership team to send messages to Contoso users, run the following Shell command:

```
New-TransportRule -Name "StopFabrikamtoContosoMail" -
FromMemberOf "AllFabrikamEmployees" -SentToMemberOf
"AllContosoEmployees" -DeleteMessage -ExceptIfFrom
seniorleadership@fabrikam.com
```

- If you want to enforce a feature similar to ABP in the Lync client, you can set the `msRTCSIP-GroupingID` attribute on specific user objects. For details, see PartitionByOU Replaced with msRTCSIP-GroupingID topic.

General deployment steps

Migrating from address list segmentation to ABPs

If your organization configured the Exchange 2007 address list segregation solution in place by using the instructions in the white paper Configuring Virtual Organizations and Address List Segregation in Exchange 2007, you should first migrate to Exchange Server 2010 using the steps outlined in Migrate to Exchange Server 2010 Address Book Policies from Exchange Server 2007 Address List Segregation. This procedure will require some down-time for your organization and you will therefore need to plan accordingly.

New deployment of ABPs

If your organization is deploying Exchange 2013 ABPs and hasn't used the Exchange 2007 address list segregation, you can use these instructions to deploy ABPs in your organization.

The steps in this section will walk you through Scenario 2: Two companies sharing a CEO. In this scenario, two companies (Fabrikam and Tailspin Toys) are separate but share a CEO and senior leadership team.

Step 1: Install and configure the Address Book Policy Routing agent

If you're using ABPs, and you don't want users in separate virtual organizations to view each other's potentially private information, you can turn on the Address Book Policy Routing agent. The Address Book Policy Routing agent is a Transport agent that runs on the Mailbox server that controls how recipients are resolved in the organization. When the Address Book Policy Routing Agent is installed and configured, users that are assigned different GALs appear as external recipients in that they can't view external recipients' contact cards.

For detailed instructions, see Install and configure the Address Book Policy Routing agent.

Step 2: Divide your virtual organizations

You'll need to develop a way to divide your organizations. We recommend using the CustomAttribute1-15 property on the mailboxes, contacts, and groups instead of the pre-canned conditional attributes such as Company, Department, or StateOrProvince to divide the virtual organizations for the following reasons:

- Not all recipient types of objects have precanned conditional attributes in Active Directory. For example, Distribution Group and Dynamic Distribution Group do not support company, department, or state attributes.
- Not all precanned conditional attributes are exposed in cmdlets for some recipients. For example, the *Company*, *department*, and *StateOrProvince* parameters are not available on the exposed in cmdlets for mail users, contacts, distribution groups, and mail-enabled public folders.
- Multiple cmdlets are required to segregate recipient when you use the pre-canned conditional attribute. For example, you need to run Set-User to tag *Company*, *Department*, *StateOrProvince* for a UserMailbox after you run **New-Mailbox** or **Set-Mailbox** cmdlets.
- The *CustomAttributeX* parameters are all exposed in the Set-* cmdlet for each recipient type, we can complete all segregation for that type via single Set- cmdlet
- CustomAttributeX attributes are explicitly reserved for customization of an organization and are entirely under the control of the organization administrators.

Another best practice to consider implementing when segregating your organization is to use company identifiers in the names of distribution groups and dynamic distribution groups. Exchange has a Group Naming policy feature that will automatically add a suffix or prefix to the name of the distribution group based on many attributes of the user creating the distribution group including the creator of the distribution group's Company, StateorProvince, Title, and CustomAttribute1 to CustomAttribute15. The group naming policy is especially important if you are allowing users to create their own distribution groups. For more information, see Create a distribution group naming policy.

Group naming policies don't apply to dynamic distribution groups, so you will need to manually

segregate them and manually apply a naming policy.

Step 3: Create the address lists, GALs, and OABs

When you create the address lists and global address lists do not use "IncludedRecipient" and "ConditionalX" parameters, such as ConditionalCompany and ConditionalCustomAttribute5. You should use a recipient filter instead. You must use the Shell to create recipient filters. For more information about Recipient Filters, see Recipient filtering on Edge Transport servers

In creating the ABP, you will create multiple address lists based on how you want your users to view the address lists in Outlook or Outlook Web App. This organization has four address lists:

- AL_FAB_Users_DGs
- AL_FAB_Contacts
- AL_TAIL_Users_DGs
- AL_TAIL_Contacts

This example creates the address list AL_TAIL_Users_DGs. The address list contains all users and distribution groups where CustomAttribute15 equals TAIL.

```
New-AddressList -Name "AL_TAIL_Users_DGs" -RecipientFilter
{((RecipientType -eq 'UserMailbox') -or (RecipientType -eq
"MailUniversalDistributionGroup") -or (RecipientType -eq
"DynamicDistributionGroup")) -and (CustomAttribute15 -eq
"TAIL")}
```

For more information about creating address lists by using recipient filters, see Create an address list by using recipient filters.

In order to create an ABP, you have to provide a room address list. If your organization doesn't have resource mailboxes such as room or equipment mailboxes, we suggest that you create a blank room address list. The following example creates a blank room address list because there are no room mailboxes in the organization.

```
New-AddressList -Name AL_BlankRoom -RecipientFilter {(Alias
-ne $null) -and ((RecipientDisplayType -eq
'ConferenceRoomMailbox') -or (RecipientDisplayType -eq
'SyncedConferenceRoomMailbox'))}
```

However, in this scenario, Fabrikam and Contoso both have room mailboxes. This example creates room list for Fabrikam by using a recipient filter where CustomAttribute15 equals FAB.

```
New-AddressList -Name AL_FAB_Room -RecipientFilter {(Alias
-ne $null) -and (CustomAttribute15 -eq "FAB")-and
(RecipientDisplayType -eq 'ConferenceRoomMailbox') -or
(RecipientDisplayType -eq 'SyncedConferenceRoomMailbox')}
```

The global address list used in an ABP must be a superset of the address lists. Do not create a GAL with fewer objects than exists in any or all of the address lists in the ABP. This example creates the global address list for Tailspin Toys that includes all of the recipients that exists in the address lists and room address list.

```
New-GlobalAddressList -Name "GAL_TAIL" -RecipientFilter
{(CustomAttribute15 -eq "TAIL")}
```

For more information, see Create a global address list.

When you create the OAB you should include the appropriate GAL when providing the *AddressLists* parameter of New- or Set-OfflineAddressBook to ensure no entry is unexpectedly missed. Basically, you can customize the set of entries that a user will see or reduce the download size of the OAB by specifying a list of AddressLists in AddressLists of New/Set-OfflineAddressBook. However, if you want users to see the full set of GAL entries in OAB, make sure that you include the GAL in the AddressLists.

This example creates the OAB for Fabrikam named OAB_FAB.

```
New-OfflineAddressBook -Name "OAB_FAB" -AddressLists
"GAL_FAB"
```

For more information, see Create an offline address book.

Step 4: Create the ABPs

After you've created all of the required objects you can then create the ABP. This example creates the ABP named ABP_TAIL.

```
New-AddressBookPolicy -Name "ABP_TAIL" -AddressLists
"AL_TAIL_Users_DGs"," AL_TAIL_Contacts" -OfflineAddressBook
"\OAB_TAIL" -GlobalAddressList "\GAL_TAIL" -RoomList
"\AL_TAIL_Rooms"
```

For more information, see Create an address book policy.

Step 5: Assign the ABPs to the mailboxes

Assigning the ABP to the user is the last step in the process. ABPs take effect when a user's application connects to the Microsoft Exchange Address Book service on the Client Access server. If the user is already connected to Outlook or Outlook Web App when the ABP is applied to their account, they will need to close and restart the client application before they can see their new address lists and GAL.

This example assigns ABP_FAB to all mailboxes where CustomAttribute15 equals "FAB".

```
Get-Mailbox -resultsize unlimited | where
{$_.CustomAttribute15 -eq "TAIL"} | Set-Mailbox -
AddressBookPolicy "ABP_TAIL"
```

For more information, see Assign an address book policy to mail users.

Create an address book policy

Assign an address book policy to mail users

Change the settings of an address book policy

Remove an address book policy

Install and configure the Address Book Policy Routing agent

Email addresses and address books > Address book policies > Address book policy procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-01-09*

The Address Book Policy Routing agent is a Transport agent that runs on the Mailbox server that controls how recipients are resolved in your organization. When the ABP Routing agent is installed and configured, users that are assigned to different GALs appear as external recipients in that they can't view external recipients' contact cards.

For additional management tasks related to ABPs, see Address book policy procedures.

Looking for the Exchange Online version of this topic? See **Turn on address book policy routing**.

What do you need to know before you begin?

- Estimated time to complete this task: 15 minutes.

- After the ABP Routing agent is installed and configured, it may take up to 30 minutes for email in the organization to be evaluated by agent.
- You can't use the EAC to perform this procedure. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

How do you do this?

Step 1: Install the ABP Routing agent

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport Agents" entry in the Mail flow permissions topic.

Install the ABP Routing agent by running the following command. This is the exact command and syntax you'll need to use.

```
Install-TransportAgent -Name "ABP Routing Agent" -
TransportAgentFactory
"Microsoft.Exchange.Transport.Agent.AddressBookPolicyRoutin
gAgent.AddressBookPolicyRoutingAgentFactory" -AssemblyPath
$env:ExchangeInstallPath\TransportRoles\agents
\AddressBookPolicyRoutingAgent
\Microsoft.Exchange.Transport.Agent.AddressBookPolicyRoutin
gAgent.dll
```

You'll get a warning that the Transport service needs to be restarted for your changes to take effect, but perform Step 2 first so you only have to restart the Transport service once.

For detailed syntax and parameter information, see Install-TransportAgent.

Step 2: Enable the Transport Routing agent

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport Agents" entry in the Mail flow permissions topic.

After the ABP Routing agent is installed, you need to enable it by running the following command:

```
Enable-TransportAgent "ABP Routing Agent"
```

For detailed syntax and parameter information, see Enable-TransportAgent.

Step 3: Restart the Transport service and verify the ABP Routing agent is installed and enabled

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport Agents" entry in the Mail flow permissions topic.

1. Restart the Transport service by running the following command.

```
Restart-Service MSExchangeTransport
```

2. After the service has restarted, verify that the ABP Routing agent is installed and enabled by running the following cmdlet.

```
Get-TransportAgent
```

If the ABP Routing agent is listed, the agent has been correctly installed.

For detailed syntax and parameter information, see Get-TransportAgent.

Step 4: Enable the ABP Routing agent

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport configuration" entry in the Mail flow permissions topic.

The final step in this process is to enable ABP routing for the organization. Run the following command.

```
Set-TransportConfig -AddressBookPolicyRoutingEnabled $true
```

For detailed syntax and parameter information, see Set-TransportConfig.

Create an address book policy

Email addresses and address books > Address book policies > Address book policy procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-03-19*

Address book policies (ABPs) allow you to segment users into specific groups to provide customized views of your organization's global address list (GAL). When creating an ABP, you assign a GAL, an offline address book (OAB), a room list, and one or more address lists to the

policy. You can then assign the ABP to mailbox users, providing them with access to a customized GAL in Outlook and Outlook Web App. The goal is to provide a simpler mechanism to accomplish GAL segmentation for on-premises organizations that require multiple GALs. To learn more about ABPs, see Address book policies.

For additional management tasks related to ABPs, see Address book policy procedures.

Interested in scenarios that use this procedure? See Scenario: Deploying address book policies.

What do you need to know before you begin?

- Estmated time to complete: Less than 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Address book policies" entry in the Email address and address book permissions topic.
- By default in Exchange Online, the Address List role isn't assigned to any role groups. To use any cmdlets that require the Address List role, you need to add the role to a role group. For details, see the "Add a role to a role assignment policy" section of Manage role assignment policies.
- Creating an ABP for an organization is a multi-step process that requires planning. For more information, see Scenario: Deploying address book policies.
- You can't use the Exchange Administration Center (EAC) to create ABPs. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.
- Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to create an ABP

This example creates an ABP with the following settings:

- **Name:** All Fabrikam ABP
- **GAL:** All Fabrikam
- **OAB:** Fabrikam-All-OAB
- **Room list:** All Fabrikam Rooms
- **Address lists:** All Fabrikam, All Fabrikam Mailboxes, All Fabrikam DLs, and All Fabrikam Contacts

```
New-AddressBookPolicy -Name "All Fabrikam ABP" -
AddressLists "\All Fabrikam","\All Fabrikam
Mailboxes","\All Fabrikam DLs","\All Fabrikam Contacts" -
OfflineAddressBook \Fabrikam-All-OAB -GlobalAddressList
"\All Fabrikam" -RoomList "\All Fabrikam Rooms"
```

For detailed syntax and parameter information, see New-AddressBookPolicy.

For more information

Assign an address book policy to mail users

Assign an address book policy to mail users

Email addresses and address books > Address book policies > Address book policy procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-11*

After you create an address book policy (ABP), you must assign it to mailbox users. Users aren't assigned a default ABP when their user account is created. If you don't assign an ABP to a user, the global address list (GAL) for your entire organization will be accessible to the user through Outlook and Outlook Web App. To learn more, see Address book policies.

For additional management tasks related to ABPs, see Address book policy procedures.

Interested in scenarios that use this procedure? See Scenario: Deploying address book policies.

What do you need to know before you begin?

- Estmated time to complete: Less than 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Address book policies" entry in the Email address and address book permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to assign an ABP to a mailbox user

1. Navigate to **Recipients** > **Mailboxes**.
2. In the list view, select the user that you want to assign the policy to, and then click **Edit** .

3. Click **Mailbox features**.
4. In the **Address book policy** list, select the ABP that you want to apply to this user.
5. Click **Save**.

Use the EAC to assign an ABP to multiple mailbox users

1. Navigate to **Recipients** > **Mailboxes**.
2. In the list view use the Ctrl key to select multiple users.
3. In the details pane, click **More options**.
4. Under **Address Book Policy**, click **Update**.
5. In the **Select Address Book Policy** list, select the ABP that you want to apply to these users.
6. Click **Save**.

Use the Shell to assign an ABP to mailbox users

This example assigns the ABP All Fabrikam to the existing mailbox user joe@fabrikam.com.

```
Set-Mailbox -Identity joe@fabrikam.com -AddressBookPolicy
"All Fabrikam"
```

This example assigns the ABP ABP_EngineeringDepartment to all mailbox users whose `CustomAttribute11` value contains "Engineering Department".

```
Get-Mailbox -Filter {(CustomAttribute11 -like "Engineering
Department")} | Set-Mailbox -AddressBookPolicy
ABP_EngineeringDepartment
```

For detailed syntax and parameter information, see Set-Mailbox and Get-Mailbox.

Change the settings of an address book policy

Email addresses and address books > Address book policies > Address book policy procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-16*

After you create an address book policy (ABP), you can view or modify the name and the assigned global address list (GAL), offline address book (OAB), room list, and address lists.

For additional management tasks related to ABPs, see Address book policy procedures.

What do you need to know before you begin?

- Estmated time to complete: Less than 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Address book policies" entry in the Email address and address book permissions topic.
- Creating an ABP for an organization is a multi-step process that requires planning. For more information, see Scenario: Deploying address book policies
- You can't use the Exchange Administration Center (EAC) to configure ABPs. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.
- Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Change the OAB, room list, and GAL for an ABP

This example changes the OAB, room list, and GAL that will be used by mailbox users who are assigned the ABP named All Fabrikam ABP.

```
Set-AddressBookPolicy -Identity "All Fabrikam ABP" -
OfflineAddressBook \Fabrikam-OAB-2 -GlobalAddressList "\All
Fabrikam GAL" -RoomList "\All Fabrikam Rooms"
```

Add an address list to an existing ABP

This example adds the address lists Contoso-Chicago and Contoso-Seattle to the ABP named ABPContoso.

```
Set-AddressBookPolicy -Identity "ABPContoso" -AddressLists
@{Add="Contoso-Chicago","Contoso-Seattle"}
```

Remove an address list from an ABP

This example removes the address lists Fabrikam-HR and Fabrikam-Finance from the ABP named ABPFabrikam.

```
Set-AddressBookPolicy -Identity "ABPFabrikam" -AddressLists
@{Remove="Fabrikam-HR","Fabrikam-Finance"}
```

Replace an address list in an ABP

This example replaces the address lists GovernmentAgencyA-ALL and GovernmentAgenceB-ALL with address lists GovernmentAgencyA-Atlanta and GovernmentAgencyA-Moscow for the ABP named GovernmentAgencyA.

```
Set-AddressBookPolicy -Identity GovernmentAgencyA -
AddressLists @{Remove="GovernmentAgencyA-
ALL","GovernmentAgencyB-All";Add="GovernmentAgencyA-
Atlanta","GovernmentAgencyA-Moscow"}
```

For more information

For detailed syntax and parameter information, see Set-AddressBookPolicy.

Remove an address book policy

Email addresses and address books > Address book policies > Address book policy procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-03-25*

Use this procedure to remove an address book policy (ABP).

For additional management tasks related to ABPs, see Address book policy procedures.

What do you need to know before you begin?

- Estimated time to complete: Less than 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Address book policies" entry in the Email address and address book permissions topic.
- You can't remove an ABP if it's assigned to a user's mailbox or to a soft-deleted mailbox. To determine if an ABP is assigned to a user, run the following Shell command:

```
Get-Mailbox | Where $._AddressBookPolicy -eq <AddressBookPolicyName>
```

To determine if an ABP is assigned to a soft-deleted mailbox, run the following command:

```
Get-Mailbox -SoftDeletedMailbox | Where $._AddressBookPolicy -eq <AddressBookPolicyName>
```

- To remove an ABP from a user's mailbox, you can use the **Mailbox features** page of the mailbox's properties or the **Set-Mailbox** cmdlet.
- You can't use the Exchange Administration Center (EAC) to remove an ABP. You must use the

Shell.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to remove an ABP

This example removes the ABP ABP_TailspinToys.

```
Remove-AddressBookPolicy -Identity "ABP_TailspinToys"
```

For detailed syntax and parameter information, see Remove-AddressBookPolicy.

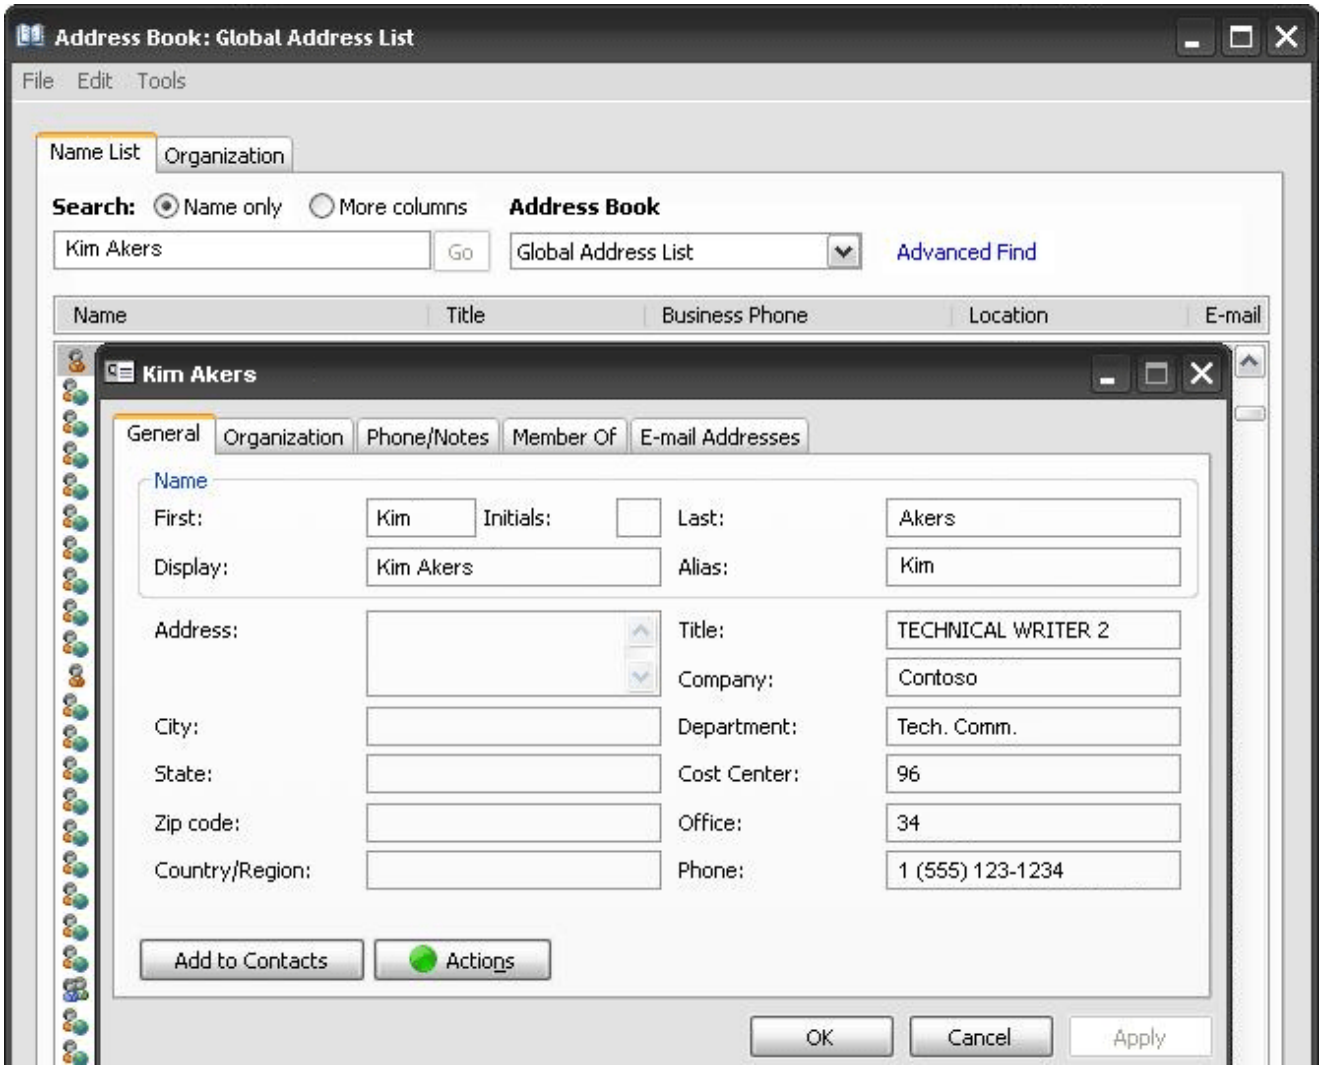
Details templates

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-12*

Details templates control the appearance of the object properties that are accessed by using address lists in an email client, such as Microsoft Outlook. For example, when a user opens an address list in Outlook, the properties of the recipients in that address list are presented as defined by the details template that exists in your Exchange organization. The following figure illustrates the properties of the recipient Kim Akers as it appears in Outlook 2013. Using the Details Templates Editor in Exchange 2013 Toolbox, you can modify the organization of and content within the various objects that appear on this property page.

Default details template as viewed from Outlook 2013



You can use the default details template or you can customize the template to better suit the needs of your users. The objects can be customized by changing field sizes, adding or removing fields, adding or removing tabs, and rearranging fields. The layout of these templates may vary by language. Use the Details Templates Editor to customize the following Outlook objects:

- Contacts
- Users
- Groups
- Mailbox agents
- Public folders
- Search dialog boxes

For More Information

Customize details templates

Restore a details template to the default configuration

Customize details templates

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-25*

Use the Details Templates Editor to customize the client-side graphical user interface (GUI) presentation of object properties that are accessed by using address lists in Microsoft Outlook. For example, when a user opens an address list in Outlook, the properties of a particular object are presented as defined by the details template in the Exchange organization. The objects can be customized by changing field sizes, adding or removing fields, adding or removing tabs, and rearranging fields. The layout of these templates may vary by language.

What do you need to know before you begin?

- There is no undo option in the details template editor. If you make a mistake, you will need to revert back to the previous version. For more information, see Restore a details template to the default configuration.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Details templates" entry in the Email address and address book permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Customize the details template

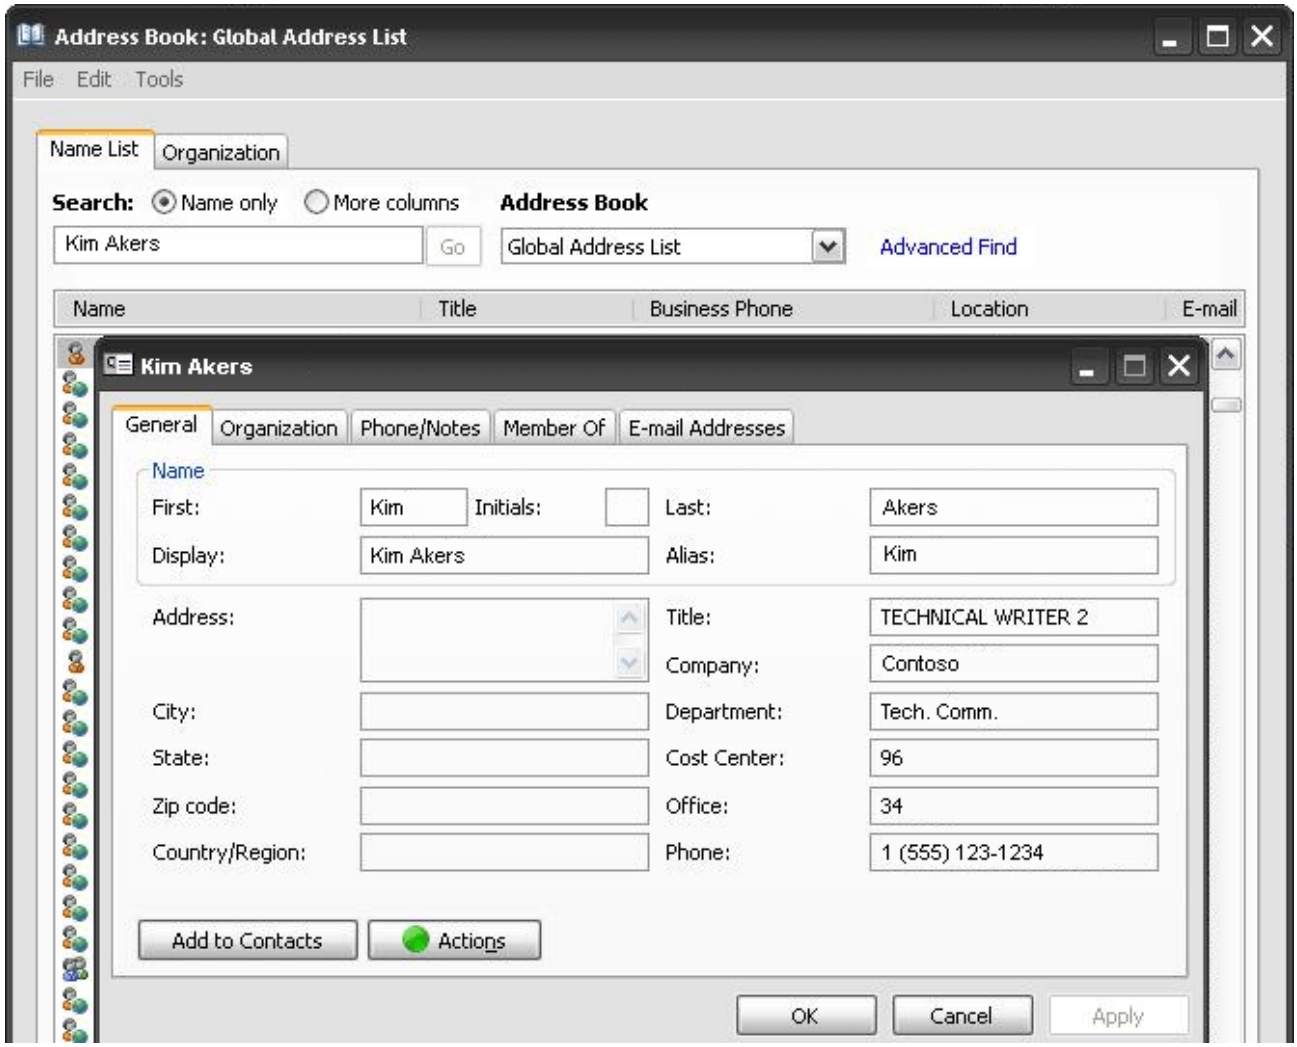
1. In the **Exchange Toolbox**, click **Details Templates Editor**, and then in the action pane, click **Open Tool**.
2. In the console tree of the Details Templates Editor, click **Details Templates**.

In the details pane, the following columns are displayed:

- **Language** This column lists the language in which the template was created.
- **Template Type** This column lists the type of template that you can customize.
- **Identity** This column lists the unique identity of the template.
- **Created** This column lists the date and time that the template was created.
- **Modified** This column lists the date and time that the template was last modified.

3. To edit a template, click the template you want, and then, in the action pane, click **Edit**. For example, the **English (United States)** contacts details template is shown in the following figure.

Default details template as viewed from Outlook 2013



4. After you click **Edit**, there are several tasks you can perform to customize a details template:
   - To move an object in the designer pane, select the object, and then drag it to its new location on the template. As you move the object, you are provided with alignment lines.
   - To change a label's text, select the label in the design pane. In the properties pane, type the new text in the **Text** box. To create keyboard shortcuts, you can use the ampersand (&) symbol. Place the ampersand (&) before the letter that you want to use as the shortcut.
   - To change the size of an object, select the object, and then drag the sizing handles until the object is the shape and size you want.
   - To delete an object, select the object, and then press the DELETE key.

Note:

The Details Templates Editor doesn't contain an **Undo** button, nor can you use a keyboard shortcut to undo an action. To undo an addition you made to the template, you must use the DELETE key. To undo a deletion, you must reapply the setting. You can also revert to the original settings by exiting the Details Templates Editor without saving your changes. If you want to undo changes after you have saved, you can restore the template. When you restore a template, all customization is lost, and the template is restored to its original configuration. For more information about how to restore the details template, see Restore a details template to the default configuration.

   - To add an "Edit" text boxes, list boxes, multi-valued drop-down boxes, or multi-valued list boxes, in the toolbox pane, drag the object to the design pane. Set the attribute of the object by clicking the attribute drop-down box in the properties pane and then selecting the attribute

that will be used by Exchange.

Note:

You must link the object to an attribute for it to be used by Exchange. In addition, the attribute determines the content that is displayed to the end user in Outlook. If you don't select an attribute, a random attribute is selected automatically.

- To add a group box, drag the object to the design pane. Then, in the properties pane, type a name in the **Text** box. Use group boxes to group similar objects.
- To add a tab to the template, right-click an existing tab, and then click **Add Tab**. A blank tab appears. To name the tab, type the name in the **Text** box in the properties pane.
- To remove a tab from the template, right-click the tab, and then click **Remove Tab**. A warning appears. Click **OK** to confirm that you want to remove the tab.
- To change the tabbing order of the objects on a tab so that users can use the TAB key to navigate the objects in the order you want, select the object in the design pane. Then, in the properties pane, use the **TabIndex** box to change the order.

Note:

To make sure that users cannot use the TAB key to access the labels of an object (for example **Name** or **Alias**), change the order of the labels so that they are last in the tabbing order.

5. To save changes to the details template, on the **File** menu, click **Save**.
6. To close the template, on the **File** menu, click **Exit**.

Restore a details template to the default configuration

Exchange Server 2013 > Email addresses and address books > Details templates >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-12*

The Details Templates Editor doesn't contain an **Undo** button, nor can you use a keyboard shortcut to undo an action. To undo an addition you made to the template, you must use the DELETE key. To undo a deletion, you must reapply the setting. You can also revert to the original settings by exiting the Details Templates Editor without saving your changes. If you want to undo changes after you have saved, you can restore the template. When you restore a template, all customization is lost, and the template is restored to its original configuration.

This topic explains how to use the Exchange 2013 Toolbox or the Exchange Management Shell to restore a details template to its default configuration.

To learn more about details templates, see Details templates.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Details templates" entry in the Email address and address book permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Exchange Toolbox to restore a details template to its default configuration

1. Click **Start** > **All Programs** > **Microsoft Exchange Server 2013** > **Exchange Toolbox**.
2. In **Exchange Toolbox**, click **Details Templates Editor**, and then, in the action pane, click **Open Tool**.
3. In the **Details Templates Editor**, in the details pane, select the template you want to restore, and then in the action pane, click **Restore**.
4. Click **Yes** to confirm that you want to restore the template to its original state. All customization will be lost.

Use the Shell to restore a details template to its default configuration

This example restores the United States English contacts details template.

```
Restore-DetailsTemplate -Identity "en-US\Contact"
```

For detailed syntax and parameter information, see Restore-DetailsTemplate.

Email address policies

Exchange Server 2013 > Email addresses and address books >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-16*

Recipients (which include users, resources, contacts, and groups) are any mail-enabled object in Active Directory to which Microsoft Exchange can deliver or route messages. For a recipient to send or receive email messages, the recipient must have an email address. Email address policies generate the primary and secondary email addresses for your recipients so they can receive and send email.

By default, Exchange contains an email address policy for every mail-enabled user. This default policy specifies the recipient's alias as the local part of the email address and uses the default accepted domain. The local part of an email address is the name that appears before the at sign (@). However, you can change how your recipients' email addresses will display. For example, you can specify that the addresses display as *firstname.lastname*@contoso.com.

Furthermore, if you want to specify additional email addresses for all recipients or just a subset, you can modify the default policy or create additional policies. For example, the user mailbox for David Hamilton can receive email messages addressed to hdavid@mail.contoso.com and hamilton.david@mail.contoso.com.

Looking for management tasks related to email address policies? See Email address policy procedures.

Behaviors of recipient policies

Exchange applies a policy to all recipients that match the recipient filtering criteria:

- The recipient policy functionality is divided into two features: email address policies and accepted domains. For more information about accepted domains, see Accepted domains.
- When you run the **Update-EmailAddressPolicy** cmdlet in the Exchange Management Shell, the recipient object is updated with the email address policy.
- Each time a recipient object is modified and saved, Exchange enforces the correct application of the email address criteria and settings. When an email address policy is modified and saved, all associated recipients are updated with the change. In addition, if a recipient object is modified, that recipient's email address policy membership is reevaluated and enforced.

Creating email address policies

When creating an email address policy, you can use the following email address types:

- **Precanned SMTP email address**. *Precanned* SMTP email addresses are commonly used email address types that are provided for you.
- **Custom SMTP email address**. If you don't want to use one of the precanned SMTP email addresses, you can specify a custom SMTP email address.

When creating a custom SMTP email address, you can use the variables in the following table to specify alternate values for the local part of the email address.

Variable	Value

%g	Given name (first name)
%i	Middle initial
%s	Surname (last name)
%d	Display name
%m	Exchange alias
%*x*s	Uses the first *x* letters of the surname. For example, if *x* = 2, the first two letters of the surname are used.
%*x*g	Uses the first *x* letters of the given name. For example, if *x* = 2, the first two letters of the given name are used.

- **Non-SMTP email address**. The following types of non-SMTP email addresses are supported:
  - EX (Legacy DN Proxy Address Prefix DisplayName)
  - X.500
  - X.400
  - MSMail
  - CcMail
  - Lotus Notes
  - Novell GroupWise
  - Exchange Unified Messaging proxy address (EUM proxy address)

Important:
In Exchange, all non-SMTP email addresses are considered custom addresses. Exchange doesn't provide unique dialog boxes or property pages for X.400, GroupWise, or Lotus Notes email address types. If you add a non-SMTP custom email address, you must have the appropriate dynamic-link library (DLL) files. If you don't provide the appropriate DLL files, you won't be able to create a customized email address policy. The following error will be logged in Event Viewer: "The email address description object in the Microsoft Exchange directory for the 'SADF' address type on 'i386' machines are missing."

For detailed instructions about how to create an email address policy, see the following topics:

Create an Email Address Policy

Create an email address policy by using recipient filters

Topic Last Modified: *2012-12-10*

For a recipient to receive or send email messages, the recipient must have an email address. Email address policies generate the primary and secondary email addresses for your recipients (which include users, contacts, and groups) so they can receive and send email.

When creating an email address policy, you can use the following email address types:

- **Precanned SMTP email address**. *Precanned* SMTP email addresses are commonly used email address types that are provided for you.
- **Custom SMTP email address**. If you don't want to use one of the precanned SMTP email addresses, you can specify a custom SMTP email address.

When creating a custom SMTP email address, you can use the variables in the following table to specify alternate values for the local part of the email address.

Variable	Value
%g	Given name (first name)
%i	Middle initial
%s	Surname (last name)
%d	Display name
%m	Exchange alias
%*x*s	Uses the first *x* letters of the surname. For example, if *x* = 2, the first two letters of the surname are used.
%*x*g	Uses the first *x* letters of the given name. For

	example, if *x* = 2, the first two letters of the given name are used.

- **Non-SMTP email address**. The following types of non-SMTP email addresses are supported:
  - EX (Legacy DN Proxy Address Prefix DisplayName)
  - X.500
  - X.400
  - MSMail
  - CcMail
  - Lotus Notes
  - Novell GroupWise
  - Exchange Unified Messaging proxy address (EUM proxy address)

Important:

In Exchange, all non-SMTP email addresses are considered custom addresses. Exchange doesn't provide unique dialog boxes or property pages for X.400, GroupWise, or Lotus Notes email address types. If you add a non-SMTP custom email address, you must have the appropriate dynamic-link library (DLL) files. If you don't provide the appropriate DLL files, you won't be able to create a customized email address policy. The following error will be logged in Event Viewer: "The email address description object in the Microsoft Exchange directory for the 'SADF' address type on 'i386' machines are missing."

For detailed instructions about how to create an email address policy, see the following topics:

Create an Email Address Policy

Create an email address policy by using recipient filters

What do you need to know before begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Email address policies" entry in the Email addresses and address books topic.
- Before an SMTP address domain can be used in an email address policy, you must configure an accepted domain. To learn more, see Accepted domains.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Warning:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to create an email address policy

1. Navigate to **Mail flow** > **Email address policies**, and then click **Add +**.
2. In **Email Address Policy**, complete the following fields:
   - **Policy name**
   - **Email address format**
   - **Specify the types of recipients this email address will apply to**
3. Click **Add a rule** to further restrict the recipients that this policy will apply to. This creates a Boolean **And** statement.

Caution:
If you apply too many rules, it's possible to restrict the email address policy to the point that it doesn't contain any users.

4. Click **Preview recipients the policy applies to** to view the recipients that policy will apply to.
5. Click **Save** to save your changes and create the policy.
6. You'll get a warning that the email address policy won't be applied until you update it. After it's created, select it, and then, in the details pane, click **Apply**.

Use the Shell to create an email address policy

This example creates an email address policy that includes mailbox users in the Southeast offices who will have email addresses that include their last name combined with the first two letters of their first name.

```
New-EmailAddressPolicy -Name "southeast offices" -
IncludedRecipients MailboxUsers -ConditionalStateorProvince
"Georgia","Alabama","Louisiana" -
EnabledEmailAddressTemplates "SMTP:%s%
2g@southeast.contoso.com"
```

For detailed syntax and parameter information, see New-EmailAddressPolicy.

Create an email address policy by using recipient filters

Email addresses and address books > Email address policies > Email address policy procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-16*

You can use the Shell to create an email address policy by using recipient filters. To learn more about email address policies, see Email address policies.

For additional management tasks related to email address policies, see Email address policy procedures.

What do you need to know before begin?

- Estimated time to complete: 5 minutes.
- To use the *RecipientFilter* parameter to create a custom filter, you must specify a string for the filter. The Shell uses OPath for the filtering syntax. OPath is a querying language designed to query object data sources.

Important:

If you use a recipient filter to create or edit an email address policy, you can't use the Exchange Administration Center (EAC) to edit the email address policy. You must use the Shell. For detailed syntax and parameter information, see Set-EmailAddressPolicy.

- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Email address policies" entry in the Email addresses and address books topic.
- Before an SMTP address domain can be used in an email address policy, you must configure an accepted domain. For more, see Accepted domains.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Warning:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to create an email address policy by using recipient filters

To create an email address policy by using recipient filters, use the following syntax.

```
New-EmailAddressPolicy -Name <String> -RecipientFilter
<String>
```

This example creates an email address policy that applies to all executives and for which the local part of the email address consists of the first two letters of their first name and their entire last name.

```
New-EmailAddressPolicy -Name 'Execs' -
```

```
EnabledEmailAddressTemplates 'SMTP:%2g%s@contoso.com' -
RecipientFilter {((RecipientType -eq 'UserMailbox') -and
(Title -like 'executive'))}
```

For detailed syntax and parameter information, see New-EmailAddressPolicy.

Edit an email address policy

Email addresses and address books > Email address policies > Email address policy procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-12-10*

Email address policies generate the primary and secondary email addresses for your recipients (which include users, contacts, and groups) so they can receive and send email.

For additional management tasks related to email address policies, see Email address policy procedures.

What do you need to know before begin?

- Estimated time to complete: 5 minutes.
- You can't use the Exchange Administration Center (EAC) to edit an email address policy if the policy was created by using the Shell.
- If the email address policy was created using a recipient filter, you must use the Shell to edit the email address policy. For more information, see Create an email address policy by using recipient filters.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Email address policies" entry in the Email addresses and address books topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

⚠**Warning:**
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to change the recipients that the policy

applies to

1. Navigate to **Mail flow** > **Email address policies**.
2. In the list view, select the email address policy you want to change, and then click **Edit** ✎.
3. In **Email Address Policy**, click **Apply to** and modify the settings.

Use the EAC to change the email address policy's priority

A user can have multiple proxy email addresses for the same email account (for example, ayla@exchange.mail.contoso.com or ayla@contoso.com). These email addresses can then be applied by priority. For example, consider this scenario: you have two email address policies, and you assign them priorities of 1 and 2. If you create another policy, it will automatically be assigned a priority of 3. However, let's say you have two policies, and you specify that one of them is priority 1, but the other policy was assigned a default priority of 2 when it was created. In this case, the next policy you create will, by default, become the priority 2 policy. The previous priority 2 policy will be assigned a priority of 3.

1. Navigate to **Mail flow** > **Email address policies**.
2. Select the email address policy for which you want to change the priority, and then click **Increase priority** ↑ or **Decrease priority** ↓.

Use the Shell to edit an email address policy

This example edits the email address policy South East Offices that currently includes recipients in Georgia, Alabama, and Louisiana to also include recipients in Texas.

```
Set-EmailAddressPolicy -Identity "South East Offices" -
ConditionalStateorProvince
"Georgia","Alabama","Louisiana","Texas"
```

Note:

Although the email address policy is already applied to recipients in Georgia, Alabama, and Louisiana, you must include them in the parameter because the parameter overwrites values; it doesn't append values to existing ones.

For detailed syntax and parameter information, see Set-EmailAddressPolicy.

Remove an email address policy

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-13*

By default, Exchange contains an email address policy that specifies the recipient's alias as the local part of the email address and uses the default accepted domain. The local part of an email address is the name that appears before the "at" sign (@).This email address policy applies to all users in the organization. You can't remove this email address policy.

For additional management tasks related to e-mail address policies, see Email address policy procedures.

What do you need to know before begin?

- Estimated time to complete: 5 minutes.
- If you remove an email address policy that's used by recipients as the primary policy and no other policies have been configured for recipients, the default policy will be used.
- You can’t delete the default policy. If you want to delete the default policy, you must first assign a different policy as the default.
- If the email address policy you’re deleting contains more than 3,000 recipients, you should use the Shell to perform this procedure.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Email address policies" entry in the Email addresses and address books topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

⚠**Warning:**
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to remove an email address policy

1. Navigate to **Mail flow** > **Email address policies**.
2. In the list view, select the email address policy that you want to delete and then click **Delete** 🗑.
3. In the warning, click **Yes** to remove the policy.

Use the Shell to remove an email address policy

This example removes the e-mail address policy South East Offices.

```
Remove-EmailAddressPolicy -Identity "South East Offices"
```

Type **Y** to confirm that you want to remove the policy, and then press ENTER.

For detailed syntax and parameter information, see Remove-EmailAddressPolicy.

Offline address books

Exchange Server 2013 > Email addresses and address books >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-28*

An offline address book (OAB) is a copy of an address list collection that's been downloaded so a Microsoft Outlook user can access the address book while disconnected from the server. Microsoft Exchange generates the new OAB files and then compresses the files and places them on a local share. You can decide which address lists are made available to users who work offline, and you can also configure the method by which the address books are distributed.

To learn more about address lists, see Address lists.

Important:
OAB data is produced by the Microsoft Exchange OABGen service, which is a mailbox assistant. If you use the security descriptor to prevent users from viewing certain recipients in Active Directory, users who download the OAB will be able to view those hidden recipients. Therefore, to hide a recipient from an address list, set the *HiddenFromAddressListsEnabled* parameter on the Set-PublicFolder, Set-MailContact, Set-MailUser, Set-DynamicDistributionGroup, Set-Mailbox, and Set-DistributionGroup cmdlets. Alternatively, you can create a new default OAB that doesn't contain the hidden recipients. For details about how to add or remove address lists from an OAB, see Add an address list to or remove an address list from an offline address book.

Looking for management tasks related to OABs? See Offline address book procedures.

Contents

Moving OABs between Exchange versions

In Exchange 2007 and Exchange 2010, you use the **Move-OfflineAddressBook** cmdlet to move the OAB generation to another Mailbox server. Exchange 2013 supports only OAB (version 4). This is the same version that was the default in Exchange 2010. You can't configure Exchange 2013 to generate

other OAB versions, and the OAB generation occurs on the Mailbox server on which the organization mailbox resides. Therefore, to move OAB generation in Exchange 2013, you must move the organization mailbox. You can only move the OAB generation to another Exchange 2013 mailbox database. You can't move OAB generation to a previous version of Exchange. To find the Exchange 2013 OAB organization mailbox, run the following Shell command:

```
Get-Mailbox -Arbitration | where {$_.PersistedCapabilities
-like "*oab*"}
```

You can then use the **MoveRequest** cmdlets to move the mailbox.

OAB version 4 and Outlook clients

Exchange 2013 only supports OAB version 4. OAB version 4 was introduced in Exchange 2003 Service Pack 2 (SP2) and is supported by Outlook 2007, Outlook 2010, and Outlook 2013. This Unicode OAB allows client computers to receive differential updates rather than full OAB downloads and a reduced file size.

Outlook clients that use OAB version 4

For Outlook 2013, Outlook 2010, Outlook 2007, and clients that use OAB version 4, if the size of the changes.oab files is half the size (or more) of the entire OAB files, Outlook initiates a full OAB download.

Web-based distribution

Web-based distribution is the distribution method by which Outlook 2013, Outlook 2010, or Outlook 2007 clients that are working offline can access the OAB.

There are several advantages to using Web-based distribution, including:

- Support of more concurrent client computers.
- Reduction in bandwidth usage.
- More control over the OAB distribution points. With Web-based distribution, the distribution point is the HTTPS web address where client computers can download the OAB.

To benefit most from Web-based distribution, client computers must be running Outlook 2013, Outlook 2010, or Outlook 2007.

To function properly, Web-based distribution depends on the following components:

- **OAB generation process** This is the process by which Exchange creates and updates the OAB. To create and update the OAB, the OABGen service runs on the Mailbox server on which the organization mailbox is located. To support OAB distribution, this server must be an Exchange Mailbox server.
- **OAB distribution** If a client initiates the OAB distribution request, the request be directed

through a Client Access server. The Client Access server then routes the request to the Mailbox server that's hosting the OAB files. The OAB files are then distributed directly from the Mailbox server to the client.

- **OAB virtual directory** The OAB virtual directory is the distribution point used by the Web-based distribution method. By default, when Exchange is installed, a new virtual directory named **OAB** is created in the default internal website in Internet Information Services (IIS). If you have client-side users that connect to Outlook from outside your organization's firewall, you can add an external website. Alternatively, when you run the **New-OABVirtualDirectory** cmdlet in the Shell, a new virtual directory named OAB is created in the default IIS website on the local Exchange Client Access server. For information, see Create an offline address book virtual directory.
- **Autodiscover service** This is a feature available in Outlook 2013, Outlook 2010, Outlook 2007, and in some mobile devices that automatically configure the clients for access to Exchange. The service runs on a Client Access server and returns the correct OAB URL for a specific client connection.

OAB considerations

As a best practice, whether you use a single OAB or multiple OABs, consider the following factors as you plan and implement your OAB strategy:

- Size of each OAB in your organization. For more information, see OAB size considerations later in this topic.
- Number of OAB downloads.
- Number and frequency of parent distinguished name changes.
- SMTP address mismatches.
- Overall number of changes made to the directory.

OAB size considerations

For some organizations, the OAB is a small file that remote users occasionally download. For these organizations, downloading the OAB is usually not a concern. However, for some large organizations that have large directories, or for organizations that have deployed Outlook 2003 in Cached Exchange Mode, it may be a concern, especially if the organizations have consolidated Exchange servers into a regional datacenter.

OAB sizes can vary from a few megabytes to a few hundred megabytes. The following factors can affect the size of the OAB:

- Usage of certificates in a company. The more public key infrastructure (PKI) certificates, the larger the OAB. PKI certificates range from 1 kilobyte (KB) to 3 KB. They're the single largest contributor to the OAB size.
- Number of mail recipients in Active Directory.
- Number of distribution groups in Active Directory.
- Information that a company adds to Active Directory for each mailbox-enabled or mail-enabled object. For example, some organizations populate the address properties on each user; others

don't.

Offline address book procedures

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-03-19*

An offline address book (OAB) in Exchange Server 2013 is a downloaded copy of an address book that allows an Outlook user to access the information while disconnected from the server. Exchange administrators can decide which address books are made available to users who work offline, and they can also configure the method by which the address books are distributed (web-based distribution or public folder distribution).

For additional management tasks related to OABs, see Offline address book procedures.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.

- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Offline address books" entry in the Email address and address book permissions topic.
- By default in Exchange Online, the Address List role isn't assigned to any role groups. To use any cmdlets that require the Address List role, you need to add the role to a role group. For details, see the "Add a role to a role assignment policy" section of Manage role assignment policies.
- You can't use the Exchange Administration Center (EAC) to perform this procedure. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to create an OAB with web-based distribution

This example creates an OAB named OAB_Contoso that uses web-based distribution for Outlook 2007 or later clients by using the default virtual directory.

```
New-OfflineAddressBook -Name "OAB_Contoso" -AddressLists
"\Default Global Address List" -VirtualDirectories
"SERVER01\OAB (Default Web Site)"
```

For detailed syntax and parameter information, see New-OfflineAddressBook.

Add an address list to or remove an address list from an offline address book

Email addresses and address books > Offline address books > Offline address book procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-03-19*

You can use the Shell to add or remove an address list from an offline address book (OAB). By

default, there is an OAB named the Default Offline Address Book that contains the global address list (GAL). OABs are generated based on the address lists that they contain. To create custom OABs that users can download, you can add or remove address lists from OABs.

For additional management tasks related to OABs, see Offline address book procedures.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Offline address books" entry in the Recipients Permissions topic.
- By default in Exchange Online, the Address List role isn't assigned to any role groups. To use any cmdlets that require the Address List role, you need to add the role to a role group. For details, see the "Add a role to a role assignment policy" section of Manage role assignment policies.
- Changes to the address list aren't available for client download until after the OAB in which the address list resides has been generated. For more information, see Update an offline address book.
- You can't use the Exchange Administration Center (EAC) to perform this procedure. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to add an address list to an OAB

When using the *AddressLists* parameter, any address lists that currently exist will be overwritten. You must include existing address lists when you use the *AddressLists* parameter to continue to generate those address lists in your OAB. This example, in which you have AddressList1 and AddressList2, adds AddressList3.

```
Set-OfflineAddressBook -Identity "My OAB" -AddressLists
AddressList1,AddressList2,AddressList3
```

For detailed syntax and parameter information, see Set-OfflineAddressBook.

Use the Shell to remove an address list from an OAB

To remove an address list from an OAB, simply omit that address list from the list of address lists. This example, in which you have AddressList1, AddressList2, and AddressList3, removes AddressList3.

```
Set-OfflineAddressBook -Identity "My OAB" -AddressLists
AddressList1,AddressList2
```

For detailed syntax and parameter information, see Set-OfflineAddressBook.

Change the default offline address book

Email addresses and address books > Offline address books > Offline address book procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-03-19*

By default, when you install the Mailbox server role, a Web-based default offline address book (OAB) named Default Offline Address Book is created. You can set any OAB in your Exchange organization as the default OAB. This new default OAB is associated with all newly created mailbox databases. You can have only one default OAB in your organization. If you delete the default OAB, Microsoft Exchange doesn't automatically assign another OAB as the default. You must manually designate another OAB as the default.

For additional management tasks related to OABs, see Offline address book procedures.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Offline address books" entry in the Recipients Permissions topic.
- By default in Exchange Online, the Address List role isn't assigned to any role groups. To use any cmdlets that require the Address List role, you need to add the role to a role group. For details, see the "Add a role to a role assignment policy" section of Manage role assignment policies.
- You can't use the Exchange Administration Center (EAC) to perform this procedure. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to change the default OAB

This example sets the OAB named My OAB as the default OAB.

```
Set-OfflineAddressBook -Identity "My OAB" -IsDefault $true
```

For detailed syntax and parameter information, see Set-OfflineAddressBook.

Provision recipients for offline address book downloads

Email addresses and address books > Offline address books > Offline address book procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-15*

If you use multiple offline address books (OABs) in your organization, there are several ways to specify which recipients download which OABs:

- **Per mailbox database** You can use the EAC or the Shell to provision recipients for OAB downloads by linking a mailbox database to a default OAB for Office Outlook 2007, Outlook 2010 and Outlook 2013 clients.
- **Per recipient** You can use the **Set-Mailbox** cmdlet in the Shell to specify which OAB is downloaded by linking the OAB directly to a recipient's mailbox.
- **Per multiple recipients** You can use a pipelined command in the Shell to specify the OAB that multiple recipients download, based on common attributes.
- **Per address book policy** You can assign an address book policy (ABP) to a mailbox user's account to specify which OAB is downloaded to a recipient's mailbox. If you assign an ABP to a user account that already has an OAB assigned, the OAB that's explicitly assigned to the mailbox will take precedence. For more information, see Assign an address book policy to mail users.

For additional management tasks related to OABs, see Offline address book procedures.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You can't use the Exchange admin center (EAC) to perform these procedures. You must use the

Shell.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to provision recipients for OAB downloads by linking their mailbox database to a public folder database or to a default OAB

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mailbox databases" entry in the Recipients Permissions topic.

This example sets up the web-based distribution of My OAB for the default mailbox database.

```
Set-MailboxDatabase -Identity "Mailbox Database" -
OfflineAddressBook "My OAB"
```

For detailed syntax and parameter information, see Set-MailboxDatabase.

Use the Shell to specify which OAB will be downloaded by linking the OAB directly to a recipient's mailbox

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.

To specify which OAB is downloaded by linking the OAB directly to a recipient's mailbox, use the following syntax.

```
Set-Mailbox -Identity <MailboxIDParameter> -
OfflineAddressBook <OfflineAddressBookIdParameter>
```

Note:
The *Identity* parameter identifies the mailbox and can take the following values: GUID, ADObjectID, distinguished name (DN), *domain**account*, user principal name (UPN), LegacyExchangeDN, SmtpAddress, and alias.

This example specifies that the user Kim will download the OAB My OAB.

```
Set-Mailbox -Identity Kim -OfflineAddressBook "My OAB"
```

For detailed syntax and parameter information, see Set-Mailbox.

Use the Shell to specify the OAB that multiple recipients will download

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.

This example specifies that all user mailboxes in the United States for Contoso will download the OAB Contoso United States.

```
Get-User -ResultSize Unlimited -Filter { Company -eq
"Contoso" -and RecipientType -eq "UserMailbox" } | Where
{ $_.CountryOrRegion -eq "United States"} | Set-Mailbox -
OfflineAddressBook "Contoso United States"
```

For detailed syntax and parameter information, see Get-User and Set-Mailbox.

Remove an offline address book

Email addresses and address books > Offline address books > Offline address book procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-03-19*

This topic explains how to remove an offline address book (OAB).

For additional management tasks related to OABs, see Offline address book procedures.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Offline address books" entry in the Email address and address book permissions topic.
- By default in Exchange Online, the Address List role isn't assigned to any role groups. To use any

cmdlets that require the Address List role, you need to add the role to a role group. For details, see the "Add a role to a role assignment policy" section of Manage role assignment policies.

- After you remove an OAB that's linked to a user or to a mailbox database, the recipient will download the default OAB until you assign a new OAB for that user. If you remove the default OAB, you must assign a different OAB as the default OAB. For instructions about how to change the default OAB, see Change the default offline address book.
- You can't use the Exchange Administration Center (EAC) to perform this procedure. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to remove an OAB

This example removes an OAB named My OAB.

```
Remove-OfflineAddressBook -Identity "My OAB"
```

Type **Y** to confirm that you want to remove the OAB, and then press ENTER.

For detailed syntax and parameter information, see Remove-OfflineAddressBook.

Update an offline address book

Email addresses and address books > Offline address books > Offline address book procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-11-15*

After you create an OAB or modify OAB settings, the changes aren't available to users until the OAB generation (OABGen) process has completed.

For additional management tasks related to OABs, see Offline address book procedures.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Offline address books" entry in the Email address and address book permissions topic.

- You can't use the Exchange Administration Center (EAC) to perform this procedure. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to update an OAB

This example updates the OAB named My OAB.

```
Update-OfflineAddressBook -Identity "My OAB"
```

For detailed syntax and parameter information, see Update-OfflineAddressBook.

Create an offline address book virtual directory

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-16*

The OAB virtual directory is the distribution for the OAB. By default, when Microsoft Exchange Server 2013 is installed, a new virtual directory named OAB is created in the default internal website in Internet Information Services (IIS). If you have client-side users that connect to Microsoft Outlook from outside your organization's firewall, you can add an external website. Alternatively, when you run the **New-OABVirtualDirectory** cmdlet in the Shell, a new virtual directory named OAB is created in the default IIS website on the local Exchange server.

Creating an OAB virtual directory isn't a common task. Exchange allows for one OAB virtual directory named OAB, and you should create an OAB virtual directory only if there is a problem with the existing OAB virtual directory, and the previous OAB virtual directory was removed.

For additional management tasks related to OABs, see Offline address book procedures.

Important:

Before you create an OAB virtual directory, make sure that your users are aware of the changes you are making. This procedure may interrupt the OAB downloading process for your users.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Offline address books" entry in the Email address and address book permissions topic.
- The local Exchange server must have the Client Access server role installed.
- A default IIS website must exist (for example, /w3svc/1/root).
- A virtual directory named OAB doesn't already exist.
- Although Web-based distribution is enabled by default and doesn't require further configuration, we recommend that you enable Secure Sockets Layer (SSL) for the OAB distribution point.
- You can't use the Exchange Administration Center (EAC) to perform this procedure. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to create an OAB virtual directory

To create an OAB virtual directory with all of the default settings, you can run the **New-OABVirtualDirectory** cmdlet without any parameters. Use the following procedure to create an OAB virtual directory with custom settings.

Note:

When creating an OAB virtual directory, we recommend that you have SSL enabled.

This example creates an OAB virtual directory on the Client Access server named CASServer01 that has SSL enabled and an external URL.

```
New-OABVirtualDirectory -Server CASServer01 -RequireSSL
$true -ExternalURL "https://www.contoso.com/OAB"
```

After you create a new OAB virtual directory, you must edit the settings on each OAB that uses Web-based distribution to reconnect to the OAB virtual directory. For more information, see Change the offline address book generation schedule.

For detailed syntax and parameter information, see New-OabVirtualDirectory.

Change the offline address book

generation schedule

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-12-05*

An offline address book (OAB) is a copy of an address book that's been downloaded so that an Outlook user can access the information it contains while disconnected from the server. You can configure how often the OAB is generated by using the *OABGeneratorWorkCycle* and *OABGeneratorWorkCycleCheckpoint* parameters on the Set-MailboxServer cmdlet.

For additional management tasks related to OABs, see Offline address book procedures.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Offline address books" entry in the Email address and address book permissions topic.
- You can't use the Exchange Administration center (EAC) to perform this procedure. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to configure OAB properties

In this example, the offline address book is generated every six hours each day on the Mailbox server, MBXServer01.

```
Set-MailboxServer -Identity MBXServer01 -
OABGeneratorWorkCycle 01.00:00:00 -
OABGeneratorWorkCycleCheckpoint 06:00:00
```

For detailed syntax and parameter information, see Set-OfflineAddressBook.

Configure offline address book distribution properties

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-14*

For each offline address book (OAB) distribution point in Exchange, you can configure two URLs—an internal URL that can be accessed only from your internal corporate network and an external URL that can be accessed from the Internet.

For additional management tasks related to OABs, see Offline address book procedures.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Offline address books" entry in the Email address and address book permissions topic.
- You can't use the Exchange Administration Center (EAC) to perform this procedure. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to configure OAB distribution properties

This example sets the polling interval for OAB distribution on the OAB virtual directory OAB (Default Web Site) to six hours.

```
Set-OABVirtualDirectory "OAB (Default Web Site)" -
PollInterval 360
```

This example sets the external distribution point to https://contoso.com/OAB for the default OAB virtual directory OAB (Default Web Site).

```
Set-OABVirtualDirectory "OAB (Default Web Site)" -
```

```
ExternalUrl https://contoso.com/OAB
```

For detailed syntax and parameter information, see Set-OabVirtualDirectory.

For More Information

Offline address books

Address lists

Exchange Server 2013 > Email addresses and address books >

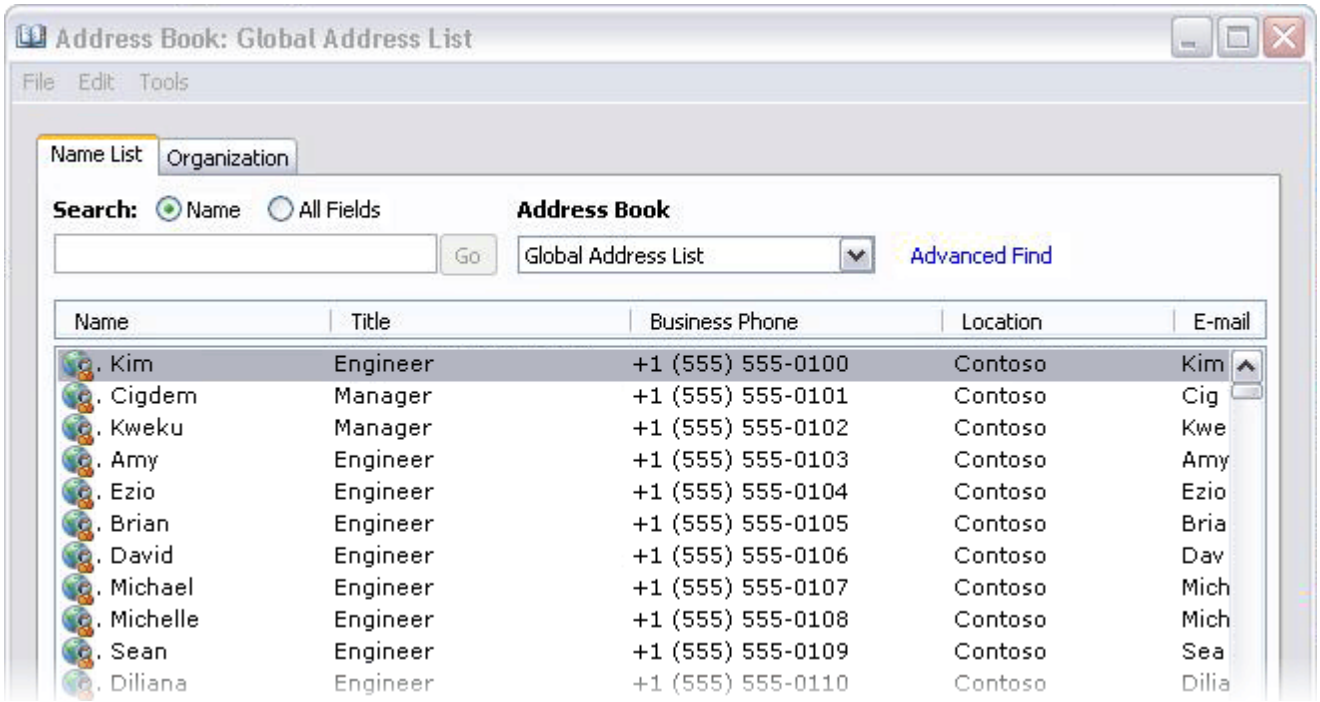
Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-05-23*

An *address list* is a collection of recipient and other Active Directory objects. Each address list can contain one or more types of objects (for example, users, contacts, groups, public folders, and room and equipment resources). You can use address lists to organize recipients and resources, making it easier to find the recipients and resources you want. Address lists are updated dynamically. Therefore, when new recipients are added to your organization, they're automatically added to the appropriate address lists.

As shown in the following figure, client applications, such as Microsoft Outlook, display the available address lists that Exchange provides.

Global address list as displayed in Microsoft Office Outlook 2007



Address lists reside in Active Directory. Therefore, mobile users who are disconnected from the

network are also disconnected from these server-side address lists. However, you can create offline address books (OABs) for users who are disconnected from the network. These OABs can be downloaded to a user's hard disk. Frequently, to conserve resources, OABs are subsets of the information in the actual address lists that reside on your servers. For more information, see Offline address books.

Contents

Default address lists

When users want to use their client application to find recipient information, they can select from available address lists. Several address lists, such as the global address list (GAL), are created by default. Exchange contains the following default address lists, which are then automatically populated with new users, contacts, groups, or rooms as they're added to your organization:

- **All Contacts** This address list contains all mail-enabled contacts in your organization. Mail-enabled contacts are those recipients who have an external email address. If you want mail-enabled contact information to be available to all users in your organization, you must include the contact in the GAL. To learn more about mail contacts, see Recipients.
- **All Distribution Lists** This address list contains mail-enabled groups, such as mail-enabled security groups, distribution groups and dynamic distribution groups in your organization. Mail-enabled groups are lists of recipients that are created to expedite the mass sending of email messages and other information. When an email message is sent to a mail-enabled group, all members of that list receive a copy of the message. To learn more about mail-enabled groups, see Recipients.
- **All Rooms** This address list contains all resources that have been designated as a room in your organization. Rooms are resources in your organization that can be scheduled by sending a meeting request from a client application. The user account that's associated with a room is disabled. To learn more about resource mailboxes, see Recipients.
- **All Users** This address list contains all mail-enabled users in your organization. A mail-enabled user represents a user outside your Exchange organization. Each mail-enabled user has an external email address. All messages sent to mail-enabled users are routed to this external email address. A mail-enabled user is similar to a mail contact, except that a mail-enabled user has Active Directory logon credentials and can access resources. To learn more about mail-enabled users, see Recipients.
- **Default Global Address List** This address list contains all mail-enabled users, contacts, groups, or rooms in the organization. During setup, Exchange creates various default address lists. The most familiar address list is the GAL. By default, the GAL contains all recipients in an Exchange organization. In other words, any mailbox-enabled or mail-enabled object in an Active Directory

forest that has Exchange installed is listed in the GAL. For ease of use, the GAL is organized by name, not by email address. For more information, see Create a global address list.

- **Public Folders** This address list contains all public folders in your organization. Access permissions determine who can view and use the folders. Public folders are stored on computers running Exchange. For more information about public folders in Exchange 2013, see Public folders. For more information about public folders in Exchange Online, see **Public folders in Office 365 and Exchange Online**.

Custom Address Lists

An Exchange organization can contain thousands of recipients. If you compile all your recipients in the default address lists, those lists could become quite large. To prevent this, you can create custom address lists to help users in your organization find what they are looking for more easily.

For example, consider a company that has two large divisions and one Exchange organization. One division, named Fourth Coffee, imports and sells coffee beans. The other division, Contoso, Ltd, underwrites insurance policies. For most day-to-day activities, the employees at Fourth Coffee don't communicate with the employees at Contoso, Ltd. Therefore, to make it easier for employees to find recipients who exist only in their division, you can create two new custom address lists—one for Fourth Coffee and one for Contoso, Ltd. When searching for recipients in their division, these custom address lists allow employees to select only the address list that's specific to their division. However, if an employee is unsure about the division in which the recipient exists, the employee can search within the GAL, which contains all recipients in both divisions.

You can also create subcategories of address lists called hierarchical address lists. For example, you can create an address list that contains all recipients in Manchester and another that contains all recipients in Stuttgart.

Best Practices for Creating Address Lists

Although address lists are useful tools for users, poorly planned address lists can cause frustration. To make sure that your address lists are practical for users, consider the following best practices:

- Avoid creating so many address lists that users won't be sure which list to search for recipients.
- Address lists should make it easier for users to find addresses in the GAL.
- Name your address lists in such a way that, when users glance at them, they will know immediately which recipient types are contained in the list. If you have difficulty naming your address lists, create fewer lists and remind users that they can find anyone in your organization by using the GAL.

Note:

By default in Exchange Online, the Address List role isn’t assigned to any role groups. To use any cmdlets that require the Address List role, you need to add the role to a role group. For details, see the “Add a role to a role assignment policy” section of Manage role assignment policies.

For detailed instructions about creating an address list in Exchange 2013, see Create an address list. For detailed instructions about creating an address list in Exchange Online, see **Manage address lists**.

Address lists are a collection of recipient and other Active Directory objects. Each address list can contain one or more types of objects (for example, users, contacts, groups, public folders, conferencing, and other resources). Address lists also provide a mechanism to partition mail-enabled objects in Active Directory for the benefit of specific groups of users.

For other management tasks related to address lists, see Address list procedures.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Address lists" entry in the Email address and address book permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to create an address list

1. Navigate to **Organization** > **Address lists**, and then click **Add +**.
2. In **Address List**, type a name and specify the types of recipients to include in the list.
3. By default, Exchange creates address lists that contain all members of your organization. To create a unique custom address list, click **Add a rule**.

Important:

If you don't add a rule, you'll create an address list that's redundant with one of the default address lists.

4. In the list, select a filtering option (for example, **Custom attribute 1**).
5. In **Specify words or phrases**, type words or phrases to filter by, click **Add +**, and then click **OK**.

You can continue to add several phrases or words by repeating Step 4. The filter is a Boolean **OR** statement. For example, you can create a filter that will apply the address list to users whose Custom 1 attribute equals **Oregon**, **Idaho**, or **Washington**.

6. (Optional) Click **Add a rule** again to add additional filters. Additional filters create a Boolean **And** statement. The more filters you add, the fewer number of users the address list will apply to.
7. Click **Preview recipients the address lists includes** to see the recipients that this address list is going to apply to.
8. Click **Save**.
9. You'll get a warning that the address list won't be applied until you update it. Depending on the size of your organization and the filters that you added to the address list, some address lists can contain thousands or tens of thousands of recipients. Updating address lists can impact your resources, so you may want to update the address during off-peak hours.

For details about updating an address list, see Update an address list.

Use the Shell to create an address list

This example creates the address list MyAddressList by using the *RecipientFilter* parameter and includes recipients that are mailbox users and have `StateOrProvince` set to `Washington` or `Oregon`.

```
New-AddressList -Name MyAddressList -RecipientFilter
{((RecipientType -eq 'UserMailbox') -and ((StateOrProvince
-eq 'Washington') -or (StateOrProvince -eq 'Oregon')))}
```

This example creates the child address list Building 34 Meeting Rooms in the All Rooms parent container, using built-in conditions.

```
New-AddressList -Name "Building 34 Meeting Rooms" -
Container "\All Rooms" -IncludedRecipients Resources -
ConditionalCustomAttribute1 "Building 34"
```

For detailed syntax and parameter information, see New-AddressList.

Update an address list

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-14*

Address lists are a collection of recipient and other Active Directory objects. You apply an address list when the address list filter rule has been edited. To update the membership of the address list to include new recipients and remove those who no longer meet the filtering criteria, you must apply the address list.

For additional management tasks related to address lists, see Address list procedures.

What do you need to know before you begin?

- Estimated time to complete: This process may take a long time to finish depending on the number of recipients in the address list.
- Some address lists contain thousands or tens of thousands of recipients depending on the size of your organization and the filters that you added to the address list. Updating address lists can take up a lot of computer resources. So, you may want to update the address list during off-peak hours.
- If the address list contains more than 3,000 recipients, we recommend that you use the Exchange Management Shell to update the address list.

For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server,

Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to update an address list

1. Navigate to **Organization** > **Address lists**.
2. In the list view, select the address list that you want to update.
3. In the details pane, click **Update**.

Use the Shell to update an address list

This example updates the address list Washington State.

```
Update-AddressList "Washington State"
```

If you have more than one address list with the same name, you must specify the full path to the address list you want to update. For example, if you want to update the address list Sales under North America but there is also a Sales address list under Europe, use the following command:

```
Update-AddressList "North America\Sales"
```

For detailed syntax and parameter information, see Update-AddressList.

Create an address list by using recipient filters

Email addresses and address books > Address lists > Address list procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-03-18*

This topic explains how to create an address list by using recipient filters. To learn more about address lists, see Address lists.

For additional management tasks related to address lists, see Address list procedures.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To

see what permissions you need, see the "Address lists" entry in the Email address and address book permissions topic.

- By default in Exchange Online, the Address List role isn't assigned to any role groups. To use any cmdlets that require the Address List role, you need to add the role to a role group. For details, see the "Add a role to a role assignment policy" section of Manage role assignment policies.
- To use the *RecipientFilter* parameter to create a custom filter, you must specify a string for the filter. The Shell uses OPATH for the filtering syntax. OPATH is a querying language designed to query object data sources.
- You can't use the Exchange Administration Center (EAC) to perform this procedure. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to create an address list by using recipient filters

This example creates an address list for all users with Exchange mailboxes who reside in Washington or Oregon.

```
New-AddressList -Name "Pacific Northwest Mailboxes" -
RecipientFilter {((RecipientType -eq 'UserMailbox') -and
((StateOrProvince -eq 'Washington') -or (StateOrProvince -
eq 'Oregon')))}
```

This example creates an address list for all users with Exchange mailboxes who have AgencyB as the value for the *CustomAttribute15* parameter.

```
New-AddressList -Name "AgencyB" -RecipientFilter
{(RecipientType -eq 'UserMailbox') -and (CustomAttribute15
-like *AgencyB*)}
```

For detailed syntax and parameter information, see New-AddressList.

Move an address list

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-14*

This topic explains how to move an existing address list to a new container under the root address list.

For additional management tasks related to address lists, see Address list procedures.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Address Lists" entry in the Email address and address book permissions topic.
- You can't use the Exchange Administration Center (EAC) to perform this procedure. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to move an address list

This example uses the address list's GUID to move the address list to the Building 4 container, which is located in the All Users\Sales container.

```
Move-AddressList -Identity c3fffd8e-026b-41b9-88c4-
8c21697ac8ac -Target "\All Users\Sales\Building4"
```

Type **Y** to confirm that you want to move this address list, and then press ENTER.

For detailed syntax and parameter information, see Move-AddressList.

Remove an address list

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-14*

This topic explains how to remove an address list. You can't remove the default global address list

(GAL).

For additional management tasks related to address lists, see Address list procedures.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Address list" entry in the Email address and address book permissions topic.
- You can't remove a parent address list that contains child address lists. However, you can remove both the child and parent address lists by pressing the CTRL key on the keyboard, and then selecting the parent and child address lists. If you attempt to remove a parent address list without removing the child address lists, you'll receive an error.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to remove an address list

1. Navigate to **Organization** > **Address lists**.
2. In the list view, select the address list you want to remove, and then click **Delete** .
3. In the warning, click **Yes** to remove the address list.

Use the Shell to remove an address list

This example removes the address list Sales Department, which doesn't contain child address lists.

```
Remove-AddressList -Identity "Sales Department"
```

Type **Y** to confirm that you want to remove this address list, and then press ENTER.

For detailed syntax and parameter information, see Remove-AddressList.

Use the Shell to remove an address list that contains child address lists

This example removes the parent address list Departments and all its child address lists.

```
Remove-AddressList -Identity Departments -Recursive
```

Type **Y** to confirm that you want to remove the parent address list and its child address lists, and then press ENTER.

For detailed syntax and parameter information, see Remove-AddressList.

Create a global address list

Email addresses and address books > Address lists > Address list procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-03-18*

The global address list (GAL) is a directory that contains entries for every group, user, and contact within an organization's implementation of Microsoft Exchange. If your organization uses address book policies, you may want to create additional GALs. To learn more, see Address book policies.

For additional management tasks related to address lists, see Address list procedures.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Address lists" entry in the Email address and address book permissions topic.
- By default in Exchange Online, the Address List role isn't assigned to any role groups. To use any cmdlets that require the Address List role, you need to add the role to a role group. For details, see the "Add a role to a role assignment policy" section of Manage role assignment policies.
- You can't use the Exchange Administration Center (EAC) to perform this procedure. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to create a GAL using conditional filter

properties

This example creates a GAL named GAL_Contoso that includes recipients who are mailbox users and have their company listed as Contoso.

```
New-GlobalAddressList -Name "GAL_Contoso" -
IncludedRecipients MailboxUsers -ConditionalCompany Contoso
```

Note:

If you're using precanned conditional filter properties, the *IncludedRecipients* parameter can't be blank.

For detailed syntax and parameter information, see New-GlobalAddressList.

Use the Shell create a GAL using a recipient filter

This example creates a GAL named GAL_AgencyA that includes recipients for which the *CustomAttribute15* parameter has a value of AgencyA.

```
New-GlobalAddressList -Name "GAL_AgencyA" -RecipientFilter
{CustomAttribute15 -like "AgencyA"}
```

For detailed syntax and parameter information, see New-GlobalAddressList.

Configure global address list properties

Email addresses and address books > Address lists > Address list procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-03-18*

This topic explains how to modify the settings of a global address list (GAL).

For additional management tasks related to address lists, see Address list procedures.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Address lists" entry in the Email address and address book permissions topic.
- By default in Exchange Online, the Address List role isn't assigned to any role groups. To use any

cmdlets that require the Address List role, you need to add the role to a role group. For details, see the "Add a role to a role assignment policy" section of Manage role assignment policies.

- You can't edit the settings of the default GAL.
- You can't use the Exchange Administration Center (EAC) to perform this procedure. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to configure GAL properties

This example assigns a new name, FourthCoffee, to the GAL that has the GUID 96d0c505-eba8-4103-ad4f-577a1bf4ad7b.

```
Set-GlobalAddressList -Identity 96d0c505-eba8-4103-ad4f-577a1bf4ad7b -Name FourthCoffee
```

Note:

If you're using precanned conditional filter properties, the value for the *IncludedRecipients* parameter can't be blank.

This example changes the recipients who will be included in the Fourth Coffee global GAL to those whose company is set to Fourth Coffee.

```
Set-GlobalAddressList -Identity Fourth Coffee -RecipientFilter {Company -eq "Fourth Coffee"}
```

For detailed syntax and parameter information, see Set-GlobalAddressList.

Remove a global address list

Email addresses and address books > Address lists > Address list procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-03-18*

The global address list (GAL) is a directory that contains entries for every group, user, and contact within an Exchange organization.

For additional management tasks related to address lists, see Address list procedures.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Address lists" entry in the Email address and address book permissions topic.
- By default in Exchange Online, the Address List role isn't assigned to any role groups. To use any cmdlets that require the Address List role, you need to add the role to a role group. For details, see the "Add a role to a role assignment policy" section of Manage role assignment policies.
- You can't remove the default GAL.
- You can't use the Exchange Administration Center (EAC) to perform this procedure. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to remove a GAL

This example removes the GAL Fourth Coffee from the domain controller ad-server.fourthcoffee.com.

```
Remove-GlobalAddressList -Identity "Fourth Coffee" -
DomainController ad-server.fourthcoffee.com
```

To confirm that you want to remove the GAL, type **Y**, and then press ENTER.

For detailed syntax and parameter information, see Remove-GlobalAddressList.

Update a global address list

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-03-18*

You can use the Shell to update a global address list (GAL). A GAL is a directory that contains entries for every group, user, and contact within an organization's implementation of Microsoft Exchange.

For additional management tasks related to address lists, see Address list procedures.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Address lists" entry in the Email address and address book permissions topic.
- By default in Exchange Online, the Address List role isn't assigned to any role groups. To use any cmdlets that require the Address List role, you need to add the role to a role group. For details, see the "Add a role to a role assignment policy" section of Manage role assignment policies.
- You can't use the Exchange Administration Center (EAC) to perform this procedure. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to update a GAL

This example updates a GAL for the Fourth Coffee company.

Note:

Running this command only starts the update process. It may take several hours for the GAL to be updated.

```
Update-GlobalAddressList -Identity "Fourth Coffee"
```

For detailed syntax and parameter information, see Update-GlobalAddressList.

Hierarchical address books

Exchange Server 2013 > Email addresses and address books >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-03-26*

The hierarchical address book (HAB) allows end users to look for recipients in their address book using an organizational hierarchy. Normally, users are limited to the default global address list (GAL) and its recipient properties and the structure of the GAL often doesn't reflect the

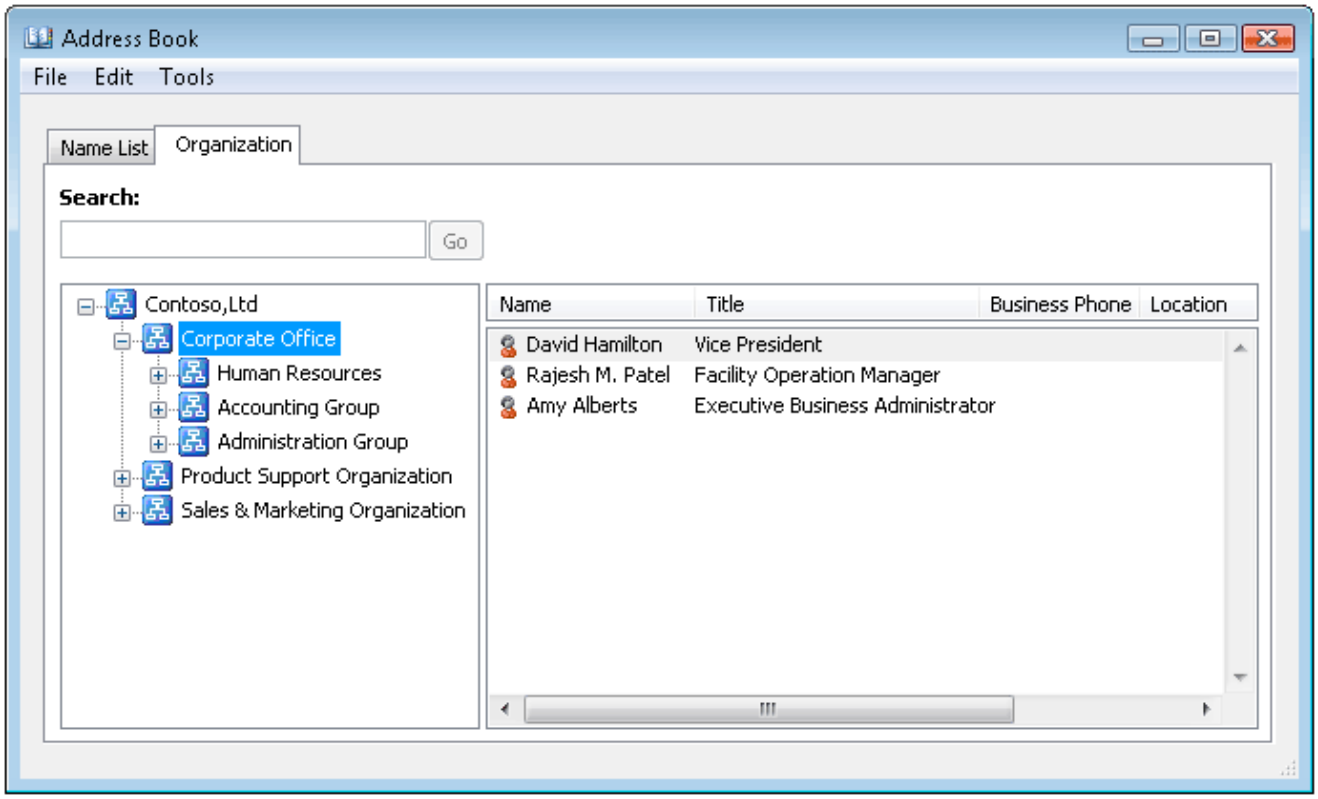
management or seniority relationships of recipients in your organization. Being able to customize an HAB that maps to your organization's unique business structure provides your users with an efficient method for locating internal recipients.

Using hierarchical address books

In an HAB, your root organization (for example, Contoso, Ltd) is used as the top-level tier. Under this top-level tier, you can add several child tiers to create a customized HAB that's segmented by division, department, or any other organizational tier you want to specify. The following figure illustrates an HAB for Contoso, Ltd with the following structure:

- The top-level tier represents the root organization Contoso, Ltd.
- The second-level child tiers represent the business divisions within Contoso, Ltd: Corporate Office, Product Support Organization, and Sales & Marketing Organization.
- The third-level child tiers represent departments within the Corporate Office division: Human Resources, Accounting Group, and Administration Group.

Example HAB for Contoso, Ltd



You can provide an additional level of hierarchical structure by using the *SeniorityIndex* parameter. When creating an HAB, use the *SeniorityIndex* parameter to rank individual recipients or organizational groups by seniority within these organizational tiers. This ranking specifies the order in which the recipients or groups are displayed in the HAB. For example, in the preceding example, the *SeniorityIndex* parameter for the recipients in the Corporate Office division is set to the following:

- 100 for David Hamilton

- 50 for Rajesh M. Patel
- 25 for Amy Alberts

Note:
If the *SeniorityIndex* parameter isn't set or is equal for two or more users, the HAB sorting order uses the *PhoneticDisplayName* parameter value to list the users in ascending alphabetical order. If the *PhoneticDisplayName* parameter value isn't set, the HAB sorting order defaults to the *DisplayName* parameter value and lists the users in ascending alphabetical order.

Configuring hierarchical address books

Detailed instructions for creating HABs are included in the topic Enable or disable hierarchical address books. The general steps are as follows:

1. Create a distribution group that will be used for the root organization (top-level tier). If desired, you can use an existing organizational unit in your Exchange forest for the distribution group.
2. Create distribution groups for the child tiers and designate them as members of the HAB. Modify the *SeniorityIndex* parameter of these groups so they're listed in the proper hierarchical order within the root organization.
3. Add organization members. Modify the *SeniorityIndex* parameter of the members so they're listed in the proper hierarchical order within the child tiers.
4. For accessibility purposes, you can use the *PhoneticDisplayName* parameter, which specifies a phonetic pronunciation of the *DisplayName* parameter.

Enable or disable hierarchical address books

Exchange Server 2013 > Email addresses and address books > Hierarchical address books >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-03-26*

You can configure a hierarchical address book (HAB), which is a feature available to end users in Microsoft Outlook 2010 or later. With an HAB, users can look for recipients in their Exchange organization by using an organizational hierarchy based on seniority or management structure. To learn more about HABs, see Hierarchical address books.

What do you need to know before you begin?

- Estimated time to complete: 1 hour.

- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Distribution groups" entry in the Recipients Permissions topic.
- You can't use the Exchange Administration Center (EAC) to perform this procedure. You must use the Shell.
- Before you get started, read the topic Hierarchical address books. You should understand if a HAB is appropriate for your Exchange organization.
- Understand how organizational units (OUs), groups, users, and contacts are currently configured in your Exchange organization.
- Understand the cmdlets and associated parameters in the following table, which are required to configure a HAB.

Cmdlet	Parameter
Set-OrganizationConfig	*HierarchicalAddressBookRoot*
Set-Group	*IsHierarchicalGroup* *SeniorityIndex* *PhoneticDisplayName*
Set-User	*SeniorityIndex* *PhoneticDisplayName*
Set-Contact	*SeniorityIndex* *PhoneticDisplayName*

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to enable a HAB

Note:
Although you can't use the EAC to enable a HAB, after it's enabled you can use the EAC to manage the membership of the groups in the organizational hierarchy.

For this example, an OU called HAB will be created for the HAB. The name of the domain for the organization is Contoso-dom, and Contoso,Ltd will be the name of the top-level organization in the hierarchy (the *root organization*). Subordinate groups named Corporate Office, Product Support Organization, and Sales & Marketing Organization will be created as child organizations under Contoso,Ltd. Additionally, the groups Human Resources, Accounting Group, and Administration

Group will be created as child organizations under Corporate Office.

For detailed information about creating distribution groups, see Manage Distribution Groups.

1. Create an OU named HAB in the Contoso organization. You can use Active Directory Users and Computers or type the following at a command prompt.

Note:
Alternatively, you can use an existing OU in your Exchange forest.

```
dsadd ou "OU=HAB,DC=Contoso-dom,DC=Contoso,DC=com"
```

Note:
For details, see Create a New Organizational Unit.

2. Create the root distribution group Contoso,Ltd for the HAB.

Note:
For the purposes of this topic, the Shell example is provided. However, you can also use the EAC to create a distribution group. For details, see Manage Distribution Groups.

```
New-DistributionGroup -Name "Contoso,Ltd" -DisplayName
"Contoso,Ltd" -Alias "ContosoRoot" -OrganizationalUnit
"Contoso-dom.Contoso.com/HAB" -SamAccountName "ContosoRoot"
-Type "Distribution"
```

3. Designate Contoso,Ltd as the root organization for the HAB.

```
Set-OrganizationConfig -HierarchicalAddressBookRoot
"Contoso,Ltd"
```

4. Create distribution groups for the other tiers in the HAB. For this example, you would create the following groups: Corporate Office, Product Support Organization, Sales & Marketing Organization, Human Resources, Accounting Group, and Administration Group. This example creates the distribution group Corporate Office.

Note:
For the purposes of this topic, the Shell example is provided. However, you can also use the EAC to create distribution groups. For details, see Manage Distribution Groups.

```
New-DistributionGroup -Name "Corporate Office" -DisplayName
"Corporate Office" -Alias "CorporateOffice" -
OrganizationalUnit "Contoso-dom.Contoso.com/HAB" -
SamAccountName "CorporateOffice" -Type "Distribution"
```

5. Designate each of the groups as members of the HAB. For this example, you would designate the following groups as being hierarchical groups: Contoso,Ltd, Corporate Office, Product Support Organization, Sales & Marketing Organization, Human Resources, Accounting Group, and

Administration Group. This example designates the distribution group Contoso,Ltd as a member of the HAB.

```
Set-Group -Identity "Contoso,Ltd" -IsHierarchicalGroup
$true
```

6. Add each of the subordinate groups as members of the root organization. For this example, distribution groups Corporate Office, Product Support Organization, and Sales & Marketing Organization, are added as members of the root organization Contoso,Ltd in the HAB. This example adds the Corporate Office distribution group as a member of the Contoso,Ltd root distribution group.

Note:
This example uses the alias of the distribution groups.

```
Add-DistributionGroupMember -Identity "ContosoRoot" -Member
"CorporateOffice"
```

7. Add each of the groups that are subordinate to the distribution group Corporate Office as members of the group. For this example, distribution groups Human Resources, Accounting Group, and Administration Group, are added as members of the distribution group Corporate Office. This example adds the Human Resources distribution group as a member of the Corporate Office distribution group.

Note:
This example uses the alias of the distribution groups and assumes the Human Resources distribution group alias is HumanResources.

```
Add-DistributionGroupMember -Identity "CorporateOffice" -
Member "HumanResources"
```

8. Add users to the groups in the HAB. For this example, David Hamilton (SMTP address DHamilton@contoso.com) is an existing user in the OU Contoso-dom.Contoso.com/Users and will be added to the group Corporate Office. Repeat this step to add other users to groups in the HAB.

```
Add-DistributionGroupMember -Identity "CorporateOffice" -
Member "DHamilton"
```

9. Set the *SeniorityIndex* parameter for groups in the HAB. For this example, the Corporate Office group contains three child groups: Human Resources, Accounting Group, and Administration Group. Instead of having the groups listed in ascending alphabetical order, which is the default, the preferred sorting will be Human Resources (*SeniorityIndex* = 100), Accounting Group (*SeniorityIndex* = 50), and then Administration Group (*SeniorityIndex* = 25). This example sets the *SeniorityIndex* parameter for the Human Resources group to 100.

```
Set-Group -Identity "Human Resources" -SeniorityIndex 100
```

Note:

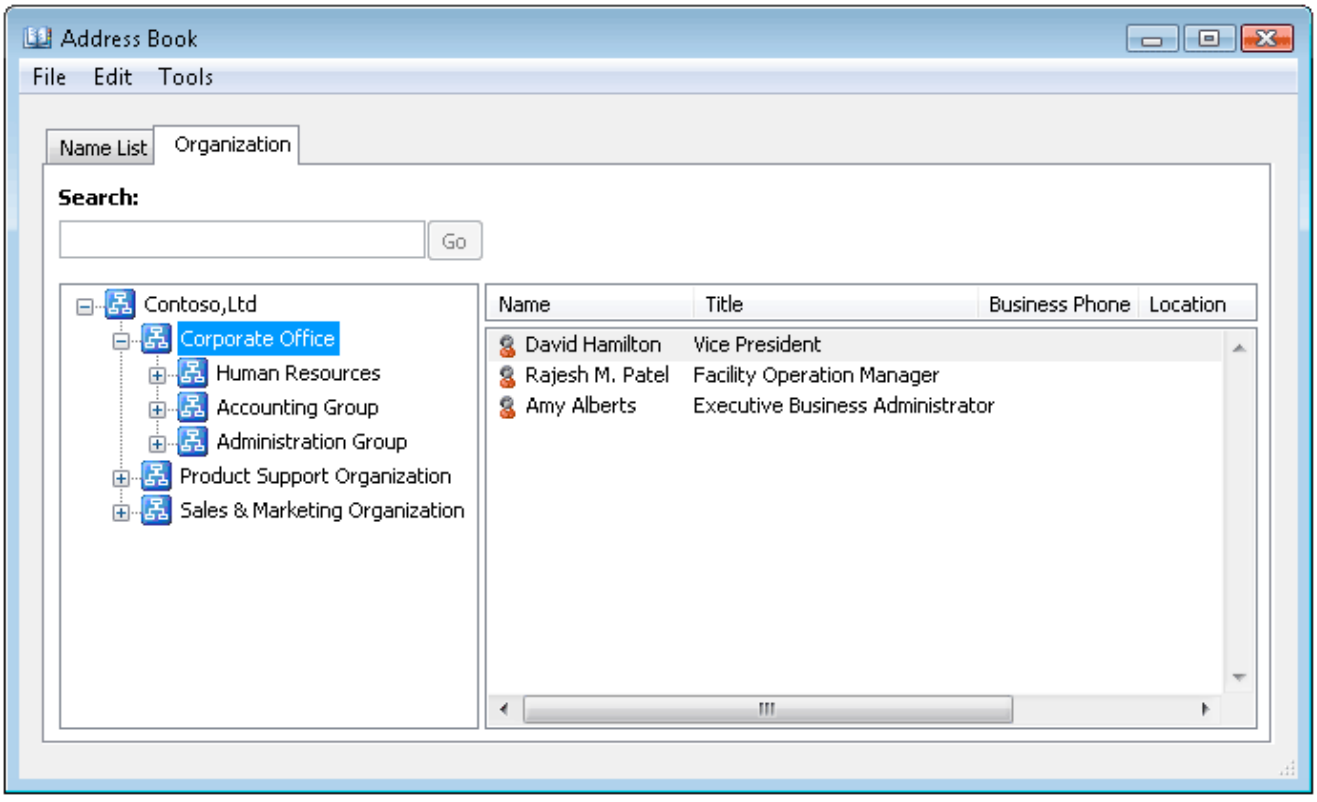
The *SeniorityIndex* parameter is a numerical value used to sort groups or users in descending numerical order in a HAB. If the *SeniorityIndex* parameter isn't set or is equal for two or more users, the HAB sorting order uses the *PhoneticDisplayName* parameter value to list the users in ascending alphabetical order. If the *PhoneticDisplayName* value isn't set, the HAB sorting order defaults to the *DisplayName* parameter value and lists the users in ascending alphabetical order.

10. Set the *SeniorityIndex* parameter for users in the HAB groups. For this example, the Corporate Office group contains three users: Amy Alberts, David Hamilton, and Rajesh M. Patel. Instead of having the users listed in ascending alphabetical order by default, the preferred sorting will be David Hamilton (*SeniorityIndex* = 100), Rajesh M. Patel (*SeniorityIndex* = 50), and then Amy Alberts (*SeniorityIndex* = 25). This example sets the *SeniorityIndex* parameter for the user David Hamilton to 100.

```
Set-User -Identity "DHamilton@contoso.com" -SeniorityIndex
100
```

After completing the preceding steps, the HAB will be visible in Outlook. To view the HAB, open Outlook and click **Address Book**. The HAB is displayed on the **Organization** tab, similar to the following figure.

Example HAB for Contoso,Ltd



After the HAB is created, you can use the EAC to manage the membership of the groups in the organizational hierarchy. However, you must use the Shell to modify the *SeniorityIndex* parameter for any new groups or users.

For detailed syntax and parameter information, see the following:

- New-DistributionGroup
- Set-OrganizationConfig
- Set-Group
- Add-DistributionGroupMember
- Set-User

Use the Shell to disable a hierarchical address book

This example disables the root organization used for the HAB.

```
Set-OrganizationConfig -HierarchicalAddressBookRoot $null
```

Note:

This command doesn't delete the root organization or child groups used in the HAB structure or reset the *SeniorityIndex* values for groups or users. It only prevents the HAB from being displayed in Outlook. To enable the HAB with the same configuration settings again, you only need to enable the root organization again.

For detailed syntax and parameter information, see Set-OrganizationConfig.

Sharing

Exchange Server 2013 >

Applies to: *Outlook 2013*

Topic Last Modified: *2014-02-14*

You may need to coordinate schedules with people in different organizations or with friends and family members so that you can work together on projects or plan social events. With Exchange 2013, administrators can set up different levels of calendar access to allow businesses to collaborate with other businesses and to let users share their schedules with others. Business-to-business calendar sharing is set up by creating *organization relationships*. User-to-user calendar sharing is set up by applying *sharing policies*.

Important:

This feature of Exchange Server 2013 isn't fully compatible with Office 365 operated by 21Vianet in China and some feature limitations may apply. For more information, see Learn about Office 365 operated by 21Vianet.

Contents

Limitations of free/busy sharing

Firewall considerations for federated sharing

Coexistence with Exchange 2010

Coexistence with Exchange 2007

Sharing Documentation

Sharing Scenarios in Exchange 2013

The following sharing scenarios are supported in Exchange 2013:

Sharing goal	Setting to use	Requirements
Share calendars with an Office 365 organization	Organization relationships	The Office 365 organization is ready to configure. The on-premises Exchange administrator has to set up an authentication relationship with the cloud (also known as "federation") and must meet minimum software requirements. To learn more about setting up federation, see Federation.
Share calendars with another on-premises Exchange organization	Organization relationships	Both on-premises Exchange organizations have to set up federation and must meet minimum software requirements
Share an Exchange user's calendar with an Internet user	Sharing policies	None, ready to configure
Share an Exchange user's calendar with another Exchange on-premises user	Sharing policies	Both on-premises Exchange organizations have to set up federation and must meet minimum software

		requirements.

The following table lists the differences between organization relationships and sharing policies.

Organization relationships vs. sharing policies

Functionality	Organization relationship	Sharing policy
Requires a federation trust for your organization	Yes	Yes when sharing with other federated domain organizations. Not required for Internet sharing policies.
Recommends that the external domain be federated	Yes	Yes when sharing with other federated domain organizations. Not required for Internet sharing policies.
Allows sharing of free/busy information (including subject and location) with external organizations for a set of many users.	Yes	No
Allows sharing of Calendar folders with free/busy information	No	Yes
Allows sharing of Calendar folders with free/busy information, including subject and body	No	Yes
Requires users to send a sharing invitation to external recipients	No	Yes
Provides an access method	Your Client Access server accesses the Client Access	Your Client Access server accesses the Client Access

	server of the external organization and retrieves free/busy information for the external user when requested.	server of the external organization and subscribes to the external user's Calendar folder. For Internet sharing policies, external users access either a restricted or public URL on the Client Access server.
Can be applied to all external domains	No (a one-to-one relationship between two Exchange 2013 organizations)	Yes
Provides users with different sharing experiences with external recipients	No	Yes, based on the sharing policy that's applied
Disables sharing for some users	Yes, by specifying a security distribution group for the organization relationship	Yes, by disabling the sharing policy that's applied
Requires that the mailbox reside on an Exchange 2013 Mailbox server	No	Yes

Return to top

Limitations of free/busy sharing

The following limitations apply when sharing free/busy information between Exchange organizations:

1. **Outlook Web Access 2003** When a user in an Exchange 2003 organization uses Outlook Web Access to access free/busy for users in a remote Exchange 2013 organization, the request will fail. Outlook Web Access connections from Exchange 2003 can't make WebDAV (Web-based Distributed Authoring and Versioning) connections to a free/busy system folder to retrieve the free/busy information for remote users. Because Exchange 2013 doesn't support WebDAV connections, the Exchange 2003 server can't connect to External (FYDIBOHF25SPDLT) on the Exchange 2013 CAS server for Outlook Web Access requests. Outlook clients don't experience this

limitation because they use MAPI instead of WebDAV when connecting to External (FYDIBOHF25SPDLT).

2. **Wide Area Network (WAN) latency** In Exchange 2003 organizations, the replicas for all free/busy folders must reside on Exchange 2010 SP2 or higher Mailbox servers. In environments where Exchange 2003 public folder databases are located in multiple physical sites, there may be excessive latency and performance issues if internal free/busy queries have to traverse WAN links to access Exchange 2010 public folder databases not located in the same physical site.
3. **Free/busy information period** Free/busy information requests to an Exchange 2007 organization from an Exchange 2013 organization may fail due to a mismatch in the requested free/busy information period. By default, Exchange 2007 accepts availability requests for 42 days of free/busy information and Exchange 2013 may request 62 days of free/busy information. If the request exceeds the default 42 limit imposed by Exchange 2007, the request will fail.

Follow the steps below to configure your Exchange 2007 CAS servers to accept longer period free/busy information requests:

a. On all your Exchange 2007 CAS servers, open the following file with a text editor such as Notepad: <Exchange Installation Path>\V14\ClientAccess\ExchWeb\EWS\web.config

Caution:

Before you make any changes to the web.config file, make a copy of the file and store it in a safe location.

b. Locate the **appSettings** section in the web.config file.

c. Add a new key "<add key="maximumQueryIntervalDays" value="62" />" and save the web.config file.

Note:

The maximumQueryIntervalDays value isn't present by default. When this value isn't present, Exchange 2007 uses the default interval of 42 days.

d. Stop and restart the Microsoft Internet Information Services (IIS) on all the Exchange 2007 CAS servers.

4. **Exchange organizations that have both on-premises and cloud users** If you set up calendar sharing with another Exchange organization that is configured in a hybrid deployment with Microsoft Office 365, free/busy availability lookups for Office 365-based or remote users that have been moved to the cloud will fail. Because the organization relationship for your Exchange organization is with the remote on-premises Exchange organization, not the Office 365-based Exchange Online organization, the free/busy request can't query the Office 365-based users. Exchange 2013 doesn't support functionality to proxy these availability requests through the on-premises organization to the Office 365 service.

For details about how to configure free/busy sharing between common Exchange deployments, see Configuring federated sharing between Exchange organizations.

Firewall considerations for federated sharing

Federated sharing features require that the Client Access servers in your organization have

outbound access to the Internet by using HTTPS. You must allow outbound HTTPS access (port 443 for TCP) to all Exchange 2013 Client Access servers in the organization.

For an external organization to access your organization's free/busy information, you must publish at least one Client Access server to the Internet. This requires inbound HTTPS access from the Internet to the Client Access server. Client Access servers in Active Directory sites that don't have a Client Access server published to the Internet can use Client Access servers in other Active Directory sites that are accessible from the Internet. The Client Access servers that aren't published to the Internet must have the external URL of the Web services virtual directory set with the URL that's visible to external organizations.

Return to top

Coexistence with Exchange 2010

In organizations that contain both Exchange 2010 and Exchange 2013 servers, users who have a mailbox on an Exchange 2010 Mailbox server can use organization relationships to share free/busy information with recipients in external Exchange 2013 federated domain organizations. The Exchange 2010 Client Access and Mailbox servers must be running SP2 or higher, and you must have at least one Exchange 2013 Client Access server in the Exchange 2010 organization.

Coexistence with Exchange 2007

In organizations that contain both Exchange 2013 and Exchange 2007 servers, users who have a mailbox on an Exchange 2007 Mailbox server can use organization relationships to share free/busy information with recipients in external federated domain organizations. The Mailbox server must be running Exchange 2007 SP2 or higher, and you must have at least one Exchange 2013 Client Access server in the Exchange organization. You can use organization relationships by introducing a single Exchange 2013 Client Access server in the organization, providing a more robust solution than solutions that synchronize free/busy information and require GAL synchronization.

When using Outlook 2010 or Outlook Web App to scheduling a meeting on an Exchange 2007 server, a user who has a mailbox on an Exchange 2007 server can see free/busy information for a user in the external organization. Free/busy information for Exchange 2007 mailboxes is visible to recipients in the external organization.

Sharing policies are assigned to Exchange 2013 mailbox users. To use sharing policies, a mailbox must be located on an Exchange 2013 Mailbox server. Only Outlook 2010 and Outlook Web App clients can be used to generate or respond to sharing invitations.

Sharing documentation

The following table contains links to topics that will help you learn about and manage sharing in Exchange 2013.

Topic	Description
Federation	Learn more about the underlying trust infrastructure that supports sharing, an easy method for users to share calendar information with external recipients.
Organization relationships	Learn more about the one-to-one relationships between Exchange organizations that enable calendar free/busy sharing.
Sharing policies	Learn more about the person-to-person policies that enable sharing.

Federation

Exchange Server 2013 > Sharing >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-06-17*

Information workers frequently need to collaborate with external recipients, vendors, partners, and customers and share their free/busy (also known as calendar availability) information. Federation in Microsoft Exchange Server 2013 helps with these collaboration efforts. *Federation* refers to the underlying trust infrastructure that supports *federated sharing*, an easy method for users to share calendar information with recipients in other external federated organizations. To learn more about federated sharing, see Sharing.

Important:
This feature of Exchange Server 2013 isn't fully compatible with Office 365 operated by 21Vianet in China and some feature limitations may apply. For more information, see Learn about Office 365 operated by 21Vianet.

Contents

Federated organization identifier

Federation example

Certificate requirements for Federation

Transitioning to a new certificate

Firewall Considerations for Federation

Key terminology

The following table defines the core components associated with federation in Exchange 2013.

application identifier (AppID)

A unique number generated by the Windows Azure AD authentication system to identify Exchange organizations. The AppID is automatically generated when you create a federation trust with the Windows Azure AD authentication system.

delegation token

A Security Assertion Markup Language (SAML) token issued by the Windows Azure AD authentication system that allows users from one federated organization to be trusted by another federated organization. A delegation token contains the user's email address, an immutable identifier, and information associated with the offer for which the token is issued for action.

external federated organization

An external Exchange organization that's established a federation trust with the Windows Azure AD authentication system.

federated sharing

A group of Exchange features that leverage a federation trust with the Windows Azure AD authentication system to work across Exchange organizations, including cross-premises Exchange deployments. Together, these features are used to make authenticated requests between servers on behalf of users across multiple Exchange organizations.

federated domain

An accepted authoritative domain that's added to the organization identifier (OrgID) for an Exchange organization.

domain proof encryption string

A cryptographically secure string used by an Exchange organization to provide proof that the organization owns the domain used with the Windows Azure AD authentication system. The string is generated automatically when using the **Enable federation trust** wizard or can be generated by using the **Get-FederatedDomainProof** cmdlet.

federated sharing policy

An organization-level policy that enables and controls user-established, person-to-person sharing of calendar information.

federation

A trust-based agreement between two Exchange organizations to achieve a common purpose.

With federation, both organizations want authentication assertions from one organization to be recognized by the other.

federation trust

A relationship with the Windows Azure AD authentication system that defines the following components for your Exchange organization:

- Account namespace
- Application identifier (AppID)
- Organization identifier (OrgID)
- Federated domains

To configure federated sharing with other federated Exchange organizations, a federation trust must be established with the Windows Azure AD authentication system.

non-federated organization

Organizations that don't have a federation trust established with the Windows Azure AD authentication system.

organization identifier (OrgID)

Defines which of the authoritative accepted domains configured in an organization are enabled for federation. Only recipients that have e-mail addresses with federated domains configured in the OrgID are recognized by the Windows Azure AD authentication system and are able to use federated sharing features. The OrgID is a combination of a pre-defined string and the first accepted domain selected for federation in the **Enable federation trust** wizard. For example, if you specify the federated domain contoso.com as your organization's primary SMTP domain, the account namespace FYDIBOHF25SPDLT.contoso.com will be automatically created as the OrgID for the federation trust.

organization relationship

A one-to-one relationship between two federated Exchange organizations that allows recipients to share free/busy (calendar availability) information. An organization relationship requires a federation trust with the Windows Azure AD authentication system and replaces the need to use Active Directory forest or domain trusts between Exchange organizations.

Windows Azure AD authentication system

A free, cloud-based identity service that acts as the trust broker between federated Microsoft Exchange organizations. It's responsible for issuing delegation tokens to Exchange recipients when they request information from recipients in other federated Exchange organizations. To learn more, see Windows Azure Active Directory.

Windows Azure AD authentication system

The Windows Azure AD authentication system, a free cloud-based service offered by Microsoft, acts as the trust broker between your on-premises Exchange 2013 organization and other federated Exchange 2010 and Exchange 2013 organizations. If you want to configure federation in your Exchange organization, you must establish a one-time federation trust with the Windows Azure AD authentication system, so that it can become a federation partner with your organization. With this

trust in place, users authenticated by Active Directory (known as *identity providers*) are issued Security Assertion Markup Language (SAML) delegation tokens by the Windows Azure AD authentication system. These delegation tokens allow users from one federated Exchange organization to be trusted by another federated Exchange organization. With the Windows Azure AD authentication system acting as the trust broker, organizations aren't required to establish multiple individual trust relationships with other organizations, and users can access external resources using a single sign-on (SSO) experience. For more information, see Windows Azure Active Directory.

Return to top

Federation trust

To use Exchange 2013 federated sharing features, you must establish a federation trust between your Exchange 2013 organization and the Windows Azure AD authentication system. Establishing a federation trust with the Windows Azure AD authentication system exchanges your organization's digital security certificate with the Windows Azure AD authentication system and retrieves the Windows Azure AD authentication system certificate and federation metadata. You can establish a federation trust by using the **Enable federation trust** wizard in the Exchange Administration Center (EAC) or the **New-FederationTrust** cmdlet in the Exchange Management Shell. A self-signed certificate is automatically created by the **Enable federation trust** wizard and is used for signing and encrypting delegation tokens from the Windows Azure AD authentication system that allow users to be trusted by external federated organizations. For details about certificate requirements, see Certificate Requirements for Federation later in this topic.

When you create a federation trust with the Windows Azure AD authentication system, an *application identifier* (AppID) is automatically generated for your Exchange organization and provided in the output of the **Get-FederationTrust** cmdlet. The AppID is used by the Windows Azure AD authentication system to uniquely identify your Exchange organization. It's also used by the Exchange organization to provide proof that your organization owns the domain for use with the Windows Azure AD authentication system. This is done by creating a text (TXT) record in the public Domain Name System (DNS) zone for each federated domain.

Return to top

Federated organization identifier

The *federated organization identifier* (OrgID) defines which of the authoritative accepted domains configured in your organization are enabled for federation. Only recipients that have e-mail addresses with accepted domains configured in the OrgID are recognized by the Windows Azure AD authentication system and are able to use federated sharing features. When you create a new federation trust, an OrgID is automatically created with the Windows Azure AD authentication system. This OrgID is a combination of a pre-defined string and the accepted domain selected as

the primary shared domain in the wizard. For example, in the Edit Sharing-Enabled Domains wizard, if you specify the federated domain **contoso.com** as the primary shared domain in your organization, the **FYDIBOHF25SPDLT.contoso.com** account namespace will be automatically created as the OrgID for the federation trust for your Exchange organization.

Although typically the primary SMTP domain for the Exchange organization, this domain doesn't have to be an accepted domain in your Exchange organization and doesn't require a domain name system (DNS) proof of ownership TXT record. The only requirement is that accepted domains selected to be federated are limited to a maximum of 32 characters. The only purpose of this subdomain is to serve as the federated namespace for the Windows Azure AD authentication system to maintain unique identifiers for recipients that request SAML delegation tokens. For more information about SAML tokens, see SAML Tokens and Claims

You can add or remove accepted domains from the federation trust at any time. If you want to enable or disable all federation sharing features in your organization, all you have to do is enable or disable the OrgID for the federation trust.

Important:
If you change the OrgID, accepted domains, or the AppID used for the federation trust, all federation sharing features are affected in your organization. This also affects any external federated Exchange organizations, including Exchange Online and hybrid deployment configurations. We recommend that you notify all external federated partners of any changes to these federation trust configuration settings.

Return to top

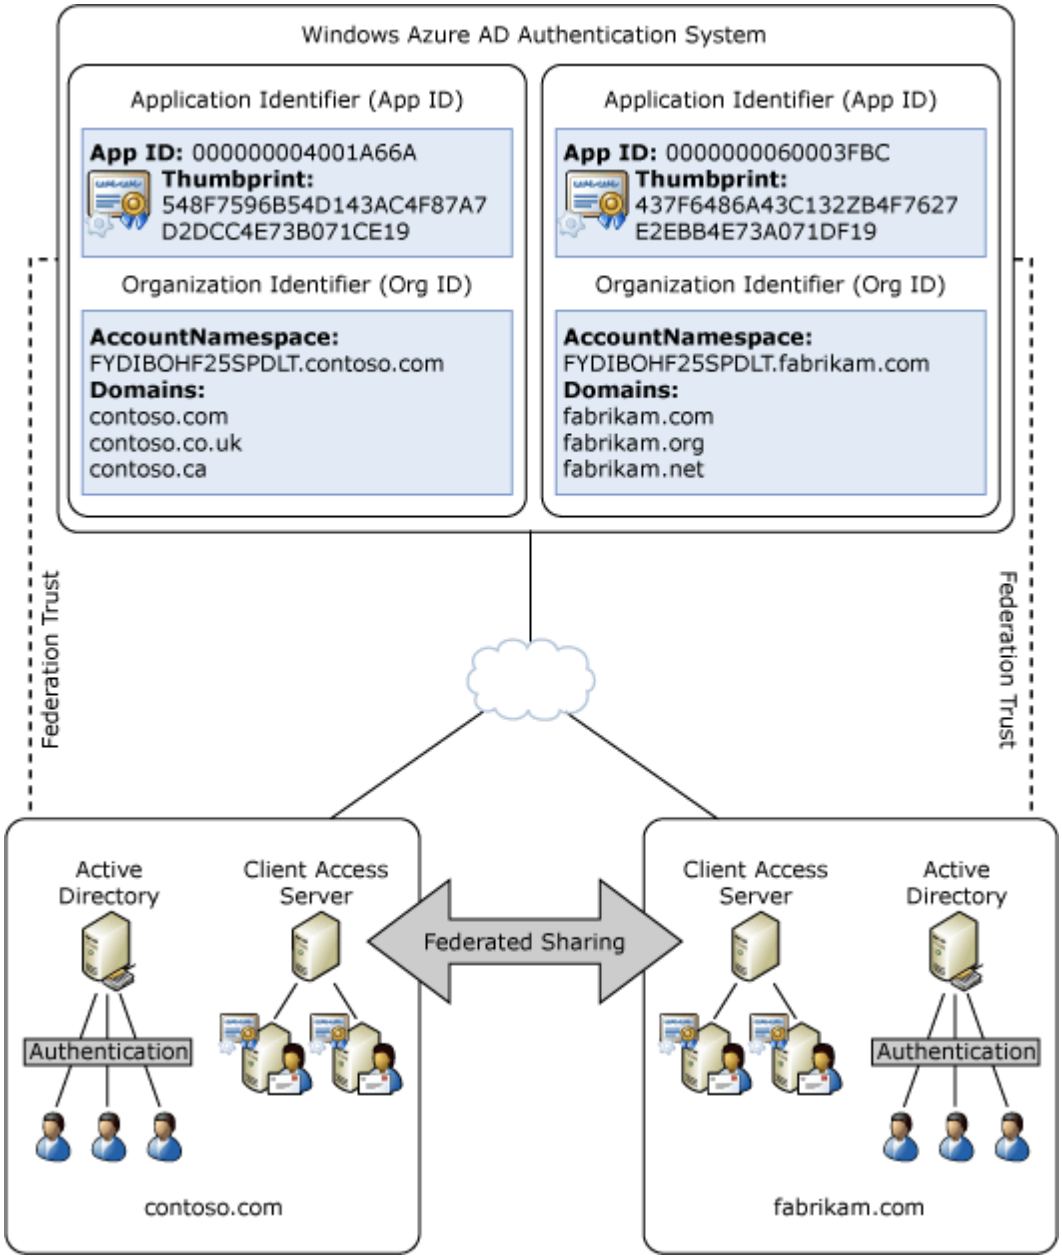
Federation example

Two Exchange organizations, Contoso, Ltd. and Fabrikam, Inc., want their users to be able to share calendar free/busy information with each other. Each organization creates a federation trust with the Windows Azure AD authentication system and configures its account namespace to include the domain used for its user's e-mail address domain.

Contoso employees use one of the following e-mail address domains: contoso.com, contoso.co.uk, or contoso.ca. Fabrikam employees use one of the following e-mail address domains: fabrikam.com, fabrikam.org, or fabrikam.net. Both organizations make sure that all accepted e-mail domains are included in the account namespace for their federation trust with the Windows Azure AD authentication system. Rather than requiring a complex Active Directory forest or domain trust configuration between the two organizations, both organizations configure an organization relationship with each other to enable calendar free/busy sharing.

The following figure illustrates the federation configuration between Contoso, Ltd. and Fabrikam, Inc.

Federated sharing example



Certificate requirements for Federation

To establish a federation trust with the Windows Azure AD authentication system, either a self-signed certificate or an X.509 certificate signed by a certification authority (CA) must be created and installed on the Exchange 2013 server used to create the trust. We strongly recommend using a self-signed certificate, which is automatically created and installed using the **Enable federation trust** wizard in the EAC. This certificate is used only to sign and encrypt delegation tokens used for federated sharing and only one certificate is required for the federation trust. Exchange 2013 automatically distributes the certificate to all other Exchange 2013 servers in the organization.

If you want to use an X.509 certificate signed by an external CA, the certificate must meet the following requirements:

- **Trusted CA** If possible, the X.509 Secure Sockets Layer (SSL) certificate should be issued from a CA trusted by Windows Live. However, you can use certificates issued by CAs that aren't currently certified by Microsoft. For a current list of trusted CAs, see Trusted root certification authorities for federation trusts.

- **Subject key identifier** The certificate must have a subject key identifier field. Most X.509 certificates issued by commercial CAs have this identifier.
- **CryptoAPI cryptographic service provider (CSP)** The certificate must use a CryptoAPI CSP. Certificates that use Cryptography API: Next Generation (CNG) providers aren't supported for federation. If you use Exchange to create a certificate request, a CryptoAPI provider is used. For more information, see Cryptography API: Next Generation.
- **RSA signature algorithm** The certificate must use RSA as the signature algorithm.
- **Exportable private key** The private key used to generate the certificate must be exportable. You can specify that the private key be exportable when you create the certificate request using the **New Exchange certificate** wizard in the EAC or the New-ExchangeCertificate cmdlet in the Shell.
- **Current certificate** The certificate must be current. You can't use an expired or revoked certificate to create a federation trust.
- **Enhanced key usage** The certificate must include the enhanced key usage (EKU) type **Client Authentication (1.3.6.1.5.5.7.3.2)**. This usage type is used to prove your identity to a remote computer. If you use the EAC or the Shell to generate a certificate request, this usage type is included by default.

Note:
Because the certificate isn't used for authentication, it doesn't have any subject name or subject alternative name requirements. You can use a certificate with a subject name that's the same as the host name, the domain name, or any other name.

Return to top

Transitioning to a new certificate

The certificate used to create the federation trust is designated as the current certificate. However, you may need to install and use a new certificate for the federation trust periodically. For example, you may need to use a new certificate if the current certificate expires or to meet a new business or security requirement. To ensure a seamless transition to a new certificate, you must install the new certificate on your Exchange 2013 server and configure the federation trust to designate it as the new certificate. Exchange 2013 automatically distributes the new certificate to all other Exchange 2013 servers in the organization. Depending on your Active Directory topology, distribution of the certificate may take a while. You can verify the certificate status using the Test-FederationTrustCertificate cmdlet in the Shell.

After you verify the certificate's distribution status, you can configure the trust to use the new certificate. After switching certificates, the current certificate is designated as the previous certificate, and the new certificate is designated as the current certificate. The new certificate is published to the Windows Azure AD authentication system, and all new tokens exchanged with the Windows Azure AD authentication system are encrypted using the new certificate.

Note:
This certificate transition process is used only by federation. If you use the same certificate for other Exchange 2013 features that require certificates, you must take the feature requirements

into consideration when planning to procure, install, or transition to a new certificate.

Return to top

Firewall Considerations for Federation

Federation features require that the Mailbox and Client Access servers in your organization have outbound access to the Internet by using HTTPS. You must allow outbound HTTPS access (port 443 for TCP) from all Exchange 2013 Mailbox and Client Access servers in the organization.

For an external organization to access your organization's free/busy information, you must publish one Client Access server to the Internet. This requires inbound HTTPS access from the Internet to the Client Access server. Client Access servers in Active Directory sites that don't have a Client Access server published to the Internet can use Client Access servers in other Active Directory sites that are accessible from the Internet. The Client Access servers that aren't published to the Internet must have the external URL of the Web services virtual directory set with the URL that's visible to external organizations.

Trusted root certification authorities for federation trusts

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-05-09*

To establish a federation trust between your Microsoft Exchange Server 2013 organization and the Windows Azure Active Directory authentication system, you need a digital certificate installed on the Exchange server used to create the trust. We strongly recommend using a self-signed certificate. A self-signed certificate is created and installed automatically when using the **Enable federation trust** wizard in the Exchange Administration Center (EAC).

If you don't want to use the recommended self-signed certificate, you should request and install an X.509 Secure Sockets Layer (SSL) certificate from a certification authority (CA) trusted by Microsoft. Although certificates issued by other CAs may also be used to establish a federation trust with the Windows Azure AD authentication system, they aren't certified by Microsoft to date.

The following table lists CAs currently trusted Microsoft. These CAs have been tested for use with Exchange 2013.

CA friendly name	Issued by	Intended purposes

Comodo	Comodo Certification Authority	Server authentication, client authentication
Digicert	Digicert Global Root Certification Authority	Server authentication, client authentication
Digicert High Assurance EV	Digicert Global Root Certification Authority	Server authentication, client authentication
Entrust	Entrust.net Secure Server Certification Authority	Server authentication, client authentication
Entrust (2048)	Entrust.net Secure Server Certification Authority	Server authentication, client authentication
Equifax	Equifax Secure Certification Authority	Server authentication, client authentication
GlobalSign	GlobalSign Certification Authority	Server authentication, client authentication
Go Daddy	Go Daddy Class 2 Certification Authority	Server authentication, client authentication
Network Solutions	Network Solutions Certification Authority	Server authentication, client authentication
PositiveSSL	Comodo Certification Authority	Server authentication, client authentication
SECOM	SECOM Trust Systems Certification Authority	Server authentication, client authentication
UTN-UserFirst-Hardware	Comodo Certification Authority	Server authentication, client authentication
VeriSign	Class 3 Public Primary Certification Authority	Server authentication, client authentication

VeriSign	VeriSign Trust Network	Server authentication, client authentication

For more information about certificate requirements for Federation, see Federation.

Configure federated sharing

Sharing > Federation > Federation procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-15*

With federated sharing in Exchange Server 2013, users can share information with recipients in external federated organizations. This includes sharing their free/busy (also known as calendar availability) information for scheduling purposes or, depending on the nature of the business relationship, sharing more detailed calendar information. To learn more about federation sharing, see Sharing.

Important:

This feature of Exchange Server 2013 isn't fully compatible with Office 365 operated by 21Vianet in China and some feature limitations may apply. For more information, see Learn about Office 365 operated by 21Vianet.

What do you need to know before you begin?

- Estimated time to complete this task: 1 hour.
- Procedures in this topic require specific permissions. See each procedure for its permissions information.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

How do you do this?

Step 1: Create and configure a federation trust

A federation trust establishes a trust relationship between an Exchange 2013 organization and the Windows Azure AD authentication system and is a requirement for federated sharing.

For detailed instructions, see Configure a federation trust.

Step 2: Create an organization relationship

An organization relationship enables users in your Exchange organization to share calendar free/busy information as part of federated sharing with other federated Exchange organizations. Federated sharing can be configured between two federated Exchange 2013 organizations or between a federated Exchange 2013 organization and federated Exchange 2010 organizations.

For detailed instructions, see Create an organization relationship.

Step 3: Create a sharing policy

Sharing policies enable user-established, people-to-people sharing of calendar information with different types of external users. They support the sharing of calendar and contact information with external federated organizations, external non-federated organizations, and individuals with Internet access. If you don't need to configure people-to-people or contact sharing (organization-level sharing only), you don't need to configure a sharing policy.

For detailed instructions, see Create a sharing policy.

Step 4: Configure an Autodiscover public DNS record

You need to add an alias canonical name (CNAME) resource record to your public-facing DNS. The new CNAME record should point to an Internet-facing Exchange 2013 Client Access server that's running the Autodiscover service.

For detailed instructions about how to add CNAME records, see the host service for your public DNS records. Typically this is an Internet-based service that may also host your domain website.

Configure a federation trust

Sharing > Federation > Federation procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-21*

A federation trust establishes a trust relationship between a Microsoft Exchange 2013 organization and the Windows Azure Active Directory authentication system. By configuring a federation trust, you can configure federated sharing with other federated Exchange organizations to share calendar free/busy information among recipients. Federated sharing can be configured between two federated Exchange 2013 organizations or between a federated Exchange 2013 organization and federated Exchange 2010 organizations. You can also set up sharing with an Office 365 organization.

Note:

Creating a federation trust is one of several steps in setting up federated sharing in your Exchange organization. To review all the steps, see Configure federated sharing.

For additional management tasks related to federation, see Federation procedures.

Important:

This feature of Exchange Server 2013 isn't fully compatible with Office 365 operated by 21Vianet in China and some feature limitations may apply. For more information, see Learn about Office 365 operated by 21Vianet.

What do you need to know before you begin?

- Estimated time to complete: 30 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Federation and certificates" permissions entry in the Exchange and Shell infrastructure permissions topic.
- The domain used for establishing a federation trust should be resolvable from the Internet. This requires that the domain be registered with a domain registrar and the Domain Name System

(DNS) zone for the domain to be hosted on a DNS server accessible from the Internet. If the organization receives Internet email for the domain, these requirements are already met.

- You will need to add a TXT record to your public DNS. Review the requirements for adding a TXT record with the organization that hosts your public DNS records.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.
- Both Exchange organizations in a federated sharing relationship must use the same Windows Azure AD authentication system for their federation trusts. This requirement applies when configuring federated sharing between two on-premises Exchange organizations or between an on-premises Exchange organization and an Exchange organization hosted by Office 365.
- When you create a federation trust with the Windows Azure AD authentication system for your Exchange 2013 organization, the federation trust will use the business instance of the Windows Azure AD authentication system. However, other federated Exchange organizations with previous versions of Exchange and existing federation trusts may be using either the business or consumer instance of the Windows Azure AD authentication system.

The following Exchange organizations use the business instance of the Windows Azure AD authentication system by default:

- Exchange 2013 organizations by using the **Enable federation trust** wizard and self-signed certificates for a federation trust.
- Exchange 2010 SP1 or later organizations by using the **New Federation Trust** wizard and self-signed certificates for a federation trust.
- Exchange organizations hosted by Office 365, such as the Exchange Online.

The following Exchange organizations use the consumer instance of the Windows Azure AD authentication system by default:

- Release to manufacturing (RTM) version of Exchange 2010 organizations using certificates issued by third-party certification authorities.

We recommend that all Exchange organizations use the business instance of the Windows Azure AD authentication system for federation trusts. Before configuring federated sharing between the two Exchange organizations, you need to verify which Windows Azure AD authentication system instance each Exchange organization is using for any existing federation trusts. To determine which Windows Azure AD authentication system instance an Exchange organization is using for an existing federation trust, run the following Shell command.

```
Get-FederationInformation -DomainName <hosted Exchange domain namespace>
```

The business instance returns a value of `<uri:federation:MicrosoftOnline>` for the *TokenIssuerURIs* parameter.

The consumer instance returns a value of `<uri:WindowsLiveID>` for the *TokenIssuerURIs* parameter.

To configure federated sharing with an Exchange organization that has an existing federation trust that's using the business instance of the Windows Azure AD authentication system, follow the steps in this topic. These steps are all you need to perform to create federation trusts that can be used to enable federated sharing between two Exchange 2013 organizations or between an Exchange 2013

organization and an Exchange 2010 organization that's already using the business instance of the Windows Azure AD authentication system.

To configure federated sharing between your Exchange 2013 organization and an Exchange organization that has an existing federation trust that's using the consumer instance of the Windows Azure AD authentication system , the Exchange organization using the consumer instance should install Exchange 2010 SP2 or later, or upgrade to Exchange 2013. If you decide to install Exchange 2010 SP2 or later, use the **New Federation Trust** wizard to remove and re-create the existing federated domains and federation trusts. When the federation trusts are re-created, the business instance of the Windows Azure AD authentication system will be used.

What do you want to do?

Use the EAC to create and configure a federation trust

1. On an Exchange 2013 server in your on-premises organization, navigate to **Organization** > **Sharing**.
2. Click **Enable** to start the **Enable federation trust** wizard.
3. After the wizard completes, click **Close**.
4. In the **Federation Trust** section of the **Sharing** tab, click **Modify**.
5. In **Sharing-Enabled Domains**, next to **Step 1**, click **Browse**.
6. In **Select Accepted Domains**, select the primary shared domain from the list, and then click **OK**.

Note:

The domain you select will be used to configure the OrgID for the federation trust. For more information about the OrgID, see Federation.

7. Make a note of the federated domain proof that's generated for the primary shared domain. You'll use this string to create a TXT record on your public DNS server.

Important:

The federated domain proof is a string of alphanumeric characters. To avoid input errors, we recommend that you copy the string from the EAC, paste it into a text editor such as Notepad. You can then copy it from the text editor to the Clipboard, and then paste it into the **Text** field when creating the TXT record. If the TXT record is created by using an incorrect federated domain proof string, the Windows Azure AD authentication system won't be able to verify proof of domain ownership, and you won't be able to add it to the federated organization identifier.

8. In **Step 2**, click **Add +** to add additional domains to the federated trust for email addresses that will used by users in your organization that require federated sharing features. For example, if you have users that use a subdomain in their email address such as sales.contoso.com, you' would add the sales.contoso.com domain to the federation trust.

Note:

A federated domain proof string will be created for each additional domain selected. You must create separate TXT records on your public DNS for each additional domain.

9. Using the federated domain proof strings created for each domain, create TXT records for each of these domains on your public DNS server. Depending on the update schedule of your public DNS host, replication of DNS changes may take 15 minutes or longer.
10. After the TXT records are created and replicated, click **Update**.

Use the Shell to create and configure a federation trust

1. This example creates a unique subject key identifier to be used with the certificate.

```
$ski = [System.Guid]::NewGuid().ToString("N")
```

2. This example creates a self-signed certificate for the federation trust with the Windows Azure AD authentication system.

```
New-ExchangeCertificate -FriendlyName "Exchange Federated
Sharing" -DomainName $env:USERDNSDOMAIN -Services
Federation -KeySize 2048 -PrivateKeyExportable $true -
SubjectKeyIdentifier $ski
```

3. This example retrieves the self-signed certificate and creates the federation trust "Azure AD authentication". This automatically deploys the self-signed certificate to the Exchange servers in your organization.

```
Get-ExchangeCertificate | ?{$_.friendlyname -eq "Exchange
Federated Sharing"} | New-FederationTrust -Name "Azure AD
authentication"
```

For detailed syntax and parameter information, see New-ExchangeCertificate and New-FederationTrust.

How do you know this worked?

The successful completion of the **Enable federation trust** and **Sharing-Enabled Domains** wizards will be your first indication that the federation trust was configured as expected.

To further verify that you have successfully created and configured the federation trust, do the following:

1. Run the following Shell command to verify the federation trust information.

```
Get-FederationTrust | format-list
```

2. Run the following Shell command to verify that federation information can be retrieved from your organization.

```
Get-FederationInformation -DomainName <your primary sharing
```

domain>

For detailed syntax and parameter information, see Get-FederationTrust and Get-FederationInformation.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-15*

A federation trust establishes a trust relationship between a Microsoft Exchange 2013 organization and the Windows Azure Active Directory authentication system and supports federated sharing with other federated Exchange organizations. Normally, you shouldn't have to manage or modify the federation trust after it's created. However, there may be circumstances that require adding or removing federated domains or resetting the domain used to configure the organization identifier (OrgID) for the federation trust.

Note:
Modifying an existing federation trust, especially the primary shared domain used to define the OrgID, can disrupt federated sharing between federated Exchange organizations or for hybrid deployments with Office 365 organizations.

For additional management tasks related to Federation, see Federation procedures.

Important:
This feature of Exchange Server 2013 isn't fully compatible with Office 365 operated by 21Vianet in China and some feature limitations may apply. For more information, see Learn about Office 365 operated by 21Vianet.

What do you need to know before you begin?

- Estimated time to complete: 30 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the *Federation and certificates* permissions entry in the Exchange and Shell infrastructure permissions topic.
- You will need to add a TXT record to your public DNS for each new federated domain added to the federation trust. Review the requirements for adding a TXT record with the organization that hosts your public DNS records.

- For the purposes of this topic, an existing federation trust was configured with the following settings:
  - **Contoso.com** is the primary shared domain for the federation trust. (This domain will not be changed.)
  - The federated domains **service.contoso.com** and **sales.contoso.com** are included in the existing federation trust.
  - **Marketing.contoso.com** is an accepted domain in the Exchange organization.
- This topic also covers other federation management tasks, such as viewing and managing certificates used for the federation trust and viewing federation trust parameter information in the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

What do you want to do?

Use the EAC to manage a federation trust

1. On an Exchange 2013 server in your on-premises organization, navigate to the **Organization** > **Sharing**.
2. In the **Federation Trust** section, click **Modify**.
3. In **Sharing-Enabled Domains**, skip **Step 1** because the primary sharing domain isn't changing.
4. In **Step 2**, select the **service.contoso.com** domain and then click **Remove —** to remove the domain from the federated trust.
5. In **Step 2**, click **Add +**.
6. In **Select Accepted Domains**, select **marketing.contoso.com** from the list of accepted domains, and then click **OK** to add the domain to the federated trust.

Important:
A federated domain proof string will be created for the **marketing.contoso.com** domain. You must create separate TXT record on your public DNS for this domain.

7. Using the federated domain proof string created for the **marketing.contoso.com** domain, create a TXT record on your public DNS server. Depending on the update schedule of your public DNS host, replication of DNS changes may take 15 minutes or longer.
8. After the TXT record is created and replicated, click **Update**.

Use the Shell to manage a federation trust

1. This example removes the service.contoso.com domain from the federation trust.

```
Remove-FederatedDomain -DomainName service.contoso.com
```

2. This example adds the marketing.contoso.com domain to the federation trust.

```
Add-FederatedDomain -DomainName marketing.contoso.com
```

For detailed syntax and parameter information, see Remove-FederatedDomain and Add-FederatedDomain.

Run the following Shell commands to manage other aspects of a federation trust:

1. View the federated OrgID and federated domains

This example displays the Exchange organization's federated OrgID and related information, including federated domains and status.

```
Get-FederatedOrganizationIdentifier
```

2. View federation trust certificates

This example displays the previous, current, and next certificates used by the federation trust "Azure AD authentication".

```
Get-FederationTrust "Azure AD authentication" | Select Org*certificate
```

3. Check federation certificates status

This example displays the state of federation certificates on all Mailbox and Client Access servers in the organization.

```
Test-FederationTrustCertificate
```

4. Configure the federation trust to use a certificate as the next certificate

This example configures the federation trust "Azure AD authentication" to use the certificate with the provided thumbprint as the next certificate. After the certificate is deployed to all Exchange servers in the organization, you can use the *PublishCertificate* switch to configure the federation trust to use this certificate as the current certificate.

```
Set-FederationTrust "Azure AD authentication" -Thumbprint AC00F35CBA8359953F4126E0984B5CCAFA2F4F17
```

5. Configure the federation trust to use the next certificate as the current certificate

This example configures the federation trust Azure AD authentication to use the next certificate as the current certificate and publishes it to the Windows Azure AD authentication system.

```
Set-FederationTrust "Azure AD authentication" -PublishFederationCertificate
```

Caution:

Before configuring the federation trust to use the next certificate as the current federation certificate, make sure that the certificate is deployed on all Exchange servers in your organization. Use the Test-FederationTrustCertificate cmdlet to check the deployment status of the certificate.

6. Refresh federation metadata and certificate from the Windows Azure AD authentication system

This example refreshes the federation metadata and certificate of the Windows Azure AD authentication system for the federation trust Azure AD authentication.

```
Set-FederationTrust "Azure AD authentication" -RefreshMetadata
```

For detailed syntax and parameter information, see the following topics:

- Get-FederatedOrganizationIdentifier
- Get-FederationTrust
- Test-FederationTrustCertificate
- Set-FederationTrust

How do you know this worked?

The successful completion of the **Sharing-enabled domains** wizard is your first indication that you configured the federation trust as expected.

To further verify success, do the following:

1. Run the following Shell command to verify the federation trust information.

```
Get-FederationTrust | format-list
```

2. Run the following Shell command to verify that federation information can be retrieved from your organization. For example, verify that the sales.contoso.com and marketing.contoso.com domains are returned in the *DomainNames* parameter.

```
Get-FederationInformation -DomainName <your primary sharing domain>
```

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Remove a federation trust

Sharing > Federation > Federation procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-17*

A federation trust establishes a trust relationship between a Microsoft Exchange 2013 organization and the Windows Azure Active Directory authentication system and supports sharing with other federated Exchange organizations. Removing a federation trust from your on-premises Exchange

organization will disable federated sharing with other federated Exchange organizations and with Office 365 organizations connected to your organization as part of a hybrid deployment. You should carefully consider the overall impact to your organization before removing a federation trust.

For additional management tasks related to federation trusts, see Federation procedures.

Important:
This feature of Exchange Server 2013 isn't fully compatible with Office 365 operated by 21Vianet in China and some feature limitations may apply. For more information, see Learn about Office 365 operated by 21Vianet.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Federation and certificates" permissions entry in the Exchange and Shell infrastructure permissions topic.
- After removing the federation trust, you can remove the TXT records from your public DNS server for each federated domain. Review the requirements for removing a TXT record with the organization that hosts your public DNS records.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

What do you want to do?

Use the EAC to remove a federation trust

1. On an Exchange 2013 server in your on-premises organization, navigate to **organization** > **sharing**.
2. In the **Federation Trust** section, click **Remove**.
3. In the warning, click **yes** to confirm that you want to remove the federation trust.
4. After the federation trust is removed, click **Close**.

Use the Shell to remove a federation trust

This example removes the federation trust.

```
Remove-FederationTrust
```

For detailed syntax and parameter information, see Remove-FederationTrust.

How do you know this worked?

To verify that you have successfully removed the federation trust, do one of the following:

- In the EAC, navigate to **organization** > **sharing**. If you successfully removed the federation trust, only the **Enable** button will be available under **Federation Trust**.
- In the Shell, run the following command to verify that federation trust information isn't returned for your Exchange organization.

```
Get-FederationTrust
```

For detailed syntax and parameter information, see Get-FederationTrust.

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Disable or Re-enable federated sharing for your Exchange organization

Sharing > Federation > Federation procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-17*

There may be situations when you need to temporarily disable federated sharing for your organization. Instead of deleting the existing federation trust or deleting organization relationships and sharing policies that you may need in the future, you can simply disable the organization identifier (OrgID) for the federation trust.

Caution:
For hybrid deployments with Office 365, disabling the federation trust for your on-premises servers will also disable hybrid features such as shared calendar free/busy information, MailTips, and message tracking. However, secure mail transport won't be disabled in the hybrid deployment if the federation trust for the on-premises organization is disabled.

To learn more about federation trusts, see Federation. To learn more about federated sharing, see Sharing.

For additional management tasks related to federated sharing, see Federation procedures.

Important:
This feature of Exchange Server 2013 isn't fully compatible with Office 365 operated by 21Vianet in China and some feature limitations may apply. For more information, see Learn about Office 365 operated by 21Vianet.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the *Federation and certificates* permissions entry in the Exchange and Shell infrastructure permissions topic.
- Any existing organization relationships and sharing policies for other federated Exchange organizations won't be modified and won't be functional. Sharing policies that are configured to provide Internet recipients with access to calendar information won't be affected.
- You can't use the Exchange Administration Center (EAC) to disable or enable the OrgID for a federation trust. You must use the Shell.

Use the Shell to disable or re-enable federated sharing

This example disables the OrgID and disables federation and federated sharing for the Exchange organization.

```
Set-FederatedOrganizationIdentifier -Enabled $false
```

This example enables the OrgID and re-enables federation and federated sharing for the Exchange organization.

```
Set-FederatedOrganizationIdentifier -Enabled $true
```

For detailed syntax and parameter information, see Set-FederatedOrganizationIdentifier.

How do you know this worked?

Successful completion of the **Set-OrganizationIdentifier** cmdlet will be the first indication that the OrgID has been disabled or enabled.

To further verify success, run the following Shell command and verify the value returned for the *Enabled* parameter

```
Get-FederatedOrganizationIdentifier
```

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Configuring federated sharing between Exchange organizations

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-07-10*

With federated sharing, users in your on-premises Exchange organization can share free/busy calendar information with recipients in other Exchange organizations that are also configured for federated sharing. Free/busy sharing can be enabled between two organizations running Exchange 2013 and also between organizations with a mixed Exchange deployment. To learn more about federated sharing, see Sharing.

This topic provides a summary of the requirements and configuration steps necessary to enable free/busy sharing between different types of the following common Exchange deployments:

- Two Exchange 2013 organizations.
- An Exchange 2013 organization and an Exchange 2010 SP2 organization.
- An Exchange 2007 organization (or mixed Exchange 2007 and Exchange 2010 SP2 organization) and an Exchange 2013 organization.
- An Exchange 2003 organization (or mixed Exchange 2003 and Exchange 2010 SP2 organization) and an Exchange 2013 organization.

For additional management tasks related to federated sharing, see Federation procedures.

Important:
This feature of Exchange Server 2013 isn't fully compatible with Office 365 operated by 21Vianet in China and some feature limitations may apply. For more information, see Learn about Office 365 operated by 21Vianet.

What do you need to know before you begin?

- Estimated time to complete each procedure: 2 hours.
- Procedures in this topic require specific permissions. See each procedure for its permissions information.
- Before you perform the procedures in this topic, make sure you understand the limitations associated with sharing free/busy information across Exchange organizations. For details, see Limitations of free/busy sharing.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

What do you want to do?

Configure free/busy sharing between Exchange 2013 organizations

Complete the steps in Configure federated sharing for both organizations.

Configure free/busy sharing between Exchange 2013 and Exchange 2010 SP2 organizations

- Configure federated sharing for the Exchange 2013 organization. Complete the steps in Configure federated sharing.
- Configure federated delegation (previous name for federated sharing) for the Exchange 2010 SP2 organization. Complete the steps in Configure federated delegation.

Configure free/busy sharing between Exchange 2013 and Exchange 2007 organizations

- Configure federated sharing for the Exchange 2013 organization. Complete the steps in Configure federated sharing.
- Complete the following steps in the Exchange 2007 organization:

1. **Add an Exchange 2010 SP2 server**

An Exchange 2010 SP2 server with the Client Access server role must be installed in the Exchange 2007 organization. If you have existing Exchange 2010 servers, they should also be updated to Exchange 2010 SP2. For information about installing Exchange 2010 in an Exchange 2007 organization, see Exchange 2007 - Planning Roadmap for Upgrade and Coexistence.

2. **Configure federated delegation**

Configure federated delegation for the Exchange 2007 organization. On an Exchange 2010 SP2 server in the Exchange 2007 organization, complete the steps in Configure federated delegation.

3. **Configure Active Directory synchronization**

Active Directory synchronization must be configured for all users that need to share free/busy information between the organizations. You can either configure the Active Directory synchronization manually or use an automated Active Directory synchronization service. To configure Active Directory synchronization, see the steps below:

- **Prerequisites** Make sure your organization meets the requirements for installing Active Directory synchronization.

To learn more, see Prepare for Active Directory Synchronization

- **Plan** Understand the Microsoft Online Services Directory Synchronization tool and installation roadmap.

To learn more, see Active Directory Synchronization: Roadmap

- **Install and Configure** Configure Active Directory synchronization between your on-premises organization and the Office 365 tenant service organization.

To learn more, see Install and Upgrade the Microsoft Online Services Directory Synchronization tool

4. **Create an availability address space**

Create an availability address space for the remote Exchange 2013 organization that directs availability requests from Exchange 2007 mailbox users to the Exchange 2010 SP2 Client Access

server in the Exchange 2007 organization. This setting enables user availability requests from Exchange 2007 users for users in the remote Exchange 2013 organization to be proxied through the Exchange 2010 Client Access server in the Exchange 2007 organization. The Exchange 2010 Client Access server in the Exchange 2007 organization uses the federation trust and organization relationship to send the availability requests to the remote Exchange 2013 organization forest availability endpoint.

To configure the availability address space, on the Exchange 2010 Client Access server in the Exchange 2007 organization, run the following command in the Exchange Management Shell:

```
Add-AvailabilityAddressSpace -AccessMethod InternalProxy -
ProxyUrl https://<Exchange 2010 CAS server name>/ews/
exchange.asmx -ForestName <SMTP domain of the remote
Exchange organization> -UseServiceAccount $True
```

For detailed syntax and parameter information, see Add-AvailabilityAddressSpace

Configure Free/Busy Sharing Between Exchange 2013 and Exchange 2003 Organizations

- Configure federated sharing for the Exchange 2013 organization. Complete the steps in Configure federated sharing.
- Complete the following steps in the Exchange 2003 organization:

1. **Add Exchange 2010 SP2 server**.

An Exchange 2010 SP2 server with the Client Access server role must be installed in the Exchange 2003 organization. If you have existing Exchange 2010 servers, they should also be updated to Exchange 2010 SP2. For information about installing Exchange 2010 in an Exchange 2003 organization, see Exchange 2003 - Planning Roadmap for Upgrade and Coexistence.

⚠**Warning:**
For free/busy sharing to work properly between Exchange 2013 and Exchange 2003 organizations, the **OU=EXTERNAL (FYDIBOHF25SPDLT)** public folder must exist in the public folder hierarchy. This folder is automatically created on the Exchange 2010 Mailbox server in the Exchange 2003 organization only if you select the option to create public folders as part of configuring client settings for Outlook 2003 support during Exchange 2010 Setup. Additionally, this option is presented during the setup process only if the Exchange 2010 Mailbox server is the first Mailbox server installed in the organization. If the **OU=EXTERNAL (FYDIBOHF25SPDLT)** public folder wasn't created during Setup, you must manually create it. For details about how to create this public folder, see How to troubleshoot Free/Busy issues when you use Exchange Federation in the Microsoft Office 365 for enterprises environment.

2. **Configure federated delegation**.

Configure federated delegation for the Exchange 2003 organization. On an Exchange 2010 SP2 server in the Exchange 2003 organization, complete the steps in Configure federated delegation.

3. **Configure Active Directory synchronization**.

Active Directory synchronization must be configured for all users that need to share free/busy information between the organizations. You can either configure the Active Directory synchronization manually or use an automated Active Directory synchronization service. To learn more about Active Directory synchronization, see Forefront Identity Management.

- **Prerequisites** Make sure your organization meets the requirements for installing Active Directory synchronization.

To learn more, see Prepare for Active Directory Synchronization

- **Plan** Understand the Microsoft Online Services Directory Synchronization tool and installation roadmap.

To learn more, see Active Directory Synchronization: Roadmap

- **Install and Configure** Configure Active Directory synchronization between your on-premises organization and the Office 365 tenant service organization.

To learn more, see Install and Upgrade the Microsoft Online Services Directory Synchronization tool

4. **Configure public folders for free/busy sharing in your Exchange 2003 organization.**

Complete the following steps on an Exchange 2003 server:

- In Exchange System Manager, in the console tree, navigate to **Administrative Groups** > **First Administrative Group** > **Servers**.
- Select your Exchange 2003 server, and then navigate to **First Storage Group** > **Public Folder Store** > **Public Folders** > **Schedule+ FREE BUSY**.
- In the action pane, select the **OU=EXTERNAL (FYDIBOHF25SPDLT)** folder for the **First Administrative Group**.
- Right-click the **OU=EXTERNAL (FYDIBOHF25SPDLT)** folder, and then click **Properties**.
- In **OU=EXTERNAL (FYDIBOHF25SPDLT) Properties**, select the **Replication** tab.
- To replicate the **OU=EXTERNAL (FYDIBOHF25SPDLT)** folder to the Exchange 2010 Client Access/Mailbox server, click **Add**.
- In **Select a Public Folder Store**, select the **Public Folder Database** for the Exchange 2010 Client Access/Mailbox server, and then click **OK**.

Note:

By default, Exchange uses the replication schedule set on the public folder database.

- Click **OK** to close **OU=EXTERNAL (FYDIBOHF25SPDLT) Properties** and save your changes.
- Complete the same steps above for the **OU=Exchange Administrative Group (FYDIBOHF23SPDLT)** folder.

Warning:

Depending on the size of your public folders, this replication could take several hours to complete.

- After the **OU=EXTERNAL (FYDIBOHF25SPDLT)** and **OU=Exchange Administrative Group (FYDIBOHF23SPDLT)** public folders have replicated to the Exchange 2010 Client Access/Mailbox server, you must remove the replicas for these public folders on the Exchange 2003 server.

5. **Modify the LegacyExchangeDN parameter**

Modify the *LegacyExchangeDN* parameter on all mail-enabled objects in the Exchange 2003

organization that reference the remote Exchange 2013 organization. Change the existing organizational unit (OU) value for the mail-enabled object to **External (FYDIBOHF25SPDLT)**. For example, **LegacyExchangeDN=/o=First Organization/ou=External (FYDIBOHF25SPDLT)/cn=Recipients/cn=User Name**.

To modify mail-enabled objects in the Exchange 2003 organization, you can use either the Active Directory Service Interfaces Editor (ADSI Edit) tool or the Microsoft Exchange Server LegacyDN Utility.

Configure OAuth authentication between Exchange and Exchange Online organizations

Sharing > Federation > Federation procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-07-07*

Exchange 2013-only hybrid deployments configure OAuth authentication when using the Hybrid Configuration Wizard. For mixed Exchange 2013/2010 and Exchange 2013/2007 hybrid deployments, the new hybrid deployment OAuth-based authentication connection between Office 365 and on-premises Exchange organizations isn't configured by the Hybrid Configuration wizard. These deployments continue to use the federation trust process by default. However, certain Exchange 2013 features are only fully available across your organization by using the new Exchange OAuth authentication protocol.

The new Exchange OAuth authentication process currently enables the following Exchange features:

- Message Rights Management (MRM)
- Exchange In-place eDiscovery
- Exchange In-place Archiving

We recommend that all mixed Exchange organizations that implement a hybrid deployment with Exchange 2013 and Exchange Online configure Exchange OAuth authentication after configuring their hybrid deployment with the Hybrid Configuration Wizard.

Important:
This feature of Exchange Server 2013 isn't fully compatible with Office 365 operated by 21Vianet in China and some feature limitations may apply. For more information, see Learn about Office 365 operated by 21Vianet.

What do you need to know before you begin?

- Estimated time to complete this task: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Federation and certificates" permissions entry in the Exchange and Shell infrastructure permissions topic.
- Completed configuration of your hybrid deployment using the Hybrid Deployment Wizard. For more information, see **Hybrid deployments with Exchange 2013**.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

How do you configure OAuth authentication between your on-premises Exchange and Exchange Online organizations?

Step 1: Create an authorization server object for your Exchange Online organization

For this procedure, you have to specify a verified domain for your Exchange Online organization. This domain should be the same domain used as the primary SMTP domain used for the cloud-based email accounts. This domain is referred as <*your verified domain*> in the following procedure.

Run the following command in the Exchange Management Shell (the Exchange PowerShell) in your on-premises Exchange organization.

```
New-AuthServer -Name "WindowsAzureACS" -AuthMetadataUrl
https://accounts.accesscontrol.windows.net/<your verified
domain>/metadata/json/1
```

Step 2: Enable the partner application for your Exchange Online organization

Run the following command in the Exchange PowerShell in your on-premises Exchange organization.

```
Get-PartnerApplication |  ?{$_.ApplicationIdentifier -eq
```

```
"00000002-0000-0ff1-ce00-000000000000" -and $_.Realm -eq
""} | Set-PartnerApplication -Enabled $true
```

Step 3: Export the on-premises authorization certificate

In this step, you have to run a PowerShell script to export the on-premises authorization certificate, which is then imported to your Exchange Online organization in the next step.

1. Save the following text to a PowerShell script file named, for example, **ExportAuthCert.ps1**.

```
$thumbprint = (Get-AuthConfig).CurrentCertificateThumbprint
if((test-path $env:SYSTEMDRIVE\OAuthConfig) -eq $false)
{
    md $env:SYSTEMDRIVE\OAuthConfig
}
cd $env:SYSTEMDRIVE\OAuthConfig
$oAuthCert = (dir Cert:\LocalMachine\My) | where
{$_.Thumbprint -match $thumbprint}
$certType =
[System.Security.Cryptography.X509Certificates.X509ContentT
ype]::Cert
$certBytes = $oAuthCert.Export($certType)
$CertFile = "$env:SYSTEMDRIVE\OAuthConfig\OAuthCert.cer"
[System.IO.File]::WriteAllBytes($CertFile, $certBytes)
```

2. In Exchange PowerShell in your on-premises Exchange organization, run the PowerShell script that you created in the previous step. For example:

```
.\ExportAuthCert.ps1
```

Step 4: Upload the on-premises authorization certificate to Windows Azure Active Directory ACS

Next, you have to use Windows PowerShell to upload the on-premises authorization certificate that you exported in the previous step to Windows Azure Active Directory Access Control Services (ACS). To do this, the Windows Azure Active Directory (AD) Module for Windows PowerShell cmdlets has to be installed. If it's not installed, go to http://aka.ms/aadposh to install the Windows Azure AD Module. Complete the following steps after the Windows Azure AD Module is installed.

1. Click the **Windows Azure Active Directory Module for Windows PowerShell** shortcut to open a Windows PowerShell workspace that has the Windows Azure AD cmdlets installed. All commands in this step will be run using the Windows PowerShell for Windows Azure Active Directory console.

2. Save the following text to a PowerShell script file named, for example, **UploadAuthCert.ps1**.

```
Connect-MsolService;
Import-Module msonlineextended;
$CertFile = "$env:SYSTEMDRIVE\OAuthConfig\OAuthCert.cer"
$objFSO = New-Object -ComObject Scripting.FileSystemObject;
$CertFile = $objFSO.GetAbsolutePathName($CertFile);
$cer = New-Object
System.Security.Cryptography.X509Certificates.X509Certifica
te
$cer.Import($CertFile);
$binCert = $cer.GetRawCertData();
$credValue = [System.Convert]::ToBase64String($binCert);
$ServiceName = "00000002-0000-0ff1-ce00-000000000000";
$p = Get-MsolServicePrincipal -ServicePrincipalName
$ServiceName
New-MsolServicePrincipalCredential -AppPrincipalId
$p.AppPrincipalId -Type asymmetric -Usage Verify -Value
$credValue
```

3. Run the PowerShell script that you created in the previous step. For example:

```
.\UploadAuthCert.ps1
```

4. After you start the script, a credentials dialog box is displayed. Enter the credentials for the tenant administrator account in your Microsoft Online Windows Azure AD organization. After running the script, leave the Windows PowerShell for Windows Azure Active Directory session open. You will use this to run a PowerShell script in the next step.

Step 5: Register all hostname authorities for your external on-premises Exchange HTTP endpoints with Windows Azure Active Directory

You have to run the script in this step for each endpoint in your on-premises Exchange organization that is publically accessible. We recommended that you use wild cards, if possible. For example, assume that Exchange is externally available on **https://mail.contoso.com/ews/exchange.asmx**. In this case a single wildcard could be used: ***.contoso.com**. This would cover autodiscover.contoso.com and mail.contoso.com endpoints. However, it doesn't cover the top-level domain, **contoso.com**. In cases where your Exchange 2013 Client Access servers are externally accessible with the top-level hostname authority, this hostname authority must also be registered as **contoso.com**. There isn't a limit for registering additional external hostname authorities.

If you are not sure of the external Exchange endpoints in your on-premises Exchange organization, you can get a list of the external configured Web services endpoints by running the following command in Exchange PowerShell in your on-premises Exchange organization:

```
Get-WebServicesVirtualDirectory | FL ExternalUrl
```

Note:

Successfully running the following script requires that the Windows PowerShell for Windows Azure Active Directory is connected to your Microsoft Online Windows Azure AD tenant, as explained in step 4 in the previous section.

1. Save the following text to a PowerShell script file named, for example, **RegisterEndpoints.ps1**. This example uses a wildcard to register all endpoints for contoso.com. Replace **contoso.com** with a hostname authority for your on-premises Exchange organization.

```
$externalAuthority="*.contoso.com"
$ServiceName = "00000002-0000-0ff1-ce00-000000000000";
$p = Get-MsolServicePrincipal -ServicePrincipalName
$ServiceName;
$spn = [string]::Format("{0}/{1}", $ServiceName,
$externalAuthority);
$p.ServicePrincipalNames.Add($spn);
Set-MsolServicePrincipal -ObjectID $p.ObjectId -
ServicePrincipalNames $p.ServicePrincipalNames;
```

2. In Windows PowerShell for Windows Azure Active Directory, run the PowerShell script that you created in the previous step. For example:

```
.\RegisterEndpoints.ps1
```

Step 6: Create an IntraOrganizationConnector from your on-premises organization to Office 365

You must define a target address for your mailboxes that are hosted in Exchange Online. This target address is created automatically when your Office 365 tenant is created. For example, if your organization's domain hosted in the Office 365 tenant is "contoso.com", your target service address would be "contoso.mail.onmicrosoft.com".

Using Exchange PowerShell, run the following cmdlet in your on-premises organization:

```
New-IntraOrganizationConnector -name
ExchangeHybridOnPremisesToOnline -DiscoveryEndpoint
https://outlook.office365.com/autodiscover/autodiscover.svc
```

```
-TargetAddressDomains <your service target address>
```

Step 7: Create an IntraOrganizationConnector from your Office 365 tenant to your on-premises Exchange organization

You must define a target address for your mailboxes that are hosted in your on-premises organization. If you organization's primary SMTP adddress is "contoso.com", this would be "contoso.com".

You must also define the external Autodiscover endpoint for your on-premises organization. If your company is "contoso.com" this is usually either of the following:

- https://autodiscover.<your primary SMTP domain>/autodiscover/autodiscover.svc
- https://<your primary SMTP domain>/autodiscover/autodiscover.svc

Note:
You can use the Get-IntraOrganizationConfiguration cmdlet in both your on-premises and Office 365 tenants to determine the endpoint values needed by New-IntraOrganizationConnector cmdlet.

Using Windows PowerShell, run the following cmdlet:

```
$UserCredential = Get-Credential
$Session = New-PSSession -ConfigurationName
Microsoft.Exchange -ConnectionUri https://
outlook.office365.com/powershell-liveid/ -Credential
$UserCredential -Authentication Basic -AllowRedirection
Import-PSSession $Session
New-IntraOrganizationConnector -name
ExchangeHybridOnlineToOnPremises -DiscoveryEndpoint <your
on-premises Autodiscover endpoint> -TargetAddressDomains
<your on-premises SMTP domain>
```

Step 8: Configure an AvailabilityAddressSpace for any pre-Exchange 2013 SP1 servers

When you configure a hybrid deployment in a pre-Exchange 2013 organization, you have to install at least one Exchange 2013 SP1 or greater server with the Client Access and Mailbox server roles in your existing Exchange organization. The Exchange 2013 Client Access and Mailbox servers serve as frontend servers and coordinate communications between your existing Exchange on-premises

organization and the Exchange Online organization. This communication includes message transport and messaging features between the on-premises and Exchange Online organizations. We highly recommend installing more than one Exchange 2013 server in your on-premises organization to help increase reliability and availability of hybrid deployment features.

In a mixed deployment with Exchange 2013/2010 or Exchange 2013/2007, it is recommended that all the Internet-facing frontend servers for your on-premises organization are Client Access servers running Exchange 2013 SP1 or greater. All Exchange Web Services (EWS) requests originating from Office 365 and Exchange Online must connect to an Exchange 2013 Client Access server(s) in your on-premises deployment. Additionally, all EWS requests originating in your on-premises Exchange organizations for Exchange Online must be proxied through a Client Access server running Exchange 2013 SP1 or greater. Since these Exchange 2013 Client Access servers have to handle this additional incoming and outgoing EWS requests, it is important to have a sufficient number of Exchange 2013 Client Access servers available to handle the processing load and provide connection redundancy. The number of Client Access servers needed will depend on the average amount of EWS requests and will vary by organization.

Before you complete the following step, make sure:

- The frontend hybrid servers are Exchange 2013 SP1 or greater
- You have a unique external EWS URL for the Exchange 2013 server(s). The Office 365 tenant must connect to these servers in order for cloud-based requests for hybrid features to work correctly.
- The servers have both the Mailbox and Client Access server roles
- Any existing Exchange 2010/2007 Mailbox and Client Access servers have the latest Cumulative Update (CU) or Service Pack (SP) applied.

Note:

Existing Exchange 2010/2007 Mailbox servers can continue to use Exchange 2010/2007 Client Access servers for frontend servers for non-hybrid feature connections. Only hybrid deployment feature requests from the Office 365 tenant need to connect to Exchange 2013 servers.

An *AvailabilityAddressSpace* must be configured on pre-Exchange 2013 Client Access servers that points to the Exchange Web Services endpoint of your on-premises Exchange 2013 SP1 Client Access server(s). This endpoint is the same endpoint as previously outlined in Step 5 or can be determined by running the following cmdlet on your on-premises Exchange 2013 SP1 Client Access server:

```
Get-WebServicesVirtualDirectory | FL
AdminDisplayVersion,ExternalUrl
```

Note:

If virtual directory information is returned from multiple servers, make sure you use the endpoint returned for an Exchange 2013 SP1 Client Access server. It will display 15.0 (Build 847.32) or higher for the *AdminDisplayVersion* parameter.

To configure the *AvailabilityAddressSpace*, use Exchange PowerShell and run the following cmdlet in

your on-premises organization:

```
Add-AvailabilityAddressSpace -AccessMethod InternalProxy -
ProxyUrl <your on-premises External Web Services URL> -
ForestName <your Office 365 service target address> -
UseServiceAccount $True
```

How do you know this worked?

You can verify that the OAuth configuration is correct by using the Test-OAuthConnectivity cmdlet. This cmdlet verifies that the on-premises Exchange and Exchange Online endpoints can successful authenticate requests from each other.

Important:

When connecting to your Exchange Online organization using Remote PowerShell, you may have to use the *AllowClobber* parameter with the **Import-PSSession** cmdlet to import the latest commands in to the local PowerShell session.

To verify that your on-premises Exchange organization can successfully connect to Exchange Online, run the following command in Exchange PowerShell in your on-premises organization:

```
Test-OAuthConnectivity -Service EWS -TargetUri https://
outlook.office365.com/ews/exchange.asmx -Mailbox <On-
Premises Mailbox> -Verbose | fl
```

To verify that your Exchange Online organization can successfully connect to your on-premises Exchange organization, use the **Remote PowerShell** to connect to your Exchange Online organization and run the following command:

```
Test-OAuthConnectivity -Service EWS -TargetUri <external
hostname authority of your Exchange On-Premises deployment>
-Mailbox <Exchange Online Mailbox> -Verbose | fl
```

Important:

You can ignore the "The SMTP address has no mailbox associated with it." error. It's only important that the *ResultTask* parameter returns a value of **Success**. For example, the last section of the test output should read:

```
ResultType: Success
Identity: Microsoft.Exchange.Security.OAuth.ValidationResultNodeId
IsValid: True
ObjectState: New
```

Tip:

Organization relationships

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-20*

Set up an organization relationship to share calendar information with an external business partner. Exchange admins can set up an organization relationship with an Office 365 organization or with another Exchange on-premises organization. If you want to share calendars with another on-premises Exchange organization, both on-premises Exchange administrators have to set up an authentication relationship with the cloud (also known as "federation") and must meet minimum software requirements.

An organization relationship is a one-to-one relationship between businesses to allow users in each organization to view calendar availability information. When you set up the organization relationship, you are setting up your side of the relationship and specifying the level of information that the users in the external organization can view. The external organization may set up the same or different settings on their side. For example, if Contoso creates an organization relationship with Tailspin Toys, the users at Tailspin Toys will be able to schedule meetings with the users at Contoso by adding their email address to the meeting invitation. The availability of the invited Contoso user would display to the Tailspin Toys user. However, before Contoso can also see availability for users at Tailspin Toys, their administrator needs to set up an organization relationship with Contoso.

There are three of levels of access that you can specify:

- No access
- Access to availability (free/busy) time only
- Access to free/busy, including time, subject, and location

Note:

If users don't want to share their free/busy information with others, they can change the Default permission entry in Outlook. To do this, users go to the **Calendar Properties** > **Permissions** tab, select the **Default** permission, and select **None** from the **Permission Level** list. Their free/busy information won't be seen by internal or external users, even if an organization relationship exists. The permissions set by the user will apply.

The following topics will help you configure and manage organization relationships as a part of sharing for your organization:

Create an organization relationship

Modify an organization relationship

Remove an organization relationship

Looking for more information about federated sharing? See Sharing.

Create an organization relationship

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-20*

Set up an organization relationship to share calendar information with an external business partner. You can configure an organization relationship between two federated Exchange 2013 organizations or between a federated Exchange 2013 organization and federated Exchange 2010 organizations. You can also set up an organization relationship between your on-premises Exchange organization and an Office 365 organization.

Important:
Creating an organization relationship is one of several steps in setting up federated sharing in your Exchange organization and requires the configuration of a federation trust for your on-premises Exchange organization.

To learn more about federated sharing, see Sharing.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Calendar and Sharing Permissions" section in the Recipients Permissions topic.
- An active federation trust for the on-premises Exchange organization must be configured. For details, see Configure a federation trust.
- The external organization you want to configure in the organization relationship must also have a federation trust established with the Windows Azure AD authentication system. You'll use the primary federated domain for the external Exchange organization when configuring the organization relationship.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

What do you want to do?

Use the EAC to create an organization relationship

1. On an Exchange 2013 server in your on-premises organization, navigate to **organization** > **sharing**.
2. Under **Organization Sharing**, click **New +**.
3. In **new organization relationship**, in the **Relationship name** box, type a friendly name for the

organization relationship.

4. In the **Domains to share with** box, type the federated domain or federated subdomain for the Office 365 or Exchange on-premises organization you want to let see your calendars. If you need to enter multiple domains for the external organization, separate the domains with a comma. For example, **contoso.com, service.contoso.com**.
5. Select the **Enable calendar free/busy information sharing** check box to turn on calendar sharing with the domains you listed. Set the sharing level for calendar free/busy information and set which users can share calendar free/busy information.

To set the free/busy access level, select one of the following:

- **Calendar free/busy information with time only**
- **Calendar free/busy with time, subject, and location**

To set which users will share calendar free/busy information, select one of the following:

- **Everyone in your organization**
- **A specified security group**

To specify a security group, click **browse**.

6. Click **save** to create the organization relationship.

Use the Shell to create an organization relationship

This example creates an organization relationship with Contoso, Ltd with the following conditions:

- The organization relationship is enabled for contoso.com, northamerica.contoso.com, and europe.contoso.com.
- Free/busy access is enabled.
- The requesting organization receives free/busy time, subject, and location information from the target organization.

```
New-OrganizationRelationship -Name "Contoso" -DomainNames
"contoso.com","northamerica.contoso.com","europe.contoso.co
m" -FreeBusyAccessEnabled $true -FreeBusyAccessLevel
LimitedDetails
```

This example attempts to automatically discover configuration information from the external Exchange organization Contoso.com by using the domain names provided in the **Get-FederationInformation** cmdlet. If you use this method to create your organization relationship, you must first make sure that you've created an organization identifier by using the **Set-FederatedOrganizationIdentifier** cmdlet.

```
Get-FederationInformation -DomainName Contoso.com | New-
OrganizationRelationship -Name "Contoso" -
FreeBusyAccessEnabled $true -FreeBusyAccessLevel -
LimitedDetails
```

For detailed syntax and parameter information, see Get-FederationInformation and New-

OrganizationRelationship.

This example creates an organization relationship with Fourth Coffee. In this example, the connection settings with the external Exchange organization are provided. The following conditions apply:

- The organization relationship is established with the domain fourthcoffee.com, a federated domain of Fourth Coffee.
- The Exchange Web Services application URL is mail.fourthcoffee.com.
- The Autodiscover URL is https://mail.fourthcoffee.com/autodiscover/autodiscover.svc/wssecurity.
- Free/busy access is enabled.
- The requesting organization receives only free/busy information with the time.

```
New-OrganizationRelationship -Name "Fourth Coffee" -
DomainNames "fourthcoffee.com" -FreeBusyAccessEnabled $true
-FreeBusyAccessLevel -AvailabilityOnly -
TargetAutodiscoverEpr "https://mail.fourthcoffee.com/
autodiscover/autodiscover.svc/wssecurity" -
TargetApplicationUri "mail.fourthcoffee.com"
```

For detailed syntax and parameter information, see New-OrganizationRelationship.

How do you know this worked?

The successful completion of the **New organization relationship** wizard will be your first indication that the creation of the organization relationship worked as expected.

To further verify that you have successfully created the organization relationship, run the following Shell command to verify the organization relationship information:

```
Get-OrganizationRelationship | format-list
```

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Modify an organization relationship

Exchange Server 2013 > Sharing > Organization relationships >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-15*

An organization relationship lets users in your Exchange organization share calendar free/busy information with an Office 365 organization or another on-premises Exchange organization. You may want to change the settings of an organization relationship, such as changing the name, temporarily disabling calendar sharing, changing the access level, or changing which security groups will share calendars.

Before you can share calendars with another organization, you have to set up an authentication relationship with the cloud (also known as "federation") and must meet minimum software requirements. To learn more about federated sharing, see Sharing.

For additional management tasks related to federation, see Federation procedures.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the *Calendar and Sharing Permissions* entry in the Recipients Permissions topic.
- An active federation trust for the on-premises Exchange organization must be configured.
- The external organization you want to configure in the organization relationship must also have a federation trust established with the Windows Azure AD authentication system.
- The procedures in this topic make changes to an organization relationship named Contoso. The examples show how to:
  - Add a domain named service.contoso.com to the external organization.
  - Disable free/busy sharing for the organization relationship.
  - Change the free/busy access level from *Calendar free/busy information with time, subject, and location* to *Calendar free/busy information with time only*.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

What do you want to do?

Use the EAC to add a domain to an organization relationship

1. On an Exchange 2013 server in your on-premises organization, navigate to **organization** > **sharing**.
2. In list view, under **Organization Sharing**, select the organization relationship Contoso, and then click **Edit** ✎.
3. In **organization relationship**, **general** don't change the **Name** for the organization relationship
4. In the **Domains to share with** box, enter the domain **service.contoso.com**, then click **Add +**.
5. Click **save** to update the organization relationship.

Use the EAC to disable free/busy sharing for the organization relationship

1. Go to **organization** > **sharing**.
2. In list view, under **Organization Sharing**, select the organization relationship Contoso, and then click **Edit** .
3. In **organization relationship**, click **sharing**
4. Select **Calendar free/busy information with time only**.
5. Click **save** to update the organization relationship.

Use the EAC to change the free/busy access level for the organization relationship

1. Go to **organization** > **sharing**.
2. In list view, under **Organization Sharing**, select the organization relationship Contoso, and then click **Edit** .
3. In **organization relationship**, click **sharing**
4. Select **Calendar free/busy information with time only**.
5. Click **save** to update the organization relationship.

Use the Shell to modify the organization relationship

- This example adds the domain name service.contoso.com to the organization relationship Contoso.

```
$domains = (Get-OrganizationRelationship
Contoso).DomainNames
$domains += 'service.contoso.com'
Set-OrganizationRelationship -Identity Contoso -DomainNames
$domains
```

- This example disables the organization relationship Contoso.

```
Set-OrganizationRelationship -Identity Contoso -Enabled
$false
```

- This example enables calendar availability information access for the organization relationship WoodgroveBank and sets the access level to `Availabilityonly` (calendar free/busy information with time only).

```
Set-OrganizationRelationship -Identity Contoso -
FreeBusyAccessEnabled $true -FreeBusyAccessLevel
```

```
AvailabilityOnly
```

For detailed syntax and parameter information, see Get-OrganizationRelationship and Set-OrganizationRelationship.

How do you know this worked?

To verify that you have successfully updated the organization relationship, run the following Shell command and verify the organization relationship information.

```
Get-OrganizationRelationship | format-list
```

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Remove an organization relationship

Exchange Server 2013 > Sharing > Organization relationships >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-15*

An organization relationship lets users in your Exchange organization share calendar free/busy information with an Office 365 organization or with another Exchange on-premises organization. You can remove an organization relationship to disable calendar sharing with the other organization.

Before you can share calendars with another organization, you have to set up an authentication relationship with the Windows Azure AD authentication system (also known as “federation”) and must meet minimum software requirements. To learn more about federated sharing, see Sharing.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the “Calendar and Sharing Permissions” section in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

What do you want to do?

Use the EAC to remove an organization relationship

1. On an Exchange 2013 server in your on-premises organization, navigate to **organization** > **sharing**.
2. Under **Organization Sharing**, select an organization relationship, and then click **Delete** to remove organization relationship.
3. In the warning that appears, click **yes**.

Use the Shell to remove an organization relationship

This example removes the organization relationship Contoso from the Exchange organization

```
Remove-OrganizationRelationship -Identity "Contoso"
```

For detailed syntax and parameter information, see Remove-OrganizationRelationship.

How do you know this worked?

To verify that you have successfully removed the organization relationship, do one of the following:

- In the EAC, navigate to **Organization** > **Sharing** and verify that the organization relationship isn't displayed in the list view under **Organization Sharing**.
- Run the following Shell command to verify the organization relationship information is removed.

```
Get-OrganizationRelationship | Format-List
```

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Sharing policies

Exchange Server 2013 > Sharing >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-15*

A part of federated sharing, sharing policies enable user-established, people-to-people sharing of calendar information with different types of external users. Sharing polices are assigned to user mailboxes and allow your users to self-manage and share their free/busy information (including the Calendar folder) with recipients in external Office 365 organizations or other federated Exchange on-premises organizations. If you want to share calendars with recipients that aren't in one of these

types of organizations, sharing policies allow people-to-people sharing of calendar information with any email recipient through the use of Internet Calendar Publishing.

The following topics will help you configure and manage sharing policies as a part of federated sharing for your organization:

Create a sharing policy

Apply a sharing policy to mailboxes

Modify, disable, or remove a sharing policy

Looking for more information about federated sharing? See Sharing

Create a sharing policy

Exchange Server 2013 > Sharing > Sharing policies >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-15*

You can use sharing policies to control how users in your Exchange organization share calendar information with users outside your organization. Sharing policies provide user-established, people-to-people sharing of calendar information with different types of external users. They support the sharing of calendar information with external federated organizations (such as Office 365 or another on-premises Exchange organization), external non-federated organizations, and individuals with Internet access. To apply a specific sharing policy to users, see Apply a sharing policy to mailboxes.

Important:
Creating a sharing policy is one of several steps in setting up federated sharing in your Exchange organization. You have to set up a federation trust with the Windows Azure AD authentication system for your on-premises Exchange organization before you can share calendar information with other federated Exchange organizations. A federation trust isn't required for Internet sharing policies.

To learn more about federated sharing, see Sharing.

For additional management tasks related to federation, see Federation procedures.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Calendar and Sharing Permissions" section in the Recipients Permissions topic.

- The following are required for sharing policies between federated Exchange organizations:
  - An Exchange 2013 Client Access server exists in each Exchange organization. Sharing policies are also supported between Exchange organizations where one organization has Exchange 2013 Client Access servers and the other one organization has Exchange 2010 SP3 or later Client Access servers.
  - Each Exchange organization has created a federation trust with the Windows Azure AD authentication system. For details, see Configure a federation trust.
  - Each Exchange organization has configured a federated organization identifier. Domains used for generating users' e-mail addresses have been added to the organization identifiers.
  - User mailboxes are located on Exchange 2013 Mailbox servers or Exchange 2010 Mailbox servers in each Exchange organization.
  - Only Outlook 2010 or later and Outlook Web App users can create sharing invitations.
- The following are required for sharing policies with non-federated Exchange organizations or individuals:
  - An Exchange 2013 Client Access server exists in the Exchange organization that's sharing user's calendar information.
  - User mailboxes are located on Exchange 2013 Mailbox servers in the Exchange organization that's sharing user's calendar information.
  - The Exchange 2013 Client Access server must be enabled for Outlook Web App access.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

What do you want to do?

Use the EAC to create a sharing policy

1. Navigate to **organization**> **sharing**.
2. In the list view, under **Individual Sharing**, click **New +**.
3. In **new sharing policy**, type a friendly name for the sharing policy in the **Policy name** box.
4. Click **Add +** to specify the sharing rules for the sharing policy.
5. In **sharing rule**, select one of the following options to specify the domains you want to share with:
   - **Sharing with all domains**
   - **Sharing with a specific domain**
6. If you select **Sharing with a specific domain**, type the name of the domain you want to share with. If you need to enter more than one domain for this sharing policy, save the settings for the first domain, then edit the sharing rules to add more domains.
7. To define the calendar sharing levels you want to enforce for the policy, select the **Share your calendar folder** check box, and then select one of the following options:
   - **Calendar free/busy information with time only**
   - **Calendar free/busy information with time, subject, and location**
   - **All calendar appointment information, including time, subject, location and title**

8. Click **save** to set the rules for the sharing policy.
9. If you want to make this sharing policy the default sharing policy for users in your Exchange organization, select the **Make this policy my default sharing policy** check box.
10. Click **save** to create the sharing policy.

Use the EAC to allow all users to share full calendar details

You can edit the default sharing policy to allow all of your users to share full calendar details with people outside of your organization.

1. Navigate to **organization**> **sharing**.
2. In the list view, under **Individual Sharing**, select **the Default Sharing Policy**, and then click **Edit** .
3. In the **Sharing Policy** dialog box, select **Sharing with all domains**, and then click **Edit** .
4. In the **Sharing Rule** dialog box, under **Specify what information you want to share**, select **All calendar appointment information, including time, subject, location and title**, and then click **save**.
5. In the **Sharing Policy** dialog box, click **save** to set the rules for the sharing policy.

Use the Shell to create a sharing policy

- This example creates the sharing policy Contoso for the external federated domain contoso.com. This policy allows users in the contoso.com domain to see your user's detailed calendar availability (free/busy) information. By default, this policy is enabled.

```
New-SharingPolicy -Name "Contoso" -Domains contoso.com:
CalendarSharingFreeBusyDetail
```

- This example creates the sharing policy ContosoWoodgrove for two different federated domains (contoso.com and woodgrovebank.com) with different sharing actions configured for each domain. The policy is disabled.

```
New-SharingPolicy -Name "ContosoWoodgrove" -Domains
'contoso.com: CalendarSharingFreeBusySimple',
'woodgrovebank.com: CalendarSharingFreeBusyDetail -Enabled
$false
```

- This example creates the sharing policy Anonymous for an Exchange organization with the Client Access server CAS01 and the Mailbox server MAIL01 with the sharing action configured for limited calendar availability information. This policy allows users in your Exchange organization to invite users with Internet access to view their calendar availability information by sending them a link. The policy is enabled.
  1. Set the Web proxy URL for MAIL01.

```
Set-ExchangeServer -Identity "Mail01" -InternetWebProxy
```

```
"<Webproxy URL>"
```

2. Enable the publishing virtual directory on CAS01.

```
Set-OwaVirtualDirectory -Identity "CAS01" -ExternalURL
"<URL for CAS01>" -CalendarPublishingEnabled $true
```

3. Create the sharing policy Anonymous and configure limited calendar information sharing.

```
New-SharingPolicy -Name "Anonymous" -Domains 'Anonymous:
CalendarSharingFreeBusySimple' -Enabled $true
```

For detailed syntax and parameter information, see the following topics:

- New-SharingPolicy
- Set-ExchangeServer
- Set-OwaVirtualDirectory

How do you know this worked?

To verify that you have successfully created the sharing policy, run the following Shell command to verify the sharing policy information.

```
Get-SharingPolicy <policy name> | format-list
```

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Apply a sharing policy to mailboxes

Exchange Server 2013 > Sharing > Sharing policies >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-15*

Sharing policies are a part of federated sharing and enable user-established, people-to-people sharing of calendar information with different types of external users. The sharing policy that an admin applies to the user's mailbox determines what level of access a user can share and with whom. If you don't change anything, then the default sharing policy applies to all users. If you create a new sharing policy, you have to apply that policy to mailboxes before it takes effect. A sharing policy can be applied to a single user mailbox or to multiple user mailboxes simultaneously. An admin can also disable a user's sharing policy to prevent external access to calendars.

To learn more about federated sharing, see Sharing.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the *Recipient Provisioning Permissions* entry in the Recipients Permissions topic.
- A sharing policy must exist. For details, see Create a sharing policy.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

What do you want to do?

Use the EAC to apply a sharing policy to a single mailbox

1. Navigate to **recipients** > **mailboxes**.
2. In the list view, select the mailbox you want, and then click **Edit** .
3. In **User Mailbox**, click **mailbox features**.
4. In the **Sharing policy** list, select the sharing policy you want to apply to this mailbox.
5. Click **save** to apply the sharing policy.

Use the EAC to apply a sharing policy to multiple mailboxes

1. Navigate to **recipients** > **mailboxes**.
2. In the list view, hold the Ctrl key while you select multiple mailboxes..
3. In the details pane, the mailbox properties will be configured for bulk editing. Click **More options**.
4. Under **Sharing policy**, click **Update**.
5. In **bulk assign sharing policy**, use the **Select the sharing policy** list to select a sharing policy to assign to the mailboxes.
6. Click **save** to apply the sharing policy to the selected mailboxes.

Use the Shell to apply a sharing policy to one or more mailboxes

This example applies the sharing policy Contoso to a single mailbox for the user Barbara.

```
Set-Mailbox -Identity Barbara -SharingPolicy "Contoso"
```

This example specifies that all user mailboxes in the Marketing department use the sharing policy Contoso Marketing.

```
Get-Mailbox -Filter {Department -eq "Marketing"} | Set-
Mailbox -SharingPolicy "Contoso Marketing"
```

This example returns all mailboxes that have the sharing policy Contoso applied, and it sorts the users into a table that displays only their aliases and email addresses.

```
Get-Mailbox -ResultSize unlimited | Where {$_.SharingPolicy
-eq "Contoso" } | format-table Alias, EmailAddresses
```

For detailed syntax and parameter information, see Set-Mailbox and Get-Mailbox.

How do you know this worked?

To verify that you have successfully applied the sharing policy to a user mailbox, do one of the following:

- In the EAC, navigate to **Recipients** > **Mailboxes**, and then select the mailbox to which you applied the sharing policy. Click **Edit**, click **mailbox features**, and then confirm that the correct sharing policy appears in the **Sharing policy** list.
- Run the following Shell command to verify the sharing policy was assigned to a user mailbox. Verify that the correct sharing policy is listed in the *SharingPolicy* parameter.

```
Get-Mailbox <user name> | format-list
```

Modify, disable, or remove a sharing policy

Exchange Server 2013 > Sharing > Sharing policies >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-15*

Sharing policies allow individual users in your Exchange organization to share calendar free/busy information with other federated Exchange organizations, non-federated Exchange organizations, and individual Internet users. During the course of normal operations, you may want to change

some sharing policy properties, such as modifying sharing rules, changing the free/busy access level, temporarily disabling a sharing policy, or removing a sharing policy entirely.

To learn more about federated sharing, see Sharing

For details about how to create a sharing policy, see Create a sharing policy

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Calendar and Sharing Permissions" entry in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to modify a sharing policy

1. Navigate to **organization** > **sharing**.
2. Under **Individual Sharing**, select a sharing a policy, and then click **Edit** .
3. In **sharing policy**, click **Edit** .
4. In **sharing rule**, modify the sharing rules accordingly. You can change settings such as the domain you want to share information with and the sharing level for calendar appointments. When finished, click **rave** to close the **sharing rules** dialog box.
5. In **sharing policy**, click **save** to update the sharing policy.

Use the EAC to set a sharing policy as the default sharing policy

1. Navigate to **organization** > **sharing**.
2. Under **Individual Sharing**, select a sharing a policy, and then click **Edit** .
3. In **sharing policy**, select the **Make this policy my default sharing policy** check box.
4. Click **save** to update the sharing policy.

Use the EAC to disable a sharing policy

1. Navigate to **Organization** > **Sharing**.
2. Under **Individual Sharing**, select a sharing a policy.

3. In the **On** column, clear the check box for the sharing policy you want to disable.

Use the EAC to remove a sharing policy

Important:
Before you remove a sharing policy, the sharing policy must be removed from all user mailboxes.

1. Navigate to **organization** > **sharing**.
2. Under **Individual Sharing**, select a sharing a policy, and then click **Delete** 🗑.
3. In the warning, click **yes** to delete the sharing policy.

Use the Shell to modify, disable or remove a sharing policy

- This example modifies the sharing policy Contoso for contoso.com, which is a domain outside your organization. This policy allows users in the Contoso domain to see simple free/busy information.

```
Set-SharingPolicy -Identity Contoso -Domains
'sales.contoso.com: CalendarSharingFreeBusySimple'
```

- This example adds a second domain to the sharing policy Contoso. When you're adding a domain to an existing policy, you must include any previously included domains.

```
Set-SharingPolicy -Identity Contoso -Domains 'contoso.com:
CalendarSharingFreeBusySimple', 'atlanta.contoso.com:
CalendarSharingFreeBusyReviewer', 'beijing.contoso.com:
CalendarSharingFreeBusyReviewer'
```

- This example sets the sharing policy Contoso as the default sharing policy.

```
Set-SharingPolicy -Identity Contoso -Default $True
```

- This example disables the sharing policy Contoso.

```
Set-SharingPolicy -Identity "Contoso" -Enabled $False
```

- The first example removes the sharing policy Contoso. The second example removes the sharing policy Contoso and suppresses the confirmation that you want to remove the policy.

```
Remove-SharingPolicy -Identity Contoso

Remove-SharingPolicy -Identity Contoso -Confirm
```

For detailed syntax and parameter information, see Set-SharingPolicy and Remove-SharingPolicy.

Enable Internet calendar publishing

Applies to: *Exchange Online*

Topic Last Modified: *2012-12-10*

Users in Microsoft Exchange Server 2013 organizations can share calendar availability (free/busy) information with users in non-Exchange organizations and other individuals with Internet access. Internet calendar publishing provides increased flexibility and increases the number of users who can share calendar availability information.

Enabling Internet calendar publishing consists of three general steps:

1. Configure the Web proxy URL for the Mailbox server.
2. Enable the publishing virtual directory for the Client Access server.
3. Create a dedicated sharing policy specifically for Internet calendar publishing or update the default sharing policy to support the **Anonymous** domain. Either method allows users in your Exchange organization to invite other users who have Internet access to view limited calendar availability information by accessing a published URL.

For additional management tasks related to sharing policies, see Sharing policies.

What do you need to know before you begin?

- Estimated time to complete this task: 15 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Calendar and Sharing Permissions" entry in the Recipients Permissions topic.
- An Exchange 2013 Client Access server exists in the Exchange organization that's sharing users' calendar information.
- User mailboxes are on Exchange 2013 Mailbox servers in the Exchange organization that's sharing users' calendar information.
- Only Outlook 2010 or later and Outlook Web App users can create sharing invitations.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

How do you do this?

Step 1: Use the Shell to configure the Web proxy URL

Note:
You can't use the Exchange Administration Center (EAC) to configure the Web proxy URL.

This example configures a Web proxy URL on Mailbox server MAIL01.

```
Set-ExchangeServer -Identity "MAIL01" -InternetWebProxy
"<Webproxy URL>"
```

For detailed syntax and parameter information, see Set-ExchangeServer.

How do you know this step worked?

To verify that you have successfully configured the Web proxy URL, run the following Shell command and verify the *InternetWebProxy* parameter information.

```
Get-ExchangeServer | format-list
```

Step 2: Use the Shell to enable the publishing virtual directory

Note:
You can't use the EAC to enable the publishing virtual directory.

This example enables the publishing virtual directory on Client Access server CAS01.

```
Set-OwaVirtualDirectory -Identity "CAS01" -ExternalUrl
"<URL for CAS01>" -CalendarEnabled $true
```

For detailed syntax and parameter information, see Set-OwaVirtualDirectory.

How do you know this step worked?

To verify that you have successfully enabled the publishing virtual directory, run the following Shell command and verify the *ExternalURL* parameter information.

```
Get-OwaVirtualDirectory | format-list
```

Step 3, option 1: Use the EAC or the Shell to create a sharing policy specifically for Internet calendar publishing

If you want to create a sharing policy specifically for Internet calendar publishing, complete the

following steps.

Use the EAC

1. Navigate to **Organization**> **Sharing**.
2. In the list view, under **Individual Sharing**, click **New +**.
3. In **Sharing Policy**, type a friendly name for the sharing policy in the **Policy name** field (for example, **Internet**).
4. Click **Add +** to define the sharing rules for the sharing policy.
5. In **Sharing Rule**, click **Sharing with a specific domain**, and then type **Anonymous** in the corresponding box.
6. To specify the calendar sharing levels you want to enforce for the sharing policy, select the **Share your calendar folder** check box, and then select one of the following:
   - **Calendar free/busy information with time only**
   - **Calendar free/busy information with time, subject, and location**
   - **All calendar appointment information, including time, subject, location and title**
7. Click **Save** to set the rules for the sharing policy.
8. In **Sharing Policy**, click **Save** to create the policy.

Use the Shell

This example creates an Internet calendar publishing sharing policy named Internet and configures the policy to share only availability information. The policy is enabled.

```
New-SharingPolicy -Name "Internet" -Domains 'Anonymous:
CalendarSharingFreeBusySimple' -Enabled $true
```

This example adds the sharing policy Internet to a user mailbox.

```
Set-Mailbox -Identity <user name> -SharingPolicy "Internet"
```

This example adds the sharing policy Internet to an organizational unit (OU).

```
Set-Mailbox -OrganizationalUnit <OU name> -SharingPolicy
"Internet"
```

For detailed syntax and parameter information, see New-SharingPolicy and Set-Mailbox.

How do you know this step worked?

To verify that you have successfully created the sharing policy, run the following Shell command to verify the sharing policy information.

```
Get-SharingPolicy <policy name> | format-list
```

Step 3, option 2: Use the EAC or the Shell to configure the

default sharing policy for Internet calendar publishing

If you want to configure the default sharing policy for Internet calendar publishing, complete the following steps.

Use the EAC

1. Navigate to **Organization** > **Sharing**.
2. In the list view, under **Individual Sharing**, select the Default Sharing Policy, and then click **Edit** ✎.
3. In **Sharing Policy**, click **Add +** to add a sharing rule to the policy.
4. In **Sharing Rule**, click **Sharing with a specific domain**, and then and then type **Anonymous** in the corresponding box.
5. To specify the calendar sharing levels you want to enforce for the sharing policy, select the **Share your calendar folder** check box, and then select one of the following:
   - **Calendar free/busy information with time only**
   - **Calendar free/busy information with time, subject, and location**
   - **All calendar appointment information, including time, subject, location and title**
6. Click **Save** to set the rules for the sharing policy.
7. In **Sharing Policy**, click **Save** to save the changes.

Use the Shell

This example updates the Default Sharing Policy and configures the policy to share only availability information. The policy is enabled.

```
Set-SharingPolicy -Name "Default Sharing Policy" -Domains
'Anonymous: CalendarSharingFreeBusySimple' -Enabled $true
```

For detailed syntax and parameter information, see Set-Mailbox.

How do you know this step worked?

To verify that you have successfully updated the Default Sharing Policy, run the following Shell command to verify the sharing policy information.

```
Get-SharingPolicy <policy name> | format-list
```

Disable Internet calendar publishing

Exchange Server 2013 > Sharing > Sharing policies >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-15*

How you disable Internet calendar publishing depends on how you enabled it. If you created a sharing policy dedicated to Internet calendar publishing, you can either disable the policy or delete it altogether. If you configured Internet calendar publishing as a sharing rule in the default sharing policy, you can just remove the sharing rule for the **Anonymous** domain.

When you disable Internet calendar publishing, users who are provisioned to use the sharing policy won't be able to share calendar information with the **Anonymous** Internet domain specified in the policy. However, you can't delete or disable a sharing policy that's dedicated to Internet calendar publishing until all users who are provisioned to use that policy have the policy setting removed from their mailboxes. For details about changing the sharing policy setting for a user, see Manage user mailboxes.

Note:

If you disable or delete a sharing policy, users provisioned to use the policy will continue to share information until the Sharing Policy Assistant runs. To specify how often the Sharing Policy Assistant runs, use the Set-MailboxServer cmdlet with the *SharingPolicySchedule* parameter.

To fully disable Internet calendar publishing, you should also disable the Outlook Web App virtual directory used for calendar publishing. Doing this prohibits access to the published calendar links previously shared by your Exchange organization users with external Internet users. This step is detailed later in this topic.

To learn more about Internet calendar publishing and sharing policies, see Sharing.

What do you need to know before you begin?

- Estimated time to complete this task: 15 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Calendar and Sharing Permissions" entry in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

How do you do this?

Step 1: Use the EAC or the Shell to disable or delete the sharing policy for Internet calendar publishing

Use the EAC

1. Navigate to **Organization** > **Sharing**.
2. In the list view, under **Individual Sharing**, perform one of the following steps:
   - If you created a sharing policy specifically for Internet calendar publishing, select that policy, and then either clear the check box in the **On** column to disable the sharing policy or click **Delete** 🗑 to delete it.
   - If you configured Internet calendar publishing as a sharing rule in the default sharing policy, perform the following steps:
     a. Select the default sharing policy, and then click **Edit** ✎.
     b. In **sharing policy**, select the **Anonymous** sharing rule, and then click **Remove** — to remove the sharing rule.
     c. Click **Save**.

Use the Shell

This example disables a dedicated Internet calendar publishing sharing policy named **Internet**.

```
Set-SharingPolicy -Identity "Internet" -Enabled $false
```

This example deletes a dedicated Internet calendar publishing sharing policy named **Internet**.

```
Remove-SharingPolicy -Identity "Internet"
```

For detailed syntax and parameter information, see Set-SharingPolicy.

How do you know this step worked?

To verify that you have successfully removed or updated the sharing policy, run the following Shell command and verify the sharing policy information.

```
Get-SharingPolicy <policy name> | format-list
```

If you've removed the dedicated Internet calendar publishing sharing policy, you won't see the policy in the cmdlet results.

If you've updated the default sharing policy, verify that the `Anonymous` domain has been removed from the *Domains* parameter.

For detailed syntax and parameter information, see Get-SharingPolicy.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Step 2: Use the Shell to disable the Outlook Web App virtual directory Anonymous features

Note:
You can't use the EAC to disable Anonymous features for the Outlook Web App virtual directory.

This example disables Anonymous features for the Outlook Web App virtual directory on Client Access server CAS01.

```
Set-OwaVirtualDirectory -Identity "CAS01" -
AnonymousFeaturesEnabled -$false
```

For detailed syntax and parameter information, see Set-OwaVirtualDirectory.

How do you know this step worked?

To verify that you have successfully disabled the Anonymous features for the Outlook Web App virtual directory on the Client Access server, run the following Shell command and verify that the *AnonymousFeaturesEnabled* parameter is `$false`.

```
Get-OwaVirtualDirectory | format-list
```

For detailed syntax and parameter information, see Get-OwaVirtualDirectory.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Clients and mobile

Exchange Server 2013 >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-17*

There are many different clients that can be used to access information in a Microsoft Exchange Server 2013 mailbox. These clients include desktop programs such as Microsoft Outlook, Outlook Web App, and mobile clients such as mobile phones, tablets, and other mobile devices. Each of these clients offers a variety of features.

Looking for a list of all clients and mobile topics? See Clients and mobile documentation.

Clients and mobile documentation

The following table contains links to topics that will help you learn about and manage some of the clients and client access methods that can be used to access an Exchange 2013 mailbox.

Topic	Description
Outlook Anywhere	Learn about Outlook Anywhere, the client access method that provides connectivity to Microsoft Outlook 2007, Outlook 2010, and Outlook 2013. (This feature was formerly known as RPC/HTTP.)
Exchange ActiveSync	Learn about Exchange ActiveSync, the protocol that provides connectivity to a wide variety of mobile phones and tablets. Using Exchange ActiveSync, users can access email, calendar, contact, and task information.
POP3 and IMAP4	Learn about how users can access their Exchange 2013 email by using email programs that use POP3 or IMAP4.
Office Web Apps Server integration	Learn about how the integration of Microsoft Office Web Apps Server helps provide rich attachment preview functionality in Outlook Web App.
Client protocol management	Learn about management of the client protocols of Exchange ActiveSync, Outlook Web App, POP3, IMAP4, the Autodiscover service, Exchange Web Services, and the Availability service.
Outlook Web App	Learn about Outlook Web App, which provides users access to their Exchange 2013 mailbox through a web browser.
MailTips	Learn about MailTips, the informative messages displayed to users while they're composing a message.

Outlook Anywhere

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-08-26*

In Microsoft Exchange Server 2013, the Outlook Anywhere feature, formerly known as RPC over HTTP, lets clients who use Microsoft Outlook 2013, Outlook 2010, or Outlook 2007 connect to their Exchange servers from outside the corporate network or over the Internet using the RPC over HTTP Windows networking component. This topic describes the Outlook Anywhere feature and lists the benefits of using Outlook Anywhere.

Contents

Outlook Anywhere and Exchange 2013

The Windows RPC over HTTP Proxy component, which Outlook Anywhere clients use to connect, wraps remote procedure calls (RPCs) with an HTTP layer. This allows traffic to traverse network firewalls without requiring RPC ports to be opened. In Exchange 2013, this feature is enabled by default, because Exchange 2013 doesn't allow direct RPC connectivity.

Benefits of using Outlook Anywhere

Outlook Anywhere offers the following benefits to clients that use Outlook 2013, Outlook 2010, or Outlook 2007 to access your Exchange messaging infrastructure:

- Users have remote access to Exchange servers from the Internet.
- You can use the same URL and namespace that you use for Outlook Web App and Microsoft Exchange ActiveSync.
- You can use the same Secure Sockets Layer (SSL) server certificate that you use for both Outlook Web App and Exchange ActiveSync.
- Unauthenticated requests from Outlook can't access Exchange servers.
- You don't have to use a virtual private network (VPN) to access Exchange servers across the

Internet.

- If you already use Outlook Web App with SSL or Exchange ActiveSync with SSL, you don't have to open any additional ports from the Internet.
- You can test end-to-end client connectivity for Outlook Anywhere and TCP-based connections by using the **Test-OutlookConnectivity** cmdlet.

Deploying Outlook Anywhere

In Exchange 2013, Outlook Anywhere is enabled by default, because all Outlook connectivity takes place via Outlook Anywhere. The only post-deployment task you must perform to successfully use Outlook Anywhere is to install a valid SSL certificate on your Client Access server. Mailbox servers in your organization only require the default self-signed SSL certificate.

Managing Outlook Anywhere

You can manage Outlook Anywhere by using the Exchange admin center or the Exchange Management Shell.

Outlook Anywhere coexistence

If you are planning to install Exchange 2013 in a coexistence scenario with previous versions of Exchange Server, you might still have Outlook 2003 clients in your organization. Outlook 2003 is not a supported client for Exchange 2013.

Before you move your namespace to Exchange 2013, you need to ensure that all Outlook clients have been upgraded to the minimum supported version. Outlook 2007 or higher is required for an Outlook Anywhere connection to Exchange 2013, even if the target mailbox is still on Exchange 2007 or Exchange 2010.

In a coexistence scenario that still has 2007 or 2010 Client Access Servers, you need to enable Outlook Anywhere on each legacy Client Access Server. For instructions on enabling Outlook Anywhere for Client Access Servers running on Exchange Server 2007, see How to Enable Outlook Anywhere. For instructions on enabling Outlook Anywhere for Client Access Servers running on Exchange Server 2010, see Enable Outlook Anywhere.

Make sure that when you enable Outlook Anywhere on the Client Access Server, choose NTLM for IIS authentication.

Finally, configure the Outlook Anywhere external host name to point to the Exchange 2013 Outlook Anywhere host name. For instructions for Exchange Server 2007, see How to Configure an External Host Name for Outlook Anywhere. For instructions for Exchange Server 2010, see Configure an External Host Name for Outlook Anywhere.

Testing Outlook Anywhere connectivity

You can test for end-to-end client Outlook connectivity by doing either of the following:

- Running the **Test-OutlookConnectivity** cmdlet. The cmdlet tests for Outlook Anywhere (RPC over HTTP) connections. If the cmdlet test fails, the output notes the step that failed. For detailed syntax and parameters, see Test-OutlookConnectivity.
- Running the Outlook Anywhere connectivity test using the Exchange Remote Connectivity Analyzer (ExRCA). When you run this test, you get a detailed summary showing where the test failed and what steps you can take to fix issues. For more information, see Exchange Remote Connectivity Analyzer.

Both tests try to sign in through Outlook Anywhere after obtaining server settings from the Autodiscover service. End-to-end verification includes the following:

- Testing for Autodiscover connectivity
- Validating DNS
- Validating certificates (whether the certificate name matches the website, whether the certificate has expired, and whether it's trusted)
- Checking that the firewall is set up correctly (ExRCA checks overall firewall setup. The cmdlet tests for Windows firewall configuration.)
- Confirming client connectivity by signing in to the user's mailbox

Test Outlook Anywhere connectivity

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-11-27*

You can test for end-to-end client Outlook Anywhere connectivity by using either the Shell or the Exchange Remote Connectivity Analyzer (ExRCA). This includes testing for connectivity through the Autodiscover service, creating a user profile, and signing in to the user’s mailbox. All the required values are retrieved from the Autodiscover service.

For additional management tasks related to Outlook Anywhere, see Outlook Anywhere.

What do you need to know before you begin?

- Estimated time to complete: 10 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Outlook Anywhere" entry in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see

Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the Shell to test Outlook Anywhere connectivity

To use the Shell to test Outlook Anywhere connectivity, use the **Test-OutlookConnectivity** cmdlet.

Run the following command.

```
Test-OutlookConnectivity -ProbeIdentity
'OutlookMailboxDeepTestProbe' -MailboxId tony@contoso.com -
Hostname contoso.com
```

Note:

The *OutlookMailboxDeepTestProbe* parameter value tests connectivity from the Mailbox server. To test connectivity from the Client Access server, use *OutlookMailboxCTPProbe* for the *ProbeIdentity* parameter value.

Use the Exchange Remote Connectivity Analyzer to test Outlook Anywhere connectivity

The Exchange Remote Connectivity Analyzer (ExRCA) is a web-based tool designed to test connectivity with a variety of Exchange protocols. You can access the ExRCA here.

1. On the ExRCA website, under **Microsoft Office Outlook Connectivity Tests**, select **Outlook Anywhere**, and then select Next at the bottom of the page.
2. Enter the required information on the next screen, including email address, domain and user name, and password.
3. Choose whether to use Autodiscover to detect server settings or to manually specify server settings.
4. Accept the disclaimer, enter the verification code, and then select **Verify**.
5. Select **Perform Test**.

How do you know this worked?

When the ExRCA tests complete, the output will be displayed on the web page. Any failures will be listed.

MAPI over HTTP

Topic Last Modified: *2014-06-18*

Messaging Application Programming Interface (MAPI) over HTTP is a new transport protocol implemented in Microsoft Exchange Server 2013 Service Pack 1 (SP1) and Microsoft Outlook 2013 SP1. MAPI over HTTP improves the reliability and stability of the Outlook and Exchange connections by moving the transport layer to the industry-standard HTTP model. This allows a higher level of visibility of transport errors and enhanced recoverability. Additional functionality includes support for an explicit pause-and-resume function. This enables supported clients to change networks or resume from hibernation while maintaining the same server context.

Implementing MAPI over HTTP does not mean that it is the only protocol that can be used for Outlook to access Exchange. Outlook clients that are not MAPI over HTTP capable can still use Outlook Anywhere (RPC over HTTP) to access Exchange through a MAPI-enabled Client Access server.

Benefits of MAPI over HTTP

MAPI over HTTP offers the following benefits to clients that use Outlook 2013 SP1:

- Enables future innovation in authentication by using an HTTP based protocol.
- Provides faster reconnection times after a communications break because only TCP connections—not RPC connections—need to be rebuilt. Examples of a communication break include:
  - Device hibernation
  - Changing from a wired network to a wireless or cellular network
- Offers a session context that is not dependent on the connection. The server maintains the session context for a configurable period of time—even if the user changes networks.

Deploy MAPI over HTTP

Consider the following requirements to enable MAPI over HTTP.

- **Supportability** Verify that your intended configuration versions are supported.
- **Prerequisites** Verify that your environment has been upgraded and prepared for MAPI over HTTP.
- **Configuration** Configure the virtual directories, and enable MAPI for your organization.

Supportability

Use the following matrix to verify that your clients and servers support MAPI over HTTP.

Product	Exchange 2013	Exchange 2013	Exchange 2010	Exchange 2007

	SP1	RTM	SP3	SP3
Outlook 2013 SP1	• MAPI over HTTP • Outlook Anywhere	Outlook Anywhere	• RPC • Outlook Anywhere	• RPC • Outlook Anywhere
Outlook 2013 RTM	Outlook Anywhere	Outlook Anywhere	• RPC • Outlook Anywhere	• RPC • Outlook Anywhere
Outlook 2010	Outlook Anywhere	Outlook Anywhere	• RPC • Outlook Anywhere	• RPC • Outlook Anywhere
Outlook 2007	Outlook Anywhere	Outlook Anywhere	• RPC • Outlook Anywhere	• RPC • Outlook Anywhere

Prerequisites

Complete the following steps to prepare the clients and servers to support MAPI over HTTP.

1. Upgrade Outlook clients to Outlook 2013 SP1.
2. Upgrade Client Access and Mailbox servers to Exchange 2013 SP1. For information about how to upgrade, see Upgrade Exchange 2013 to the latest cumulative update or service pack.

Note:
All Client Access servers must be upgraded to Exchange 2013 SP1 before enabling MAPI over HTTP. Otherwise, Outlook can fail to connect to mailboxes. Failure to upgrade the all the Mailbox servers in a Database Availability Group (DAG) can result in email delays and a client requirement to restart Outlook in case of a database failover.

3. For any of your Exchange 2013 SP1 servers that aren't running on Windows Server 2012 R2, you need to upgrade the Microsoft .NET Framework to 4.5.1. For more information see Installing the .NET Framework 4.5, 4.5.1.
4. Install one of the following hotfix rollups for the .NET Framework 4.5.1 on all Exchange 2013 SP1 servers.
   - **Windows Server 2012 R2** KB 2908387
   - **Windows Server 2012** KB 2908385
   - **Windows Server 2008 R2 Service Pack 1** KB 2908383
5. On all Exchange 2013 SP1 Client Access servers, add the following registry key.

```
Windows Registry Editor Version 5.00
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\.NETFramework]
"DisableRetStructPinning"=dword:00000001
```

6. On all Exchange 2013 SP1 Client Access servers, add the **COMPLUS_DisableRetStructPinning**

Windows environment variable by performing the following steps.

- In a Command prompt window, run `systempropertiesadvanced` and click **Environment Variables**.
- In the **System variables** section, click **New** and enter the following information.
  - **Variable name** `COMPLUS_DisableRetStructPinning`
  - **Variable value** 1
- When you are finished, click **OK**.

Configuration

Complete the following steps to configure MAPI over HTTP for your organization.

1. **Virtual directory configuration** By default, Exchange 2013 SP1 creates a virtual directory for MAPI over HTTP. You use the **Set-MapiVirtualDirectory** cmdlet to configure the virtual directory. You must configure an internal URL, an external URL, or both. For more information see, Set-MapiVirtualDirectory.

For example, to configure the default MAPI virtual directory on the local Exchange server by setting the internal URL value to https://contoso.com/mapi, and the authentication method to `Negotiate`, run the following command:

```
Set-MapiVirtualDirectory -Identity "Contoso\mapi (Default Web Site)" -InternalUrl https://Contoso.com/mapi -IISAuthenticationMethods Negotiate
```

2. **Certificate configuration** The digital certificate used by your Exchange environment must include the same *InternalURL* and *ExternalURL* values that are defined on the MAPI virtual directory. For more information on Exchange 2013 certificate management, see Digital certificates and SSL. Make sure the Exchange certificate is trusted on the Outlook client workstation and that there are no certificate errors, especially when you access the URLs configured on the MAPI virtual directory.
3. **Update server rules** Verify that your load balancers, reverse proxies, and firewalls are configured to allow access to the MAPI over HTTP virtual directory.
4. **Enable MAPI over HTTP in your Exchange Organization**

Note:

If you enable MAPI over HTTP in your organization, Outlook 2013 SP1 clients that connect through Exchange 2013 SP1 Client Access servers might not be able to access public folders in the same forest on Exchange 2010 or Exchange 2007 servers. Don't enable MAPI over HTTP in your organization until the public folders have been migrated to Exchange 2013 servers. For more information, see the Release notes for Exchange 2013.
After running the command below, clients using Outlook 2013 SP1 with MAPI over HTTP enabled will see a message to restart Outlook to use MAPI over HTTP.

Run the following command:

```
Set-OrganizationConfig -MapiHttpEnabled $true
```

Test MAPI over HTTP connections

You can test the end-to-end MAPI over HTTP connection by using the **Test-OutlookConnectivity** cmdlet. To use the **Test-OutlookConnectivity** cmdlet, the Microsoft Exchange Health Manager (MSExchangeHM) service must be started.

The following example tests the MAPI over HTTP connection from the Exchange server named ContosoMail.

```
Test-OutlookConnectivity -RunFromServerId ContosoMail -
ProbeIdentity OutlookMapiHttpSelfTestProbe
```

A successful test returns output that's similar to the following example:

```
MonitorIdentity
StartTime                EndTime                  Result
Error     Exception
---------------
---------                -------                  ------
-----     ---------
OutlookMapiHttp.Protocol\OutlookMapiHttpSelfTestProbe
2/14/2014 7:15:00 AM   2/14/2014 7:15:10 AM   Succeeded
```

For more information, see Test-OutlookConnectivity.

Logs for MAPI over HTTP activity are at the following locations:

- %ExchangeInstallPath%Logging\MAPI Address Book Service\
- %ExchangeInstallPath%Logging\MAPI Client Access\
- %ExchangeInstallPath%Logging\HttpProxy\Mapi\

Manage MAPI over HTTP

You can manage the configuration of MAPI over HTTP by using the following cmdlets:

- Set-MapiVirtualDirectory
- Get-MapiVirtualDirectory
- New-MapiVirtualDirectory
- Remove-MapiVirtualDirectory

Exchange ActiveSync

Exchange Server 2013 > Clients and mobile >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-11-19*

Exchange ActiveSync is a client protocol that lets you synchronize a mobile device with your Exchange mailbox. Exchange ActiveSync is enabled by default when you install Microsoft Exchange 2013.

Contents

Overview of Exchange ActiveSync

Exchange ActiveSync is a Microsoft Exchange synchronization protocol that's optimized to work together with high-latency and low-bandwidth networks. The protocol, based on HTTP and XML, lets mobile phones access an organization's information on a server that's running Microsoft Exchange. Exchange ActiveSync enables mobile phone users to access their email, calendar, contacts, and tasks, and to continue to access this information while they're working offline.

Important:
Windows Phone 7 mobile phones support only a subset of all Exchange ActiveSync mailbox policy settings. For a complete list, see Windows Phone 7 Synchronization.

Features in Exchange ActiveSync

Exchange ActiveSync provides the following:

- Support for HTML messages
- Support for follow-up flags
- Conversation grouping of email messages
- Ability to synchronize or not synchronize an entire conversation
- Synchronization of Short Message Service (SMS) messages with a user's Exchange mailbox
- Support for viewing message reply status
- Support for fast message retrieval
- Meeting attendee information
- Enhanced Exchange Search
- PIN reset
- Enhanced device security through password policies
- Autodiscover for over-the-air provisioning
- Support for setting automatic replies when users are away, on vacation, or out of the office
- Support for task synchronization

- Direct Push
- Support for availability information for contacts

Managing Exchange ActiveSync

By default, Exchange ActiveSync is enabled. All users who have an Exchange mailbox can synchronize their mobile device with the Microsoft Exchange server.

You can perform the following Exchange ActiveSync tasks:

- Enable and disable Exchange ActiveSync for users
- Set policies such as minimum password length, device locking, and maximum failed password attempts
- Initiate a remote wipe to clear all data from a lost or stolen mobile phone
- Run a variety of reports for viewing or exporting into a variety of formats
- Control which types of mobile devices can synchronize with your organization through device access rules

Security in Exchange ActiveSync

You can configure Exchange ActiveSync to use Secure Sockets Layer (SSL) encryption for communications between the Exchange server and the mobile device.

Managing mobile device access in Exchange ActiveSync

You can control which mobile devices can synchronize. You do this by monitoring new mobile devices as they connect to your organization or by setting up rules that determine which types of mobile devices are allowed to connect. Regardless of the method you choose to specify which mobile devices can synchronize, you can approve or deny access for any specific mobile device for a specific user at any time

Device security features in Exchange ActiveSync

In addition to the ability to configure security options for communications between the Exchange server and your mobile devices, Exchange ActiveSync offers the following features to enhance the security of mobile devices:

- **Remote wipe** If a mobile device is lost, stolen, or otherwise compromised, you can issue a remote wipe command from the Exchange Server computer or from any Web browser by using Outlook Web App. This command erases all data from the mobile device.
- **Device password policies** Exchange ActiveSync lets you configure several options for device passwords.

⚠**Warning:**
The iOS7 fingerprint reader technology cannot be used as a device password. If you choose to

use the iOS7 fingerprint reader, you'll still need to create and enter a device password if the mobile device mailbox policy for your organization requires a device password.

The device password options include the following:

- **Minimum password length (characters)** This option specifies the length of the password for the mobile device. The default length is 4 characters, but as many as 18 can be included.
- **Minimum number of character sets** Use this text box to specify the complexity of the alphanumeric password and force users to use a number of different sets of characters from among the following: lowercase letters, uppercase letters, symbols, and numbers.
- **Require alphanumeric password** This option determines password strength. You can enforce the usage of a character or symbol in the password in addition to numbers.
- **Inactivity time (seconds)** This option determines how long the mobile device must be inactive before the user is prompted for a password to unlock the mobile device.
- **Enforce password history** Select this check box to force the mobile phone to prevent the user from reusing their previous passwords. The number that you set determines the number of past passwords that the user won't be allowed to reuse.
- **Enable password recovery** Select this check box to enable password recovery for the mobile device. Users can use Outlook Web App to look up their recovery password and unlock their mobile device. Administrators can use the Exchange Administration Center to look up a user's recovery password.
- **Wipe device after failed (attempts)** This option lets you specify whether you want the phone's memory to be wiped after multiple failed password attempts.

- **Device encryption policies** There are a number of mobile device encryption policies that you can enforce for a group of users. These policies include the following:
  - **Require encryption on device** Select this check box to require encryption on the mobile device. This increases security by encrypting all information on the mobile device.
  - **Require encryption on storage cards** Select this check box to require encryption on the mobile device's removable storage card. This increases security by encrypting all information on the storage cards for the mobile device.

Windows Phone 7 synchronization

If you have Windows Phone 7 mobile devices in your organization, these devices will experience synchronization problems if certain Mobile Device mailbox policy properties are configured. To allow Windows Phone 7 mobile phones to synchronize with an Exchange mailbox, either set the **AllowNonProvisionableDevices** property to true or configure only the following Mobile Device mailbox policy properties:

- PasswordRequired
- MinPasswordLength
- IdleTimeoutFrequencyValue
- DeviceWipeThreshold
- AllowSimplePassword
- PasswordExpiration

- PasswordHistory
- DisableRemovableStorage
- DisableIrDA
- DisableDesktopSync
- BlockRemoteDesktop
- BlockInternetSharing

Direct Push

Exchange Server 2013 > Clients and mobile > Exchange ActiveSync >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-07-11*

Direct Push is a feature that's built into Microsoft Exchange Server 2013. Direct Push keeps a mobile device current over a cellular or wireless network connection. It notifies the mobile device when new content is ready to be synchronized.

Contents

Overview

For Direct Push to work, the mobile device must be Direct Push capable. These devices include the following:

- All versions of Windows Phone
- Mobile phones that are produced by Microsoft Exchange ActiveSync licensees and are designed specifically to be Direct Push compatible

By default, Direct Push is enabled in Exchange 2013. Mobile devices that support Direct Push issue a long-lived HTTPS request to the server running Microsoft Exchange. The Exchange server monitors activity on the user's mailbox and sends a response to the mobile device if there are any changes, such as new or changed email, calendar, contact, or task items. If changes occur within the lifespan of the HTTPS request, the Exchange server issues a response to the device that states that changes have occurred and the device should initiate synchronization with the Exchange server. The device then issues this request to the server. When synchronization is complete, a new long-lived HTTPS request is generated to start the process again. This guarantees that email, calendar, contact, and task items are delivered quickly to the mobile device, and that it is always synchronized with the Exchange server.

Direct Push topology

Direct Push operates in the following way:

1. A mobile device that's configured to synchronize with an Exchange 2013 server issues an HTTPS request to the server. This request is known as a PING. The request tells the server to notify the device if any items change in the next 15 minutes in any folder that's configured to synchronize. Otherwise, the server should return an HTTP 200 OK message. The mobile device then stands by. The 15-minute time span is known as a *heartbeat interval*.
2. If no items change in 15 minutes, the server returns a response of HTTP 200 OK. The mobile device receives this response, resumes activity (known as *waking up*), and issues its request again. This restarts the process.
3. If any items change or new items are received within the 15-minute heartbeat interval, the server sends a response that informs the mobile device that there's a new or changed item and provides the name of the folder in which the new or changed item resides. After the mobile device receives this response, it issues a synchronization request for the folder that has the new or changed item. When synchronization is complete, the mobile device issues a new PING request and the whole process starts over.

Direct Push depends on network conditions that support a long-standing HTTPS request. If the carrier network for the mobile device or the firewall doesn't support long-standing HTTPS requests, the HTTPS request is stopped. The following steps describe how Direct Push operates when the carrier network for a mobile device has a time-out value of 13 minutes.

1. A mobile device issues an HTTPS request to the server. The request tells the server to notify the device if any items change in the next 15 minutes in any folder that’s configured to synchronize. Otherwise, the server should return an HTTP 200 OK message. The mobile device then stands by.
2. If the server doesn’t respond after 15 minutes, the mobile device wakes up and concludes that the connection to the server was timed out by the network. The device reissues the HTTPS request, but this time it uses a heartbeat interval of 8 minutes.
3. After 8 minutes, the server sends an HTTP 200 OK message. The device then tries to gain a longer connection by issuing a new HTTPS request to the server that has a heartbeat interval of 12 minutes.
4. After 4 minutes, a new email message is received and the server responds by sending an HTTPS request that tells the device to synchronize. The device synchronizes and reissues the HTTPS request that has a heartbeat of 12 minutes.
5. After 12 minutes, if there are no new or changed items, the server responds by sending an HTTP 200 OK message. The device wakes up and concludes that network conditions support a heartbeat interval of 12 minutes. The device then tries to gain a longer connection by reissuing an HTTPS request that has a heartbeat interval of 16 minutes.
6. After 16 minutes, no response is received from the server. The device wakes up and concludes that network conditions cannot support a heartbeat interval of 16 minutes. Because this failure occurred directly after the device tried to increase the heartbeat interval, it concludes that the heartbeat interval has reached its maximum limit. The device then issues an HTTPS request that

has a heartbeat interval of 12 minutes because this was the last successful heartbeat interval.

The mobile device tries to use the longest heartbeat interval the network supports. This extends battery life on the device and reduces how much data is transferred over the network. Mobile carriers can specify a maximum, minimum, and initial heartbeat value in the registry settings for the mobile device.

Configuring Direct Push to work through your firewall

For Direct Push to work through your firewall, you must open TCP port 443. This port is required for Secure Sockets Layer (SSL) and must be opened between the Internet and the Client Access server.

In addition to opening ports on your firewall, for optimal Direct Push performance, you should increase the time-out value on your firewall from the default of 15 minutes to 30 minutes. The maximum length of the HTTPS request is determined by the following settings:

- The maximum time-out value that's set on the firewalls that control the traffic from the Internet to the Client Access server
- The firewall time-out values that are set by the mobile service provider

Mobile device mailbox policies

Exchange Server 2013 > Clients and mobile > Exchange ActiveSync >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-04-14*

In Microsoft Exchange Server 2013, you can create mobile device mailbox policies to apply a common set of policies or security settings to a collection of users. After you deploy Exchange ActiveSync in your Exchange 2013 organization, you can create new mobile device mailbox policies or modify existing policies. When you install Exchange 2013, a default mobile device mailbox policy is created. All users are automatically assigned this default mobile device mailbox policy.

Important:

Windows Phone 7 mobile phones only support a subset of all Exchange ActiveSync mailbox policy settings. For a complete list, see Windows Phone 7 Synchronization.

Warning:

The iOS7 fingerprint reader is not supported as a device password. If you enable the fingerprint reader to secure your iOS7 device, you will still need to create and enter a password if your mobile device mailbox policies require a password.

Overview of mobile device mailbox policies

You can use mobile device mailbox policies to manage many different settings. These include the following:

- Require a password
- Specify the minimum password length
- Require a number or special character in the password
- Designate how long a device can be inactive before requiring the user to re-enter a password
- Wipe a device after a specific number of failed password attempts

For more information about all the settings you can configure, see Mobile device policy settings.

Managing Exchange ActiveSync mailbox policies

Mobile device mailbox policies can be created in the Exchange Administration Center (EAC) or the Exchange Management Shell. If you create a policy in the EAC, you can configure only a subset of the available settings. You can configure the rest of the settings using the Shell.

Windows Phone 7 synchronization

If you have Windows Phone 7 mobile phones in your organization, these phones will experience synchronization problems if certain Exchange ActiveSync mailbox policy properties are configured. To allow Windows Phone 7 mobile phones to synchronize with an Exchange mailbox, either set the **AllowNonProvisionableDevices** property to True or only configure the following Exchange ActiveSync mailbox policy properties:

- PasswordRequired
- MinPasswordLength
- IdleTimeoutFrequencyValue
- DeviceWipeThreshold
- AllowSimplePassword
- PasswordExpiration
- PasswordHistory
- DisableRemovableStorage
- DisableIrDA
- DisableDesktopSync
- BlockRemoteDesktop
- BlockInternetSharing

Mobile device mailbox policy settings

The following table summarizes the settings you can specify using mobile device mailbox policies.

Mobile device mailbox policy settings

Setting	Description

Allow Bluetooth	This setting specifies whether a mobile device allows Bluetooth connections. The available options are Disable, HandsFree Only, and Allow. The default value is Allow. The Exchange Enterprise Client Access License is required to change the values of this setting.
Allow Browser	This setting specifies whether Pocket Internet Explorer is allowed on the mobile device. This setting doesn't affect third-party browsers installed on the mobile device. The default value is `$true`. The Exchange Enterprise Client Access License is required to change the values of this setting.
Allow Camera	This setting specifies whether the mobile device camera can be used. The default value is `$true`. The Exchange Enterprise Client Access License is required to change the values of this setting.
Allow Consumer EMail	This setting specifies whether the mobile device user can configure a personal email account (either POP3 or IMAP4) on the mobile device. The default value is `$true`. This setting doesn’t control access to email accounts that are using third-party mobile device email programs. The Exchange Enterprise Client Access License is required to change the values of this setting.
Allow Desktop Sync	This setting specifies whether the mobile device can synchronize with a computer through a cable, Bluetooth, or IrDA connection. The default value is `$true`. The Exchange Enterprise Client Access License is required to change the values of this setting.

Allow External Device Management	This setting specifies whether an external device management program is allowed to manage the mobile device.
Allow HTML Email	This setting specifies whether email synchronized to the mobile device can be in HTML format. If this setting is set to `$false`, all email is converted to plain text.
Allow Internet Sharing	This setting specifies whether the mobile device can be used as a modem for a desktop or a portable computer. The default value is `$true`. The Exchange Enterprise Client Access License is required to change the values of this setting.
AllowIrDA	This setting specifies whether infrared connections are allowed to and from the mobile device. The Exchange Enterprise Client Access License is required to change the values of this setting.
Allow Mobile OTA Update	This setting specifies whether the mobile device mailbox policy settings can be sent to the mobile device over a cellular data connection. The default value is `$true`.
Allow non-provisionable devices	This setting specifies whether mobile devices that may not support application of all policy settings are allowed to connect to Exchange 2013 by using Exchange ActiveSync. Allowing non-provisionable mobile devices has security implications. For example, some non-provisionable devices may not be able to implement an organization's password requirements.
Allow POPIMAPEmail	This setting specifies whether the user can

	configure a POP3 or an IMAP4 email account on the mobile device. The default value is `$true`. This setting doesn't control access by third-party email programs.
Allow Remote Desktop	This setting specifies whether the mobile device can initiate a remote desktop connection. The default value is `$true`. The Exchange Enterprise Client Access License is required to change the values of this setting.
Allow simple password	This setting enables or disables the ability to use a simple password such as 1111 or 1234. The default value is `$true`.
Allow S/MIME encryption algorithm negotiation	This setting specifies whether the messaging application on the mobile device can negotiate the encryption algorithm if a recipient's certificate doesn't support the specified encryption algorithm.
Allow S/MIME software certificates	This setting specifies whether S/MIME software certificates are allowed on the mobile device.
Allow storage card	This setting specifies whether the mobile device can access information that's stored on a storage card. The Exchange Enterprise Client Access License is required to change the values of this setting.
Allow text messaging	This setting specifies whether text messaging is allowed from the mobile device. The default value is `$true`. The Exchange Enterprise Client Access License is required to change the values of this setting.

Allow unsigned applications	This setting specifies whether unsigned applications can be installed on the mobile device. The default value is `$true`. The Exchange Enterprise Client Access License is required to change the values of this setting.
Allow unsigned installation packages	This setting specifies whether an unsigned installation package can be run on the mobile device. The default value is `$true`. The Exchange Enterprise Client Access License is required to change the values of this setting.
Allow Wi-Fi	This setting specifies whether wireless Internet access is allowed on the mobile device. The default value is `$true`. The Exchange Enterprise Client Access License is required to change the values of this setting.
Alphanumeric password required	This setting requires that a password contains numeric and non-numeric characters. The default value is `$true`.
Approved Application List	This setting stores a list of approved applications that can be run on the mobile device. The Exchange Enterprise Client Access License is required to change the values of this setting.
Attachments enabled	This setting enables attachments to be downloaded to the mobile device. The default value is `$true`.
Device encryption enabled	This setting enables encryption on the mobile device. Not all mobile devices can enforce encryption. For more information, see the device and mobile operating system documentation.

Device policy refresh interval	This setting specifies how often the mobile device mailbox policy is sent from the server to the mobile device.
IRM enabled	This setting specifies whether Information Rights Management (IRM) is enabled on the mobile device.
Max attachment size	This setting controls the maximum size of attachments that can be downloaded to the mobile device. The default value is Unlimited.
Max calendar age filter	This setting specifies the maximum range of calendar days that can be synchronized to the mobile device. The following values are accepted: 1. All 2. OneDay 3. ThreeDays 4. OneWeek 5. TwoWeeks 6. OneMonth
Max email age filter	This setting specifies the maximum number of days of email items to synchronize to the mobile device. The following values are accepted: 1. All 2. OneDay 3. ThreeDays 4. OneWeek 5. TwoWeeks 6. OneMonth
Max email body truncation size	This setting specifies the maximum size at which email messages are truncated when synchronized to the mobile device. The value is in kilobytes (KB).

Max email HTML body truncation size	This setting specifies the maximum size at which HTML email messages are truncated when synchronized to the mobile device. The value is in kilobytes (KB).
Max inactivity time lock	This value specifies the length of time that the mobile device can be inactive before a password is required to reactivate it. You can enter any interval between 30 seconds and 1 hour. The default value is 15 minutes.
Max password failed attempts	This setting specifies the number of attempts a user can make to enter the correct password for the mobile device. You can enter any number from 4 through 16. The default value is 8.
Min password complex characters	This setting specifies the minimum number of complex characters required in the mobile device's password. A complex character is a character that is not a letter.
Min password length	This setting specifies the minimum number of characters in the mobile device password. You can enter any number from 1 through 16. The default value is 4.
Password enabled	This setting enables the mobile device password.
Password expiration	This setting enables the administrator to configure a length of time after which a mobile device password must be changed.
Password history	This setting specifies the number of past passwords that can be stored in a user's mailbox. A user can't reuse a stored password.
Password recovery enabled	When this setting is enabled, the mobile device

	generates a recovery password that's sent to the server. If the user forgets their mobile device password, the recovery password can be used to unlock the mobile device and enable the user to create a new mobile device password.
Require device encryption	This setting specifies whether device encryption is required. If set to `$true`, the mobile device must be able to support and implement encryption to synchronize with the server.
Require encrypted S/MIME messages	This setting specifies whether S/MIME messages must be encrypted. The default value is `$false`.
Require encryption S/MIME algorithm	This setting specifies what required algorithm must be used when encrypting S/MIME messages.
Require manual synchronization while roaming	This setting specifies whether the mobile device must synchronize manually while roaming. Allowing automatic synchronization while roaming will frequently lead to larger-than-expected data costs for the mobile device data plan.
Require signed S/MIME algorithm	This setting specifies what required algorithm must be used when signing a message.
Require signed S/MIME messages	This setting specifies whether the mobile device must send signed S/MIME messages.
Require storage card encryption	This setting specifies whether the storage card must be encrypted. Not all mobile device operating systems support storage card encryption. For more information, see your mobile device and mobile operating system

	documentation.
Unapproved InROM application list	This setting specifies a list of applications that cannot be run in ROM. The Exchange Enterprise Client Access License is required to change the values of this setting.

Add or remove users from a mobile mailbox policy

Clients and mobile > Exchange ActiveSync > Mobile device mailbox policies >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-16*

A mobile device mailbox policy allows you to apply a common set of security and mobile device settings to a group of users. You can create multiple mobile device mailbox policies.

Caution:

When you install Microsoft Exchange Server 2013, a default mobile device mailbox policy is created and all users are automatically assigned this policy.

For additional management tasks related to mobile device mailbox policies, see Mobile device mailbox policies.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mobile Device mailbox policy" entry in the Clients and mobile devices permissions topic.
- You must have one mobile device mailbox policy available in the EAC in **Mobile** > **Mobile Device Mailbox Policies**.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Change a user's mobile device mailbox policy

You can use the EAC or the Shell to change a user's mobile device mailbox policy.

Use the EAC to change a user's mobile device mailbox policy

You change a single user's mobile device mailbox policy using the EAC.

1. In the EAC, click **Recipients** > **Mailboxes** and then select a mailbox.
2. In the Details pane, scroll to **Phone and Voice Features** and select **View details** to display the **Mobile Device Details** screen.
3. The mobile device mailbox policy that's currently assigned is displayed. To change the mobile device mailbox policy, click **Browse**.
4. Choose the appropriate mobile device mailbox policy from the list, click **OK** and then click **Save**.

Use the Shell to add a user to a mobile device mailbox policy

You can change a single user's mobile device mailbox policy using the **Get-CASMailbox** cmdlet in the Shell.

1. In the Shell, run the following command.

```
Get-CASMailbox -Identity tony@contoso.com -
ActiveSyncMailboxPolicy "Sales"
```

How do you know this worked?

To verify that you've successfully changed a user's mobile device mailbox policy, do one of the following:

1. In the EAC, click **Recipients** > **Mailboxes**, and then choose a specific recipient. In the Details pane, scroll down to **Phone and Voice Features** and click **View details**.
2. In the Shell, run the following command.

```
Get-CASMailbox -Identity tony@contoso.com
```

Change the mobile device mailbox policy for multiple users at the same time

If you want to change the mobile device mailbox policy for multiple users at the same time, you can use the bulk edit functionality in the EAC or use the Shell to change the mobile device mailbox policy for a filtered set of users.

Use the bulk edit tool in the EAC to change the mobile device mailbox policy for multiple

users

You can update the mobile device mailbox policy for multiple users at once using the Bulk Edit functionality.

1. In the EAC, click **Recipients** > **Mailboxes**.
2. Select multiple users.
3. In the Details pane, scroll down to **Exchange ActiveSync** and click **Update a policy**.
4. Click **Browse** to choose a mobile device mailbox policy.
5. Click **OK** and then click **Save**.

Use the Shell to change the mobile device mailbox policy for a filtered set of users

You can use the Shell to change the mobile device mailbox policy for a filtered set of users. You can filter users on a variety of attributes.

1. In the Shell, run the following command.

```
Get-Mailbox | where { $_.CustomAttribute1 -match "Manager"
 } | Set-CASMailbox -activesyncmailboxpolicy(Get-
ActiveSyncMailboxPolicy "Contoso").Identity
```

Note:

You can substitute `CustomAttribute1` for any of the properties on the **Get-Mailbox** object. To view the full list, type: `Get-Mailbox username |fl`.

How do you know this worked?

To verify that you've successfully changed a user's mobile device mailbox policy, do one of the following:

1. In the EAC, click **Recipients** > **Mailboxes**, and choose a specific recipient. In the Details pane, scroll down to **Phone and Voice Features** and click **View details**.
2. In the Shell, run the following command.

```
Get-CASMailbox -Identity tony@contoso.com
```

Create or modify a mobile device mailbox policy

Clients and mobile > Exchange ActiveSync > Mobile device mailbox policies >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-16*

A mobile device mailbox policy allows you to apply a common set of security and mobile device settings to a group of users. You can create multiple mobile device mailbox policies. Each recipient in your organization must have a mobile device mailbox policy assigned to them. When you install Microsoft Exchange Server 2013, a default mobile device mailbox policy is created and new users are automatically assigned this policy. To assign specific users to a mobile device mailbox policy, see Add or remove users from a mobile mailbox policy.

For additional information related to mobile device mailbox policies, see Mobile device mailbox policies.

What do you need to know before you begin?

- Estimated time to complete each procedure: 10 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mobile Device mailbox policy" entry in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Create a new mobile device mailbox policy

You can use the EAC or the Shell to create a new mobile device mailbox policy.

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mobile Device mailbox policy" entry in the Clients and mobile devices permissions topic.

Use the EAC to create a new mobile device mailbox policy

You can create a new mobile device mailbox policy using the EAC.

Note:

You can only set a subset of mobile device mailbox policy settings in the EAC. To set all the mobile device mailbox policy settings, you need to use the Shell.

1. In the EAC, click **Mobile** > **Mobile Device Mailbox Policies**, and then click **New**.
2. Use the various check boxes and drop-down lists to configure the settings for the mobile device mailbox policy.

Warning:

Select **This is the default policy** to make the new mobile mailbox policy the default mobile

mailbox policy. After you make a mobile mailbox policy the default policy, all new users will be assigned this policy automatically when they are created.

3. Click **Save**.

Use the Shell to create a new mobile device mailbox policy

You create a new mobile device mailbox policy using the **New-MobileDeviceMailboxPolicy** cmdlet.

⚠Warning:

There are two cmdlets that can be used to create a new mobile device mailbox policy. The **New-ActiveSyncMailboxPolicy** cmdlet and the **New-MobileDeviceMailboxPolicy** cmdlets perform identical tasks. In a future version of Microsoft Exchange Server, the **New-ActiveSyncMailboxPolicy** cmdlet will be removed. We recommend that you update your scripts and procedures to use the **New-MobileDeviceMailboxPolicy** cmdlet.

1. In the Shell, run the following command.

```
New-MobileDeviceMailboxPolicy -Name:"Management" -
AllowBluetooth:$true -AllowBrowser:$true -AllowCamera:$true
-AllowPOPIMAPEmail:$false -PasswordEnabled:$true -
AlphanumericPasswordRequired:$true -
PasswordRecoveryEnabled:$true -MaxEmailAgeFilter:10 -
AllowWiFi:$true -AllowStorageCard:$true -
AllowPOPIMAPEmail:$false
```

How do you know this worked?

To verify that you've successfully created a mobile device mailbox policy, use one of the following options:

1. In the EAC, click **Mobile** > **Mobile Device mailbox policies**, and verify that your new policy is displayed in the List view.
2. In the Shell, run the following command.

```
Get-MobileDeviceMailboxPolicy -Identity <PolicyName>
```

Edit an existing mobile device mailbox policy

If you want to edit a mobile device mailbox policy, you can use the EAC or the Shell.

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mobile Device mailbox policy" entry in the Clients and mobile devices permissions topic.

Use the EAC to edit a mobile device mailbox policy

You can edit a mobile device mailbox policy using the EAC.

Note:
You can only edit a subset of mobile device mailbox policy settings in the EAC. To edit all the mobile device mailbox policy settings, you need to use the Shell.

1. In the EAC, click **Mobile** > **Mobile Device Mailbox Policies**.
2. Select a policy from the List view and click the **Edit** button.
3. Use the **General** and **Security** tabs to edit the mobile device mailbox policy settings.
4. Click **Save** to update the policy.

Use the Shell to edit mobile device mailbox policy settings

You can use the Shell to edit a mobile device mailbox policy.

Warning:
There are two cmdlets that can be used to edit a mobile device mailbox policy. The **Set-ActiveSyncMailboxPolicy** cmdlet and the **Set-MobileDeviceMailboxPolicy** cmdlets perform identical tasks. In a future version of Microsoft Exchange Server, the **Set-ActiveSyncMailboxPolicy** cmdlet will be removed. We recommend that you update your scripts and procedures to use the **Set-MobileDeviceMailboxPolicy** cmdlet.

1. In the Shell, run the following command.

```
Set-MobileDeviceMailboxPolicy -Identity:Default -
DevicePasswordEnabled:$true -
AlphanumericDevicePasswordRequired:$true -
PasswordRecoveryEnabled:$true -MaxEmailAgeFilter:ThreeDays
-AllowWiFi:$false -AllowStorageCard:$true -
AllowPOPIMAPEmail:$false -IsDefault:$true -
AllowTextMessaging:$true -Confirm:$true
```

How do you know this worked?

To verify that you've successfully edited a mobile device mailbox policy, do one of the following:

1. In the EAC, click **Mobile** > **Mobile Device Mailbox Policy**, and then choose a specific policy. In the Details pane, you'll see a number of the policy settings listed.
2. In the Shell, run the following command.

```
Get-MobileDeviceMailboxPolicy -Identity <PolicyName>
```

Supported mobile device mailbox policies for Windows Phones and

devices

Topic Last Modified: *2013-02-19*

With the release of Windows Phone 8, Windows 8, and Windows RT, there are a number of devices that support Exchange ActiveSync and mobile device mailbox policies. Each device operating system supports a specific set of mobile device mailbox policy settings.

Windows client and Exchange Server compatibility matrix

The following tables list the compatible mobile device mailbox policy parameters for the various versions of Windows Phone, Windows 8, Windows RT, and Exchange server.

Windows Phone 7 supported policy parameters

The following table lists the mobile device mailbox policy settings for Windows Phone 7.

Exchange 2007	Exchange 2010	Exchange 2013
DevicePasswordEnabled	DevicePasswordEnabled	DevicePasswordEnabled
AllowSimpleDevicePassword	AllowSimpleDevicePassword	AllowSimpleDevicePassword
AllowIRDA	AllowIRDA	AllowIRDA
MinPasswordLength	MinDevicePasswordLength	MinDevicePasswordLength
PasswordExpiration	DevicePasswordExpiration	DevicePasswordExpiration
AllowDesktopSync	AllowDesktopSync	AllowDesktopSync
MaxInactivityTimeDeviceLock	MaxInactivityTimeDeviceLock	MaxInactivityTimeDeviceLock
DevicePasswordHistory	DevicePasswordHistory	DevicePasswordHistory
AllowRemoteDesktop	AllowRemoteDesktop	AllowRemoteDesktop
AllowStorageCard	AllowStorageCard	AllowStorageCard
AllowInternetSharing	AllowInternetSharing	AllowInternetSharing
AllowNonProvisionableDevices	AllowNonProvisionableDevices	AllowNonProvisionableDevices

Windows Phone 8 supported policy parameters

The following table lists the mobile device mailbox policy settings for Windows Phone 8.

Exchange 2007	Exchange 2010	Exchange 2013
DevicePasswordEnabled	DevicePasswordEnabled	DevicePasswordEnabled
AllowSimpleDevicePassword	AllowSimpleDevicePassword	AllowSimpleDevicePassword
AlphanumericDevicePasswordRequired	AlphanumericDevicePasswordRequired	AlphanumericDevicePasswordRequired
MinDevicePasswordLength	MinDevicePasswordLength	MinDevicePasswordLength
MinDevicePasswordComplexCharacters	MinDevicePasswordComplexCharacters	MinDevicePasswordComplexCharacters
RequireDeviceEncryption	RequireDeviceEncryption	RequireDeviceEncryption

Mobile devices

Exchange Server 2013 > Clients and mobile > Exchange ActiveSync >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-24*

Mobile devices that are enabled for Microsoft Exchange ActiveSync let users access most of their Microsoft Exchange mailbox data any time, anywhere. There are many different mobile phones and devices enabled for Exchange ActiveSync. These include Windows Phones, Nokia mobile phones, Android phones and tablets, and the Apple iPhone, iPod, and iPad.

Although both phone and non-phone mobile devices support Exchange ActiveSync, in most Exchange ActiveSync documentation, we use the term *mobile device*. Unless the feature or features we're discussing require a cellular telephone signal, such as SMS message notification, the term mobile device applies to both mobile phones and other mobile devices such as tablets.

Exchange ActiveSync

Exchange ActiveSync is a communications protocol that enables mobile access, over the air, to email messages, scheduling data, contacts, and tasks. Exchange ActiveSync is available on Windows Phones and third-party phones that are enabled for Exchange ActiveSync.

Exchange ActiveSync offers Direct Push technology. Direct Push uses an encrypted HTTPS connection that's established and maintained between the mobile device and the server to push new email messages and other Exchange data to the phone.

To use Direct Push with Microsoft Exchange Server 2013, your users must have a mobile device that's designed to support Direct Push.

Exchange ActiveSync features

Exchange ActiveSync provides access to many different features that enable you to enforce security policies on mobile devices. By using Exchange 2013, you can configure multiple mobile device mailbox policies and control which mobile devices can synchronize with your Exchange server. Exchange ActiveSync enables you to send a remote device wipe command that wipes all data from a mobile device in case that mobile device is lost or stolen. Users can also initiate a remote device wipe from Outlook Web App.

Exchange ActiveSync allows users to generate a recovery password. This recovery password is saved on the mobile device and is used when a user forgets their password. The user generates the recovery password at the same time that they generate the device password or PIN. This recovery password can be used to unlock the mobile device. Immediately after this recovery password is used, the user will be required to create a new PIN.

POP3 and IMAP4

If your mobile device doesn’t support Exchange ActiveSync, or you don’t need the rich feature set

that Exchange ActiveSync provides, you can use POP3 or IMAP4 to access your email on your mobile device. For more information about POP3 and IMAP4 access to your mailbox, see POP3 and IMAP4.

Remote device wipe

Clients and mobile > Exchange ActiveSync > Mobile devices >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-19*

Mobile phones, tablets, and other devices can store sensitive corporate data and provide access to many corporate resources. If a mobile device is lost or stolen, that data can be compromised. Through Microsoft Exchange mobile device mailbox policies, you can add a password requirement to your mobile devices. This requires users to enter a password to access their mobile devices. We recommend that, in addition to requiring a device password, you configure your mobile devices to automatically prompt for a password after a period of inactivity. The combination of a device password and inactivity locking provides enhanced security for your corporate data.

In addition to these features, Exchange Server 2013 provides a remote device wipe feature. You can issue a remote device wipe command from the Exchange Management Shell or the Exchange Administration Center (EAC). Users can issue their own remote device wipe commands from the Microsoft Outlook Web App user interface.

The remote device wipe feature also includes a confirmation function that writes a time stamp in the sync state data of the user's mailbox. This time stamp is displayed in Outlook Web App and in the user's mobile phone properties dialog box in the EAC.

Important:

A remote device wipe can reset a mobile phone to the factory default condition. Although the remote device wipe protocol as implemented in Exchange 2013 only requires the deletion of personal corporate data, all current mobile device manufacturers interpret the command as one that wipes all data on the phone. Many mobile device operating systems also wipe all data on any storage card that's inserted in the mobile device. If you're performing a remote device wipe on a mobile phone in your possession and want to keep the data on the storage card, we recommend removing the storage card before you initiate the remote device wipe.

Caution:

After a remote device wipe has occurred, data recovery is very difficult. However, no data removal process leaves a mobile device as free from residual data as when it's new. Recovery of data from a mobile device may still be possible using sophisticated tools.

Remote device wipe vs. local device wipe

Local device wipe occurs when a mobile device wipes itself without the request coming from the server. If your organization has implemented mobile device mailbox policies that specify a maximum number of unsuccessful password attempts and that maximum is exceeded, the mobile device performs a local device wipe. The result of a local device wipe is the same as that of a remote device wipe. The device is returned to its factory default condition. When a mobile device performs a local device wipe, no confirmation is sent to the Exchange server.

View mobile device information for users

Clients and mobile > Exchange ActiveSync > Mobile devices >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-11-29*

Users can configure multiple mobile devices for synchronization with Microsoft Exchange Server 2013. You can use the EAC or the Shell to view a list of mobile devices that are associated with a specific user.

For additional management tasks related to mobile devices, see Exchange ActiveSync.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mobile Device mailbox policy" entry in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to view mobile device information for users

The EAC displays a list of mobile devices that are currently synchronizing with a user's mailbox. You can view mobile devices by family, model, phone number, or status.

1. In the EAC, click **Recipients** > **Mailboxes** and choose a mailbox.
2. In the Details pane, scroll to **Phone and Voice Features** and click **View details** to display the **Mobile Device Details** screen.

Use the Shell to view mobile device information for users

You can use the **Get-MobileDevice** cmdlet to view a list of mobile devices for a specific user.

1. Run the following command.

```
Get-MobileDevice -Mailbox useralias
```

Mobile phone and tablet features

Clients and mobile > Exchange ActiveSync > Mobile devices >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-12-07*

Users can access their email, calendar, contacts, and task information on mobile phones, tablets, and other portable devices through Microsoft Exchange ActiveSync. They can also use it to set up their signature and automatic replies. A wide variety of mobile phones and devices work with Exchange ActiveSync.

Note:

Although we consistently refer to devices that access Exchange Server 2013 as mobile phones, there are many devices that can access Exchange 2013 but don't have cellular phone functionality. The term "mobile phone" in this documentation refers to those devices, as well.

Exchange ActiveSync-compatible devices

Users can take advantage of the rich features of Exchange ActiveSync by selecting mobile phones that are compatible with Exchange ActiveSync. These mobile phones are available from many manufacturers and on many carriers. For more information, see the specific mobile phone documentation.

Mobile phones that are compatible with Microsoft Exchange include the following:

- **Apple** The Apple iPhone, iPod Touch, and iPad all support Exchange ActiveSync.
- **Windows Phone** Windows Phone 8, Windows Phone 7, and previous versions all support Exchange ActiveSync.
- **Android** Many mobile phones and tablets with the Android operating system support Exchange ActiveSync. However, these mobile devices may not support all available mobile device mailbox policies. For more information, see Mobile device mailbox policies.

Windows Phone software features

Mobile phones that have a version of Windows Phone software as their operating system offer the greatest functionality when synchronizing with Exchange 2013. The following table lists the mobile device mailbox policies that are available with Windows Phone 8 and Windows Phone 7.

Windows Phone 7 and 8 features

Operating system	Features
Windows Phone 8	Windows Phone 8 supports the following mobile device mailbox policies: • Allow simple device password • Alphanumeric password required • Device password enabled • Device password expiration • IRM enabled • Maximum device password failed attempts • Maximum inactivity device time lock • Minimum device password complex characters • Minimum device password length • Require device encryption • Remote wipe **⚠Warning:** If your organization uses other mobile device mailbox policy settings, you'll need to set the **Allow non-provisionable devices** policy to true. This can have security implications for your organization, because other mobile phones and devices that don't meet all the requirements of your mobile device policy settings will be allowed to synchronize. For more information, see Mobile device mailbox policies.
Windows Phone 7	Windows Phone 7 mobile phones support only a subset of all Exchange ActiveSync mailbox policy settings: • Password required • Minimum password length • Maximum inactivity time lock

	• Maximum device password failed attempts • Allow simple password • Password expiration • Password history • Disable removable storage • Disable IrDA • Disable desktop sync • Block remote desktop • Block Internet sharing

Perform a remote wipe on a mobile phone

Clients and mobile > Exchange ActiveSync > Mobile devices >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-06*

Your users carry sensitive corporate information in their pockets every day. If one of them loses their mobile phone, your data can end up in the hands of another person. If one of your users loses their mobile phone, you can use the Exchange Administration Center (EAC) or the Exchange Management Shell to wipe their phone clean of all corporate and user information.

Note:

This topic also provides instructions for how to use Microsoft Outlook Web App to perform a remote wipe on a phone. The user must be signed in to Outlook Web App to perform a remote wipe.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mobile devices" entry in the Clients and mobile devices permissions topic.
- This procedure will clear all data on the mobile phone, including installed applications, photos, and personal information.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to wipe a user's phone

You can use the EAC to wipe a user's phone or cancel a remote wipe that has not yet completed.

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. Select the user, and under **Mobile Devices**, choose **View details**.
3. On the **Mobile Device Details** page, select the lost mobile device, and then select **Wipe Data**.
4. Select **Save**.

Use the Shell to wipe a user's phone

You can use the **Clear-MobileDevice** cmdlet in the Shell to wipe a user's phone.

The following command wipes the device named WM_TonySmith and sends a confirmation message to admin@contoso.com.

```
Clear-MobileDevice -Identity WM_TonySmith -
NotificationEmailAddresses "admin@contoso.com"
```

Use Outlook Web App to wipe a user's phone

Your users can wipe their own phone using Outlook Web App.

1. In Outlook Web App, select **Settings** > **Phone** > **Mobile devices**.
2. Select the mobile phone.
3. Click or tap the **Wipe Device** icon.

How do you know this worked?

There are several ways to verify that the remote wipe completed.

- Run the **Clear-MobileDevice** cmdlet with the *–NotificationEmailAddresses* parameter configured. A message will be sent to the supplied email address when the remote wipe has completed.
- In the EAC, check the status of the mobile device. The status will change from **Wipe Pending** to **Wipe Successful**.
- In Outlook Web App, check the status of the mobile device. The status will change from **Wipe Pending** to **Wipe Successful**.

Configure mobile phones to access email

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-19*

You can configure a mobile phone, such as a Windows Phone, to use Microsoft Exchange ActiveSync. You should perform this procedure on each mobile phone in your organization.

Prerequisites

- You've reviewed the manufacturer's documentation for the mobile phone you want to configure.
- Exchange ActiveSync is enabled in your organization.

Configure a mobile phone to use Exchange ActiveSync

Most mobile phones and devices are capable of using Autodiscover to configure the mobile email client to use Exchange ActiveSync. To configure an email account on most mobile phones, you'll need two pieces of information.

- The user's email address
- The user's password

If Autodiscover can't contact the Exchange server, you'll need to set up the mobile phone manually. Manual setup requires the user's email address and password as well as the Exchange ActiveSync server name. In most organizations, the Exchange ActiveSync server name is the same as the Outlook Web App server name without the /owa, for example, mail.contoso.com.

Windows Phone synchronization

If you're configuring a Windows Phone mobile phone to synchronize with an Exchange mailbox using Exchange ActiveSync, only a subset of mobile device mailbox policy settings are supported. Those policy settings are detailed in Supported mobile device mailbox policies for Windows Phones and devices.

If you configure mobile device mailbox policy settings that are not supported for the version of Windows Phone you're using, you must also set the **AllowNonProvisionableDevices** policy setting to true or create a separate mobile device mailbox policy for Windows Phone mobile phones.

POP3 and IMAP4

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-04-21*

By default, POP3 and IMAP4 are disabled in Microsoft Exchange Server 2013. To support POP3 clients that still rely on these protocols, you need to start two POP3 services: the Microsoft Exchange POP3 service and the Microsoft Exchange POP3 Backend service. To support IMAP4 clients that still rely on these protocols, you need to start two IMAP4 services: the Microsoft Exchange IMAP4 service and the Microsoft Exchange IMAP4 Backend service.

For detailed steps for enabling the POP3 and IMAP4 services, see Enable POP3 in Exchange 2013 and Enable IMAP4 in Exchange 2013.

By default, users who have mailboxes on computers that are running Exchange 2013 can access their mailboxes by using Microsoft Outlook or Outlook Web App, Microsoft Exchange ActiveSync, or Outlook Voice Access. Outlook, Outlook Web App, and Outlook Voice Access enable your email users to use the comprehensive set of features that are available to users who have mailboxes on Exchange 2013 servers.

Contents

Overview of POP3 and IMAP4 functionality

This section describes the POP3 and IMAP4 functionality for Exchange 2013.

The POP3 and IMAP4 protocols have the following benefits and limitations:

- **POP3** POP3 was designed to support offline mail processing. With POP3, email messages are removed from the server and stored on the local POP3 client unless the client has been set to leave mail on the server. This puts the data management and security responsibility in the hands of the user. POP3 doesn't offer advanced collaboration features such as calendaring, contacts, and tasks.

- **IMAP4** IMAP4 offers offline and online access but, like POP3, IMAP4 doesn't offer advanced collaboration features such as calendaring, contacts, and tasks.

POP3 and IMAP4 email applications don’t use POP3 and IMAP4 to send messages to the email server. Email applications that use POP3 and IMAP4 rely on the SMTP protocol to send messages. The connector for receiving email submissions from client applications that use POP3 or IMAP4 is created automatically upon installation of Exchange. For more information about connectors, see Receive connectors.

Note:
Each time a user uses a POP or IMAP based email program to open their Office 365 email, they will experience a delay of several seconds. The delay is due using a proxy server, which introduces an additional hop for authentication. The proxy server first looks up the assigned pod server (client access server), and then authenticates against that.

POP3 and IMAP4 cross-site connectivity

In earlier versions of Exchange, you had to perform a manual configuration step to allow your POP3 and IMAP4 clients to connect to their mail from one site in your organization when their mailbox was located in a different site in your organization. By default, Exchange 2013 automatically proxies from a Client Access server in one site to the correct server.

Using non-standard accounts with POP3 and IMAP4

You can't use an Anonymous account or Guest account to sign in to an Exchange 2013 mailbox through POP3 or IMAP4. This kind of access is blocked because of security vulnerabilities when you use non-standard accounts for POP3 and IMAP4 access. Additionally, you can't connect to the Administrator mailbox through POP3 or IMAP4. This limitation was included intentionally in Exchange 2013 to enhance security for the Administrator mailbox. To access the Administrator mailbox, you must use Microsoft Office Outlook or Outlook Web App.

Understanding differences between POP3 and IMAP4

POP3 is a frequently used email Internet protocol. By default, when POP3 email applications download email messages to a client computer, the downloaded messages are removed from the server. When a copy of your user's email isn't kept on the email server, the user can't access the same email messages from multiple computers. However, some POP3 email applications can be configured to keep copies of the messages on the server so that the same email messages can be accessed from another computer. POP3 client applications can only be used to download messages from the email server to a single folder (usually the Inbox) on the client computer. The POP3 protocol can't synchronize multiple folders on the email server with multiple folders on the client computer.

Email client applications that use IMAP4 are more flexible and generally offer more features than

email client applications that use POP3. By default, when IMAP4 email applications download email messages to a client computer, a copy of downloaded messages remains on the email server. Because a copy of the user's email message is kept on the email server, the user can access the same email message from multiple computers. With IMAP4 email, the user can access and create multiple email folders on the email server. Users can then access any of their messages on the server from computers in multiple locations. For example, most IMAP4 applications can be configured to keep a copy of a user's sent items on the server so that they can view their sent items from any other computer. IMAP4 supports additional features that are supported by most IMAP4 applications. For example, some IMAP4 applications include a feature that lets the user view only the headers of their email messages on the server—who the message is from and the subject—and then download only the messages that they want to read.

Note:

IMAP4 and POP3 clients have limited access to calendar information for Exchange. For more information, see Configure calendar options for POP3 and Configure calendar options for IMAP4.

Send and receive options for POP3 and IMAP4 email applications

POP3 and IMAP4 email applications let users choose when they want to connect to the server to send and receive email. This section discusses some of the most common connectivity options and also provides some factors your users should consider when they select connection options available in their POP3 and IMAP4 email applications.

Common configuration settings

Three of the most common connection settings that can be set on the POP3 or IMAP4 client application are:

- To send and receive messages every time the email application is started. When this option is used, mail is only sent and received upon starting the email application.
- To send and receive messages manually. When this option is used, messages are only sent and received when the user clicks a "send and receive" option in the client user interface.
- To send and receive messages every set number of minutes. When this option is used, the client application connects to the server every set number of minutes to send messages and download any new messages.

For information about how to configure these settings for the email application that you use, see the Help documentation that's provided with the respective email application.

Considerations when selecting send/receive options

If the device or computer that's running the POP3 or IMAP4 email application is always connected to the Internet, users may want to configure their email application to send and receive messages every set number of minutes. Connecting to the server at frequent intervals lets the user keep their email application up-to-date with the most current information on the server. However, if the device or computer that's running the POP3 or IMAP4 email application isn't always connected to the Internet (for example, if the user connects to the Internet by using a dial-up connection), the user may want to configure the email application to send and receive messages manually. In a dial-up connectivity scenario, sending and receiving messages manually can potentially reduce the time that a user is connected to the Internet.

Note:

If the user is using an IMAP4-compliant email application that supports the IMAP4 IDLE command, the user may be able to send email to and receive email from their Exchange mailbox in near real time. For this connection method to work, both the email server application and the client application must support the IMAP4 IDLE command. In most cases, users don't have to configure any settings in their IMAP4 application to use this connection method.

POP3 and IMAP4 applications

Because Exchange 2013 supports POP3 and IMAP4, users can use any applications that support POP3 and IMAP4 client applications to connect to Exchange 2013. These applications include Outlook, Windows Live Mail, Microsoft Outlook Express, Entourage, and many third-party applications such as Mozilla Thunderbird and Eudora. The features supported by each email client applications vary. For information about the specific features offered by specific POP3 and IMAP4 client applications, see the documentation that's included with each application.

User settings to configure POP3 or IMAP4 access to their Exchange 2013 mailboxes

After you enable POP3 and IMAP4 client access, you have to give users the information they need to connect their email programs to their Exchange 2013 mailbox. They'll need the following information:

To connect from inside the corporate network, users will need the following information:

- Internal POP3 or IMAP4 server name
- Internal POP3 or IMAP4 port number
- Internal POP3 or IMAP4 encryption method
- Internal SMTP (outgoing server) name
- Internal SMTP (outgoing server) port number
- Internal SMTP (outgoing server) encryption method

To connect from the Internet, they'll need the following information:

- External POP3 or IMAP4 server name
- External POP3 or IMAP4 port number
- External POP3 or IMAP4 encryption method
- External SMTP (outgoing server) name
- External SMTP (outgoing server) port number
- External SMTP (outgoing server) encryption method

You can make these settings available to your users through email or other manual communication methods. You can also configure Exchange so that your users can use Outlook Web App to look up their own settings.

Configuring Exchange so users can look up their POP3, IMAP4, and SMTP server settings

By default, users can't look up their POP3, IMAP4, and SMTP server settings through Outlook Web App. To allow your users to look up their POP3 and IMAP4 server settings through Outlook Web App, you need to use the **Set-PopSettings** and **Set-ImapSettings** cmdlets. To allow your users to look up their SMTP (outgoing) server settings, you must use the **Set-ReceiveConnector** cmdlet.

Do the following to allow users to look up their own POP3, IMAP4, and SMTP settings

- POP3 settings Run the **Set-POPSettings** cmdlet with the *ExternalConnectionSettings* parameter. Use the format `Set-POPSettings -ExternalConnectionSetting {<FQDN>:995:SSL}`. For example, run `Set-PopSettings -ExternalConnectionSetting {Dublin01.Contoso.com:995:SSL}` if you want clients that connect through the server with FQDN Dublin01.Contoso.com to be able to look up their own POP settings.

You must restart IIS after applying this setting.

- IMAP4 settings Run the **Set-IMAPSettings** cmdlet with the *ExternalConnectionSettings* parameter. Use the format `Set-ImapSettings -ExternalConnectionSetting {<FQDN>:993:SSL}`. For example, run `Set-IMAPSettings -ExternalConnectionSetting {Dublin01.Contoso.com:993:SSL}` if you want clients that connect through the server with FQDN Dublin01.Contoso.com to be able to look up their own IMAP setting.

You must restart IIS after applying this setting.

- SMTP settings Run the **Set-ReceiveConnector** cmdlet with the *AdvertiseClientSettings* parameter. Use the format `Set-ReceiveConnector "Client Frontend <Server Name>" -AdvertiseClientSettings $True -FQDN <FQDN>`. For example, run `Set-ReceiveConnector "Client Frontend <Server Name>" -AdvertiseClientSettings $True -FQDN Dublin01.Contoso.com` if you want clients that connect through the server with FQDN Dublin01.Contoso.com to be able to look up their own SMTP setting.

You must restart IIS after applying this setting.

After you change your default settings by running the **Set-POPSettings**, **Set-IMAPSettings**, and **Set-ReceiveConnector** cmdlets, your users can look up their external POP, IMAP, and SMTP server settings in Outlook Web App by clicking **Settings** > **Options** > **Account** > **My account** > **Settings for POP or IMAP access**.

Leaving a copy of messages on the server

The default setting on some email programs isn't to keep a copy of messages on the server after they're retrieved. Be sure to recommend that your users set up their email program to keep a copy of all messages the client retrieves on the server. By keeping a copy of messages on the server, your users can access their messages from a different email program.

Start and stop the POP3 services

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-03-13*

By default, the two POP3 services, the Microsoft Exchange POP3 service and the Microsoft Exchange POP3 Backend service, aren't started on computers running Microsoft Exchange Server 2013. You must start these two services to allow your email clients to connect to Exchange using POP3. When these services are running, Exchange 2013 accepts unsecured POP3 client communications on port 110 and over port 995 using Secure Sockets Layer (SSL).

The Microsoft Exchange POP3 service runs on Exchange 2013 computers that are running the Client Access server role. The Microsoft Exchange POP3 Backend service runs on the Exchange 2013 computer that's running the Mailbox server role. In environments where the Client Access and Mailbox roles are running on the same computer, you manage both services on the same computer.

For additional information related to POP3 and IMAP4, see POP3 and IMAP4.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "POP3 and IMAP4 Permissions" section in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the Microsoft Management Console Services snap-in

to start or stop the POP3 services

To start the POP3 services:

1. On the computer running the Client Access server role, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Services**. Right-click **Microsoft Exchange POP3**, and then click **Start**.
2. On the computer running the Mailbox server role, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Services**. In the result pane, right-click **Microsoft Exchange POP3 Backend**, and then click **Start**.

To stop the POP3 services:

1. On the computer running the Client Access server role, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Services**. Right-click **Microsoft Exchange POP3**, and then click **Stop**.
2. On the computer running the Mailbox server role, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Services**. Right-click **Microsoft Exchange POP3 Backend**, and then click **Stop**.

Use the Shell to start or stop the POP3 services

To start the POP3 services:

1. On the computer running the Client Access server role, from the Shell, run the following command to start the Microsoft Exchange POP3 service.

```
Start-service MSExchangePOP3
```

2. On the computer running the Mailbox server role, from the Shell, run the following command to start the Microsoft Exchange POP3 Backend service.

```
Start-service MSExchangePOP3BE
```

To stop the POP3 services:

1. On the computer running the Client Access server role, from the Shell, run the following command to stop the Microsoft Exchange POP3 service.

```
Stop-service MSExchangePOP3
```

2. On the computer running the Mailbox server role, from the Shell, run the following command to stop the Microsoft Exchange POP3 Backend service.

```
Stop-service MSExchangePOP3BE
```

Use net start to start or stop the POP3 services

To start the POP3 services:

1. On the computer running the Client Access server role, at the command prompt, run the following command to start the Microsoft Exchange POP3 service.

```
Net Start msExchangePOP3
```

2. On the computer running the Mailbox server role, at the command prompt, run the following command to start the Microsoft Exchange POP3 Backend service.

```
Net Start msExchangePOP3BE
```

To stop the POP3 services:

1. On the computer running the Client Access server role, at the command prompt, run the following command to stop the Microsoft Exchange POP3 service.

```
Net Stop MSExchangePOP3
```

2. On the computer running the Mailbox server role, at the command prompt, run the following command to stop the Microsoft Exchange POP3 Backend service.

```
Net Stop MSExchangePOP3BE
```

How do you know this worked?

1. On the Exchange Client Access server, open Windows Task Manager. On the **Services** tab, the status for **MSExchangePOP3** will show as **Running** if the Microsoft Exchange POP3 service is running.
2. On the Exchange Mailbox server, open Windows Task Manager. On the **Services** tab, the status for **MSExchangePOP3BE** will show as **Running** if the Microsoft Exchange POP3 Backend service is running.

Start and stop the IMAP4 services

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-05*

By default, the two IMAP4 services, the Microsoft Exchange IMAP4 service and the Microsoft Exchange IMAP4 Backend service, aren't started on computers running Microsoft Exchange Server 2013. You must start these two services to allow your email clients to connect to Exchange using IMAP4. When these services are running, Exchange 2013 accepts unsecured IMAP4 client communications on port 143 and over port 993 using Secure Sockets Layer (SSL).

The Microsoft Exchange IMAP4 service runs on Exchange 2013 computers that are running the Client Access server role. The Microsoft Exchange IMAP4 Backend service runs on the Exchange 2013 computer that's running the Mailbox server role. In environments where the Client Access and Mailbox server roles are running on the same computer, you manage both services on the same computer.

For additional information related to POP3 and IMAP4, see POP3 and IMAP4.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "POP3 and IMAP4 Permissions" section in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

What do you want to do?

Use the Microsoft Management Console Services snap-in to start or stop the IMAP4 services

To start the IMAP4 services:

1. On the computer running the Client Access server role, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Services**. Right-click **Microsoft Exchange IMAP4**, and then click **Start**.
2. On the computer running the Mailbox server role, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Services**. Right-click **Microsoft Exchange IMAP4 Backend**, and then click **Start**.

To stop the IMAP4 services:

1. On the computer running the Client Access server role, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Services**. Right-click **Microsoft Exchange IMAP4**, and then click **Stop**.
2. On the computer running the Mailbox server role, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Services**. Right-click **Microsoft Exchange IMAP4 Backend**, and then click **Stop**.

Use the Shell to start or stop the IMAP4 services

To start the IMAP4 services:

1. On the computer running the Client Access server role, from the Shell, run the following command to start the Microsoft Exchange IMAP4 service.

```
Start-service msExchangeIMAP4
```

2. On the computer running the Mailbox server role, from the Shell, run the following command to start the Microsoft Exchange IMAP4 Backend service.

```
Start-service msExchangeIMAP4BE
```

To stop the IMAP4 services:

1. On the computer running the Client Access server role, from the Shell, run the following command to stop the Microsoft Exchange IMAP4 service.

```
Stop-service msExchangeIMAP4
```

2. On the computer running the Mailbox server role, from the Shell, run the following command to stop the Microsoft Exchange IMAP4 Backend service.

```
Stop-service msExchangeIMAP4BE
```

Use net start to start or stop the IMAP4 services

To start the IMAP4 services:

1. On the computer running the Client Access server role, at the command prompt, run the following command to start the Microsoft Exchange IMAP4 service.

```
net start msExchangeIMAP4
```

2. On the computer running the Mailbox server role, at the command prompt, run the following command to start the Microsoft Exchange IMAP4 Backend service.

```
net start msExchangeIMAP4BE
```

To stop the IMAP4 services:

1. On the computer running the Client Access server role, at the command prompt, run the following command to stop the Microsoft Exchange IMAP4 service.

```
Net Stop MSExchangeIMAP4
```

2. On the computer running the Mailbox server role, at the command prompt, run the following command to stop the Microsoft Exchange IMAP4 Backend service.

```
Net Stop MSExchangeIMAP4BE
```

How do you know this worked?

1. On the Exchange Client Access server, open Windows Task Manager. On the **Services** tab, the status for **MSExchangeIMAP4** will show as **Running** if the Microsoft Exchange IMAP4 service is running.
2. On the Exchange Mailbox server, open Windows Task Manager. On the **Services** tab, the status for **MSExchangeIMAP4BE** will show as **Running** if the Microsoft Exchange IMAP4 Backend service is running.

Enable POP3 in Exchange 2013

Exchange Server 2013 > Clients and mobile > POP3 and IMAP4 >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-03-13*

When you install Microsoft Exchange Server 2013, POP3 client connectivity isn't enabled. To enable POP3 client connectivity, you need to start two POP3 services, the Microsoft Exchange POP3 service and the Microsoft Exchange POP3 Backend service. When you enable POP3, Exchange 2013 accepts unsecured POP3 client communications on port 110 and over port 995 using Secure Sockets Layer (SSL).

The Microsoft Exchange POP3 service runs on Exchange 2013 computers that are running the Client Access server role. The Microsoft Exchange POP3 Backend service runs on the Exchange 2013 computer that's running the Mailbox server role. In environments with the Client Access and Mailbox roles on the same computer, you manage both services on the same computer.

For more information related to setting up POP3 and IMAP4, see POP3 and IMAP4.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "POP3 and IMAP4 Permissions" section in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the Microsoft Management Console Services snap-in to enable POP3

On the computer running the Client Access server role:

1. In the **Services** snap-in, in the console tree, click **Services (Local)**.
2. In the result pane, right-click **Microsoft Exchange POP3**, and then click **Properties**.
3. On the **General** tab, under **Startup type**, select **Automatic**, and then click **Apply**.
4. Under **Service status**, click **Start**, and then click **OK**.

On the computer running the Mailbox server role:

1. In the **Services** snap-in, in the console tree, click **Services (Local)**.
2. In the result pane, right-click **Microsoft Exchange POP3 Backend**, and then click **Properties**.
3. On the **General** tab, under **Startup type**, select **Automatic**, and then click **Apply**.
4. Under **Service status**, click **Start**, and then click **OK**.

Use the Shell to enable POP3

On the computer running the Client Access server role:

1. Set the Microsoft Exchange POP3 service to start automatically.

```
Set-service msExchangePOP3 -startuptype automatic
```

2. Start the Microsoft Exchange POP3 service.

```
Start-service msExchangePOP3
```

On the computer running the Mailbox server role:

1. Set the Microsoft Exchange POP3 Backend service to start automatically.

```
Set-service msExchangePOP3BE -startuptype automatic
```

2. Start the Microsoft Exchange POP3 Backend service.

```
Start-service msExchangePOP3BE
```

How do you know this worked?

1. On the Exchange Client Access server, open Windows Task Manager. On the **Services** tab, the status for **MSExchangePOP3** will show as **Running** if POP3 is enabled.
2. On the Exchange Mailbox server, open Windows Task Manager. On the **Services** tab, the status for **MSExchangePOP3BE** will show as **Running** if POP3 is enabled.

Enable IMAP4 in Exchange 2013

Exchange Server 2013 > Clients and mobile > POP3 and IMAP4 >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-05*

When you install Microsoft Exchange Server 2013, IMAP4 client connectivity isn't enabled. To enable IMAP4 client connectivity, you need to start two IMAP services, the Microsoft Exchange IMAP4 service and the Microsoft Exchange IMAP4 Backend service. When you enable IMAP4, Exchange 2013 accepts unsecured IMAP4 client communications on port 143 and over port 993 using Secure Sockets Layer (SSL).

The Microsoft Exchange IMAP4 service runs on Exchange 2013 computers that are running the Client Access server role. The Microsoft Exchange IMAP4 Backend service runs on the Exchange 2013 computer that's running the Mailbox server role. In environments where the Client Access and Mailbox roles are running on the same computer, you manage both services on the same computer.

For more information related to setting up POP3 and IMAP4, see POP3 and IMAP4.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "POP3 and IMAP4 Permissions" section in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

What do you want to do?

Use the Microsoft Management Console Services snap-in to enable IMAP4

On the computer running the Client Access server role:

1. In the **Services** snap-in, in the console tree, click **Services (Local)**.
2. In the result pane, right-click **Microsoft Exchange IMAP4**, and then click **Properties**.
3. On the **General** tab, under **Startup type**, select **Automatic**, and then click **Apply**.

4. Under **Service status**, click **Start**, and then click **OK**.

On the computer running the Mailbox server role:

1. In the **Services** snap-in, in the console tree, click **Services (Local)**.
2. In the result pane, right-click **Microsoft Exchange IMAP4 Backend**, and then click **Properties**.
3. On the **General** tab, under **Startup type**, select **Automatic**, and then click **Apply**.
4. Under **Service status**, click **Start**, and then click **OK**.

Use the Shell to enable IMAP4

On the computer running the Client Access server role:

1. Set the Microsoft Exchange IMAP4 service to start automatically.

```
Set-service msExchangeIMAP4 -startuptype automatic
```

2. Start the Microsoft Exchange IMAP4 service.

```
Start-service msExchangeIMAP4
```

On the computer running the Mailbox server role:

1. Set the Microsoft Exchange IMAP4 Backend service to start automatically.

```
Set-service msExchangeIMAP4BE -startuptype automatic
```

2. Start the Microsoft Exchange IMAP4 Backend service.

```
Start-service msExchangeIMAP4BE
```

How do you know this worked?

1. On the Exchange Client Access server, open Windows Task Manager. On the **Services** tab, the status for **MSExchangeIMAP4** will show as **Running** if IMAP4 is enabled.
2. On the Exchange Mailbox server, open Windows Task Manager. On the **Services** tab, the status for **MSExchangeIMAP4BE** will show as **Running** if IMAP4 is enabled.

Enable or disable POP3 access for a user

Exchange Server 2013 > Clients and mobile > POP3 and IMAP4 >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-01-06*

You can enable or disable POP3 for a user.

Note:

After you've enabled or disabled POP3 for a user, you must restart the Microsoft Exchange POP3 service and the Microsoft Exchange POP3 Backend service. For more information about how to restart the POP3 service, see Start and stop the POP3 services.

For additional information related to managing user mailboxes, see Manage user mailboxes.

For additional information related to POP3 and IMAP4, see POP3 and IMAP4.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient provisioning permissions" section in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to enable or disable POP3 for a user

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the result pane, select the user for which you want to enable or disable POP3, and then click **Edit** .
3. In the **User Mailbox** dialog box, in the console tree, click **Mailbox Features**.

In the result pane, under **Email Connectivity**, do one of the following:

- To disable POP3 for the user, under **POP3: Enabled**, click **Disable**.
- To enable POP3 for the user, under **POP3: Disabled**, click **Enable**.

4. Click **Save**.

Use the Shell to enable or disable POP3 for a user

This example enables POP3 for the user John Smith.

```
Set-CASMailbox -Identity "John Smith" -POPEnabled $true
```

This example disables POP3 for the user John Smith.

```
Set-CASMailbox -Identity "John Smith" -POPEnabled $false
```

How do you know this worked?

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the result pane, select the user for which you want to enable or disable POP3, and then click **Edit**.
3. In the **User Mailbox** dialog box, in the console tree, click **Mailbox Features**.

In the result pane, look under **Email Connectivity**.

- If POP3 is enabled for the user, you will see **POP3: Enabled**.
- If POP3 is disabled for the user, you will see **POP3: Disabled**.

4. Click **Save**.

Enable or disable IMAP4 access for a user

Exchange Server 2013 > Clients and mobile > POP3 and IMAP4 >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-01-18*

You can enable or disable IMAP4 for a user.

Note:

After you've enabled or disabled IMAP4 for a user, you must restart the Microsoft Exchange IMAP4 service and the Microsoft Exchange IMAP4 Backend service. For more information about how to restart the IMAP4 service, see Start and stop the IMAP4 services.

Set connection limits for POP3

Exchange Server 2013 > Clients and mobile > POP3 and IMAP4 >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-11-28*

You can use the EAC or the Shell to manage POP3 connection limits for your organization.

When you specify connection limits for POP3, you can select connection limits for the server, an IP address, or a specific user.

For additional information related to POP3, see POP3 and IMAP4.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "POP3 settings" entry in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EMC to set POP3 connection limits for a server, an IP address, or a user

1. In the EAC, navigate to **Servers > Servers**.
2. In the list of servers, select the Client Access server, and then click **Edit** .
3. On the server properties page, click **POP3**.
4. Scroll down and click **More options**.
5. Under **Connection limits**, use the following settings:
   - **Maximum connections** Specifies the total number of connections the specified server will accept. This includes authenticated and unauthenticated connections. The default value is 2,147,483,647. The possible values are from 1 through 2,147,483,647.
   - **Maximum connections from a single IP address** Specifies the number of connections that the server will accept from a single IP address. The default value is 2,147,483,647. The possible values are from 1 through 2,147,483,647.
   - **Maximum connections from a single user** Specifies the maximum number of connections that the server will accept from a particular user. The default value is 16. The possible values are from 1 through 2,147,483,647.
   - **Maximum command size (bytes)** specifies the maximum size of a single command. The default size is 512. The possible values are from 40 through 1,024.
6. Click **Apply**, and then click **OK** to save your changes.

After you set connection limits, you must restart the POP3 services. For information about how to restart the POP3 services, see Start and stop the POP3 services.

Use the Shell to set POP3 connection limits for a server, an IP address, or a user

This example sets the connection limit for a server.

```
Set-PopSettings -Identity CAS01 -MaxConnections Value
```

This example sets the connection limit for an IP address.

```
Set-PopSettings -Identity CAS01 -MaxConnectionsFromSingleIP Value
```

This example sets the connection limit for a user.

```
Set-PopSettings -MaxConnectionsPerUser Value
```

This example sets the maximum command size.

```
Set-PopSettings -MaxCommandSize Value
```

After you set connection limits, you must restart the POP3 services. For information about how to restart the POP3 services, see Start and stop the POP3 services.

For more information about syntax and parameters, see Set-PopSettings.

How do you know this worked?

To verify that you've successfully set connection limits, do one of the following:

1. In the EAC, navigate to **Servers** > **Servers**.
2. In the list of servers, select the Client Access server, and then click **Edit** .
3. On the server properties page, click **POP3**.
4. Scroll down and click **More options**.
5. Under **Connection limits**, verify the connection settings are correct.

Or

1. Run the following command in the Shell.

```
Get-PopSettings | format-list
```

2. Verify the connection settings are correct.

For more information

After you set POP3 connection limits for a server, an IP address, or a user, you may also want to:

Enable POP3 in Exchange 2013

Set connection time-out limits for POP3

Set connection limits for IMAP4

Topic Last Modified: *2012-11-27*

You can use the Shell to configure calendaring access settings for your users who connect to their mailboxes using POP3 connections. The settings you specify determine how your POP3 users can access their calendar and exchange calendar information (for example, send or respond to a meeting request) with other users.

For additional information related to POP3, see POP3 and IMAP4.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To

see what permissions you need, see the "POP3 settings" entry in the Clients and mobile devices permissions topic.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

Use the Shell to set the calendar options for POP3

This example enables POP3 users to use the iCalendar standard, a standard for exchanging calendar information.

```
Set-PopSettings -Identity CAS01 -
CalendarItemRetrievalOption iCalendar
```

This example enables POP3 users to access calendar information from an internal server.

```
Set-PopSettings -Identity CAS01 -
CalendarItemRetrievalOption IntranetUrl
```

This example enables POP3 users to access calendar information from the Internet on an external server.

```
Set-PopSettings -CalendarItemRetrievalOption InternetUrl
```

This example enables POP3 users to access calendar information by using a direct Outlook Web App URL. If you're using `Custom`, you must specify an Outlook Web App URL using the *OWAServerUrl* parameter.

```
Set-PopSettings -CalendarItemRetrievalOption Custom -
OwaServerUrl "https://OwaServer01"
```

After you've specified the calendar options for POP3, you must restart the POP3 services. For information about how to restart the POP3 services, see Start and stop the POP3 services.

For more information about syntax and parameters, see Set-PopSettings.

How do you know this worked?

To verify that you've successfully set calendar options, do the following:

Run the following command in the Shell.

```
Get-PopSettings | format-list
```

Verify that the calendar settings are correct.

For more information

After you set the calendar options for POP3, you may also want to:

Configure POP3 and IMAP4 message retrieval format options

Set connection time-out limits for POP3

Configure calendar options for IMAP4

Exchange Server 2013 > Clients and mobile > POP3 and IMAP4 >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-11-27*

You can use the Shell to configure calendaring access settings for your users who connect to their mailboxes using IMAP4 connections. The settings you specify determine how your IMAP4 users can access their calendar and exchange calendar information (for example, send or respond to a meeting request) with other users.

For additional information related to IMAP4, see POP3 and IMAP4.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "IMAP4 settings" entry in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

Use the Shell to set the calendar options for IMAP4

This example enables IMAP4 users to use the iCalendar standard, a standard for exchanging calendar information.

```
Set-ImapSettings -Identity CAS01 -
CalendarItemRetrievalOption iCalendar
```

This example enables IMAP4 users to access calendar information from an internal server.

```
Set-ImapSettings -Identity CAS01 -
CalendarItemRetrievalOption IntranetUrl
```

This example enables IMAP4 users to access calendar information from the Internet on an external server.

```
Set-ImapSettings -CalendarItemRetrievalOption InternetUrl
```

This example enables IMAP4 users to access calendar information by using a direct Outlook Web App URL. If you're using `Custom`, you must specify an Outlook Web App URL using the *OWAServerUrl* parameter.

```
Set-Imap4Settings -CalendarItemRetrievalOption Custom -
OwaServerUrl "https://OwaServer01"
```

After you've specified the calendar options for IMAP4, you must restart the IMAP4 services. For information about how to restart the IMAP4 services, see Start and stop the IMAP4 services.

For more information about syntax and parameters, see Set-ImapSettings.

How do you know this worked?

To verify that you've successfully set calendar options, do the following:

Run the following command in the Shell.

```
Get-ImapSettings | format-list
```

Verify that the calendar settings are correct.

For more information

After you set the calendar options for IMAP4, you may also want to:

Configure POP3 and IMAP4 message retrieval format options

Set connection time-out limits for IMAP4

Configure POP3 and IMAP4 message retrieval format options

Exchange Server 2013 > Clients and mobile > POP3 and IMAP4 >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-11-28*

You can configure the message retrieval format for users who connect to their email using POP3 and IMAP4. Message retrieval options can be configured at the server level using the EAC or the Shell, and can be configured at the user level using the Shell.

For additional information related to POP3 and IMAP4, see POP3 and IMAP4.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "POP3 settings" and "IMAP4 settings" entries in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Set the POP3 message retrieval format at the server level

Use the EAC to set the POP3 message retrieval format at the server level

1. In the EAC, navigate to **Servers** > **Servers**.
2. In the list of servers, select the Client Access server, and then click **Edit** .
3. On the server properties page, click **POP3**.
4. Under **Message MIME format**, choose from the following settings:
   - Text
   - HTML
   - HTML and alternative text
   - Enriched text
   - Enriched text and alternative text

- Best body format
- TNEF

5. Click **Save**.

After you've set the message retrieval format settings for POP3, you must restart the POP3 services for the settings to take effect. For information about how to restart the POP3 services, see Start and stop the POP3 services.

Use the Shell to set the POP3 message retrieval format at the server level

This example sets the message retrieval format option to text only for all POP3 users on server CAS01.

```
Set-PopSettings -Identity CAS01 -MessageRetrievalMimeFormat TextOnly
```

You can choose from the following settings. You can specify the value for the *MessageRetrievalMimeFormat* parameter by using a numerical value or a text string.

Message format	**Value**
Text	0 or `TextOnly`
HTML	1 or `HtmlOnly`
HTML and alternative text	2 or `HtmlAndTextAlternative`
Enriched text	3 or `TextEnriched`
Enriched text and alternative text	4 or `TextEnrichedAndTextAlternative`
Best body format	5 or `BestBodyFormat`
TNEF	6 or `Tnef`

After you've set the message retrieval format settings for POP3, you must restart the POP3 services for the settings to take effect. For information about how to restart the POP3 services, see Start and stop the POP3 services.

For more information about syntax and parameters, see Set-PopSettings.

How do you know this worked?

Do the following to verify that you've successfully set POP3 message retrieval settings on a server.

1. Run the following command in the Shell.

```
Get-PopSettings | format-list
```

2. Verify the *MessageRetrievalMimeFormat* setting is correct.

Set the IMAP4 message retrieval format at the server level

Use the EAC to set the IMAP4 message retrieval format at the server level

1. In the EAC, navigate to **Servers** > **Servers**.
2. In the list of servers, select the Client Access server, and then click **Edit** .
3. On the server properties page, click **IMAP4**.
4. Under **Message MIME format**, choose from the following settings:
   - Text
   - HTML
   - HTML and alternative text
   - Enriched text
   - Enriched text and alternative text
   - Best body format
   - TNEF
5. Click **Save**.

After you've set the message retrieval format settings for IMAP4, you must restart the IMAP4 services for the settings to take effect. For information about how to restart the IMAP4 services, see Start and stop the IMAP4 services.

Use the Shell to set the IMAP4 message retrieval format at the server level

This example sets the message retrieval format option to text only for all IMAP4 users on server CAS01.

```
Set-ImapSettings -Identity CAS01 -
MessageRetrievalMimeFormat TextOnly
```

You can choose from the following settings. You can specify the value for the *MessageRetrievalMimeFormat* parameter by using a numerical value or a text string.

Message format	**Value**
Text	0 or `TextOnly`
HTML	1 or `HtmlOnly`
HTML and alternative text	2 or `HtmlAndTextAlternative`
Enriched text	3 or `TextEnriched`

Enriched text and alternative text	4 or `TextEnrichedAndTextAlternative`
Best body format	5 or `BestBodyFormat`
TNEF	6 or `Tnef`

After you've set the message retrieval format settings for IMAP4, you must restart the IMAP4 services for the settings to take effect. For information about how to restart the IMAP4 services, see Start and stop the IMAP4 services.

For more information about syntax and parameters, see Set-ImapSettings.

How do you know this worked?

Do the following to verify that you've successfully set IMAP4 message retrieval settings on a server.
1. Run the following command in the Shell.

```
Get-ImapSettings | format-list
```

2. Verify the *MessageRetrievalMimeFormat* setting is correct.

Set the POP3 message retrieval format for a user

Use the Shell to set the POP3 message retrieval format for a user

This example sets the message retrieval format to text only for POP3 access for `USER01`.

```
Set-CASMailbox -Identity USER01 -
PopMessagesRetrievalMimeFormat TextOnly
```

You can choose from the following settings. You can specify the value for the *PopMessagesRetrievalMimeFormat* parameter by using a numerical value or a text string.

Message format	**Value**
Text	0 or `TextOnly`
HTML	1 or `HtmlOnly`
HTML and alternative text	2 or `HtmlAndTextAlternative`
Enriched text	3 or `TextEnriched`
Enriched text and alternative text	4 or `TextEnrichedAndTextAlternative`

Best body format	5 or `BestBodyFormat`
TNEF	6 or `Tnef`

After you've set the message retrieval format settings for POP3, you must restart the POP3 services for the settings to take effect. For information about how to restart the POP3 services, see Start and stop the POP3 services.

For more information about syntax and parameters, see Set-CASMailbox.

How do you know this worked?

Do the following to verify that you've successfully set POP3 message retrieval format options for a user.

1. Run the following command in the Shell.

```
Get-CAS Mailbox <identity> | format-list
```

2. Verify the value for *PopMessagesRetrievalMimeFormat* is correct.

Set the IMAP4 message retrieval format for a user

Use the Shell to set the IMAP4 message retrieval format for a user

This example sets the message retrieval format to text only for IMAP4 access for USER01.

```
Set-CASMailbox -Identity USER01 -
ImapMessagesRetrievalMimeFormat TextOnly
```

You can specify the value for the *ImapMessagesRetrievalMimeFormat* parameter by using a numerical value or a text string.

Message format	**Value**
Text	0 or `TextOnly`
HTML	1 or `HtmlOnly`
HTML and alternative text	2 or `HtmlAndTextAlternative`
Enriched text	3 or `TextEnriched`
Enriched text and alternative text	4 or `TextEnrichedAndTextAlternative`
Best body format	5 or `BestBodyFormat`

TNEF	6 or `Tnef`

After you've set the message retrieval format settings for IMAP4, you must restart the IMAP4 services for the settings to take effect. For information about how to restart the IMAP4 services, see Start and stop the IMAP4 services.

For more information about syntax and parameters, see Set-CASMailbox.

How do you know this worked?

Do the following to verify that you've successfully set IMAP4 message retrieval format options for a user.

1. Run the following command in the Shell.

```
Get-CAS Mailbox <identity> | format-list
```

2. Verify the value for *ImapMessagesRetrievalMimeFormat* is correct.

For more information

After you set the message retrieval format for IMAP4 and POP3 users, you may also want to:

Enable or disable POP3 access for a user

Enable or disable IMAP4 access for a user

Configure calendar options for IMAP4

Configure calendar options for POP3

Configure IP addresses and ports for POP3 and IMAP4 access

Exchange Server 2013 > Clients and mobile > POP3 and IMAP4 >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-11-28*

You can use the EAC and the Shell to configure the Microsoft Exchange POP3 and IMAP4 services to use IP addresses and ports that are different from the default settings.

Note:
Enter IP addresses and IP address ranges in the Internet Protocol Version 4 (IPv4) format, Internet Protocol Version 6 (IPv6) format, or both formats. A default installation of Windows Server 2008 enables support for IPv4 and IPv6.

For additional information related to POP3 and IMAP4, see POP3 and IMAP4.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "POP3 settings" and “IMAP4 settings” entries in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Configure IP addresses and ports for POP3

Use the EAC to configure IP addresses and ports for POP3

1. In the EAC, navigate to **Servers** > **Servers**.
2. In the list of servers, select the Client Access server, and then click **Edit** .
3. On the server properties page, click **POP3**.
4. Under **TLS or unencrypted connections**, click **Add +**.
5. On the **Add IP address** page, under **IP address**, choose one of the following:
   - **All available IPv4 addresses** Use all available IPv4 IP addresses for a server.
   - **All available IPv6 addresses** Use all available IPv6 IP addresses for a server.
   - **Specify an IP address** Use a specific IP address.
6. Under **Port**, enter a port number, or accept the default port.
7. Click **Save** to save your changes.

After you've set the IP address and port settings for POP3, you must restart the POP3 service for the settings to take effect. For information about how to restart the POP3 service, see Start and stop the POP3 services.

Use the Shell to configure IP addresses and ports for POP3

This example sets the IP address and port for communicating with Exchange by using POP3 with Secure Sockets Layer (SSL).

```
Set-PopSettings -SSLBindings: IPaddress:Port
```

This example sets the IP address and port for communicating with Exchange by using POP3 with no encryption or Transport Layer Security (TLS) encryption.

```
Set-PopSettings -UnencryptedOrTLSBindings IPaddress:Port
```

After you've set the IP address and port settings for POP3, you must restart the POP3 service for the settings to take effect. For information about how to restart the POP3 service, see Start and stop the POP3 services.

For more information about syntax and parameters, see Set-PopSettings.

How do you know this worked?

Do the following to verify that you have changed POP3 IP address and port settings on a server.
1. Run the following command in the Shell.

```
Get-PopSettings | format-list
```

2. Verify the *UnencryptedOrTLSBindings* and *SSLBindings* settings are correct.

Configure IP addresses and ports for IMAP4

Use the EAC to configure IP addresses and ports for IMAP4

1. In the EAC, navigate to **Servers > Servers**.
2. In the list of servers, select the Client Access server, and then click **Edit** .
3. On the server properties page, click **IMAP4**.
4. If you want to set TLS or unencrypted connection settings, under **TLS or unencrypted connections**, click **Add +**. If you want to change Secure Sockets Layer (SSL) connection settings, under **Secure Sockets Layer (SSL) connections**, click **Add +**.
5. On the **Add IP address** page, under **IP address**, choose one of the following:
   - **All available IPv4 addresses** Use all available IPv4 IP addresses for a server.
   - **All available IPv6 addresses** Use all available IPv6 IP addresses for a server.
   - **Specify an IP address** Use a specific IP address.
6. Under **Port**, enter a port number, or accept the default port.
7. Click **Save** to save your changes.

After you've set the IP address and port settings for IMAP4, you must restart the IMAP4 services for the settings to take effect. For information about how to restart the IMAP4 services, see Start and stop the IMAP4 services.

Use the Shell to configure IP addresses and ports for IMAP4

This example sets the IP address and port for communicating with Exchange by using IMAP4.

```
Set-ImapSettings -SSLBindings: IPaddress:Port
```

This example sets the IP address and port for communicating with Exchange by using IMAP4 with no encryption or TLS encryption.

```
Set-ImapSettings -UnencryptedOrTLSBindings IPaddress:Port
```

After you've set the IP address and port settings for IMAP4, you must restart the IMAP4 service for the settings to take effect. For information about how to restart the IMAP4 service, see Start and stop the IMAP4 services.

For more information about syntax and parameters, see Set-ImapSettings.

How do you know this worked?

Do the following to verify that you have changed IMAP4 IP address and port settings on a server.
1. Run the following command in the Shell.

```
Get-ImapSettings | format-list
```

2. Verify the *UnencryptedOrTLSBindings* and *SSLBindings* settings are correct.

For more information

After you configure IP addresses and ports for POP3 and IMAP4, you may also want to:

Enable IMAP4 in Exchange 2013

Enable POP3 in Exchange 2013

Allow POP3, IMAP4, and SMTP server settings to be viewed by end users in Outlook Web App

Exchange Server 2013 > Clients and mobile > POP3 and IMAP4 >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-11-28*

If you have users who use POP3 or IMAP4 to connect to their Microsoft Exchange Server 2013 mailboxes, they need to know the correct server settings to connect. After a default Exchange 2013 installation, your users can't look up their own incoming POP3 or IMAP4 server settings or outgoing SMTP server settings. However, you can configure Exchange so that your users can look up their own settings using Microsoft Outlook Web App.

After you perform these procedures, your users can look up their server settings in Outlook Web App as follows:
1. In Outlook Web App, click **Settings** > **Options**.

2. In **Options**, click **Account** > **My account** > **Settings for POP or IMAP access**.

For additional information related to POP3 and IMAP4, see POP3 and IMAP4.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- Procedures in this topic require specific permissions. See each procedure for its permissions information.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the Shell to allow POP3 and IMAP4 users to view their incoming POP3 and IMAP4 settings in Outlook Web App

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "POP3 settings" and "IMAP4 settings" entries in the Clients and mobile devices permissions topic.

This example allows external POP3 server settings to be viewed by end users.

```
Set-PopSettings -ExternalConnectionSettings
{Dublin01.Contoso.com:995:SSL}
```

For detailed syntax and parameter information, see Set-PopSettings.

This example allows external IMAP4 server settings to be viewed by end users.

```
Set-ImapSettings -ExternalConnectionSettings
{Dublin01.Contoso.com:993:SSL}
```

For detailed syntax and parameter information, see Set-ImapSettings.

To apply these changes, you must restart IIS. You don't need to restart the POP3 services. To restart IIS, from a command prompt, enter the following:

```
iisreset
```

How do you know this worked?

To verify that you've configured Exchange to allow users to view their POP3 server settings:
1. Run the following command in the Shell.

```
Get-PopSettings | format-list
```

2. Verify that the *ExternalConnectionSettings* property is set.

To verify that you've configured Exchange to allow users to view their IMAP4 server settings:
1. Run the following command in the Shell.

```
Get-ImapSettings | format-list
```

2. Verify that the *ExternalConnectionSettings* property is set.

Use the Shell to allow POP3 and IMAP4 users to view their outgoing SMTP settings in Outlook Web App

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Receive connectors" entry in the Mail flow permissions topic.

This example allows internal and external SMTP server settings to be viewed by end users using Outlook Web App.

```
Get-ReceiveConnector "*Client Frontend*" | Set-
ReceiveConnector -Fqdn Server.Contoso.com -
AdvertiseClientSettings $true
```

For detailed syntax and parameter information, see Set-ReceiveConnector.

How do you know this worked?

To verify that you've configured Exchange to allow users to view their SMTP server settings:
1. Run the following command in the Shell.

```
Get-ReceiveConnector | format-list
```

2. If the *AdvertiseClientSettings* property is set to `true`, users can view their SMTP server settings in Outlook Web App. If *AdvertiseClientSettings* is set to `false`, users can't view their SMTP sever settings in Outlook Web App.

For more information

After you make it possible for end users to view their POP3, IMAP4, and SMTP settings, you may also want to:

Enable or disable POP3 access for a user

Protocol logging for POP3 and IMAP4

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-11-27*

You can use protocol logging to review the POP3 and IMAP4 connections in your Exchange environment. This can be useful if you're troubleshooting issues related to POP3 or IMAP4 performance.

Enabling POP3 and IMAP4 protocol logging

You can enable, disable, or change protocol logging using the Exchange Management Shell. If you enable protocol logging using the Shell, the default protocol logging settings will be used. In most cases, the default settings will be sufficient.

Alternatively, you can enable, disable, and modify protocol logging options by editing the Microsoft.Exchange.Pop3.exe.config and Microsoft.Exchange.Imap4.exe.config configuration files located on your Microsoft Exchange Server 2013 Client Access server. For more information about how to manage POP3 and IMAP4 protocol settings, see Configure protocol logging for POP3 and IMAP4.

Reviewing the protocol log

The protocol log files are text files that contain data in the comma-separated value (CSV) file format. The protocol log stores each protocol event on a single line. The information stored on each line is organized by fields. These fields are separated by commas. The following table describes the fields that are used to classify each protocol event.

Fields used to classify each protocol event

Field name	Description
date-time	The date and time of the protocol event. The value is formatted as *yyyy-mm-ddhh:mm:ss.fffZ*, where *yyyy* = year, *mm* = month, *dd* = day, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and *Z* signifies Zulu. Zulu is another

	way to indicate Coordinated Universal Time (UTC).
connector-id	This field isn't used for POP3 and IMAP4 protocol logging.
session-id	A GUID that uniquely identifies the SMTP session that is associated with a protocol event.
sequence-number	A counter that starts at 0 and is incremented for each event in the same session.
local-endpoint	The local endpoint of a POP3 or IMAP4 session. This consists of an IP address and TCP port number, formatted as follows: <*IP address*>:<*port*>.
remote-endpoint	The remote endpoint of a POP3 or IMAP4 session. This consists of an IP address and TCP port number, formatted as follows: <*IP address*>:<*port*>.
event	A single character that represents the protocol event. The possible values for the event are as follows: • + Connect • - Disconnect • > Send • < Receive • * Information
data	Text information that's associated with the POP3 or IMAP4 event.
context	This field isn't used for POP3 and IMAP4 protocol logging.

Configure protocol logging for POP3 and IMAP4

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-11-27*

You can use the Shell to enable, disable, or modify protocol logging settings for POP3 and IMAP4. By default, protocol logging isn't enabled.

Protocol logging lets you review the POP3 and IMAP4 connections in your Exchange environment. This can be useful if you're troubleshooting issues related to POP3 or IMAP4 performance. For more information, see Protocol logging for POP3 and IMAP4. For more information related to POP3 and IMAP4, see POP3 and IMAP4.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "POP3 settings" and "IMAP4 settings" entries in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the Shell to enable protocol logging for POP3 or IMAP4

This example enables protocol logging for IMAP4 or POP3 on the Client Access server CAS01.

```
Set-ImapSettings -Server "CAS01" -ProtocolLogEnabled $true
Set-PopSettings -Server "CAS01" -ProtocolLogEnabled $true
```

Note:

After you've changed protocol logging settings for POP3 or IMAP4, you must restart whichever services you're using: POP3 or IMAP4. For information about how to restart the POP3 and IMAP4 services, see Start and stop the POP3 services and Start and stop the IMAP4 services.

For detailed syntax and parameter information, see Set-ImapSettings and Set-PopSettings.

Use the Shell to disable protocol logging for POP3 or IMAP4

This example disables protocol logging for IMAP4 or POP3 on the Client Access server CAS01.

```
Set-ImapSettings -Server "CAS01" -protocolLogEnabled $false
Set-PopSettings -Server "CAS01" -protocolLogEnabled $false
```

Note:

After you've changed protocol logging settings for POP3 or IMAP4, you must restart whichever services you're using: POP3 or IMAP4. For information about how to restart the POP3 and IMAP4 services, see Start and stop the POP3 services and Start and stop the IMAP4 services.

For detailed syntax and parameter information, see Set-ImapSettings and Set-PopSettings.

Use the Shell to modify protocol logging for POP3 or IMAP4

To modify POP3 or IMAP4 logging settings, run the **Set-ImapSettings** or **Set-PopSettings** cmdlets with one or more of the following parameters.

- *LogFileLocation* This parameter specifies the location for the POP3 or IMAP4 protocol log files. By default, POP3 protocol log files are located in the C:\Program Files\Microsoft\Exchange Server \V15\Logging\Pop3 directory. This example turns on POP3 protocol logging on the Client Access server CAS01. It also changes the POP3 protocol logging directory to C:\Pop3Logging.

```
Set-PopSettings -Server "CAS01" -ProtocolLogEnabled $true -
LogFileLocation "C:\Pop3Logging"
```

- *LogFileRollOverSettings* This parameter defines how frequently POP3 or IMAP4 protocol logging creates a new log file. By default, a new log file is created every day. The possible values are:

Hourly

Daily

Weekly

Monthly

This setting applies only when the value for the parameter *LogPerFileSizeQuota* is set to zero. This example changes the POP3 protocol logging on the Client Access server CAS01 to create a new log

file every hour.

```
Set-PopSettings -Server "CAS01" -LogPerFileSizeQuota 0 -
LogFileRollOverSettings Hourly
```

- *LogPerFileSizeQuota* This parameter defines the maximum size of a POP3 or IMAP4 protocol log file in bytes. By default, this value is set to zero. When this value is set to zero, a new protocol log file is created at the frequency specified by the *LogFileRollOverSettings* parameter.

This example changes the POP3 protocol logging on the Client Access server CAS01 to create a new log file when a log file reaches 2 megabytes (MB).

```
Set-PopSettings -Server "CAS01" -LogPerFileSizeQuota
2000000
```

This example changes the POP3 protocol logging on the Client Access server CAS01 to use the same log file regardless of its creation date and size.

```
Set-PopSettings -Server "CAS01" -LogPerFileSizeQuota
unlimited
```

Note:

After you've changed protocol logging settings for POP3 or IMAP4, you must restart whichever services you're using: POP3 or IMAP4. For information about how to restart the POP3 and IMAP4 services, see Start and stop the POP3 services and Start and stop the IMAP4 services.

For detailed syntax and parameter information, see Set-ImapSettings and Set-PopSettings.

How do you know this worked?

Run the following command in the Shell to verify POP3 protocol logging settings. If POP3 protocol logging is enabled, the value for the *ProtocolLogEnabled* parameter is `True`. If POP3 protocol logging is disabled, the value is `False`. You can also make sure the values for the *LogFileLocation*, *LogPerFileSizeQuota*, and *LogFileRollOverSettings* parameters are correct.

```
Get-PopSettings | format-list
```

Run the following command in the Shell to verify IMAP4 protocol logging settings. If IMAP4 protocol logging is enabled, the value for the *ProtocolLogEnabled* parameter is `True`. If IMAP4 protocol logging is disabled, the value is `False`. You can also make sure the values for the *LogFileLocation*, *LogPerFileSizeQuota*, and *LogFileRollOverSettings* parameters are correct.

```
Get-ImapSettings | format-list
```

For more information

After you configure protocol logging settings for POP3 and IMAP4, you may also want to:

Start and stop the IMAP4 services

Start and stop the POP3 services

Office Web Apps Server integration

Exchange Server 2013 > Clients and mobile >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-03-26*

Outlook Web App in Microsoft Exchange Server 2013 provides rich attachment preview functionality. All attachments in an email message are displayed in a filmstrip that includes a thumbnail of each attachment. Users are able to preview attachments online in full fidelity. For Office attachments, this means users can use a rich user interface to preview and modify the attachment online. This functionality is made possible by the integration of Microsoft Office Web Apps Server.

By default, the following file types are displayed using Office Web Apps Server:

- Word documents (doc, docx, dotx, dot, dotm extensions)
- Excel documents (xls, xlsx, xlsm, xlm, xlsb extensions)
- PowerPoint documents (ppt, pptx, pps, ppsx, potx, pot, pptm, potm, ppsm extensions)

Note:
Office Web Apps Server won't be used to render attachments in IRM protected messages.

In Exchange 2010, the attachment previews were displayed using the web-ready document viewing technology, which is built in to Exchange. With Office Web Apps Server integration in Exchange Server 2013, when the user wants to preview an Office attachment, Exchange makes a call to the Office Web Apps Server which renders the document instead. This provides a richer preview experience for the user.

Office Web Apps Server integration for attachment previews is available to all Exchange Online customers. Exchange on-premises customers need to deploy an Office Web Apps Server to enable the functionality.

Configure Office Web Apps Server integration

This section provides detailed steps for configuring Office Web Apps Server integration with Exchange Server 2013 for on-premises customers. This procedure doesn't apply to Exchange Online customers because the functionality is already enabled in Exchange Online.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- Procedures in this topic require specific permissions. See each procedure for its permissions information.
- You have Office Web Apps Server deployed in your organization. For more information, see Deploy the infrastructure: Office Web Apps Server
- Your Office Web Apps Server is accessible from the Internet. If it isn't accessible from the Internet, Office Web Apps Server integration will work only when users access Outlook Web App within your corporate network.
- You can't use the Exchange Administration Center (EAC) to perform these procedures. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to configure the Office Web Apps Server URL

To use Office Web Apps Server to render attachments in Outlook Web App, you must specify the URL of your Office Web Apps Server. Use the **Set-OrganizationConfig** cmdlet to configure the URL.

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Exchange server configuration settings" entry in the Exchange and Shell infrastructure permissions topic.

This example sets the Office Web Apps Server URL to **https://Server1/hosting/discovery**.

```
Set-OrganizationConfig -WACDiscoveryEndPoint https://
Server1/hosting/discovery
```

For detailed syntax and parameter information, see Set-OrganizationConfig.

How do you know this worked?

To verify that you have configured the Office Web App Server URL correctly, do the following:

1. Run the following Shell command:

```
Get-OrganizationConfig | Format-List WACDiscoveryEndPoint
```

2. Verify that the correct URL is listed for the *WACDiscoveryEndPoint* attribute.
3. Once you verify that the URL is successfully updated, recycle the **MSExchangeOWAAppPool** on your CAS servers.

4. At this point when users log on to OWA, the CAS server will perform Office Web Apps discovery on the URL you configured. In the CAS server application event log, look for event ID 142 with source MSExchange OWA. This event indicates a successful Office Web Apps discovery, and OWA will use Office Web Apps to render attachments.
5. If you see event ID 141 with source MSExchange OWA, it means the CAS server was unable to locate the Office Web Apps on the given URL, In this case, make sure that the URL you configured is correct.

Use the Shell to enable or disable Office Web Apps Server rendering

You can enable rendering of attachments using Office Web Apps Server for both public and private computers. Use the **Set-OwaVirtualDirectory** cmdlet for both options.

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Clients and mobile devices permissions topic.

This example enables Office Web Apps Server rendering on the default Outlook Web App virtual directory on server Server01 for users who logged on to Outlook Web App using the **Private** option:

```
Set-OwaVirtualDirectory "Server01\owa (Default Web Site)" -WacViewingOnPrivateComputersEnabled $true
```

This example disables Office Web Apps Server rendering on the default Outlook Web App virtual directory on server Server01 for users who logged on to Outlook Web App using the **Public** option.

```
Set-OwaVirtualDirectory "Server01\owa (Default Web Site)" -WacViewingOnPublicComputersEnabled $false
```

For detailed syntax and parameter information, see Set-OwaVirtualDirectory.

How do you know this worked?

To verify that you have configured Office Web Apps server rendering correctly, do the following:
1. Run the following Shell command:

```
Get-OwaVirtualDirectory "Server01\owa (Default Web Site)" | Format-List Name,WacViewing*
```

2. Verify that the *WacViewingOnPrivateComputersEnabled* attribute is set to `True` and that *WacViewingOnPublicComputersEnabled* is set to `False`.

Use the Shell to force Office Web Apps Server rendering

You can force users to render attachments using the Office Web Apps Server first before they can open them directly.

You need to be assigned permissions before you can perform this procedure or procedures. To see

what permissions you need, see the "Outlook Web App virtual directories" entry in the Clients and mobile devices permissions topic.

This example configures the Outlook Web App virtual directory on Server01 so that users always first view supported attachments using Office Web Apps Server before they can open them, regardless of the option they chose when logging on to Outlook Web App.

```
Set-OwaVirtualDirectory "Server01\owa (Default Web Site)" -
ForceWacViewingFirstOnPublicComputers $true -
ForceWacViewingFirstOnPrivateComputers $true
```

For detailed syntax and parameter information, see Set-OwaVirtualDirectory.

How do you know this worked?

To verify that you have configured Office Web Apps server rendering correctly, do the following:
1. Run the following Shell command:

```
Get-OwaVirtualDirectory "Server01\owa (Default Web Site)" |
Format-List Name,ForceWacViewing*
```

2. Verify that the *ForceWacViewingFirstOnPrivateComputers* and *ForceWacViewingFirstOnPublicComputers* attributes are both set to `True`.

Client protocol management

Exchange Server 2013 > Clients and mobile >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-05*

Management of the client protocols of Exchange ActiveSync, Outlook Web App, POP3, IMAP4, the Autodiscover service, Exchange Web Services, and the Availability service occurs in three different areas: the Exchange Administration Center (EAC), the Exchange Management Shell, and Internet Information Services (IIS) Manager. The settings that are managed in each location vary per client protocol.

Managing Outlook Web App settings

Most of the settings that affect which Outlook Web App features are available to users can be set on the Outlook Web App virtual directory or can be configured in an Outlook Web App mailbox policy. By using Outlook Web App mailbox policies, you can define the features available to individual users. Mailbox policy settings override virtual directory settings. For more information on

managing Outlook Web App, see Outlook Web App.

Managing Exchange ActiveSync settings

In Exchange 2010, all client access protocols were implemented and managed on a single server role, the Client Access server role. Management of the protocols was performed on a single instance of IIS, there was a single virtual directory object in Active Directory for each client protocol, and a single set of cmdlets were used to configure the virtual directory.

In Exchange 2013, the client protocol management for Exchange ActiveSync is split between the Client Access server and the Mailbox server. Because of this architecture change, you can run different virtual directory management tasks on both the Client Access server and the Mailbox server. If these two servers aren't installed on the same physical computer, the parameters that you use with the virtual directory cmdlets will change based on the server role on which you are running them.

For more information about the architecture changes in Exchange 2013, see What's new in Exchange 2013.

There are two types of settings that can be applied to the Exchange ActiveSync virtual directory:

- Settings applicable to the mailbox session
- Settings applicable to the server and the virtual directory

The settings that are applicable to the mailbox session are user session settings. When a user connects to a Client Access server, the connection is proxied to the Mailbox server that contains the user's mailbox. A unique identifier of the virtual directory is included with the proxied request. The Mailbox server then retrieves the virtual directory settings from Active Directory and applies them to the session. The virtual directory settings are cached on the Mailbox server to improve performance.

If the connection is proxied to a different Active Directory site, the virtual directory settings will be loaded from the Client Access server in the same site as the Mailbox server, not from the Client Access server where the connection originated.

The following tables indicate which virtual directory settings can be managed on which servers. If you try to manage a particular setting on a server for which it isn't applicable, you will receive an error message indicating that the property you are trying to set is read-only for the server that you are operating on.

Exchange ActiveSync virtual directory settings on Client Access servers

Setting	Server
BadItemReportingEnabled	Client Access
BasicAuthEnabled	Client Access

ClientCertAuth	Client Access
CompressionEnabled	Client Access
ExternalAuthenticationMethods	Client Access
ExternalURL	Client Access
InternalAuthenticationMethods	Client Access
InternalURL	Client Access
MobileClientCertificateAuthorityURL	Client Access
MobileClientCertificateProvisioningEnabled	Client Access
MobileClientCertTemplateName	Client Access
RemoteDocumentsActionForUnknownServers	Client Access
RemoteDocumentsAllowedServers	Client Access
RemoteDocumentsBlockedServers	Client Access
RemoteDocumentsInternalDomainSuffixList	Client Access
SendWatsonReport	Client Access

Exchange ActiveSync virtual directory settings on Client Access and Mailbox servers

Setting	Server
ApplicationRoot	Client Access and Mailbox
AppPoolID	Client Access and Mailbox
MetabasePath	Client Access and Mailbox
Name	Client Access and Mailbox
Path	Client Access and Mailbox
ProxySubVdir	Client Access and Mailbox

VirtualDirectoryName	Client Access and Mailbox
WebsiteName	Client Access and Mailbox

Managing POP3 and IMAP4 settings

In Exchange 2013, the implementation of the POP3 and IMAP4 protocols has also been segmented between the Client Access and Mailbox server roles. Due to the new implementation, POP3 and IMAP4 connectivity are each managed by a service on the Client Access server, as well as by a service on the Mailbox server. The names of the services that run on the Client Access server are the same as the names that existed in Exchange 2010: Microsoft Exchange IMAP4 service and Microsoft Exchange POP3 service. The names of the two new services that run on the Mailbox server are the Microsoft Exchange IMAP4 Backend service and the Microsoft Exchange POP3 Backend service.

Consider the following as you manage POP3 and IMAP4 connectivity in your organization:

- If you are running the Client Access server role and the Mailbox server role on the same computer, any changes you make to POP3 or IMAP4 settings are automatically applied to the correct POP3 and IMAP4 services.
- If you are running the Client Access server role and the Mailbox server role on separate computers, you need to manage the settings on the computer that manages the setting you want to change.

Use the following tables indicate which POP/IMAP settings are each server role.

POP3 and IMAP4 settings on Client Access server

Setting	Server
AuthenticatedConnectionTimeout	Client Access
Banner	Client Access
ExternalConnectionSettings	Client Access
InternalConnectionSettings	Client Access
MaxCommandSize	Client Access
MaxConnectionFromSingleIP	Client Access
MaxConnections	Client Access
MaxConnectionsPerUser	Client Access
PreAuthenticatedConnectionTimeout	Client Access

UnencryptedOrTLSBindings	Client Access

POP3 and IMAP4 settings on Mailbox server

Setting	Server
CalendarItemRetrivalOption	Mailbox
EnableExactRFC822Size	Mailbox
MessageRetrievalSortOrder	Mailbox
OWAServerURL	Mailbox
ProxyTargetPort	Mailbox
ShowHiddenFoldersEnabled	Mailbox
SuppressReadReceipt	Mailbox

POP3 and IMAP4 settings on Client Access and Mailbox servers

Setting	Server
X509CertificateName	Client Access and Mailbox
EnforceCertificateErrors	Client Access and Mailbox
LogFileLocation	Client Access and Mailbox
LogFileRolloverSettings	Client Access and Mailbox
LoginType	Client Access and Mailbox
LogPerFileSizeQuota	Client Access and Mailbox
ProotocolLogEnabled	Client Access and Mailbox
Server	Client Access and Mailbox
X509CertificateName	Client Access and Mailbox

Virtual directory management

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-05*

Many of the client protocols used with Exchange Server 2013 are accessed through virtual directories. A virtual directory is used by Internet Information Services (IIS) to allow access to a web application such as Exchange ActiveSync, Outlook Web App, or the Autodiscover service. You can manage a variety of virtual directory settings on Exchange 2013 including authentication, security, and reporting settings.

Understanding virtual directories

The tasks that you can perform on the various virtual directories vary per client protocol. For example, on the Exchange ActiveSync virtual directory you can enable bad item logging and configure the accepted authentication types for the Exchange ActiveSync virtual directory among other tasks. For the Outlook Web App virtual directory, you can configure authentication, segmentation, and file access settings.

Managing virtual directories

Virtual directory management can be performed in three places. You can manage a variety of settings in the Exchange Administration Center (EAC), as well as the Exchange Management Shell. You can also manage certain virtual directory settings in Internet Information Services Manager. For more information about the various settings you can manage on the virtual directories for Exchange ActiveSync, Outlook Web App, and the Autodiscover service, see the following topics:

- View or configure Outlook Web App virtual directories
- Exchange ActiveSync virtual directory management tasks

Exchange ActiveSync virtual directory management tasks

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-05*

You can manage several of the Exchange ActiveSync application settings in Exchange Server 2013 through the Exchange ActiveSync virtual directory. A virtual directory is used by Internet Information Services (IIS) to allow access to a web application such as Exchange ActiveSync. Some of the virtual

directory settings you can manage for Exchange ActiveSync include authentication, security, and reporting.

Exchange ActiveSync virtual directory settings

You can modify the following properties and settings on the Exchange ActiveSync virtual directory:

- **InternalURL** The InternalURL is the URL that internal clients can use to access the virtual directory. It is usually in the format https://servername/Microsoft-Server-ActiveSync. For example, if the server's NetBIOS name is Sequoia, the InternalURL would be https://sequoia/Microsoft-Server-ActiveSync.
- **ExternalURL** The ExternalURL is the URL that external clients can use to access the virtual directory. This URL should be accessible from outside your internal network. For example, your ExternalURL could be https://www.contoso.com/.
- **Authentication settings** The two methods of authentication you can configure for the Exchange ActiveSync virtual directory are Basic authentication and Client certificate authentication.

Default settings for Exchange virtual directories

Clients and mobile > Client protocol management > Virtual directory management >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-19*

Exchange Server 2013 automatically configures multiple Internet Information Services (IIS) virtual directories during installation. This topic contains information about the default IIS authentication settings and default Secure Sockets Layer (SSL) settings for the Client Access and Mailbox servers.

Client Access server

The following table lists the default settings on a stand-alone Exchange 2013 Client Access server.

Default Client Access server IIS authentication and SSL settings

Virtual directory	Authentication method	SSL settings	Management method
Default website	• Anonymous	• Required	IIS management console
aspnet_client	• Anonymous	• SSL required	IIS management

	authentication	• Requires 128-bit encryption	console
Autodiscover	• Anonymous authentication • Basic authentication • Windows authentication	• SSL required • Requires 128-bit encryption	Exchange Management Shell (Shell)
ecp	• Anonymous authentication • Basic authentication	• SSL required • Requires 128-bit encryption	Exchange admin center (EAC) or Shell
EWS	• Anonymous authentication • Windows authentication	• SSL required • Requires 128-bit encryption	Shell
Microsoft-Server-ActiveSync	• Basic authentication	• SSL required • Requires 128-bit encryption	EAC or Shell
OAB	• Windows authentication	• Not required	EAC or Shell
owa	• Basic authentication	• SSL required • Requires 128-bit encryption	EAC or Shell
PowerShell	• Anonymous authentication	• Not required	Shell
Rpc	• Basic authentication • Windows authentication	• SSL required • Requires 128-bit encryption	Shell
RpcWithCert	By default, all authentication methods are disabled.	• Required	

Mailbox server

The following table lists the default settings on a stand-alone Exchange 2013 Mailbox server.

Default Mailbox server IIS authentication and SSL settings

Virtual directory	Authentication method	SSL settings	Management method
Default website	• Anonymous authentication	• SSL required • Requires 128-bit encryption	This virtual directory can't be configured by the user.
PowerShell	• Anonymous authentication	• Not required	Shell

Outlook Web App

Exchange Server 2013 > Clients and mobile >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-24*

By default, when you install Microsoft Exchange 2013, you enable Outlook Web App. Microsoft Outlook Web App lets users access their Exchange mailbox from almost any Web browser.

The Client Access server role provides proxy and redirection services for Outlook Web App.

Note:
Outlook Web App was called Outlook Web Access in versions of Microsoft Exchange earlier than Exchange 2010.

For information about new features, see What's new in Exchange 2013. For information about the Client Access server role in Exchange 2013, see Client Access server.

Overview of Outlook Web App

Fully supported web browsers give users access to features such as conversation view, Inbox rules, the reading pane, and the Scheduling Assistant. Browsers that aren't fully supported can still be used, but users will see the light version of Outlook Web App, which has fewer features. For information about new features in Outlook Web App, see What's new for Outlook Web App in Exchange 2013.

Managing Outlook Web App

In Exchange 2013, the most common Outlook Web App management tasks can be accomplished in

the Exchange Administration Center (EAC). All these tasks, and many others, can be accomplished by using the Exchange Management Shell. You'll still use tools such as Internet Information Services (IIS) Manager for some tasks, for example, to configure Secure Sockets Layer (SSL) or set up simple URLs for users.

Outlook Web App mailbox policies

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-05*

Use Microsoft Outlook Web App mailbox policies to create organization-level policies to manage access to features in Outlook Web App.

Contents

Outlook Web App mailbox policies

In Exchange 2013, you can create multiple Outlook Web App mailbox policies and apply them to individual mailboxes. When an Outlook Web App mailbox policy is applied to a mailbox, it will override the settings of the virtual directory.

Outlook Web App features can also be managed by configuring the Outlook Web App virtual directories. Virtual directory settings will be used for any mailbox that a mailbox policy hasn't been applied to.

Creating or deleting Outlook Web App mailbox policies

A default Outlook Web App mailbox policy is created automatically when Exchange is installed. By default, all options are enabled on the default Outlook Web App mailbox policy. You can create as many Outlook Web App mailbox policies as necessary to meet the needs of your organization.

Note:
The default Outlook Web App mailbox policy isn't automatically applied to any mailboxes.

For information about creating or removing mailbox policies, see Create an Outlook Web App

mailbox policy and Remove an Outlook Web App mailbox policy from Exchange.

Configuring Outlook Web App mailbox policies

The default Outlook Web App mailbox policy has all options enabled by default. For information about configuring Outlook Web App mailbox policies, see View or configure Outlook Web App mailbox policy properties.

Applying Outlook Web App mailbox policies

Only one Outlook Web App mailbox policy can be applied to a mailbox.

If there's no Outlook Web App mailbox policy applied to a mailbox, the settings defined on the virtual directory will be applied.

An Outlook Web App mailbox policy can be applied to a mailbox by using the Exchange Administration Center (EAC) to modify an existing mailbox, or by using the Shell and the Set-CASMailbox cmdlet to apply a mailbox policy. For more information, see Apply or remove an Outlook Web App mailbox policy on a mailbox.

Create an Outlook Web App mailbox policy

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-05-30*

You can create an Outlook Web App mailbox policy to apply a common set of policy settings. Outlook Web App mailbox policies are useful for applying and standardizing settings, for example, attachment settings, for specific groups of users.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can run this cmdlet. Although all parameters for this cmdlet are listed in this topic, you may not have access to some parameters if they're not included in the permissions assigned to you. To see what permissions you need, see the "Outlook Web App mailbox policies" entry in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to create an Outlook Web App mailbox policy

1. In the EAC, click **Permissions** > **Outlook Web App policies**.
2. Click the **New** button.
3. Enter a name for your policy.
4. Use the check boxes to enable or disable features. By default, the most common features are displayed. To see all features that can be enabled or disabled, click **More options**.

Note:

Features settings for Outlook Web App mailbox policies override Outlook Web App virtual directory settings. You can change segmentation settings for individual users by using the **Set-CASMailbox** cmdlet in the Shell.

5. Click **Save** to save the policy.

Use the Shell to create an Outlook Web App mailbox

policy

This example creates an Outlook Web App mailbox policy named `Policy1`.

- In the Shell, run the following command.

```
New-OwaMailboxPolicy -Name Policy1
```

For more information about syntax and parameters, see New-OwaMailboxPolicy. For information about using the Shell to configure an Outlook Web App mailbox policy, see Set-OwaMailboxPolicy.

How do you know this worked?

To verify that you've successfully created an Outlook Web App mailbox policy:

- In the EAC, click **Permissions** > **Outlook Web App Policies**, and look for your new mailbox policy.

Apply or remove an Outlook Web App mailbox policy on a mailbox

Outlook Web App > Outlook Web App mailbox policies > Outlook Web App mailbox policy procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-12*

You can apply an Outlook Web App mailbox policy to one or more mailboxes or remove one using either the EAC or the Shell.

What do you need to know before you begin?

- Estimated time to complete each procedure: 10 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Outlook Web App mailbox policies" entry in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Apply an Outlook Web App mailbox policy

Use the EAC to apply an Outlook Web App mailbox policy

1. In the EAC, click **Recipients** > **Mailboxes**.
2. In the work pane, click to select the mailbox that you want to apply an Outlook Web App mailbox policy to. You can also select multiple mailboxes.
3. **If you've selected one mailbox:**
   a. Scroll down in the details pane to **Email Connectivity** and click **View Details**.
   b. Click **Browse** to view and select from the available mailbox policies.
   c. Click **Save** to assign the selected policy to the selected mailbox.

If you've selected more than one mailbox:

   d. Scroll down in the details pane to **Outlook Web App** and click **Assign a policy**.
   e. Click **Browse** to view and select from the available mailbox policies.
   f. Click **Save** to assign the selected policy to the selected mailboxes.

Use the Shell to apply an Outlook Web App mailbox policy to an existing mailbox

This example applies the Outlook Web App mailbox policy named "Calendar" to the mailbox of the user tony@contoso.com.

```
Set-CASMailbox -Identity tony@contoso.com -
OwaMailboxPolicy:Calendar
```

For more information about syntax and parameters, see Set-CASMailbox.

Remove an Outlook Web App mailbox policy

Use the EAC to remove an Outlook Web App mailbox policy

1. In the EAC, click **Recipients** > **Mailboxes**.
2. In the work pane, click to select the mailbox that you want to remove an Outlook Web App mailbox policy from.
3. Scroll down in the details pane to **Email Connectivity** and click **View details**.

If a mailbox policy has been assigned, click **Clear** to remove it from the mailbox.

4. Click **Save** to save your changes.

Use the Shell to remove an Outlook Web App mailbox policy from an existing mailbox.

This example removes the Outlook Web App mailbox policy from mailbox of the user tony@contoso.com.

```
Set-CASMailbox -Identity tony@contoso.com -
OwaMailboxPolicy:$null
```

For more information about syntax and parameters, see Set-CASMailbox.

Remove an Outlook Web App mailbox policy from Exchange

Outlook Web App > Outlook Web App mailbox policies > Outlook Web App mailbox policy procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-03-15*

You can remove a Microsoft Outlook Web App mailbox policy from an Exchange organization by using either the EAC or the Shell.

For additional management tasks related to Outlook Web App mailbox policies, see Outlook Web App mailbox policies.

What do you need to know before you begin?

- Estimated time to complete each procedure: 3 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Outlook Web App mailbox policies" entry in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to remove an Outlook Web App mailbox policy

1. In the EAC, click **Permissions** > **Outlook Web App policies**.
2. In the result pane, click to select the mailbox policy you want to remove.

3. Click the **Delete** button.
4. In the confirmation window, click **Yes** to remove the mailbox policy, or click **No** to cancel.

Use the Shell to remove an Outlook Web App mailbox policy

This example removes an Outlook Web App mailbox policy named `Policy1`.

```
Remove-OwaMailboxPolicy -Name Policy1
```

For more information about syntax and parameters, see Remove-OwaMailboxPolicy.

How do you know this worked?

To verify that you've successfully removed an Outlook Web App mailbox policy:

- In the EAC, click **Permissions** > **Outlook Web App policies**. The policy you removed should no longer appear in the list.

View or configure Outlook Web App mailbox policy properties

Outlook Web App > Outlook Web App mailbox policies > Outlook Web App mailbox policy procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-11*

After you create an Outlook Web App mailbox policy, you can configure a variety of options to control the features available to users in Outlook Web App. For example, you can enable or disable Inbox rules or create a list of allowed file types for attachments.

What do you need to know before you begin?

- Estimated time to complete each procedure: 3 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Outlook Web App mailbox policies" entry in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to view or configure Outlook Web App mailbox policies

1. In the EAC, click **Permissions** > **Outlook Web App policies**.
2. In the result pane, click to select the mailbox policy you want to view or configure.
3. Click the **Edit** button.
4. On the **General** tab, you can view and edit the name of the policy.
5. On the **Features** tab, use the check boxes to enable or disable features. By default, the most common features are displayed. To see all features that can be enabled or disabled, click **More options**.

Note:

Features settings for Outlook Web App mailbox policies override Outlook Web App virtual directory settings. You can change segmentation settings for individual users by using the **Set-CASMailbox** cmdlet in the Shell.

Note:

The option to enable or disable the standard version of Outlook Web App by using the **Premium client** check box has been deprecated and will be removed from the settings. The standard version of Outlook Web App is always enabled.

6. On the **File Access** tab, use the check boxes to configure the file access and viewing options for users. File access lets a user open or view the contents of files attached to an email message.

File access can be controlled based on whether a user has signed in on a public or private computer. The option for users to select private computer access or public computer access is available only when you're using forms-based authentication. All other forms of authentication default to private computer access.

- **Direct file access** Select this check box if you want to enable direct file access. Direct file access lets users open files attached to email messages.
- **WebReady Document Viewing** Select this check box if you want to enable supported documents to be converted to HTML and displayed in a web browser.
- **Force WebReady Document Viewing when a converter is available** Select this check box if you want to force documents to be converted to HTML and displayed in a web browser before users can open them in the viewing application. Documents can be opened in the viewing application only if direct file access has been enabled.

7. On the **Offline access** tab, use the option buttons to configure offline access availability.
8. Click **Save** to update the policy.

Use the Shell to configure Outlook Web App mailbox policies

This example enables calendar access in the default mailbox policy.

```
Set-OwaMailboxPolicy -Identity Default -CalendarEnabled $true
```

For more information about syntax and parameters, see Set-OwaMailboxPolicy.

Use the Shell to view Outlook Web App mailbox policies

This example retrieves the properties of the Outlook Web App mailbox policy `Executives` in the organization `Fabrikam`.

```
Get-OwaMailboxPolicy -Identity Fabrikam\Executives
```

For more information about syntax and parameters, see Get-OwaMailboxPolicy.

How do you know this worked?

To verify that you've successfully edited an Outlook Web App mailbox policy:

1. In the EAC, click **Permissions** > **Outlook Web App Policies**, and then choose a specific Outlook Web App mailbox policy.
2. Click the **Edit** button to view the properties of the mailbox policy.
3. Click **Save** or **Cancel** to close the properties page.

Integrate Outlook Web App with Lync Server

Exchange Server 2013 > Clients and mobile > Outlook Web App >

Topic Last Modified: *2013-02-17*

Outlook Web App supports the integration of Outlook Web App and Microsoft Lync Server 2013. When integration with Lync Server 2013 is configured and instant messaging (IM) is enabled in Outlook Web App, users can initiate or respond to IM sessions by using Outlook Web App.

To integrate Outlook Web App with Lync Server 2013, see Integrating Microsoft Lync Server 2013

and Microsoft Outlook Web App 2013.

View or configure Outlook Web App virtual directories

Exchange Server 2013 > Clients and mobile > Outlook Web App >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-08-12*

You can use the EAC or the Shell to view or configure the properties of an Outlook Web App virtual directory.

Warning:

In Exchange Online, administrators don't have the ability to view or configure Outlook Web App virtual directories.

If you use the Shell to view the properties of an Outlook Web App virtual directory, the information returned is a subset of the information that's available. For example, if you use the **Get-OWAVirtualDirectory** cmdlet to view properties, Exchange returns the following information:

- Virtual directory name
- Server name
- Exchange server version

You can also retrieve information for a specific virtual directory on a specific server by using the available parameters. For more information about the parameters for the **Get-OWAVirtualDirectory** cmdlet, see Get-OwaVirtualDirectory.

If you use the EAC to view the properties of an Outlook Web App virtual directory, you'll be able to view most of the properties for the virtual directory that you're viewing.

What do you need to know before you begin?

- Estimated time to complete each procedure: 10 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to view or configure Outlook Web App virtual directory properties

1. In the EAC, click **Servers** > **Virtual Directories**.

You can use the drop-down lists to select the server and virtual directory type. By default, all servers and virtual directories are displayed.

2. In the result pane, click to select the virtual directory you want to view or edit, then click **Edit**.
3. On the **General** tab, you can view the properties of the Outlook Web App default website and specify an external URL and an internal URL. View or select the following options:
   - **Server** (Read-only.) **Server** displays the name of the server that hosts the Outlook Web App virtual directory.
   - **Version** (Read-only.) **Version** displays the version of the Exchange server that the virtual directory is on.
   - **Web site** (Read-only.) **Web site** displays the name of the website.
   - **Outlook Web App version** (Read-only.) **Outlook Web App version** displays the Exchange server version.
   - **Modified** (Read-only.) **Modified** displays the last date and time that the virtual directory was modified.
   - **Internal URL** In this text box, specify the URL used to access this website from an internal network. An internal URL is configured automatically during Exchange 2013 Setup. The default internal URL setting for an Internet-facing or non-Internet-facing server is https://<Computer Name>/owa.
   - **External URL** In this text box, specify the URL used to access the website from the Internet. By default, **External URL** is blank. For Internet-facing Client Access servers, **External URL** should be set to the value published in DNS for that Active Directory site. For Exchange 2013 servers that don't have an Internet presence, the **External URL** setting should remain blank.
4. On the **Authentication** tab, specify the authentication methods, sign-in format, and sign-in domain.
   - **Use one or more standard authentication methods** Select this option to use one or more of the following standard authentication methods:

Integrated Windows authentication This method requires that users have a valid Windows Server 2008 or Windows Server 2012 user account name and password to access information. Users aren't prompted for their account names and passwords. Instead, the server negotiates with the Windows security packages installed on the client computer. Integrated Windows authentication enables the server to authenticate users without prompting them for information and without transmitting information that isn't encrypted over the network. For this method to work, the client computer must be a member of the same domain as the servers running Exchange, or of a domain that's trusted by the domain that the Exchange server is in.

Digest authentication for Windows domain servers This method transmits passwords over the network as a hash value for additional security. Digest authentication can be used only in Windows Server 2008 and Windows Server 2012 domains for users who have an account that's stored in Active Directory. For more information about Digest authentication, see the Windows Server documentation.

Basic authentication (password is sent in clear text) This method is a simple authentication mechanism defined by the HTTP specification that encodes a user's sign-in name and password before the user's credentials are sent to the server. To make sure that the password is as secure as possible, you should use Secure Sockets Layer (SSL) encryption between client computers and the server that has the Client Access server role installed.

- **Use forms-based authentication** Forms-based authentication provides enhanced security for Outlook Web App virtual directories. Forms-based authentication creates a sign-in page for Outlook Web App. You can configure the type of sign-in prompt used by forms-based authentication. For example, you can configure forms-based authentication to require users to provide their domain and user name information, in the domain\user name format on the Outlook Web App sign-in page.

Important:

Forms-based authentication won't provide a secure channel unless SSL is enabled.

Select one of the following:

Domain\user name This requires the user to enter their domain and user name in the format domain\user name. For example, for a user named Kweku in the domain Contoso, the sign-in would be contoso\kweku.

User principal name (UPN) If the user principal name (UPN) sign-in format is specified, the **User name** box on the Outlook Web App sign-in page guides users to enter their email address, for example, kweku@contoso.com. If a user's UPN isn't identical to the email address, the user can't access Outlook Web App by using the **PrincipalName** sign-in prompt. It's a best practice to use the **PrincipalName** sign-in prompt only if users' UPNs match their email addresses.

User name only The user enters their user name only, without the domain name, for example, Kweku. If you use the **User name only** sign-in prompt for forms-based authentication, you must also specify the **Logon Domain** property. The **Logon Domain** property determines the default domain to use when a user tries to sign in to Outlook Web App. For example, if the default domain is Contoso, and a domain user named Kweku signs in to Outlook Web App, only Kweku must be entered as the user name. The server will use the default domain Contoso. If the user isn't a member of the Contoso domain, the domain and user name must be entered.

5. On the **Features** tab, specify the features that you want to enable or disable for Outlook Web App users on a virtual directory.

Note:

Features settings for individual users override virtual directory settings. You can change segmentation settings for individual users by using the **Set-CASMailbox** cmdlet or by using Outlook Web App mailbox policies. For more information, see Outlook Web App mailbox policies.

Use the check boxes to enable or disable features. By default, the most common features are displayed. To see all features that can be enabled or disabled, click **More options**.

Note:
The option to enable or disable the standard version of Outlook Web App by using the **Premium client** check box has been deprecated and will be removed from the settings. The standard version of Outlook Web App is always enabled.

6. On the **File access** tab, use the check boxes to configure the file access and viewing options for users. File access lets a user open or view the contents of files attached to an email message.

File access can be controlled based on whether a user has signed in on a public or private computer. The option for users to select private computer access or public computer access are available only when you're using forms-based authentication. All other forms of authentication default to private computer access.

- **Direct file access** Select this check box if you want to enable direct file access. Direct file access lets users open files attached to email messages.
- **WebReady Document Viewing** Select this check box if you want to enable supported documents to be converted to HTML and displayed in a web browser.
- **Force WebReady Document Viewing when a converter is available** Select this check box if you want to force documents to be converted to HTML and displayed in a web browser before users can open them in the viewing application. Documents can be opened in the viewing application only if direct file access has been enabled.

7. Click **Save** to update the policy.

Use the Shell to configure Outlook Web App virtual directory properties

This example enables forms-based authentication on the default Outlook Web App virtual directory on the server Contoso.

```
set-OwaVirtualDirectory -Identity "Contoso\owa (default web site)" -FormsAuthentication $true
```

For more information about syntax and parameters, see Set-OwaVirtualDirectory.

Use the Shell to view Outlook Web App virtual directory properties

This example lets you view the properties for all Outlook Web App virtual directories in all Internet Information Services (IIS) websites on all computers that have the Client Access server role installed in an Exchange organization.

```
Get-OWAVirtualDirectory
```

This example lets you view the properties for an Outlook Web App virtual directory on the default IIS website on the local Exchange server.

```
Get-OWAVirtualDirectory -identity "<Exchange Server Name>
\owa (default web site)"
```

This example lets you view the properties for all Outlook Web App virtual directories on an IIS website on a specific Exchange server.

```
Get-OWAVirtualDirectory -server <Exchange Server Name>
```

This example lets you view the values of the properties for every Outlook Web App virtual directory in all IIS websites on all Client Access servers in an Exchange organization.

```
Get-OWAVirtualDirectory | format-list
```

For more information about syntax and parameters, see Get-OwaVirtualDirectory.

How do you know this worked?

To verify that you've successfully edited an Outlook Web App virtual directory:

1. In the EAC, click **Servers** > **Virtual Directories**, and then choose a specific Outlook Web App virtual directory.
2. Click the **Edit** button to view the properties of the virtual directory.
3. Click **Save** or **Cancel** to close the properties page.

Simplify the Outlook Web App URL

Exchange Server 2013 > Clients and mobile > Outlook Web App >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-08-25*

You can use Internet Information Services (IIS) Manager to simplify the Microsoft Outlook Web App URL that users use to access their Exchange Server 2013 mailbox.

To simplify access to Outlook Web App for your users, you may want to configure the Outlook Web App Web page, which is usually the default website in IIS, to automatically redirect users to https. The procedure in the "Use IIS Manager to simplify the Outlook Web App URL and force redirection to SSL" section redirects a request for http://*server* to https://*server*/owa. To help secure the information that's sent between the client and the server, the default Web site is set to require

Secure Sockets Layer (SSL) at installation.

When you configure redirection from a top-level directory in Windows Server 2008, the settings are propagated to lower-level directories. For example, when you configure redirection on the default website to the /owa virtual directory, the settings that you configure also appear on the HTTP Redirect page of all the virtual directories, such as /Autodiscover, /Exchange, and /Public. Therefore, you must remove redirection from all the virtual directories except the one that you want redirected.

What do you need to know before you begin?

- Estimated time to complete: 10 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "IIS Manager" entry in the Outlook Web App Permissions section of the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use IIS Manager to simplify the Outlook Web App URL and force redirection to SSL

1. Start IIS Manager.
2. Expand the local computer, expand **Sites**, and then click **Default Web Site**.
3. At the bottom of the Default Web Site Home pane, click **Features View** if this option isn't already selected.
4. In the **IIS** section, double-click **HTTP Redirect**.
5. Select the **Redirect requests to this destination** check box.
6. Type the absolute path of the /owa virtual directory. For example, type **https://mail.contoso.com/owa**.
7. Under **Redirect Behavior**, select the **Only redirect requests to content in this directory (not subdirectories)** check box.
8. In the **Status code** list, click **Found (302)**.
9. In the Actions pane, click **Apply**.
10. Click **Default Web Site**.
11. In the Default Web Site Home pane, double-click **SSL Settings**.
12. In **SSL Settings**, clear **Require SSL**.

Note:

If you don't clear **Require SSL**, users won't be redirected when they enter an unsecured URL. Instead, they'll get an access denied error.

13. For the new settings to take effect, open a Command Prompt window, and then type **iisreset /noforce** to restart IIS.

How do you know this worked?

To verify that you have successfully simplified the Outlook Web App URL and redirected it to an SSL connection, do the following:

1. Open a web browser and enter the new URL for Outlook Web App, using the format http://<*URL*>.
2. You should be redirected to the Outlook Web App sign-in page through an SSL connection.

Use IIS Manager to remove redirection from a virtual directory

To remove redirection from a virtual directory, perform the following steps:

1. Start IIS Manager.
2. Navigate to the virtual directory.
3. Double-click the **HTTP Redirect** icon in the **Features** view of the virtual directory.
4. Clear the **Redirect requests to this destination** check box.
5. In the Actions pane, click **Apply**.
6. For the new settings to take effect, open a Command Prompt window, and then type **iisreset /noforce** to restart IIS.

You may not be able to use the procedure above to remove redirection from a virtual directory that doesn't have a physical path, such as /Exchange, /Exchweb, or /Public. Use the following procedure to remove redirection from a virtual directory that doesn't appear in IIS Manager.

1. Open a Command Prompt window.
2. Navigate to <*Window directory*>\System32\Inetsrv.
3. Run the following commands:
   a. `appcmd set config "Default Web Site/autodiscover" /section:httpredirect /enabled:false -commit:apphost`
   b. `appcmd set config "Default Web Site/ecp" /section:httpredirect /enabled:false -commit:apphost`
   c. `appcmd set config "Default Web Site/ews" /section:httpredirect /enabled:false -commit:apphost`
   d. `appcmd set config "Default Web Site/owa" /section:httpredirect /enabled:false -commit:apphost`
   e. `appcmd set config "Default Web Site/oab" /section:httpredirect /enabled:false -commit:apphost`
   f. `appcmd set config "Default Web Site/powershell" /section:httpredirect /enabled:false -`

```
commit:apphost
```

g. `appcmd set config "Default Web Site/rpc" /section:httpredirect /enabled:false -commit:apphost`

h. `appcmd set config "Default Web Site/rpcwithcert" /section:httpredirect /enabled:false -commit:apphost`

i. `appcmd set config "Default Web Site/Microsoft-Server-ActiveSync" /section:httpredirect /enabled:false -commit:apphost`

4. Finish by running the command `iisreset/noforce`.

When you configure redirection from a top-level directory, a web.config file may be created under <*drive*>\Program Files\Microsoft\Exchange Server\<*version*>\ClientAccess\oab. If this has happened and you later remove redirection, Outlook may freeze when users click **Send and Receive**. To avoid this happening after you remove redirection, delete the web.config file from <*drive*>\Program Files\Microsoft\Exchange Server\<*version*>\ClientAccess\oab.

Create a theme for Outlook Web App

Exchange Server 2013 > Clients and mobile > Outlook Web App >

Applies to: *Exchange Server 2010 Service Pack 2 (SP2)*

Topic Last Modified: *2013-05-01*

A *theme* defines the background color, fonts, highlight colors, icons, and header that are used by Microsoft Outlook Web App. Each theme is a collection of media files and cascading style sheets (.css) files that are stored on the Microsoft Exchange server in the installation directory in \Client Access\OWA*version*\Owa2\resources\themes. Each theme is stored in its own subdirectory of \themes.

The default theme is found in \Client Access\OWA*version*\Owa2\resources\themes\base. Each theme folder contains all the files that are needed to define a theme. These files include CSS files, graphics, and an .xml file that defines the name of the theme. Additional themes are created by copying all the files from one theme into a new folder and modifying those files as needed.

By default, multiple themes are installed when you install Exchange Server 2013, as follows:

- CSS (.css) files define colors, gradients, and fonts.
- Image (.png) files provide the icons and other graphic elements. If you edit any of the icons, don't change their size. If you change the size of any graphic elements, test your changes to verify that the elements still fit together correctly.

These files are stored on the Client Access server in the installation directory in \Client Access\OWA\<*version*>\themes. Each theme is stored in a subdirectory of themes. You can create additional themes by copying an existing theme and modifying the copy.

After you create a theme, you may also want to Customize the Outlook Web App sign-In, language

selection, and error pages.

Note:
The light version of Outlook Web App doesn't support themes.

Caution:
If you have multiple servers that support Outlook Web App, you must copy your custom theme to each server. You should also create a backup copy of your custom theme. If you reinstall or upgrade Exchange, all files in the themes folders will be overwritten. You'll have to copy your theme back to the appropriate folder after the reinstallation or upgrade is complete.
Make backup copies of all the files that you'll be changing before you start to create your custom theme.

What do you need to know before you begin?

- Estimated time to complete this task: one hour.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Clients and mobile devices permissions topic.
- You need local server administrator access to perform these procedures.
- You'll need a text editor to change the default colors, and a graphics editor to change the images. If you must match a specific color and you can't find a match for it at Color Table, you can use an image editing tool to sample a color and determine its HTML RGB value.
- As a best practice, we recommend that you use the following guidelines any time that you change or create an Outlook Web App theme:
  - If you decide to edit an existing theme, make backup copies of the original files before you start editing them.
  - Do not delete the folder \Client Access\OWA*version*\Owa2\resources\themes\base or any of the files in it.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

How do you do this?

Step 1: Create a new Outlook Web App theme

To start, you'll create a folder for a new theme, and then copy the files from an existing theme into the new folder.

1. Log on to the Exchange server that is hosting the Outlook Web App virtual directory by using an account that has been delegated membership in the local Administrators group.

2. Open Windows Explorer, and then find the Exchange server installation directory.
3. In \Client Access\OWA*version*\Owa2\resources\themes, create a new folder and name it, for example, Fourth Coffee.
4. Copy all the files from another theme to the new folder.

Step 2: Name your new theme

To set the display name for your new theme, do the following:

1. Open the copy of themeinfo.xml that's in the custom theme folder you just created.
2. Find the theme `displayname` value, and change the value to the name you want to use. For example `displayname = "Fourth Coffee Theme"`.
3. Save and close themeinfo.xml.

Step 3: Change the sort order of your new theme (optional)

If you want, you can change the sort order of the new theme by editing the themeinfo.xml file. The sort order determines the theme position in the **Change theme** panel in the Settings menu.

To change the sort order of the new theme by using the themeinfo.xml file, do the following:

1. Open the copy of themeinfo.xml that's in the custom theme folder.
2. Find the theme `sortorder` value, and change the value to reflect where you want your new theme to appear in the list. The themes will be ordered by the numeric value in increasing order. By default, the base theme is the first one and its `sortorder` value is "0". For example `sortorder="<number>"`.
3. Save and close themeinfo.xml.

Step 4: Modify your new theme

Now that you've copied over the files and have named your theme, you can customize it. The following elements can be customized in an Outlook Web App theme:

- Image files, which define the header area and icons.
- CSS files, which define fonts and colors.

Image files

Theme images are stored in two folders in \themes\<*theme name*>\images\. The \images\0 folder contains images that will be used in left-to-right languages (like English), and languages that are read from right to left will use the images in the \images\rtl folder.

Note:
Some of the images in the \images\rtl folder are the same the images as in the \images\0 folder, but they're mirrored.

To customize the theme, you can use an image editing tool to open and modify the following

images:

- Headerbgmain.png
  - This is the main header image. We recommend that the image doesn't exceed the header height of 30 pixels. The default theme doesn't use a background image, so this image is transparent. For an example of a theme that has a custom background image, see the image in the **Blueprint** theme folder.
- Headerbgright.png
  - This is used as a tiling image behind the header. The default theme doesn't use a tiling background image, so this image is transparent. For an example of a theme that has a custom tiling background image, see the image in the **Blueprint** theme folder.
- sprite1.mouse.png
  - This contains most of the images used in a theme. You can change the color of the images to match your theme, and also change the default Outlook Web App text logo.
  - To avoid any issues, don't change the size of any individual icons in the sprite, and make sure that it's saved as a transparent .png file.
- themepreview.png
  - This image will be used to represent the theme in the **Change theme** panel in the Settings menu in Outlook Web App.

Colors and fonts

Cascading style sheet (.css) files define the colors and fonts used in a theme and are stored in multiple folders under \themes\<*theme name*>. The \<*theme name*>\0 folder contains .css files that will be used in left-to-right languages (like English), and languages that are read from right to left will use the .css files in the \<*theme name*>\rtl folder. There are also language-specific folders, (for example, \ja, \ko, \zhs, and \zht) that contain .css files to be used with those languages.

Start by modifying the \<*theme name*>\0 folder. There are four colors used throughout each theme that can be customized.

- BrandColor: #0072C6
- NavBarHoverColor: #4C9CD7
- UnreadColor: #2A8DD4
- FocusColor: #DFEDFA

You can use a text editor like Notepad to search for and replace all the instances of these values with the colors of your theme in the following two files: owa2styles.mouseCSS and owa2styles2.mouseCSS. This has to be done in every folder in your new theme that contains those .css files.

Step 5: Set the default Outlook Web App theme

Setting a new default theme will only affect users who haven't changed their theme through the Settings menu in Outlook Web App.

To force all users to use the default theme, you must disable theme selection in addition to setting

a default theme.

Use the Shell to set the default theme for Outlook Web App

This example sets the default theme for Outlook Web App, where the server name is `fourthcoffee`, the virtual directory name is `owa`, the website name is `default web site`, and the theme is in the folder named `Custom`.

```
set-owavirtualdirectory -identity "fourthcoffee\owa
(default web site)" -defaulttheme Custom
```

For detailed syntax and parameter information, see Set-OwaVirtualDirectory.

Use the Shell to disable theme selection for Outlook Web App

This example disables theme selection in Outlook Web App, where the server name is `fourthcoffee`, the virtual directory name is `owa`, and the website name is `default web site`.

```
set-owavirtualdirectory -identity "fourthcoffee\owa
(default web site)" -themeselectionenabled $false
```

You can also complete both commands at the same time as shown in the following example:

```
set-owavirtualdirectory -identity "fourthcoffee\owa
(default web site)" -defaulttheme Custom -
themeselectionenabled $false
```

For detailed syntax and parameter information, see Set-OwaVirtualDirectory.

Step 6: Run iisreset/noforce to save your changes

If you add or change a theme, change the name of a theme, or change the sort order of a theme, you must stop and start Internet Information Services (IIS) for the change to take effect. To do this, open a Command Prompt window on the server where you've created your new theme, and run the command **iisresest /nforce**.

How do you know this task worked?

1. Sign in to Outlook Web App using the virtual directory on the server where you've created your new theme. If you're testing the changes to the default website on the Exchange server that's hosting the Outlook Web App virtual directory, you can test your theme by opening Internet Explorer and entering the URL https://localhost/owa.
2. Switch to your custom theme by selecting the Settings menu > **Change theme** and selecting your custom theme.

If you don’t see your latest changes and have run iisreset/noforce

1. On the Internet Explorer toolbar, select the Settings menu > **Internet options**.
2. On the **General** tab, under **Browsing history**, select **Delete**, and then verify that **Temporary Internet files and website files** is checked. Then select **Delete** to remove those files.
3. Select **OK** to close **Internet options**.
4. Select **Refresh** to see your changes.

You may have to repeat these steps to see your changes every time that you make a change to the theme files. If you’re making several changes, you can leave Outlook Web App open and repeat running **iisreset/noforce** on the server and clearing temporary files from Internet Explorer as needed.

Customize the Outlook Web App sign-In, language selection, and error pages

Exchange Server 2013 > Clients and mobile > Outlook Web App >

Applies to: *Exchange Server 2010 Service Pack 2 (SP2)*

Topic Last Modified: *2013-05-01*

This topic explains how to customize the color and images of the sign-in, language selection, and error pages for Outlook Web App.

The Outlook Web App sign-in, language selection, and error pages are created based on graphics and .css files in the themes resources folder. Outlook Web App uses only one set of sign-in, language selection, and error pages for all themes. Any modifications to those pages will be seen by all users. You can find the theme resources folder in the Exchange installation directory at V15 \FrontEnd\HttpProxy\owa\auth\version\themes\resources. You’ll need a text editor to change the default colors, and a graphics editor to change the images. If you must match a specific color and you can't find a match for it at Color Table, you can use an image editing tool to sample a color and determine its HTML RGB value.

If you have multiple servers supporting Outlook Web App and want them all to use the same sign-in, language, and error pages, you must copy the modified files to each server. You should also create a back-up copy of your customized files. If you reinstall or upgrade Exchange, all files in the themes folders will be overwritten. You'll have to copy your customized files back to the appropriate folder after the reinstallation or upgrade is complete.

Important:

Back up copies of all the files that you'll be changing before you start to create your custom sign-in and sign-out pages.

For information about creating a custom theme, see Create a theme for Outlook Web App.

What do you need to know before you begin?

- Estimated time to complete this task: 45 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Graphics editor" entry under “Outlook Web App Permissions” in the Clients and mobile devices permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Customize the color of the sign-in page

1. Log on to the Exchange server and use Windows Explorer to go to the Exchange server installation directory and find \V15\FrontEnd\HttpProxy\owa\auth\<version>\themes\resources.
2. Use a text editor, such as Notepad, to open logon.css.
3. Search for the default color value #0072c6 and replace it with the HTML RGB value for the color you want to use. You can find HTML RGB values here: Color Table.
4. Save and close the file.

Customize the color of the error page

1. Log on to the Exchange server and use Windows Explorer to go to the Exchange server installation directory and find \V15\FrontEnd\HttpProxy\owa\auth\<version>\themes\resources.
2. Use a text editor, such as Notepad, to open errorFE.css.
3. Search for the default color value #0072c6 and replace it with the HTML RGB value for the color you want to use. You can find HTML RGB values here: Color Table.
4. Save and close the file.

Customize the color of the language selection page

1. Log on to the Exchange server and use Windows Explorer to go to the Exchange server installation directory and find \V15\Client Access\OWA\version\Owa2\resources\styles.
2. Use a text editor, such as Notepad, to open languageselection.css.

3. Search for the default color value #0072c6 and replace it with the HTML RGB value for the color you want to use. You can find HTML RGB values here: Color Table.
4. Save and close the file.

Customize the images on the sign-in and error pages

Use an image editing tool to open and edit the images used to build the sign-in and error pages.

1. Log on to the Exchange server and use Windows Explorer to go to the Exchange server installation directory and find \V15\FrontEnd\HttpProxy\owa\auth\<version>\themes\resources.
2. Use a graphics editor to open and modify the following files:
   - owa_text_blue.png, to change the "Outlook Web App" text logo.
   - olk_logo_white.png, to change the app logo in the left bar.
   - olk_logo_white_cropped.png, to change the image in the left side panel of the error page.
   - sign_in_arrow.png, to change the icon left of the "sign in" button.
   - olk_exchange_text_blue.png, to change the "Outlook Mobile" logo on tnarrow layout.
   - olk_logo_white_small.png is used in tnarrow.
   - olk_exchange_text_stacked_white_small.png is used in tnarrow.
3. Search for the default color value #0072c6 and replace it with the HTML RGB value for the color you want to use. You can find HTML RGB values here: Color Table.
4. Save and close the file.

How do you know this worked?

Open the Outlook Web App sign-in page in Internet Explorer. If you're testing the changes to the default website on the server that's hosting the Outlook Web App virtual directory, you can test them by opening Internet Explorer and entering the URL https://localhost/owa.

If you don't see your changes, do the following:

1. On the toolbar, select **Settings** > **Internet options** > **General**.
2. Under **Browsing history**, select **Delete**.
3. Select **Temporary Internet files and website files**, and then select **Delete**.
4. When Internet Explorer is finished deleting, select **OK** to close **Internet options**.
5. Refresh the browser window.

Tip:
To see the effects of your changes, you can keep the .css file that you're editing open and refresh the browser window after saving each change.

Configuring push notifications proxying for OWA for Devices

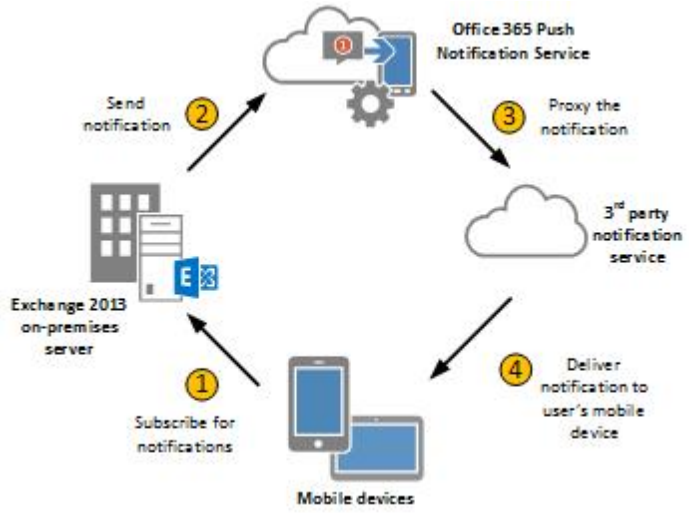
Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-02-15*

Enabling push notifications for OWA for Devices (OWA for iPhone and OWA for iPad) for an on-premises deployment of Microsoft Exchange 2013 lets a user receive updates on the Outlook Web App icon on his or her OWA for iPhone and OWA for iPad indicating the number of unseen messages in the user's inbox. If push notifications aren't configured and enabled, a user with OWA for Devices has no way of knowing that unseen messages are in the inbox without launching the app. When a new message is available, the OWA for Devices badge is updated on the user's device and looks like the following badge.

How do I enable push notifications?

In order to enable push notifications, the on-premises Exchange 2013 servers must connect to the Office 365 Push Notification Service to send push notifications to iPhones and iPads. Exchange 2013 on-premises servers route their update notifications through the Office 365 notification services to remove the need for enrolling developer accounts with third-party push notification services. The following diagram shows the process of how iPhone and iPad users can get badge updates for unseen messages.



To enable push notifications, the admin must:

1. Enroll your organization in Office 365 for business.
2. Update all on-premises servers to Exchange Server 2013 Cumulative Update 3 (CU3) or later.
3. Set up On-premises Exchange 2013 to Office 365 Authentication
4. Enable push notifications from the on-premises Exchange Server 2013 to Office 365 and verify that push notifications are working.

Enroll your organization in Office 365 for business

Office 365 is a cloud-based service that is designed to help meet your organization's needs for robust security, reliability, and user productivity. Office 365 refers to subscription plans that include access to Office applications plus other productivity services that are enabled over the Internet (cloud services), such as Lync web conferencing and Exchange Online hosted email for business.

Many Office 365 plans also include the desktop version of the latest Office applications, which users can install across multiple computers and devices. All Office 365 plans are paid for on a subscription basis, monthly or annually. To find out more or to enroll in Office 365 for your organization, see What is Office 365 for business?. For more about each of the services offered through Office 365, see Office 365 Service Descriptions.

Update to CU3 or later

Cumulative Update 3 (CU3) for Exchange Server 2013 resolves issues that were found in Exchange Server 2013 since the software was released since RTM. It contains all of the issues and fixes in CU1 and CU2 and includes other fixes and updates since CU2 was released. This update is highly recommended for all Exchange Server 2013 on-premises customers but is required for push notifications. To read about cumulative updates, including CU3, see Updates for Exchange 2013.

Set up On-premises Exchange 2013 to Office 365

Authentication

Using a single, standardized method for server-to-server authentication is the approach used by Exchange Server 2013. Exchange Server 2013 (as well as Lync Server 2013 and SharePoint 2013) and Office 2013 support the OAuth (Open Authorization) protocol for server-to-server authentication and authorization. With OAuth, a standard authorization protocol used by a number of major websites, user credentials and passwords aren't passed from one computer to another. Instead, authentication and authorization are based on the OAuth security tokens; these tokens grant access to a specific set of resources for a specific amount of time.

OAuth authentication typically involves three components: a single authorization server and the two realms that need to communicate with one another. Security tokens are issued by the authorization server (also known as a security token server) to the two realms that need to communicate; these tokens verify that communications originating from one realm should be trusted by the other realm. For example, the authorization server might issue tokens that verify that users from a specific Lync Server 2013 realm are able to access a specified Exchange 2013 realm, and vice versa.

Tip:
A realm is a security container.

However, for on-premises server-to-server authentication there is no need to use a third-party token server. Server products such as Lync Server 2013 and Exchange 2013 each have a built-in token server that can be used for authentication purposes with other Microsoft servers (such as SharePoint Server) that support server-to-server authentication. For example, Lync Server 2013 can issue and sign a security token by itself, then use that token to communicate with Exchange 2013. In a case like this, there is no need for a third-party token server.

In order to configure server-to-server authentication for an on-premises implementation of Exchange Server 2013 to Office 365, you must complete two steps:

Step 1 – Assign a certificate to the built-in token issuer of the on-premises Exchange Server. First, an on-premises Exchange admin must use the following Exchange Management Shell script to create a certificate if one wasn't created before and assign it to the built-in token issuer of the on-premises Exchange Server. This is a one-time process; after a certificate has been created, that certificate should be reused for other authentication scenarios and not replaced. Make sure to update the value of *$tenantDomain* to be the name of your domain. To do this, copy and paste the following code.

⚠Warning:

Copying and pasting the code into a text editor like Notepad and saving it with a .ps1 extension makes it easier to run Shell scripts.

```
# Make sure to update the following $tenantDomain with your
Office 365 tenant domain.
$tenantDomain = "Fabrikam.com"
# Check whether the cert returned from Get-AuthConfig is
valid and keysize must be >= 2048
$c = Get-ExchangeCertificate | ?{$_.CertificateDomains -eq
$env:USERDNSDOMAIN -and $_.Services -ge "SMTP" -and
$_.PublicKeySize -ge 2048 -and $_.FriendlyName -match
"OAuth"}
If ($c.Count -eq 0)
{
    Write-Host "Creating certificate for oAuth..."
    $ski = [System.Guid]::NewGuid().ToString("N")
    $friendlyName = "Exchange S2S OAuth"
    New-ExchangeCertificate -FriendlyName $friendlyName -
DomainName $env:USERDNSDOMAIN -Services Federation -KeySize
2048 -PrivateKeyExportable $true -SubjectKeyIdentifier $ski
    $c = Get-ExchangeCertificate | ?{$_.friendlyname -eq
$friendlyName}
```

```
}
ElseIf ($c.Count -gt 1)
{
    $c = $c[0]
}
$a = $c | ?{$_.Thumbprint -eq (get-
authconfig).CurrentCertificateThumbprint}
If ($a.Count -eq 0)
{
    Set-AuthConfig -CertificateThumbprint $c.Thumbprint
}
Write-Host "Configured Certificate Thumbprint is:"(get-
authconfig).CurrentCertificateThumbprint
# Export the certificate
Write-Host "Exporting certificate..."
if((test-path $env:SYSTEMDRIVE\OAuthConfig) -eq $false)
{
    md $env:SYSTEMDRIVE\OAuthConfig
}
cd $env:SYSTEMDRIVE\OAuthConfig
$oAuthCert = (dir Cert:\LocalMachine\My) | where
{$_.FriendlyName -match "OAuth"}
$certType =
[System.Security.Cryptography.X509Certificates.X509ContentT
ype]::Cert
$certBytes = $oAuthCert.Export($certType)
$CertFile = "$env:SYSTEMDRIVE\OAuthConfig\OAuthCert.cer"
[System.IO.File]::WriteAllBytes($CertFile, $certBytes)
# Set AuthServer
$authServer = Get-AuthServer MicrosoftSts;
if ($authServer.Length -eq 0)
{
    Write-Host "Creating AuthServer Config..."
    New-AuthServer MicrosoftSts -AuthMetadataUrl https://
accounts.accesscontrol.windows.net/metadata/json/1/?
realm=$tenantDomain
}
elseif ($authServer.AuthMetadataUrl -ne "https://
accounts.accesscontrol.windows.net/metadata/json/1/?
```

```
realm=$tenantDomain")
{
    Write-Warning "AuthServer config already exists but the
AuthMetdataUrl doesn't match the appropriate value.
Updating..."
    Set-AuthServer MicrosoftSts -AuthMetadataUrl https://
accounts.accesscontrol.windows.net/metadata/json/1/?
realm=$tenantDomain
}
else
{
    Write-Host "AuthServer Config already exists."
}
Write-Host "Complete."
```

The expected result should be similar to the following output.

```
Configured Certificate Thumbprint is:
7595DBDEA83DACB5757441D44899BCDB9911253C
Exporting certificate...
Complete.
```

⚠Warning:

Before you continue, the Windows Azure Active Directory Module for Windows PowerShell cmdlets is required. If the Windows Azure Active Directory Module for Windows PowerShell cmdlets (previously known as the Microsoft Online Services Module for Windows PowerShell) hasn't been installed, you can install it from Manage Windows Azure AD using Windows PowerShell.

Step 2 – Configure Office 365 to communicate with Exchange 2013 on-premises. Configure the Office 365 server that Exchange Server 2013 will communicate with to be a partner application. For example, if Exchange Server 2013 on-premises needs to communicate with Office 365, you need to configure Exchange on-premises to be a partner application. A partner application is any application that Exchange 2013 can directly exchange security tokens with, without having to go through a third-party security token server. An on-premises Exchange 2013 administrator must use the following Exchange Management Shell script to configure the Office 365 tenant that Exchange 2013 will communicate with to be a partner application. During execution, there will be a prompt to enter the administrator user name and password of the Office 365 tenant domain—for example, administrator@fabrikam.com. Make sure to update the value of *$CertFile* to the location of the certificate if not created from the previous script. To do this, copy and paste the following code.

```
# Make sure to update the following $CertFile with the path
```

```
to the cert if not using the previous script.
$CertFile = "$env:SYSTEMDRIVE\OAuthConfig\OAuthCert.cer"
If (Test-Path $CertFile)
{
    $ServiceName = "00000002-0000-0ff1-ce00-000000000000";
    $objFSO = New-Object -ComObject
Scripting.FileSystemObject;
    $CertFile = $objFSO.GetAbsolutePathName($CertFile);
    $cer = New-Object
System.Security.Cryptography.X509Certificates.X509Certifica
te
    $cer.Import($CertFile);
    $binCert = $cer.GetRawCertData();
    $credValue =
[System.Convert]::ToBase64String($binCert);
    Write-Host "Please enter the administrator user name
and password of the Office 365 tenant domain..."
    Connect-MsolService;
    Import-Module msonlineextended;
    Write-Host "Adding a key to Service Principal..."
    $p = Get-MsolServicePrincipal -ServicePrincipalName
$ServiceName
    New-MsolServicePrincipalCredential -AppPrincipalId
$p.AppPrincipalId -Type asymmetric -Usage Verify -Value
$credValue -StartDate $cer.GetEffectiveDateString() -
EndDate $cer.GetExpirationDateString()
}
Else
{
    Write-Error "Cannot find certificate."
}
```

The expected result should be as follows.

```
Please enter the administrator user name and password of
the Office 365 tenant domain...
Adding a key to Service Principal...
Complete.
```

Enable push notifications proxying

After OAuth authentication has been successfully set up following the preceding steps, an on-premises admin must enable push notification proxying by using the following script. Make sure to update the value of *$tenantDomain* to be the name of your domain. To do this, copy and paste the following code.

```
$tenantDomain = "Fabrikam.com"
Enable-PushNotificationProxy -Organization:$tenantDomain
```

The expected result should be similar to the following output.

```
RunspaceId          : 4f2eb5cc-b696-482f-92bb-5b254cd19d60
DisplayName         : On Premises Proxy app
Enabled             : True
Organization        : fabrikam.com
Uri                 : https://outlook.office365.com/
PushNotifications
Identity            : OnPrem-Proxy
IsValid             : True
ExchangeVersion     : 0.20 (15.0.0.0)
Name                : OnPrem-Proxy
DistinguishedName   : CN=OnPrem-Proxy,CN=Push Notifications
Settings,CN=First Organization,CN=Microsoft
                      Exchange,CN=Services,CN=Configuration,D
C=Domain,DC=extest,DC=microsoft,DC=com
Guid                : 8b567958-58a4-403c-a8f0-524d7f1e9279
ObjectCategory      : fabrikam.com/Configuration/Schema/ms-
Exch-Push-Notifications-App
ObjectClass         : {top, msExchPushNotificationsApp}
WhenChanged         : 8/27/2013 7:23:47 PM
WhenCreated         : 8/14/2013 1:30:27 PM
WhenChangedUTC      : 8/28/2013 2:23:47 AM
WhenCreatedUTC      : 8/14/2013 8:30:27 PM
OrganizationId      :
OriginatingServer   : server.fabrikam.com
ObjectState         : Unchanged
```

Verify that push notifications are working

After the preceding steps have been completed, push notifications can be tested by one of the following:

- **Sending a test email message to the user's mailbox:**
  1. Set up an account in OWA for Devices on a mobile device to subscribe for notifications.
  2. Return to the device home screen, which puts OWA for Devices in the background.
  3. Send an email message from another device, such as a PC, that goes to the inbox of the account set up on the mobile device.
  4. This should result in an unseen count being indicated on the app icon within a few minutes.
- **Enabling monitoring.** An alternate method to test push notifications, or to investigate why notifications are failing, is to enable monitoring on a mailbox server in your organization. An on-premises Exchange 2013 server admin must invoke push notification proxy monitoring by using the following script. To do this, copy and paste the following code.

```
# Send a push notification to verify connectivity.
$s = Get-ExchangeServer | ?{$_.ServerRole -match "Mailbox"}
If ($s.Count -gt 1)
{
    $s = $s[0]
}
If ($s.Count -ne 0)
{
    # Restart the monitoring service to clear the cache
from when push was previously disabled.
    Restart-Service MSExchangeHM
    # Give the monitoring service enough time to load.
    Start-Sleep -Seconds:120
    Invoke-MonitoringProbe PushNotifications.Proxy
\PushNotificationsEnterpriseConnectivityProbe -
Server:$s.Fqdn | fl ResultType, Error, Exception
}
Else
{
    Write-Error "Cannot find a Mailbox server in the
current site."
}
```

The expected result should be similar to the following output.

```
ResultType : Succeeded
Error      :
Exception  :
```

Using AD FS claims-based authentication with Outlook Web App and EAC

Topic Last Modified: *2014-09-02*

For on-premises Exchange 2013 Service Pack 1 (SP1) deployments, installing and configuring Active Directory Federation Services (AD FS) means you can now use AD FS claims-based authentication to connect to Outlook Web App and EAC. You can integrate AD FS and claims-based authentication with Exchange 2013 SP1, but you can't when you have a deployment that includes Exchange 2007, Exchange 2010, or even Exchange 2013 RTM servers. Using claims-based authentication replaces traditional authentication methods, including the following:

- Windows authentication
- Forms authentication
- Digest authentication
- Basic authentication
- Active Directory client certificate authentication

Authentication is the process of confirming the identity of a user. Authentication validates that the user is who he or she claims to be. Claims-based identity is another approach to authentication. Claims-based authentication removes the management of authentication from the application—in this case, Outlook Web App and EAC—to make it easier to manage accounts by centralizing authentication. Outlook Web App and EAC aren't responsible for authenticating users, storing user accounts and passwords, looking up user identity details, or integrating with other identity systems. Centralizing authentication helps make it easier to upgrade to authentication methods in the future.

Note:
OWA for Devices doesn't support AD FS claims-based authentication.

Exchange 2013 SP1 can be installed on servers running Windows Server 2008 R2, Windows Server 2012, and Windows Server 2012 R2. There are multiple versions of AD FS that can be used, as summarized by the following table.

Windows Serverversion	Installation	AD FS version
Windows Server 2008 R2	**Download and install** AD FS 2.0, which is an add-on Windows component.	AD FS 2.0

Windows Server 2012	Install the **built-in** AD FS server role.	AD FS 2.1
Windows Server 2012 R2	Install the **built-in** AD FS server role.	AD FS 3.0

The tasks that you will perform here are based on Windows Server 2012 R2 that includes the AD FS role service.

Overview of the required steps

Step 1 - Review the certificate requirements for AD FS

Step 2 - Install and configure Active Directory Federation Services (AD FS)

Step 3 - Create a relying party trust for Outlook Web App and EAC

Step 4 - Add AD FS claim rules for Outlook Web App and EAC

Step 5 - Install the Web Application Proxy role service

Step 6 - Configure the Web Application Proxy role service

Step 7 - Publish Outlook Web App and EAC using Web Application Proxy

Step 8 - Configure Exchange 2013 to use AD FS authentication

Step 9 - Enable AD FS authentication on the OWA and ECP virtual directories

Step 10 - Restart or recycle Internet Information Services (IIS)

Additional information you might want to know

What do I need to know before I begin?

- At a minimum, you need to install separate Windows Server 2012 R2 servers: one as a domain controller that uses Active Directory Domain Services (AD DS), an Exchange 2013 server, a Web Application Proxy server, and an Active Directory Federation Services (AD FS) server. Verify that all updates are installed.
- Install AD DS on the appropriate number of Windows Server 2012 R2 servers in your organization. You can also use **Notifications** in **Server Manager** > **Dashboard** to **Promote this server to a domain controller**.
- Install the appropriate number of Client Access and Mailbox servers for your organization. Verify that all updates are installed, including SP1, on all Exchange 2013 servers in your organization. To download SP1, see Updates for Exchange 2013.
- Deploying Web Application Proxy on a server requires local administrator permissions. You must deploy AD FS on a server running Windows Server 2012 R2 in your organization before you can deploy Web Application Proxy.
- Install and configure the AD FS role and create relying party trusts and claim rules on Windows Server 2012 R2. To do this, you need to log on with a user account that is a member of the

Domain Admins, Enterprise Admins, or local Administrators group.

- Determine the required permissions for Exchange 2013 by seeing Feature permissions.
- You need to be assigned permissions for managing Outlook Web App. To see what permissions you need, see the "Outlook Web App permissions" entry in the Clients and mobile devices permissions topic.
- You need to be assigned permissions for managing EAC. To see what permissions you need, see the "Exchange Administration Center connectivity" entry in the Exchange and Shell infrastructure permissions topic.
- You might be able to use only the Shell to perform some procedures. To learn how to open the Shell in your on-premises Exchange organization, see Open the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Step 1 – Review the certificate requirements for AD FS

Certificates play a critical role in securing communications between Exchange 2013 SP1 servers; web clients such as Outlook Web App; and EAC, Windows Server 2012 R2 servers, including Active Directory Federation Services (AD FS) servers and Web Application Proxy servers. The requirements for certificates vary depending on whether you are setting up an AD FS server, AD FS Proxy, or Web Application Proxy server. The certificates that are used for AD FS services including the SSL and token signing certificates must be imported into the Trust Root Certification Authorities store on all of your Exchange, AD FS and Web Application Proxy servers. The thumbprint for the certificate that is imported is also used on the Exchange 2013 SP1 servers when you use the Set-OrganizationConfig cmdlet.

In any AD FS design, various certificates must be used to secure communication between users on the Internet and AD FS servers. Each federation server must have a service communication certificate or Secure Socket Layer (SSL) certificate and a token-signing certificate before AD FS servers, Active Directory domain controllers, and Exchange 2013 servers can communicate and authenticate. Depending on your security and budget requirements, carefully consider which of your certificates will be obtained by a public CA or an Enterprise CA. If you want to install and configure an Enterprise Root or Subordinate CA, you can use Active Directory Certificate Services (AD CS). If you want to know more about AD CS, see Active Directory Certificate Services Overview.

Although AD FS doesn't require certificates be issued by a CA, the SSL certificate (the SSL certificate that is also used by default as the service communications certificate) must be trusted by the AD FS clients. We recommend that you don't use self-signed certificates. Federation servers use an SSL certificate to secure web services traffic for SSL communication with web clients and with federation server proxies. Because the SSL certificate must be trusted by client computers, we recommend that you use a certificate that is signed by a trusted CA. All certificates that you select

must have a corresponding private key. After you receive a certificate from a CA (Enterprise or public), make sure that all certificates are imported into the Trust Root Certification Authorities store on all servers. You can import certificates into the store with the **Certificates** MMC snap-in or distribute the certificates by using Active Directory Certificate Services. It's important that if the certificate that you imported expires, you manually import another valid certificate.

Important:

If you use the self-signed token signing certificate from AD FS, you must import this certificate into the Trust Root Certification Authorities store on all of your Exchange 2013 servers. If the self-signed token signing certificate isn't used and Web Application Proxy is deployed, then you must update the public key in the Web Application Proxy configuration and all AD FS relying party trusts.

When you are setting up Exchange 2013 SP1, AD FS, and Web Application Proxy, follow these certificate recommendations:

- **Mailbox servers** The certificates that are used on the Mailbox servers are self-signed certificates are they are created when Exchange 2013 is installed. Because all clients connect to an Exchange 2013 Mailbox server through an Exchange 2013 Client Access server, the only certificates that you need to manage are those on the Client Access servers.
- **Client Access servers** An SSL certificate used for service communications is required. If your existing SSL certificate already includes the FQDN you are using to set up the relying party trust endpoint, no additional certificates are required.
- **AD FS** Two types of certificates are required by AD FS:
  - SSL certificate used for service communications
    - Subject name: **adfs.contoso.com** (AD FS deployment name)
    - Subject Alternative Name (SAN): None
  - Token signing certificate
    - Subject name: **tokensigning.contoso.com**
    - Subject Alternative Name (SAN): None

Note:

When you are replacing the token signing certificate on AD FS any existing relying party trusts must be updated to use the new token-signing certificate.

- **Web Application Proxy**
  - SSL certificate used for service communications
    - Subject name: **owa.contoso.com**
    - Subject Alternative Name (SAN): None

Note:

If your Web Application Proxy External URL is the same as your internal URL, you can reuse Exchange's SSL certificate here.

  - AD FS Proxy SSL certificate
    - Subject name: **adfs.contoso.com** (AD FS deployment name)
    - Subject Alternative Name (SAN): None
  - Token signing certificate - This will be copied over from AD FS automatically as part of the

steps below. If this certificate is used, it must be trusted by the Exchange 2013 servers in your organization.

See the certificate requirements section in Review the requirements for deploying AD FS for more information about certificates.

Note:
An SSL encryption certificate is still needed for Outlook Web App and EAC even if you have an SSL certificate for AD FS. The SSL certificate is used on the OWA and ECP virtual directories.

Step 2 – Install and configure Active Directory Federation Services (AD FS)

AD FS in Windows Server 2012 R2 provides simplified, secured identity federation and web single sign-on (SSO) capabilities. AD FS includes a federation service that enables browser-based web SSO, multifactor, and claims-based authentication. AD FS simplifies access to systems and applications by using a claims-based authentication and access authorization mechanism to maintain application security.

To install AD FS on Windows Server 2012 R2:

1. Open **Server Manager** on the **Start** screen or **Server Manager** on the taskbar on the desktop. Click **Add Roles and Features** on the **Manage** menu.
2. On the **Before You Begin** page, click **Next**.
3. On the **Select Installation Type** page, click **Role-based or Feature-based installation**, and then click **Next**.
4. On the **Select Destination Server** page, click **Select a server from the server pool**, verify that the local computer is selected, and then click **Next**.
5. On the **Select Server Roles** page, click **Active Directory Federation Services**, and then click **Next**.

On the **Select Features** page, click **Next**. The required prerequisites or features are already selected for you. You do not need to select any other features.

6. On the **Active Directory Federation Service (AD FS)** page, click **Next**.
7. On the **Confirm Installation Selections** page, check **Restart the destination server automatically if required**, and then click **Install**.

Note:
Do not close the wizard during the installation process.

After you install the required AD FS servers and generate the required certificates, you must configure AD FS and then test that AD FS is working correctly. You can also use the checklist here to help you in setting up and configuring AD FS: Checklist: Setting Up a Federation Server.

To configure Active Directory Federation Services:

1. On the **Installation Progress** page, in the window under **Active Directory Federation Services**, click **Configure the federation service on this server**. The Active Directory Federation Service

Configuration Wizard opens.

2. On the **Welcome** page, click **Create the first federation server in a federation server farm**, and then click **Next**.
3. On the **Connect to AD DS** page, specify an account with domain administrator rights for the correct Active Directory domain that this computer is joined to, and then click **Next**. If you need to select a different user, click **Change**.
4. On the **Specify Service Properties** page, do the following, and then click **Next**:
   - Import the SSL certificate that you obtained earlier from AD CS or a public CA. This certificate is the required service authentication certificate. Browse to the location of your SSL certificate. For details on creating and importing SSL certificates, see Server Certificates.
   - Enter a name for your federation service—for example, type **adfs.contoso.com**.
   - To provide a display name for your federation service, type the name of your organization—for example, **Contoso, Ltd.**.
5. On the **Specify Service Account** page, select **Use an existing domain user account or group Managed Service Account**, and then specify the GMSA account (FsGmsa) that you created when you created the domain controller. Include the account password, and then click **Next**.

Note:

Globally Managed Service Account (GMSA) is an account that must be created when you configure a domain controller. The GMSA account is required during the AD FS installation and configuration. If you haven't created this account yet, run the following Windows PowerShell command. It creates the account for the contoso.com domain and the AD FS server:

```
Add-KdsRootKey -EffectiveTime (Get-Date).AddHours(-10)

New-ADServiceAccount FsGmsa -DNSHostName adfs.contoso.com -
ServicePrincipalNames http/adfs.contoso.com
```

6. On the **Specify Configuration Database** page, select **Create a database on this server using Windows Internal Database**, and then click **Next**.
7. On the **Review Options** page, verify your configuration selections. You can optionally use the **View Script** button to automate additional AD FS installations. Click **Next**.
8. On the **Prerequisite Checks** page, verify that all the prerequisite checks were successfully completed, and then click **Configure**.
9. On the **Installation progress** page, verify that everything installed correctly, and then click **Close**.
10. On the **Results** page, review the results, check whether the configuration completed successfully, and then click **Next steps required for completing your federation service deployment**.

The following Windows PowerShell cmdlet does the same thing as the preceding steps.

```
Import-Module ADFS
Install-AdfsFarm `-
CertificateThumbprint:"0E0C205D252002D535F6D32026B6AB074FB8
40E7"` -FederationServiceDisplayName:"Contoso Corporation"
```

```
`-FederationServiceName:"adfs.contoso.com" `-
GroupServiceAccountIdentifier:"contoso\FSgmsa$"
```

For details and syntax, see Install-AdfsFarm.

To verify the installation: On the AD FS server, open your web browser, and then browse to the URL of the federation metadata—for example, **https://adfs.contoso.com/federationmetadata/2007-06/federationmetadata.xml**.

Step 3 - Create a relying party trust for Outlook Web App and EAC

For all applications and services that you want to publish through Web Application Proxy, you must configure a relying party on the AD FS server. For deployments with multiple Active Directory sites that use separate namespaces, a relying party trust for Outlook Web App and EAC must be added for each namespace.

Note:
EAC uses the ECP virtual directory. You can view or configure settings for EAC by using the Get-EcpVirtualDirectory and the Set-EcpVirtualDirectory cmdlets. To access EAC, you must use a web browser and go to **http://server1.contoso.com/ecp**.

For Outlook Web App, to create relying party trusts by using the AD FS Management snap-in in Windows Server 2012 R2:

1. In **Server Manager**, click **Tools**, and then select **AD FS Management**.
2. In **AD FS snap-in**, under **AD FS\Trust Relationships**, right-click **Relying Party Trusts**, and then click **Add Relying Party Trust** to open the **Add Relying Party Trust** wizard.
3. On the **Welcome** page, click **Start**.
4. On the **Select Data Source** page, click **Enter data about the relying party manually**, and then click **Next**.
5. On the **Specify Display Name** page, in the **Display Name** box, type **Outlook Web App**, and then under **Notes**, type a description for this relying party trust (such as **This is a trust for https://mail.contoso.com/owa**) and then click **Next**.
6. On the **Choose Profile** page, click **AD FS profile**, and then click **Next**.
7. On the **Configure Certificate** page, click **Next**.
8. On the **Configure URL** page, click **Enable support for the WS-Federation Passive protocol**, and then under **Relying party WS-Federation Passive protocol URL**, **type https://mail.contoso.com/owa**, and then click **Next**.
9. On the **Configure Identifiers** page, specify one or more identifiers for this relying party, click **Add** to add them to the list, and then click **Next**.
10. On the **Configure Multi-factor Authentication Now?** page, select **Configure multi-factor authentication settings for this relying party trust**.
11. On the **Configure Multi-factor Authentication** page, verify that **I do not want to configure**

multi-factor authentication settings for this relying party trust at this time is selected, and then click **Next**.

12. On the **Choose Issuance Authorization Rules** page, select **Permit all users to access this relying party**, and then click **Next**.
13. On the **Ready to Add Trust** page, review the settings, and then click **Next** to save your relying party trust information.
14. On the **Finish** page, verify that **Open the Edit Claim Rules dialog for this relying party trust when the wizard closes** isn't selected, and then click **Close**.

To create a relying party trust for EAC, you must do these steps again and create a second relying party trust, but instead of putting in **Outlook Web App** for the display name, enter **EAC**. For the description, enter **This is a trust for the Exchange Admin Center**, and the **Relying party WS-Federation Passive protocol URL** is **https://mail.contoso.com/ecp**.

If you are creating the relying party trusts and claim rules for Outlook Web App and EAC, you need to do the following by using Windows PowerShell:

1. Create the two .txt files IssuanceAuthorizationRules.txt and IssuanceTransformRules.txt.
2. Import their content into two variables.
3. Run the following two cmdlets to create the relying party trusts. In this example, this will also configure the claim rules.

IssuanceAuthorizationRules.txt contains:

```
@RuleTemplate = "AllowAllAuthzRule"
=> issue(Type = "http://schemas.microsoft.com/
authorization/claims/permit",
Value = "true");
```

IssuanceTransformRules.txt contains:

```
@RuleName = "ActiveDirectoryUserSID"
c:[Type == "http://schemas.microsoft.com/ws/2008/06/
identity/claims/windowsaccountname", Issuer == "AD
AUTHORITY"]
=> issue(store = "Active Directory", types = ("http://
schemas.microsoft.com/ws/2008/06/identity/claims/
primarysid"), query = ";objectSID;{0}", param = c.Value);
@RuleName = "ActiveDirectoryGroupSID"
c:[Type == "http://schemas.microsoft.com/ws/2008/06/
identity/claims/windowsaccountname", Issuer == "AD
AUTHORITY"]
=> issue(store = "Active Directory", types = ("http://
schemas.microsoft.com/ws/2008/06/identity/claims/
```

```
groupsid"), query = ";tokenGroups(SID);{0}", param =
c.Value);
@RuleName = "ActiveDirectoryUPN"
c:[Type == "http://schemas.microsoft.com/ws/2008/06/
identity/claims/windowsaccountname", Issuer == "AD
AUTHORITY"]
=> issue(store = "Active Directory", types = ("http://
schemas.xmlsoap.org/ws/2005/05/identity/claims/upn"), query
= ";userPrincipalName;{0}", param = c.Value);
```

Run the following cmdlets:

```
[string]$IssuanceAuthorizationRules=Get-Content -Path C:
\IssuanceAuthorizationRules.txt
[string]$IssuanceTransformRules=Get-Content -Path c:
\IssuanceTransformRules.txt
Add-ADFSRelyingPartyTrust -Name "Outlook Web App" -Enabled
$true -Notes "This is a trust for https://mail.contoso.com/
owa" -WSFedEndpoint https://mail.contoso.com/owa -
Identifier https://mail.contoso.com/owa -
IssuanceTransformRules $IssuanceTransformRules -
IssuanceAuthorizationRules $IssuanceAuthorizationRules
Add-ADFSRelyingPartyTrust -Name "Exchange Admin Center
(EAC)" -Enabled $true -Notes "This is a trust for https://
mail.contoso.com/ecp" -WSFedEndpoint https://
mail.contoso.com/ecp -Identifier https://mail.contoso.com/
ecp -IssuanceTransformRules $IssuanceTransformRules -
IssuanceAuthorizationRules $IssuanceAuthorizationRules
```

Step 4 – Add AD FS claim rules for Outlook Web App and EAC

In a claims-based identity model, the function of Active Directory Federation Services (AD FS) as a federation service is to issue a token that contains a set of claims. Claims rules govern the decisions in regard to claims that AD FS issues. Claim rules and all server configuration data are stored in the AD FS configuration database.

It's required that you create three claim rules:

- Active Directory user SID
- Active Directory group SID

- Active Directory UPN

To add the required claims:

1. In **Server Manager**, click **Tools**, and then click **AD FS Management**.
2. In the console tree, under **AD FS\Trust Relationships**, click either **Claims Provider Trusts** or **Relying Party Trusts**, and then click the relying party trust for Outlook Web App.
3. In the **Relying Party Trusts** window, right-click the Outlook Web App trust, and then click **Edit Claim Rules**.
4. In the **Edit Claim Rules** window, on the **Issuance Transform Rules** tab, click **Add Rule** to start the Add Transform Claim Rule Wizard.
5. On the **Select Rule Template** page, under **Claim rule template**, select **Send Claims Using a Custom Rule** in the list, and then click **Next**.
6. On the **Configure Rule** page, in the **Choose Rule Type** step, under **Claim rule name**, enter the name for the claim rule. Use a descriptive name for the claim rule—for example, **ActiveDirectoryUserSID**. Under **Custom rule**, enter the following claim rule language syntax for this rule:

```
c:[Type == "http://schemas.microsoft.com/ws/2008/06/
identity/claims/windowsaccountname", Issuer == "AD
AUTHORITY"]
=> issue(store = "Active Directory", types = ("http://
schemas.microsoft.com/ws/2008/06/identity/claims/
primarysid"), query = ";objectSID;{0}", param = c.Value);
```

7. On the **Configure Rule** page, click **Finish**.
8. In the **Edit Claim Rules** window, on the **Issuance Transform Rules** tab, click **Add Rule** to start the Add Transform Claim Rule Wizard.
9. On the **Select Rule Template** page, under **Claim rule template**, select **Send Claims Using a Custom Rule** in the list, and then click **Next**.
10. On the **Configure Rule** page, on the **Choose Rule Type** step, under **Claim rule name**, enter the name for the claim rule. Use a descriptive name for the claim rule—for example, **ActiveDirectoryGroupSID**. Under **Custom rule**, enter the following claim rule language syntax for this rule:

```
c:[Type == "http://schemas.microsoft.com/ws/2008/06/
identity/claims/windowsaccountname", Issuer == "AD
AUTHORITY"]
=> issue(store = "Active Directory", types = ("http://
schemas.microsoft.com/ws/2008/06/identity/claims/
groupsid"), query = ";tokenGroups(SID);{0}", param =
c.Value);
```

11. On the **Configure Rule** page, click **Finish**.
12. In the **Edit Claim Rules** window, on the **Issuance Transform Rules** tab, click **Add Rule** to start

the Add Transform Claim Rule Wizard.

13. On the **Select Rule Template** page, under **Claim rule template**, select **Send Claims Using a Custom Rule** in the list, and then click **Next**.
14. On the **Configure Rule** page, on the **Choose Rule Type** step, under **Claim rule name**, enter the name for the claim rule. Use a descriptive name for the claim rule—for example, **ActiveDirectoryUPN**. Under **Custom rule**, enter the following claim rule language syntax for this rule:

```
c:[Type == "http://schemas.microsoft.com/ws/2008/06/
identity/claims/windowsaccountname", Issuer == "AD
AUTHORITY"]
=> issue(store = "Active Directory", types = ("http://
schemas.xmlsoap.org/ws/2005/05/identity/claims/upn"), query
= ";userPrincipalName;{0}", param = c.Value);
```

15. Click **Finish**.
16. In the **Edit Claim Rules** window, click **Apply**, and then **OK**.

To test the AD FS claims for Outlook Web App:

1. In your web browser, sign in to Outlook Web App—for example, **https://mail.contoso.com/owa**
2. In the browser window, if you get a certificate error, just continue on to the Outlook Web App website.
3. In the browser window, type your user name (domain\user) and password, and then click **Sign in**.
4. Outlook Web App should load in the window.

To test the AD FS claims for EAC:

1. In your web browser, go to **https://mail.contoso.com/ecp**.
2. In the browser window, if you get a certificate error, just continue on to the ECP website.
3. In the browser window, type your user name (domain\user) and password, and then click **Sign in**.
4. EAC should load in the window.

Step 5 – Install the Web Application Proxy role service

Web Application Proxy is a new Remote Access role service in Windows Server 2012 R2. Web Application Proxy provides reverse proxy functionality for web applications inside your corporate network to allow users on many devices to access them from outside the corporate network. Web Application Proxy preauthenticates access to web applications by using Active Directory Federation Services (AD FS) and also functions as an AD FS proxy. Although Web Application Proxy isn't required, it is recommended when AD FS is accessible to external clients. However, offline access in Outlook Web App isn't supported when using AD FS authentication through Web Application Proxy. You can find more information about integrating with Web Application Proxy by seeing Installing and Configuring Web Application Proxy for Publishing Internal Applications

⚠Warning:
You can't install Web Application Proxy on the same server with AD FS installed.

To deploy Web Application Proxy, you must install the Remote Access server role with the Web Application Proxy role service on a server that will act as the Web Application Proxy server. To install the Web Application Proxy role service:

1. On the Web Application Proxy server, in **Server Manager**, click **Manage**, and then click **Add Roles and Features**.
2. In the Add Roles and Features Wizard, click **Next** three times to get to the **Server Roles** page.
3. On the **Server Roles** page, select **Remote Access** in the list, and then click **Next**.
4. On the **Features** page, click **Next**.
5. On the **Remote Access** page, read the information, and then click **Next**.
6. On the **Role Services** page, select **Web Application Proxy**. Then in the **Add Roles and Features Wizard** window, click **Add Features**, and then click **Next**.
7. In the **Confirmation** window, click **Install**. You can also check **Restart the destination server automatically if required**.
8. In the **Installation progress** dialog box, verify that the installation was successful, and then click **Close**.

The following Windows PowerShell cmdlet does the same thing as the preceding steps.

```
Install-WindowsFeature Web-Application-Proxy -
IncludeManagementTools
```

Step 6 – Configure the Web Application Proxy role service

You must configure Web Application Proxy to connect to the AD FS server. Repeat this procedure for all of the servers that you want to deploy as Web Application Proxy servers.

To configure the Web Application role service:

1. On the Web Application Proxy server, in **Server Manager**, click **Tools**, and then click **Remote Access Management**.
2. In the **Configuration** pane, click **Web Application Proxy**.
3. In the **Remote Access Management** console, in the middle pane, click **Run the Web Application Proxy Configuration Wizard**.
4. In the Web Application Proxy Configuration Wizard, in the **Welcome** dialog box, click **Next**.
5. On the **Federation Server** page, do the following, and then click **Next**:
   - In the **Federation service name** box, enter the fully qualified domain name (FQDN) of the AD FS server—for example, **adfs.contoso.com**.
   - In the **User name** and **Password** boxes, type the credentials of a local administrator account on the AD FS servers.
6. In the **AD FS Proxy Certificate** dialog box, in the list of certificates currently installed on the Web Application Proxy server, select the certificate to be used by Web Application Proxy for AD FS proxy functionality, and then click **Next**. The certificate you choose here should be the one whose

subject is the Federation Service name—for example, **adfs.contoso.com**.

7. In the **Confirmation** dialog box, review the settings. If required, you can copy the Windows PowerShell cmdlet to automate additional installations. Click **Configure**.
8. In the **Results** dialog box, verify that the configuration was successful, and then click **Close**.

The following Windows PowerShell cmdlet does the same thing as the preceding steps.

```
Install-WebApplicationProxy -CertificateThumprint
'1a2b3c4d5e6f1a2b3c4d5e6f1a2b3c4d5e6f1a2b' -
FederationServiceName adfs.contoso.com
```

Step 7 – Publish Outlook Web App and EAC by using Web Application Proxy

In step 4, you created claims for Outlook Web App and EAC, and you now need to publish both of these applications. But before you do this, verify that a relying party trust for them was created, and verify that you have a certificate on the Web Application Proxy server that is suitable for Outlook Web App and EAC. For all the AD FS endpoints that you require to be published by Web Application Proxy, in the AD FS Management console, you must set the endpoint to be **Proxy Enabled**.

Follow the steps to publish Outlook Web App by using Web Application Proxy. For EAC, you repeat these steps. When you publish EAC, you need to change the name, external URL, external certificate, and back-end URL.

To publish Outlook Web App and EAC by using Web Application Proxy:

1. On the Web Application Proxy server, in the **Remote Access Management** console, in the **Navigation** pane, click **Web Application Proxy**, and then in the **Tasks** pane, click **Publish**.
2. In the Publish New Application Wizard, on the **Welcome** page, click **Next**.
3. On the **Preauthentication** page, click **Active Directory Federation Services (AD FS)**, and then click **Next**.
4. On the **Relying Party** page, in the list of relying parties, select the relying party for the application that you want to publish, and then click **Next**.
5. On the **Publishing Settings** page, do the following, and then click **Next**:
   a. In the **Name** box, enter a friendly name for the application. This name is used only in the list of published applications in the **Remote Access Management console**. You can use **OWA** and **EAC** for the names.
   b. In the **External URL** box, enter the external URL for this application—for example, **https://external.contoso.com/owa** for Outlook Web App and **https://external.contoso.com/ecp** for EAC.
   c. In the **External certificate** list, select a certificate whose subject name matches the host name of the external URL.
   d. In the **Backend server URL** box, enter the URL of the back-end server. Note that this value is

automatically entered when you enter the external URL, and you should change it only if the back-end server URL is different—for example, **https://mail.contoso.com/owa** for Outlook Web App and **https://mail.contoso.com/ecp** for EAC.

Note:
Web Application Proxy can translate host names in URLs but cannot translate paths. Therefore, you can enter different host names, but you must enter the same path. For example, you can enter an external URL of *https://external.contoso.com/app1/* and a back-end server URL of *https://mail.contoso.com/app1/*. However, you cannot enter an external URL of *https://external.contoso.com/app1/* and a back-end server URL of *https://mail.contoso.com/internal-app1/*.

6. On the **Confirmation** page, review the settings, and then click **Publish**. You can copy the Windows PowerShell command to set up additional published applications.
7. On the **Results** page, make sure that the application published successfully, and then click **Close**.

The following Windows PowerShell cmdlet performs the same tasks as the preceding procedure for Outlook Web App.

```
Add-WebApplicationProxyApplication -BackendServerUrl
'https://mail.contoso.com/owa/' -
ExternalCertificateThumbprint
'E9D5F6CDEA243E6E62090B96EC6DE873AF821983' -ExternalUrl
'https://external.contoso.com/owa/' -Name 'OWA' -
ExternalPreAuthentication ADFS -ADFSRelyingPartyName
'Outlook Web App'
```

The following Windows PowerShell cmdlet performs the same tasks as the preceding procedure for EAC.

```
Add-WebApplicationProxyApplication -BackendServerUrl
'https://mail.contoso.com/ecp/' -
ExternalCertificateThumbprint
'E9D5F6CDEA243E6E62090B96EC6DE873AF821983' -ExternalUrl
'https://external.contoso.com/ecp/' -Name 'EAC' -
ExternalPreAuthentication ADFS -ADFSRelyingPartyName
'Exchange Admin Center'
```

Step 8 – Configure Exchange 2013 to use AD FS authentication

When you are configuring AD FS to be used for claims-based authentication with Outlook Web App and EAC in Exchange 2013, you must enable AD FS for your Exchange organization. You must

use the Set-OrganizationConfig cmdlet to configure AD FS settings for your organization:

- Set the AD FS issuer to **https://adfs.contoso.com/adfs/ls**.
- Set the AD FS URIs to **https://mail.contoso.com/owa** and **https://mail.contoso.com/ecp**.
- Find the AD FS token signing certificate thumbprint by using Windows PowerShell on the AD FS server and entering `Get-ADFSCertificate -CertificateType "Token-signing"`. Then, assign the token-signing certificate thumbprint that you found. If the AD FS token-signing certificate has expired, the thumbprint from the new AD FS token-signing certificate must be updated by using the Set-OrganizationConfig cmdlet.

Using the Exchange Management Shell, enter the following code.

```
$uris = @(" https://mail.contoso.com/owa","https://
mail.contoso.com/ecp")
Set-OrganizationConfig -AdfsIssuer "https://
adfs.contoso.com/adfs/ls/" -AdfsAudienceUris $uris -
AdfsSignCertificateThumbprints"88970C64278A15D642934DC2961D
9CCA5E28DA6B"
```

Note:

The *-AdfsEncryptCertificateThumbprint* parameter isn't supported for these scenarios.

For details and syntax, see Set-OrganizationConfig and Get-ADFSCertificate.

Step 9 – Enable AD FS authentication on the OWA and ECP virtual directories

For the OWA and ECP virtual directories, enable AD FS authentication as the only authentication method and disable all other forms of authentication.

Caution:

You must configure the ECP virtual directory before you configure the OWA virtual directory.

Configure the ECP virtual directory by using the Exchange Management Shell. In the Shell window, enter the following code.

```
Get-EcpVirtualDirectory | Set-EcpVirtualDirectory -
AdfsAuthentication $true -BasicAuthentication $false -
DigestAuthentication $false -FormsAuthentication $false -
WindowsAuthentication $false
```

Configure the OWA virtual directory by using the Exchange Management Shell. In the Shell window, enter the following code.

```
Get-OwaVirtualDirectory | Set-OwaVirtualDirectory -
AdfsAuthentication $true -BasicAuthentication $false -
DigestAuthentication $false -FormsAuthentication $false -
WindowsAuthentication $false OAuthAuthentication $false
```

Note:

The preceding Exchange Management Shell commands configure the OWA and ECP virtual directories on every Client Access server in your organization. If you don't want to apply these settings to all Client Access servers, use the *–Identity* parameter and specify the Client Access server. It's likely you will want to apply these settings only to the Client Access servers in your organization that are Internet facing.

For details and syntax, see Get-OwaVirtualDirectory and Set-OwaVirtualDirectory or Get-EcpVirtualDirectory and Set-EcpVirtualDirectory.

Step 10 – Restart or recycle Internet Information Services (IIS)

After you have completed all of the required steps, including making changes to Exchange virtual directories, you need to restart Internet Information Services. To do this, you can use one of the following methods:

- Using Windows PowerShell:

```
Restart-Service W3SVC,WAS -noforce
```

- Using a command line: Click **Start**, click **Run**, type `IISReset /noforce`, and then click **OK**.
- Using Internet Information Servers (IIS) Manager: In **Server Manager** > **IIS**, click **Tools**, and then click **Internet Information Services (IIS) Manager**. In the **Internet Information Servers (IIS) Manager** window, in the action pane under **Manage Server**, click **Restart**.

Additional information you might want to know

Multifactor authentication

For on-premises Exchange 2013 SP1 deployments, deploying and configuring Active Directory Federation Services (AD FS) 2.0 by using claims means that Outlook Web App and EAC in Exchange 2013 SP1 can support multifactor authentication methods, such as certificate-based authentication, authentication or security tokens, and fingerprint authentication. Two-factor authentication is often confused with other forms of authentication. Multifactor authentication requires the use of two of the three authentication factors. These factors are:

- Something only the user knows (for example, the password, PIN, or pattern)
- Something only the user has (for example, an ATM card, security token, smart card, or mobile phone)

- Something only the user is (for example, a biometric characteristic, such as a fingerprint)

For details on multifactor authentication in Windows Server 2012 R2, see Overview: Manage Risk with Additional Multi-Factor Authentication for Sensitive Applications and Walkthrough Guide: Manage Risk with Additional Multi-Factor Authentication for Sensitive Applications.

In the Windows Server 2012 R2 AD FS role service, the federation service functions as a security token service, provides the security tokens that are used with claims, and gives you the ability to support multifactor authentication. The federation service issues tokens based on the credentials that are presented. After the account store verifies a user's credentials, the claims for the user are generated according to the rules of the trust policy and then added to a security token that is issued to the client. For more information about claims, see Understanding Claims.

MailTips

Exchange Server 2013 > Clients and mobile >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-02-03*

MailTips are informative messages displayed to users while they're composing a message. Microsoft Exchange Server 2013 analyzes the message, including the list of recipients to which it's addressed, and if it detects a potential problem, it notifies the user with MailTips prior to sending the message. With the help of the information provided by MailTips, senders can adjust the message they're composing to avoid undesirable situations or non-delivery reports (NDRs).

How MailTips work

MailTips are implemented as a web service in Exchange 2013. When a sender is composing a message, the client software makes an Exchange web service call to the Client Access server to get the list of MailTips. The server responds with the list of MailTips that apply to that message, and the client software displays the MailTips to the sender.

The following unproductive messaging scenarios are common in any messaging environment:

- NDRs resulting from messages that violate restrictions configured in an organization such as message size restrictions or maximum number of recipients per message.
- NDRs resulting from messages sent to recipients that don't exist, recipients that are restricted, or users whose mailboxes are full.
- Sending messages to users with Automatic Replies configured.

All of these scenarios involve the user sending a message, expecting it to be delivered, and instead receiving a response stating that the message isn't delivered. Even in the best-case scenario, like the automatic reply, these events result in lost productivity. In the case of an NDR, this scenario could

result in a costly call to the Help desk.

There are also several scenarios where sending a message won't result in an error, but can have undesirable, even embarrassing consequences:

- Messages sent to extremely large distribution groups.
- Messages sent to inappropriate distribution groups.
- Messages inadvertently sent to recipients outside your organization.
- Selecting **Reply to All** to a message that was received as a Bcc recipient.

All of these problematic scenarios can be mitigated by informing users of the possible outcome of sending the message as they're composing the message. For example, if senders know that the size of the message they're trying to send exceeds the corporate policy, they won't attempt to send the message. Similarly, if senders are notified that the message they're sending will be delivered to people outside the organization, they're more likely to ensure that the content and the tone of the message are appropriate.

The following messaging clients support MailTips:

- Outlook Web App
- Microsoft Outlook 2010 or later

MailTips in Exchange

The following table lists the available MailTips in Exchange 2013.

MailTip	Availability	Scenario
Invalid Internal Recipient	Outlook	The Invalid Internal Recipient MailTip is displayed if the sender adds a recipient that appears to be internal to the organization but doesn't exist. This could happen if the sender addresses a message to a user who is no longer with the company but whose address resolves due to name resolution cache or an entry in the sender's Contacts folder. It can also happen if the sender types an SMTP address with a domain for which Exchange is authoritative

		and the address doesn't resolve to an existing recipient. The MailTip indicates the invalid recipient and gives the sender the option to remove the recipient from the message.
Mailbox Full	Outlook Outlook Web App	The Mailbox Full MailTip is displayed if the sender adds a recipient whose mailbox is full and your organization has implemented a Prohibit Receive restriction for mailboxes over a specified size. The MailTip indicates the recipient whose mailbox is full and gives the sender the option to remove the recipient from the message. The MailTip is accurate at the time of display. If the message isn't immediately sent, the MailTip is updated every two hours. This also applies to messages that were saved in the Drafts folder and reopened after two hours.
Automatic Replies	Outlook Outlook Web App	The Automatic Replies MailTip is displayed if the sender adds a recipient who has turned on Automatic Replies. The MailTip indicates the recipient has Automatic Replies turned on and also displays the first 250

		characters of the automatic reply configured by the recipient. The MailTip is accurate at the time of display. If the message isn't immediately sent, the MailTip is updated every two hours. This also applies to messages that were saved in the Drafts folder and reopened after two hours. If part of your user mailboxes are hosted on Exchange Online and you're in a coexistence with Exchange Online scenario, the setting on the remote domain object that represents the remote part of your organization has a direct effect on how this MailTip is processed. In Exchange 2013, users can configure different Automatic Replies for internal and external senders. If the remote domain is configured as an internal domain (by setting the *IsInternal* parameter on the remote domain object to `$true`), the internal automatic reply is returned to all users in the organization regardless of where their mailbox resides. However, if the remote domain isn't configured as an internal domain, the internal

		automatic reply is returned to all users whose mailboxes are in the local domain and the external automatic reply is returned to users whose mailboxes are in the remote domain.
Custom	Outlook Outlook Web App	A custom MailTip is displayed if the sender adds a recipient for whom a customized MailTip is configured. A custom MailTip can be useful for providing specific information about a recipient. For example, you can create a custom MailTip for a distribution group explaining its purpose to reduce its misuse. For more information, see Configure custom MailTips for recipients. By default, custom MailTips aren't displayed if the sender isn't allowed to send to that recipient. In that case, the Restricted Recipient MailTip is displayed. However, you can change this configuration and have the custom MailTip also display.
Restricted Recipient	Outlook Outlook Web App	The Restricted Recipient MailTip is displayed if the sender adds a recipient for which delivery restrictions are configured prohibiting this sender from

		sending messages. The MailTip indicates the recipient to which the sender isn't allowed to send messages and gives the sender the option to remove the recipient from the message. It also clearly informs the sender that the message won't be delivered if sent. If the restricted recipient is an external recipient, or if it's a distribution group that contains external recipients, this information is also provided to the sender. However, the following MailTips, if applicable, are suppressed: • Automatic Replies • Mailbox Full • Custom MailTip • Moderated Recipient • Oversize Message
External Recipients	Outlook Outlook Web App	The External Recipients MailTip is displayed if the sender adds a recipient that's external, or adds a distribution group that contains external recipients. This MailTip informs senders if a message they're composing will leave the organization, helping them make the correct decisions about wording, tone, and content.

		By default, this MailTip is turned off. You can turn it on using the **Set-OrganizationConfig** cmdlet. For details, see MailTips over organization relationships. If part of your user mailboxes are hosted on Exchange Online and you're in coexistence with an Exchange Online scenario, the setting on the remote domain object that represents the remote part of your organization has a direct effect on how this MailTip is processed. If the remote domain is configured as an internal domain (by setting the *IsInternal* parameter on the remote domain object to `$true`), any recipients in this remote domain will be treated as internal and therefore the External Recipients MailTip won't be displayed. However, if the remote domain isn't configured as an internal domain, the recipients in that domain will be considered external and this MailTip will be displayed when a message is being composed to those recipients. **Note:** This MailTip isn't evaluated when composing a message to a

		distribution group in the remote domain.
Large Audience	Outlook Outlook Web App	The Large Audience MailTip is displayed if the sender adds a distribution group that has more than the large audience size configured in your organization. By default, Exchange displays this MailTip for messages to distribution groups that have more than 25 members. For details, see Configure the large audience size for your organization. The size of distribution groups isn't calculated each time. Instead, the distribution group information is read from the group metrics data.
Moderated Recipient	Outlook Outlook Web App	The Moderated Recipient MailTip is displayed if the sender adds a recipient that's moderated. The MailTip indicates which recipient is moderated and informs the sender that this may result in delay of the delivery. If the sender is also the moderator, this MailTip isn't displayed. It's also not displayed if the sender has been explicitly allowed to send messages to the recipient (by adding the sender's

		name to the Accept Messages Only From list for the recipient). For instructions on how to configure moderated recipients in Exchange 2013, see Forward a message to a manager for approval. For instructions on how to configure moderated recipients in Exchange Online, see **Configure a moderated recipient in Exchange Online**.
Reply-All on Bcc	Outlook Web App	The Reply-All on Bcc MailTip is displayed if the sender receives a Bcc copy of a message and selects **Reply to All**. When a user selects **Reply to All** to such a message, the fact that the user received a Bcc of that message is revealed to the rest of the audience to which the message was sent. In almost all cases, this is an undesirable situation, and this MailTip informs the user of this condition.
Oversize Message	Outlook	The Oversize Message MailTip is displayed if the message the sender is composing is larger than configured message size limits in your organization. The MailTip is displayed if the

		message size violates one of the following size restrictions: • Maximum send size setting on the sender's mailbox • Maximum receive size setting on the recipient's mailbox • Maximum message size restriction for the organization **Note:** Due to the complexity of the implementation, the message size limits on the connectors in your organization aren't taken into account.

MailTip restrictions

MailTips are subject to the following restrictions:

- MailTips aren't supported when working in offline mode in Outlook.
- When a message is addressed to a distribution group, the MailTips for individual recipients that are members of that distribution group aren't evaluated. However, if any of the members is an external recipient, the External Recipients MailTip is displayed, which shows the sender the number of external recipients in the distribution group.
- If the message is addressed to more than 200 recipients, individual mailbox MailTips aren't evaluated due to performance reasons.
- Custom MailTips are limited to 250 characters.
- If the sender starts composing a message and leaves it open for an extended period of time, the Automatic Replies and Mailbox Full MailTips are evaluated every two hours.

Enable or disable MailTips

Exchange Server 2013 > Clients and mobile > MailTips >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-27*

You can use the Exchange Management Shell to configure various settings that define how you use MailTips in your organization.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "MailTips" entry in the Mail flow permissions topic.
- You can only use the Shell to perform this procedure.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to enable or disable MailTips

You use the **Set-OrganizationConfig** cmdlet to enable or disable MailTips in your organization. MailTips are enabled by default when you install a new Exchange organization. This example shows how to enable MailTips in your organization.

```
Set-OrganizationConfig -MailTipsAllTipsEnabled $true
```

For detailed syntax and parameter information, see Set-OrganizationConfig.

Configure the large audience size for your organization

Exchange Server 2013 > Clients and mobile > MailTips >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-09-27*

You can use the Exchange Management Shell to configure various settings that define how you use MailTips in your organization.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "MailTips" entry in the Mail flow permissions topic.
- You can only use the Shell to perform this procedure.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to configure the large audience size for your organization

You use the **Set-OrganizationConfig** cmdlet to configure the large audience size for your organization. When senders address messages to more recipients than the size you configure, they are shown the Large Audience MailTip. The large audience size is set to 25 by default. This example configures the large audience size to 50 in your organization.

```
Set-OrganizationConfig -MailTipsLargeAudienceThreshold 50
```

For detailed syntax and parameter information, see Set-OrganizationConfig.

Configure custom MailTips for recipients

Exchange Server 2013 > Clients and mobile > MailTips >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-06-01*

MailTips are informative messages displayed to users in the InfoBar in Outlook Web App and Microsoft Outlook 2010 or later when a user does any of the following while composing an e-mail message:

- Add a recipient
- Add an attachment
- Reply or Reply all
- Open a message from the Drafts folder that's already addressed to recipients

In addition to the built-in MailTips that are available, you can create custom MailTips for all types of recipients. For more information about the built-in MailTips, see MailTips.

What do you need to know before you begin?

- Estimated time to complete: 10 minutes

- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "MailTips" entry in the Mail flow permissions topic.
- You can configure the primary MailTip in the Exchange admin center (EAC) or in the Shell. However, you can only configure additional MailTip translations in the Shell.
- When you add a MailTip to a recipient, two things happen:
  - HTML tags are automatically added to the text. For example, if you enter the text: `This mailbox is not monitored`, the MailTip automatically becomes: `<html><body>This mailbox is not monitored</body></html>`. Additional HTML tags in the MailTip aren't supported.
  - The text is automatically added to the *MailTipTranslations* property of the recipient as the default value. If you modify the MailTip text, the default value is automatically updated in the *MailTipTranslations* property.
- The length of a MailTip can't exceed 175 displayed characters.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Configure MailTips for recipients

Use the EAC to configure MailTips for recipients

1. In the EAC, navigate to **Recipients**.
2. Select any of the following recipient tabs based on the recipient type:
   - **Mailboxes**
   - **Groups**
   - **Resources**
   - **Contacts**
   - **Shared**
3. On the recipient tab, select the recipient you want to modify, and click **Edit** .
4. In the recipient properties page that appears, click **MailTips**.
5. Enter the text for the MailTip. When you are finished, click **Save**.

Use the Shell to configure MailTips for recipients

To configure a MailTip for a recipient, use the following syntax.

```
Set-<RecipientType> <RecipientIdentity> -MailTip "<MailTip text>"
```

<RecipientType> can be any type of recipient. For example, `Mailbox`, `MailUser`, `MailContact`,

`DistributionGroup`, or `DynamicDistributionGroup`.

For example, suppose you have a mailbox named "Help Desk" for users to submit support requests, and the promised response time is two hours. To configure a custom MailTip that explains this, run the following command:

```
Set-Mailbox "Help Desk" -MailTip "A Help Desk
representative will contact you within 2 hours."
```

Use the Shell to configure additional MailTips in different languages

To configure additional MailTip translations without affecting the existing MailTip text or other existing MailTip translations, use the following syntax:

```
Set-<RecipientType> -MailTipTranslations
@{Add="<culture1>:<localized text
1>","<culture2>:<localized text 2>"...;
Remove="<culture1>:<localized text
1>","<culture2>:<localized text 2>"...}
```

<culture> is a valid ISO 639 two-letter culture code associated with the language.

For example, suppose the mailbox named Notifications currently has the MailTip: "This mailbox is not monitored." To add the Spanish translation, run the following command:

```
Set-Mailbox -MailTipTranslations @{Add="ES:Esta caja no se
supervisa."}
```

How do you know this worked?

To verify that you have successfully configured a MailTip for a recipient, do the following:

1. In Outlook Web App or Outlook 2010 or later, compose an email message addressed to the recipient, but don't send it.
2. Verify the MailTip appears in the InfoBar.
3. If you configured additional MailTip translations, compose the message in Outlook Web App where the language setting matches the language of the MailTip translation to verify the results.

MailTips over organization relationships

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-15*

Microsoft Exchange Server 2013 allows you to configure organization relationships with Microsoft Exchange Online or other Exchange organizations. Establishing an organization relationship allows you to enhance the user experience when dealing with the other organization. For example, you can share free or busy data, configure secure message flow, and enable message tracking across both organizations.

Controlling the MailTips access level

You may want to restrict certain types of MailTips. You can either allow all MailTips to be returned or allow only a limited set that would prevent NDRs. You can configure this setting with the *MailTipsAccessLevel* parameter on the **Set-OrganizationRelationship** cmdlet. The following table shows which MailTips are returned over the organization relationship.

MailTip	Is the MailTip available when the access level is set to All?	Is the MailTip available when the access level is set to Limited?
Large Audience	Yes	No
Automatic Replies	Yes If the remote domain of the recipient is specified as internal, the internal automatic reply is displayed. Otherwise, the external automatic reply is displayed.	Yes The external automatic reply is displayed.
Moderated Recipient	Yes	No
Oversize Message	Yes	Yes
Restricted Recipient	Yes	Yes
Mailbox Full	Yes	No
Custom MailTips	Yes	No
External Recipients	Yes	Yes

	If the remote domain of the recipient is specified as internal, this MailTip is suppressed. Otherwise, the external MailTip is returned.	If the remote domain of the recipient is specified as internal, this MailTip is suppressed. Otherwise, the external MailTip is returned.

For detailed steps about how to configure MailTips access levels, see Manage MailTips for organization relationships.

Controlling the MailTips access scope

When you enable MailTips over an organization relationship and set the access level to `All`, the recipient-specific MailTips, Mailbox Full, Automatic Replies, and custom MailTips, are returned for all users. However, you may only want to allow these MailTips for a specific set of users. For example, if you set up an organization relationship with a partner, you may want to allow these MailTips only for the users that work with that partner.

To achieve this, you need to first create a group and add all users for whom you want to share recipient-specific MailTips to that group. You can then specify that group on the organization relationship.

After you implement this restriction, your Client Access servers will first verify whether the recipient for whom they received a MailTips query is part of this group. If the recipient is a member of this group, the Client Access servers will proxy back all MailTips including the recipient-specific MailTips. Otherwise they won't include the recipient-specific MailTips in their response.

For detailed steps about how to configure MailTips access levels, see Manage MailTips for organization relationships.

Manage MailTips for organization relationships

Clients and mobile > MailTips > MailTips over organization relationships >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-03*

You can use the Exchange Management Shell to configure custom settings for MailTips between various organizations.

By establishing an organizational relationship, you can enhance the user experience for both organizations by sharing free/busy data, configuring secure message flow, and enabling message tracking. For more information about organizational relationships, see MailTips over organization relationships.

You can use various settings to control how MailTips are used between two organizations that have established an organizational relationship. The procedures in this section illustrate these various controls. In all examples, the on-premises organization is contoso.com, the remote organization is online.contoso.com, and the organizational relationship is named Contoso Online.

You use the **Set-OrganizationRelationship** cmdlet to configure these settings.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "MailTips" entry in the Mail flow permissions topic.
- You can only use the Shell to perform this procedure.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to enable or disable MailTips between two organizations

This example configures the organizational relationship so that MailTips are returned to senders in the remote organization when composing messages to recipients in your organization.

```
Set-OrganizationRelationship "Contoso Online" -
MailTipsAccessEnabled $true
```

This example configures the organizational relationship to prevent MailTips from being returned to senders in the remote organization when composing messages to recipients in your organization.

```
Set-OrganizationRelationship "Contoso Online" -
MailTipsAccessEnabled $false
```

For detailed syntax and parameter information, see Set-OrganizationRelationship.

Use the Shell to configure which MailTips are returned to the remote organization

For each organizational relationship, you can determine which set of MailTips are returned to senders in the other organization. This example configures the organizational relationship so that all MailTips are returned.

```
Set-OrganizationRelationship "Contoso Online" -
MailTipsAccessLevel All
```

This example configures the organizational relationship so that only the Automatic Replies, Oversize Message, Restricted Recipient, and Mailbox Full MailTips are returned.

```
Set-OrganizationRelationship "Contoso Online" -
MailTipsAccessLevel Limited
```

This example configures the organizational relationship so that no MailTips are returned.

Note:

Don't use this method to disable MailTips for this relationship. To disable MailTips, set the *MailTipsAccessEnabled* parameter to `$false`.

```
Set-OrganizationRelationship "Contoso Online" -
MailTipsAccessLevel None
```

For detailed syntax and parameter information, see Set-OrganizationRelationship.

Use the Shell to configure a specific group of users for whom recipient-specific MailTips are returned

You can restrict the return of recipient-specific MailTips to a specific group of users. By default, when you enable MailTips for an organizational relationship, the following recipient-specific MailTips are returned for all users:

- Automatic Replies
- Mailbox Full
- Custom MailTip

You can specify a MailTips access group on the organizational relationship. After you specify a group, the recipient-specific MailTips are returned only for mailboxes, mail contacts, and mail users that are members of that group. This example configures the organizational relationship to return recipient-specific MailTips only for members of the ShareMailTips@contoso.com group.

```
Set-OrganizationRelationship "Contoso Online" -
MailTipsAccessScope ShareMailTips@contoso.com
```

For detailed syntax and parameter information, see Set-OrganizationRelationship.

Group metrics and MailTips

Exchange Server 2013 > Clients and mobile > MailTips >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-16*

Group metrics is the collection of the following data about distribution groups and dynamic distribution groups in your organization:

- Number of members
- Number of members who are external to your organization

Group metrics data is used to support MailTips in Microsoft Exchange Server 2013. MailTips are informative messages that are displayed to senders while they're composing messages. For more information about MailTips,including a full list of MailTips available in Exchange 2013, see MailTips.

Group metrics data is used by the following MailTips:

- **Large Audience** This MailTip is displayed when a sender adds a distribution group whose membership count is considered a large audience as configured in your organization. By default, any message addressed to more than 25 recipients is considered a large audience.
- **External Recipients** This MailTip is displayed when a sender adds a distribution group that has members who are external to your organization.

MailTips are evaluated every time a sender adds a recipient to a message. To provide this information, Exchange calculates group metrics data as a background process that can be scheduled to run outside of your organization's regular business hours. When evaluating recipients for MailTips, Exchange reads group metrics data.

Group Metrics generation

In Exchange 2013, group metrics data is stored in the **msExchGroupMemberCount** and **msExchGroupExternalMemberCount** attributes on the group object in Active Directory. The following files in the %ExchangeInstallPath%GroupMetrics folder are also associated with group metrics:

- **Cookie_<*nnnnnnn*>.dsc** This text file contains information about the Mailbox server that is configured to generate group metrics data, and the last successful group metrics generation time. This allows group metrics to generate data for groups that were changed since the last group

metrics generation.

- **ChangedGroups.txt** This file contains the list of groups that were updated the last time group metrics data was generated.

Group metrics generation is handled by an arbitration mailbox, which is also called an organization mailbox. When the *GMGen* parameter on an arbitration mailbox is set to `$true`, the arbitration mailbox is responsible for generating the group metrics data.

The Mailbox server generates full group metrics data for all distribution groups and dynamic distribution groups the first time the Group Metrics mailbox assistant runs, and incremental updates for any groups that were modified since the last full generation. By default, group metrics data is generated daily at a random time when the Exchange server workload is light. If the workload is constantly high, group metrics generation may be skipped.

To configure group metrics generation, see Configure group metrics.

Configure group metrics

Clients and mobile > MailTips > Group metrics and MailTips >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-01-30*

MailTips that provide information about the size of distribution groups and dynamic distribution groups rely on group metrics data. Group metrics data is generated on designated Mailbox servers. For more information about group metrics, see Group metrics and MailTips.

You can enable or disable group metrics generation on a Mailbox server.

What do you need to know before you begin?

- Estimated time to complete each procedure: 10 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Group metrics" entry in the Recipients Permissions topic.
- Group metrics data is only used for MailTips. Make sure that group metrics MailTips are enabled in your organization. For detailed steps, see Manage MailTips for organization relationships.
- You can only use the Shell to perform this procedure.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to enable or disable group metrics generation

Note:
By default, group metrics data is generated on any server responsible for generating the offline address book (OAB). These examples are only necessary for organizations that don't use OABs.

To enable or disable group metrics generation on a Mailbox server, run the following command:

```
Set-MailboxServer <ServerIdentity> -
ForceGroupMetricsGeneration <$true | $false>
```

This example enables group metrics generation on a Mailbox server named MBX1.

```
Set-MailboxServer MBX1 -ForceGroupMetricsGeneration $true
```

How do you know this worked?

To verify that you have successfully enabled or disabled group metrics generation in an organization that doesn't use OABs, do the following:
1. Run the following command:

```
Get-MailboxServer <ServerIdentity> | Format-List
ForceGroupMetricsGeneration
```

2. Verify the setting displayed is the setting you configured.

Apps for Outlook

Exchange Server 2013 > Clients and mobile >

Topic Last Modified: *2013-06-17*

Apps for Outlook are applications that extend the usefulness of email by adding information or tools that your users can use without having to leave Outlook Web App. Outlook Web App supports a variety of apps. When apps for Outlook are installed and enabled for a user, the apps are added to messages that meet the criteria that trigger it.

Tip:
For information about apps for Outlook from an end-user perspective, check out the Help topic Installed Apps at Office.com. That topic provides an overview of apps for Outlook and

also shows you some of the apps for Outlook that may be installed by default.

Office Store apps and custom apps

Outlook Web App supports a variety of apps that are available through the Office Store. Outlook Web App also supports custom apps that you can create and distribute to users in your organization.

Note:
Access to the Office Store isn't supported for mailboxes or organizations in specific regions. If you don't see **Add from the Office Store** as an option in the **Exchange admin center** under **Organization** > **Apps** > **+**, you may be able to install an App for Outlook from a URL or file location. For more information, contact your service provider.

Note:
Some apps for Outlook are installed by default. Default apps for Outlook only activate on English language content. For example, German postal addresses in the message body won't activate the Bing Maps app.

App access and installation

You can specify the apps for Outlook that you want your users to be able to use. You can also specify which apps are enabled by default. For more information, see Install or remove apps for Outlook for your organization.

If required, you can limit availability of an app to specific users in your organization. For more information, see Manage user access to apps for Outlook.

Allow administrators and users to install apps

You can specify which administrators in your organization have permission to install and manage apps for Outlook. You can also specify which users in your organization have permission to install and manage apps for their own use. For more information, see Specify the Administrators and Users Who Can Install and Manage Apps for Outlook.

Install or remove apps for Outlook for your organization

Exchange Server 2013 > Clients and mobile > Apps for Outlook >

Topic Last Modified: *2013-06-17*

You can install or remove apps for Outlook for your organization by using the EAC or the Shell.

Note:

By default, after you install an app for your organization, the app is available for all users in your organization. After installation, you can use the EAC or the Shell to make the app optional or required for your users, and to specify whether you want the app to be enabled or disabled. For information about how to change the default settings for an app, see Manage user access to apps for Outlook. To limit availability of apps to specific users in your organization, you must use the Shell. For more information, see Manage user access to apps for Outlook.

For additional management tasks related to apps for Outlook, see Apps for Outlook.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Apps for Outlook" entry in the Recipients Permissions topic.
- You can assign administrators permission to install and manage apps for your organization. You can also assign users permission to install and manage apps for their own use. For more information, see Specify the Administrators and Users Who Can Install and Manage Apps for Outlook.
- Access to the Office Store isn't supported for mailboxes or organizations in specific regions. If you don't see **Add from the Office Store** as an option in the **Exchange admin center** under **Organization** > **Apps** > **+**, you may be able to install an App for Outlook from a URL or file location. For more information, contact your service provider.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Add an app for Outlook

Use the EAC to add an app

1. In the EAC, navigate to **Organization** > **Apps**.
2. Click **New +**, and then choose the location that you want to install the app from.
   - **Add from the Office Store**. At the Office Store, select the app you want to install, and then click **Add**. Apps that work with Outlook Web App are listed under **Apps for Office and SharePoint** > **Outlook**.

Note:

Access to the Office Store isn't supported for mailboxes or organizations in specific regions. If you don't see **Add from the Office Store** as an option in the **Exchange admin center** under **Organization** > **Apps** > **+**, you may be able to install an App for Outlook from a URL or file location. For more information, contact your service provider.

- **Add from URL**. In **URL**, enter the full URL for the app manifest file that you want to install.
- **Add from file**. Select **Browse**, and then navigate to the location of the app manifest file that you want to install.

3. Click **Save**.

Use the Shell to add an app

This example shows you how to add an app from a URL.

```
New-App -OrganizationApp -Url <URL location for App
Manifest file>
```

This example shows you how to add an app from a file.

```
New-App -OrganizationApp -FileData <File location for App
Manifest file>
```

Tip:

When you use the Shell to install an app for your organization, you can install the app and configure settings for it at the same time.

For syntax and parameters, see New-App.

Remove an app for Outlook

Use the EAC to remove an app

1. In the EAC, navigate to **Organization** > **Apps**.
2. In the list view, select the app that you want to remove, and then click **Delete** 🗑.

Use the Shell to remove an app

You can use the Shell to remove an app from your organization.

Note:

Run the following command to look up the display names and application IDs for all the apps for Outlook installed for your organization.

```
Get-App -OrganizationApp |FL DisplayName,AppID
```

Run the following command to remove the custom app Finance Test App from the organization.

```
Remove-App -OrganizationApp -Identity <GUID for Finance
Test App>
```

For syntax and parameters, see Remove-App.

How do you know this worked?

To view the apps for Outlook that are installed in your organization, do one the following:

- In the EAC, navigate to **Organization** > **Apps**, and then review the list of installed apps.
- From the Shell, run `Get-App`, and then review the list of installed apps.

Manage user access to apps for Outlook

Exchange Server 2013 > Clients and mobile > Apps for Outlook >

Topic Last Modified: *2013-11-27*

You can use the EAC or the Shell to manage user access to apps for Outlook.

- Using the EAC, you can manage basic app access settings for your users at an organizational level. For example, you can configure whether an app is enabled or disabled for your users. You can also specify whether an app is required or optional for your users.
- With the Shell, you can manage all the settings that you can with the EAC, as well as other settings. For example, you can limit availability to specific users in your organization.

For additional management tasks related to apps for Outlook, see Apps for Outlook.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Apps for Outlook" entry in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Specify whether an app is available, enabled, or disabled

Use the EAC to specify whether an app is available, enabled, or disabled

1. In the EAC, navigate to **Organization** > **Apps**.
2. In the list view, select the app that you want to change settings for, and then click **Edit** .
3. If you don't want your users to use the app, clear the **Make this app available to users in your organization** check box, and then click **Save**.
4. If you want your users to be able to use the app, select **Make this app available to users in your organization**, and then select the option you want.
   - **Optional, enabled by default** Use this setting if you want to allow your users to turn off the app.
   - **Optional, disabled by default** Use this setting if you want to allow your users to turn on the app.
   - **Mandatory, always enabled. Users can't disable this app** Use this setting if you don't want your users to turn off the app.
5. Click **Save**.

Use the Shell to specify whether an app is available, enabled, or disabled

You can use the Shell to specify whether an app is available, enabled, or disabled.

Note:

Run the following command to look up the display names and application IDs for all the apps for Outlook installed for your organization.

```
Get-App -OrganizationApp | Format-List DisplayName,AppID
```

If you want an app to be disabled and hidden from all your users, run the following command.

```
Set-App <App ID> -OrganizationApp -Enabled $false
```

If you want the app to be enabled by default, but you want your users to be able to turn it off, run the following command.

```
Set-App <App ID> -OrganizationApp -Enabled $true -
DefaultStateForUser Enabled
```

If you want the app to be disabled by default, but you want your users to be able to turn it on, run the following command.

```
Set-App <App ID> -OrganizationApp -Enabled $true -
DefaultStateForUser Disabled
```

If you want the app to be required for your users, run the following command.

```
Set-App <App ID> -OrganizationApp -Enabled $true -
DefaultStateForUser AlwaysEnabled
```

For detailed syntax and parameters, see Set-App.

How do you know this worked?

1. In the EAC, navigate to **Organization** > **Apps**.
2. Review the values in the **User Default** and **Provided To** columns.

Or

1. From the Shell, run `Get-App -OrganizationApp | Format-List DisplayName,AppId,Enabled,Default*`.
2. Review the values for **DefaultStateForUser** and **Enabled**.

Limit availability to specific users

Use the Shell to limit availability to specific users

If you want only members of your Marketing team distribution group to be able to use the LinkedIn app, run the following commands.

```
$a = Get-DistributionGroupMember Marketing

Set-App <App ID for the LinkedIn app> -OrganizationApp -
ProvidedTo SpecificUsers -UserList $a -DefaultStateForUser
Enabled}
```

For detailed syntax and parameters, see Set-App.

How do you know this worked?

To verify that you've successfully limited access for specific users, do the following:

1. From the Shell, run `Get-App -OrganizationApp | Format-List DisplayName,AppId,Enabled,Default*,ProvidedTo,UserList`.
2. Review the value for **ProvidedTo**.

Specify the Administrators and Users Who Can Install and Manage Apps for Outlook

Topic Last Modified: *2013-06-17*

You can specify which administrators in your organization have permissions to install and manage apps for Outlook. You can also specify which users in your organization have permission to install and manage apps for their own use.

There are four built-in management roles that you use to assign these permissions to individual users or security groups.

Administrative roles

- **Org Marketplace Apps** Enables an administrator to install and manage apps that are available from the Office Store for their organization.
- **Org Custom Apps** Enables an administrator to install and manage custom apps for their organization.

User roles

- **My Marketplace Apps** Enables a user to install and manage Office Store apps for their own use.
- **My Custom Apps** Enables a user to install and manage custom apps for their own use.

For information about each of these roles, see Org Marketplace Apps role, Org Custom Apps role, My Marketplace Apps role, and My Custom Apps role.

For information about apps for Outlook, see Apps for Outlook.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can run this cmdlet. Although all parameters for this cmdlet are listed in this topic, you may not have access to some parameters if they're not included in the permissions assigned to you. To see what permissions you need, see the "Role assignments" entry in the Role management permissions topic.
- Access to the Office Store isn't supported for mailboxes or organizations in specific regions. If you don't see **Add from the Office Store** as an option in the **Exchange admin center** under **Organization** > **Apps** > **+**, you may be able to install an App for Outlook from a URL or file location. For more information, contact your service provider.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Assign administrators the permissions required to install

and manage apps for your organization

Use the EAC to assign permissions to administrators

You can use the EAC to assign administrators the permissions required to install and manage apps that available from the Office Store for your organization. For detailed information about how to do this, see Manage role groups.

Use the Shell to assign permissions to administrators

This example assigns administrator Tony Smith (TonySmith) the permissions required to install and manage apps that are available from the Office Store for your organization.

```
New-ManagementRoleAssignment -Role "Org Marketplace Apps" -
User TonySmith
```

This example assigns members of the Store App Admins security group (StoreAppAdmins) the permissions required to install and manage Office Store apps for your organization.

```
New-ManagementRoleAssignment -Role "Org Marketplace Apps" -
SecurityGroup StoreAppAdmins
```

This example assigns administrator Tony Smith (TonySmith) the permissions required to install custom apps for your organization.

```
New-ManagementRoleAssignment -Role "Org Custom Apps" -User
TonySmith
```

This example assigns members of the Custom App Admins security group (CustomAppAdmins) the permissions required to install custom apps for your organization.

```
New-ManagementRoleAssignment -Role "Org Custom Apps" -
SecurityGroup CustomAppAdmins
```

For more information about syntax and parameters, see New-ManagementRoleAssignment.

Assign users the permissions required to install and manage apps for their own use

Use the EAC to assign permissions to users

You can use the EAC to assign users the permissions required to view and modify custom apps for their own use. For detailed information about how to do this, see Manage role groups.

Use the Shell to assign permissions to users

This example assigns users Tony Smith (TonySmith) and Adam Barr (AdamBarr) the permissions required to install apps from the Office Store for their own use.

```
New-ManagementRoleAssignment -Role "My Marketplace Apps" -
UserList TonySmith,AdamBarr
```

This example assigns members of the Store App Users security group (Store AppUsers) the permissions required to install apps from the Office Store for their own use.

```
New-ManagementRoleAssignment -Role "My Marketplace Apps" -
SecurityGroup StoreAppUsers
```

This example assigns user Tony Smith (TonySmith) the permissions required to install custom apps for his own use.

```
New-ManagementRoleAssignment -Role "My Custom Apps" -User
TonySmith
```

This example assigns users of the Custom App Users (CustomAppUsers) the permissions required to install custom apps for their own use.

```
New-ManagementRoleAssignment -Role "My Custom Apps" -
SecurityGroup CustomAppUsers
```

For more information about syntax and parameters, see New-ManagementRoleAssignment.

How do you know this worked?

To verify that you've successfully assigned permissions for a user, run a Shell command using the format `Get-ManagementRoleAssignment -Role <Role Name> -GetEffectiveUsers`, where `Role Name` is the role for which you want to verify assigned permissions.

This example shows you how to verify whom you've assigned permissions to install apps from the Office Store for the organization.

1. Run `Get-ManagementRoleAssignment -Role "Org Marketplace Apps" -GetEffectiveUsers`.
2. In the results, review the entries in the **Effective Users** column.

For more information about syntax and parameters, see Get-ManagementRoleAssignment.

Configuring SSL offloading in Exchange

2013

Exchange Server 2013 > Clients and mobile >

Topic Last Modified: *2014-04-04*

The following helps you in configuring SSL offloading for the protocols and related services on Exchange 2013 Client Access servers with Service Pack 1 (SP1) installed. If you have multiple Client Access servers, you must perform the required steps for each protocol or service on every Client Access server with SP1 installed in your on-premises organization. That is not to mention that each Client Access server in your organization must be configured identically. If you are upgrading to newer Cumulative Updates (CUs) or service packs and you want to continue to use SSL offloading, you must perform the following steps again after you have upgraded or applied those updates on your Exchange 2013 Client Access servers.

One of the biggest advantages to SSL offloading is having the ability to more easily manage certificates that are used. Instead of having separate SSL certificates for each Client Access server with SP1 installed, a single SSL certificate is used and imported to all Client Access servers. The certificate used can be an existing or newly created SSL certificate.

Caution:

When you use Internet Information Services (IIS) Manager, the Exchange Management Shell, or a command-line interface to configure SSL offloading, notice that there is a **Default Web Site** and an **Exchange Back End** site. For SSL offloading, only configure the **Default Web Site** and don't make any changes to the **Exchange Back End** site.

Contents

What do I need to know before I begin?

- Install all of the required Client Access and Mailbox servers in your organization.
- Install Service Pack 1 (SP1) on each Client Access and Mailbox server in your organization. To download SP1, see Updates for Exchange 2013.
- Determine the required permissions for Exchange 2013 by seeing Feature permissions.
- To see what permissions you need for Client Access servers, see "Client Access server permissions" in Clients and mobile devices permissions.
- To see what permissions you need for Client Access servers, see "Outlook Web App permissions" in Clients and mobile devices permissions.
- You might be able to use only the Shell to perform some procedures. To learn how to open the Shell in your on-premises Exchange organization, see Open the Shell.
- To use an existing certificate on your Client Access servers and on the device you are terminating the SSL connections with, export the certificate with the private key on a Client Access server and import or install it on the device. For details, see Export-ExchangeCertificate.
- To use a new certificate, you must use EAC or the Shell to create, import, and enable the new certificate. For details, see Exchange 2013 certificate management UI.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Configure SSL offloading for Outlook Web App

To enable SSL offloading for Outlook Web App, you need to remove the SSL requirement on the **owa** virtual directory on the **Default Web Site**:

- **Step 1** You can use Internet Information Services (IIS) Manager or a command line to disable SSL on the **owa** virtual directory:
  - Using Internet Information Services (IIS) Manager, expand **Sites** > **Default Web Site**, and then select the **owa** virtual directory. In the results pane under **IIS**, double-click **SSL Settings**. In the **SSL Settings** results pane, clear the **Require SSL** check box, and then click **Apply** in the **Actions** pane.
  - Using the command line, type the following and then press Enter.

```
appcmd set config "Default Web Site/owa" /section:access /
sslFlags:None /commit:APPHOST
```

- **Step 2** You need to recycle the correct application pool or restart Internet Information Services by using one of the following methods:
  - Using a command line: Go to **Start** > **Run**, type **cmd**, and then press Enter. In the Command Prompt window, type the following and then press Enter.

```
appcmd Recycle AppPool MSExchangeOWAAppPool
```

- Using a Windows PowerShell cmdlet, type the following and then press Enter.

```
IIS:\>Restart-WebAppPool MSExchangeOWAAppPool
```

- Using a command line: Go to **Start** > **Run**, type **cmd**, and then press Enter. In the Command Prompt window, type the following and then press Enter.

```
iisreset /noforce
```

- Using Internet Information Services (IIS) Manager: In Internet Information Services (IIS) Manager, in the **Actions** pane, click **Restart**.

Configure SSL offloading for the Exchange Admin Center (EAC)

To enable SSL offloading for EAC, you need to remove the SSL requirement on the **ecp** virtual directory on the **Default Web Site**:

- **Step 1** You can use Internet Information Services (IIS) Manager or a command line to disable SSL on the **ecp** virtual directory:
  - Using Internet Information Services (IIS) Manager, expand **Sites** > **Default Web Site**, and then select the **ecp** virtual directory. In the results pane under **IIS**, double-click **SSL Settings**. In the **SSL Settings** results pane, clear the **Require SSL** check box, and then click **Apply** in the **Actions** pane.
  - Using the command line, type the following and then press Enter.

```
appcmd set config "Default Web Site/ecp" /section:access /
sslFlags:None /commit:APPHOST
```

- **Step 2** You need to recycle the correct application pool or restart Internet Information Services by using one of the following methods:
  - Using a command line: Go to **Start** > **Run**, type **cmd**, and then press Enter. In the Command Prompt window, type the following and then press Enter.

```
appcmd Recycle AppPool MSExchangeECPAppPool
```

  - Using a Windows PowerShell cmdlet, type the following and then press Enter.

```
IIS:\>Restart-WebAppPool MSExchangeECPAppPool
```

  - Using a command line: Go to **Start** > **Run**, type **cmd**, and then press Enter. In the Command Prompt window, type the following and then press Enter.

```
iisreset /noforce
```

- Using Internet Information Services (IIS) Manager: In Internet Information Services (IIS) Manager, in the **Actions** pane, click **Restart**.

Configuring SSL offloading for Outlook Anywhere

SSL offloading for Outlook Anywhere is enabled by default. Outlook Anywhere clients can get email from a private or public network. By default, the internal host name or FQDN of the server is used to enable internal Outlook clients to connect. However, if Outlook Anywhere isn't used internally, then you should remove the internal host name. To allow both internal and external access for Outlook clients, you must configure the internal and external host names, set the authentication method for each, and set both the internal and external clients to require SSL. To configure the authentication method for the external clients, you can use EAC or the Exchange Management Shell, but for internal clients, you must use the Shell:

- **Step 1** You can use EAC or the Shell if you haven't added an external host name for Outlook Anywhere:
  - Using EAC, go to **Servers**, select the name of the Client Access server in the list, and then click **Edit**. In the **Exchange Server** window, click **Outlook Anywhere**, and then in the **Specify the external host name (for example, contoso.com) that users will use to connect to your organization** box, enter the external host name. Verify that the **Allow SSL offloading** option is selected, and then click **Save**.
  - Using the Exchange Management Shell, click **Start**, and then on the **Start** menu, click **Exchange Management Shell**. In the window, type the following and then press Enter:

```
Set-OutlookAnywhere -Identity ClientAccessServer1\Rpc* -
Externalhostname ClientAccessServer1.contoso.com -
ExternalClientsRequireSsl:$True -
ExternalClientAuthenticationMethod Basic
```

- **Step 2** By default, SSL offloading is enabled. However, you can use EAC or the Exchange Management Shell if SSL offloading has been disabled and you want to enable it:
  - Using EAC, go to **Servers**, select the name of the Client Access server in the list, and then click **Edit**. In the **Exchange Sever** window, click **Outlook Anywhere**, click the **Allow SSL offloading** option, and then click **Save**.
  - Using the Shell, type the following and then press Enter.

```
Set-OutlookAnywhere -Identity ClientAccessServer1\Rpc* -
SSLOffloading $true
```

- **Step 3** By default, **Require SSL** is not selected on the **Rpc** virtual directory, but if you want to verify that SSL is disabled, you can use Internet Information Services (IIS) Manager.
  - Using Internet Information Services (IIS) Manager, expand **Sites** > **Default Web Site**, and then select the **Rpc** virtual directory. In the results pane under **IIS**, double-click **SSL Settings**. In the **SSL Settings** results pane, verify that the **Require SSL** check box is cleared, and then click **Apply** in the **Actions** pane.

- **Step 4** You need to recycle the correct application pool or restart Internet Information Services by using one of the following methods:
  - Using a command line: Go to **Start** > **Run**, type **cmd**, and then press Enter. In the Command Prompt window, type the following and then press Enter.

```
appcmd Recycle AppPool MSExchangeRpcProxyFrontEndAppPool
```

  - Using a Windows PowerShell cmdlet, type the following and then press Enter.

```
IIS:\>Restart-WebAppPool MSExchangeRpcProxyFrontEndAppPool
```

  - Using a command line: Go to **Start** > **Run**, type **cmd**, and then press Enter. In the Command Prompt window, type the following and then press Enter.

```
iisreset /noforce
```

  - Using Internet Information Services (IIS) Manager: In Internet Information Services (IIS) Manager, in the **Actions** pane, click **Restart**.

Important:
You must wait for the Service Host process to apply any changes from Active Directory to Internet Information Services (IIS) every 15 minutes even if you restart IIS on a Client Access server.

Configuring SSL offloading for the Offline Address Book (OAB)

To enable SSL offloading for the Offline Address Book (OAB), you need to remove the SSL requirement on the **OAB** virtual directory on the **Default Web Site**:

- **Step 1** You can use Internet Information Services (IIS) Manager or a command line to disable SSL on the **OAB** virtual directory:
  - Using Internet Information Services (IIS) Manager, expand **Sites** > **Default Web Site**, and then select the **OAB** virtual directory. In the results pane under **IIS**, double-click **SSL Settings**. In the **SSL Settings** results pane, clear the **Require SSL** check box, and then click **Apply** in the **Actions** pane.
  - Using the command line, type the following and then press Enter.

```
appcmd set config "Default Web Site/OAB" /section:access /
sslFlags:None /commit:APPHOST
```

- **Step 2** You need to recycle the correct application pool or restart Internet Information Services by using one of the following methods:
  - Using a command line: Go to **Start** > **Run**, type **cmd**, and then press Enter. In the Command Prompt window, type the following and then press Enter.

```
appcmd Recycle AppPool MSExchangeOABAppPool
```

- Using a Windows PowerShell cmdlet, type the following and then press Enter.

```
IIS:\>Restart-WebAppPool MSExchangeOABAppPool
```

- Using a command line: Go to **Start** > **Run**, type **cmd**, and then press Enter. In the Command Prompt window, type the following and then press Enter.

```
iisreset /noforce
```

- Using Internet Information Services (IIS) Manager: In Internet Information Services (IIS) Manager, in the **Actions** pane, click **Restart**.

Configuring SSL offloading for Exchange ActiveSync (EAS)

To enable SSL offloading for Exchange ActiveSync (EAS), you need to remove the SSL requirement on the **Microsoft-Server-ActiveSync** virtual directory on the **Default Web Site**:

- **Step 1** You can use Internet Information Services (IIS) Manager or a command line to disable SSL on the **Microsoft-Server-ActiveSync** virtual directory:
  - Using Internet Information Services (IIS) Manager, expand **Sites** > **Default Web Site**, and then select the **Microsoft-Server-ActiveSync** virtual directory. In the results pane under **IIS**, double-click **SSL Settings**. In the **SSL Settings** results pane, clear the **Require SSL** check box, and then click **Apply** in the **Actions** pane.
  - Using the command line, type the following and then press Enter.

```
appcmd set config "Default Web Site/
MSExchangeSyncAppPool" /section:access /sslFlags:None /
commit:APPHOST
```

- **Step 2** You need to recycle the correct application pool or restart the Internet Information Services by using one of the following methods:
  - Using a command line: Go to **Start** > **Run**, type **cmd**, and then press Enter. In the Command Prompt window, type the following and then press Enter.

```
appcmd Recycle AppPool MSExchangeSyncAppPool
```

- Using a Windows PowerShell cmdlet, type the following and then press Enter.

```
IIS:\>Restart-WebAppPool MSExchangeSyncAppPool
```

- Using a command line: Go to **Start** > **Run**, type **cmd**, and then press Enter. In the Command Prompt window, type the following and then press Enter.

```
iisreset /noforce
```

- Using Internet Information Services (IIS) Manager: In Internet Information Services (IIS) Manager, in the **Actions** pane, click **Restart**.

Configuring SSL offloading for Exchange Web Services (EWS)

To enable SSL offloading for Exchange Web Services (EWS), you need to remove the SSL requirement on the **EWS** virtual directory on the **Default Web Site**:

- **Step 1** You can use Internet Information Services (IIS) Manager or a command line to disable SSL on the **EWS** virtual directory:
  - Using Internet Information Services (IIS) Manager, expand **Sites** > **Default Web Site**, and then select the **EWS** virtual directory. In the results pane under **IIS**, double-click **SSL Settings**. In the **SSL Settings** results pane, clear the **Require SSL** check box, and then click **Apply** in the **Actions** pane.
  - Using the command line, type the following and then press Enter.

```
appcmd set config "Default Web Site/EWS" /section:access /
sslFlags:None /commit:APPHOST
```

- **Step 2** You need to recycle the correct application pool or restart Internet Information Services by using one of the following methods:
  - Using a command line: Go to **Start** > **Run**, type **cmd**, and then press Enter. In the Command Prompt window, type the following and then press Enter.

```
appcmd Recycle AppPool MSExchangeServicesAppPool
```

  - Using a Windows PowerShell cmdlet, type the following and then press Enter.

```
IIS:\>Restart-WebAppPool MSExchangeServicesAppPool
```

  - Using a command line: Go to **Start** > **Run**, type **cmd**, and then press Enter. In the Command Prompt window, type the following and then press Enter.

```
iisreset /noforce
```

  - Using Internet Information Services (IIS) Manager: In Internet Information Services (IIS) Manager, in the **Actions** pane, click **Restart**.

Configuring SSL offloading for the Autodiscover service

To enable SSL offloading for the Autodiscover service, you need to remove the SSL requirement on the **Autodiscover** virtual directory on the **Default Web Site**:

- **Step 1** You can use Internet Information Services (IIS) Manager or a command line to disable SSL on the **Autodiscover** virtual directory:
  - Using Internet Information Services (IIS) Manager, expand **Sites** > **Default Web Site**, and then select the **Autodiscover** virtual directory. In the results pane under **IIS**, double-click **SSL**

Settings. In the **SSL Settings** results pane, clear the **Require SSL** check box, and then click **Apply** in the **Actions** pane.

- Using the command line, type the following and then press Enter.

```
appcmd set config "Default Web Site/autodiscover" /
section:access /sslFlags:None /commit:APPHOST
```

- **Step 2** You need to recycle the correct application pool or restart Internet Information Services by using one of the following methods:
  - Using a command line: Go to **Start** > **Run**, type **cmd**, and then press Enter. In the Command Prompt window, type the following and then press Enter.

```
appcmd Recycle AppPool MSExchangeAutodiscoverAppPool
```

  - Using a Windows PowerShell cmdlet, type the following and then press Enter.

```
IIS:\>Restart-WebAppPool MSExchangeAutodiscoverAppPool
```

  - Using a command line: Go to **Start** > **Run**, type **cmd**, and then press Enter. In the Command Prompt window, type the following and then press Enter.

```
iisreset /noforce
```

  - Using Internet Information Services (IIS) Manager: In Internet Information Services (IIS) Manager, in the **Actions** pane, click **Restart**.

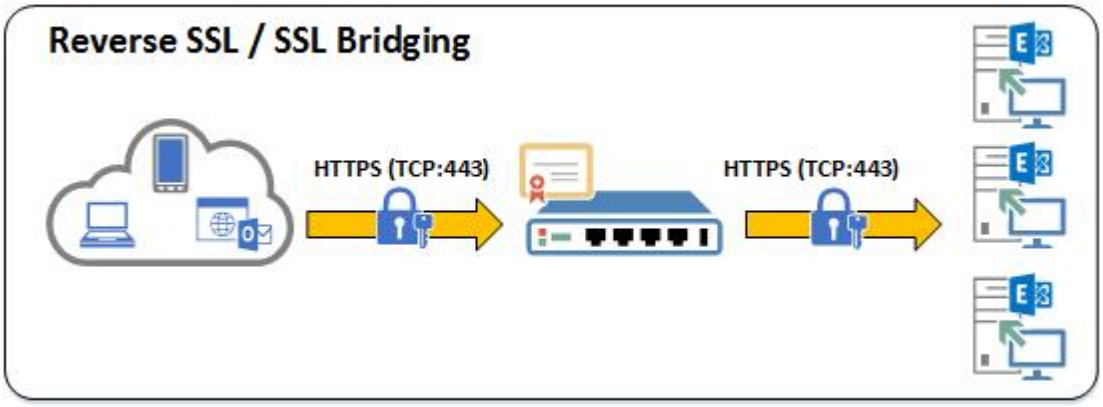
Configuring SSL Offloading for the Mailbox Replication Proxy Service (MRSProxy)

The Mailbox Replication Proxy (MRSProxy) service is installed on every Exchange 2013 Client Access server. MRSProxy helps you to make cross-forest move requests on-premises as well as moving on-premises mailboxes to Office 365. However, by default, MRSProxy is disabled. If you are enabling it, you should enable it in the remote Exchange forest for cross–forest, on-premises mailbox moves or in the on-premises Exchange forest for moving a mailbox to Office 365. Although the MRSProxy service runs under Exchange Web Services (EWS), it's not supported to configure SSL offloading.

The reason for this is that the MRSProxy service expects traffic to be signed/encrypted. Any hardware load balancer or firewall must reencrypt the MRSProxy traffic before sending it to Client Access servers. If this is the case, it is recommended that you configure SSL bridging for offloading to work.

Reverse SSL or SSL Bridging If you enable reverse SSL or SSL bridging on hardware load balancers, you won't need to perform the preceding steps on each CAS server. However, enabling reverse SSL on your hardware load balancers means that SSL encryption and decryption will stay with the Client Access servers. In this case, the SSL encryption and decryption will occur on both the

hardware load balancers and the Client Access servers. Choosing to use Exchange 2013 SSL offloading or reverse SSL (SSL bridging) is dependent on the organizational goals and the security practices that must be implemented. The following picture shows client connectivity with SSL bridging (reverse SSL) enabled.



Configuring SSL offloading for Outlook clients (MAPI virtual directory)

To enable SSL offloading for Outlook clients, you need to remove the SSL requirement on the **MAPI** virtual directory on the **Default Web Site**:

- **Step 1** You can use Internet Information Services (IIS) Manager or a command line to disable SSL on the **MAPI** virtual directory:
  - Using Internet Information Services (IIS) Manager, expand **Sites** > **Default Web Site**, and then select the **MAPI** virtual directory. In the results pane under **IIS**, double-click **SSL Settings**. In the **SSL Settings** results pane, clear the **Require SSL** check box, and then click **Apply** in the **Actions** pane.
  - Using the command line, type the following and then press Enter.

```
appcmd set config "Default Web Site/MAPI" /section:access /
sslFlags:None /commit:APPHOST
```

- **Step 2** You need to recycle the correct application pool or restart the Internet Information Services by using one of the following methods:
  - Using a command line: Go to **Start** > **Run**, type **cmd**, and then press Enter. In the Command Prompt window, type the following and then press Enter.

```
appcmd Recycle AppPool MSExchangeMapiFrontEndAppPool
```

  - Using a Windows PowerShell cmdlet, type the following and then press Enter.

```
IIS:\>Restart-WebAppPool MSExchangeMapiFrontEndAppPool
```

- Using a command line: Go to **Start** > **Run**, type **cmd**, and then press Enter. In the Command Prompt window, type the following and then press Enter.

```
iisreset /noforce
```

- Using Internet Information Services (IIS) Manager: In Internet Information Services (IIS) Manager, in the **Actions** pane, click **Restart**.

Using a script to enable SSL offloading for all protocols and services

If you're working with a large organization with multiple Exchange 2013 Client Access servers, you might want to speed up the preceding steps that you went through. You can copy and paste the commands in either of the following scripts into Notepad, make any changes, save the file with a .ps1 extension, and then run it from the Exchange Management Shell. Depending on your needs, both of these scripts can be used to configure SSL offloading for all protocols and services for a single Client Access server or for multiple ones.

Note:
For the **Set-OutlookAnywhere** cmdlet entries, replace "MyServer" with the name of your Client Access server(s).

Using Set-WebConfigurationProperty

```
Set-OutlookAnywhere -Identity MyServer\Rpc* -
Externalhostname MyServer.mail.contoso.com -
ExternalClientsRequireSsl $True -
ExternalClientAuthenticationMethod Basic
Set-OutlookAnywhere -Identity MyServer\Rpc* -SSLOffloading
$true
Set-WebConfigurationProperty -Filter //security/access -
name sslflags -Value "None" -PSPath IIS:  -Location
"Default Web Site/OWA"
Set-WebConfigurationProperty -Filter //security/access -
name sslflags -Value "None" -PSPath IIS: -Location "Default
Web Site/ecp"
Set-WebConfigurationProperty -Filter //security/access -
name sslflags -Value "None" -PSPath IIS: -Location "Default
Web Site/EWS"
Set-WebConfigurationProperty -Filter //security/access -
```

```
name sslflags -Value "None" -PSPath IIS: -Location "Default
Web Site/Autodiscover"
Set-WebConfigurationProperty -Filter //security/access -
name sslflags -Value "None" -PSPath IIS: -Location "Default
Web Site/Microsoft-Server-ActiveSync"
Set-WebConfigurationProperty -Filter //security/access -
name sslflags -Value "None" -PSPath IIS: -Location "Default
Web Site/OAB"
Set-WebConfigurationProperty -Filter //security/access -
name sslflags -Value "None" -PSPath IIS: -Location "Default
Web Site/MAPI"
iisreset /noforce
```

Using appcmd

Note:

For the **Set-OutlookAnywhere** cmdlet entries, replace "MyServer" with the name of your Client Access server(s).

```
Set-OutlookAnywhere -Identity MyServer\Rpc* -
Externalhostname MyServer.mail.contoso.com -
ExternalClientsRequireSsl $True -
ExternalClientAuthenticationMethod Basic
Set-OutlookAnywhere -Identity MyServer\Rpc* -SSLOffloading
$true
&$env:systemroot\system32\inetsrv\appcmd set config
"Default Web Site/owa" /section:access /sslFlags:None /
commit:APPHOST
&$env:systemroot\system32\inetsrv\appcmd set config

&$env:systemroot\system32\inetsrv\appcmd set config
"Default Web Site/MAPI" /section:access /sslFlags:None /
commit:APPHOST
iisreset /noforce
```

Configuring coexistence with Exchange 2007 and Exchange 2010

During a coexistence scenario where you have a mix of Exchange 2003 and Exchange 2010 servers in the organization, one of the first steps you need to perform after deploying the Exchange 2010 Client Access Servers is to change DNS so that Exchange 2003 users access their mailboxes from a group of Exchange 2010 Client Access servers. In such a scenario, it's fully supported to enable SSL offloading on the load balancer used to distribute client traffic across the Client Access servers.

Coexistence with other versions of Outlook Web App

With SSL offloading configured on the Exchange 2013 Client Access servers, coexistence works with Exchange 2007 and Exchange 2010:

- To coexist with Exchange 2007, an earlier namespace is required, and redirection will happen to it only for Outlook Web App and Exchange Web Services. Autodiscover, Outlook Anywhere, and Exchange ActiveSync will be proxied over to the earlier versions.
- To coexist with Exchange 2010, if you have the external URL set, a redirect will be used. If not, a proxy will be used.

Unified Messaging

Exchange Server 2013 >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-23*

Unified Messaging (UM) enables users to use voice mail and other features, including Outlook Voice Access and Call Answering Rules. UM combines voice messaging and email messaging into one mailbox that can be accessed from many different devices. Users can listen to their messages from their email Inbox or by using Outlook Voice Access from any telephone. You have control over how users place outgoing calls from UM, and the experience people have when they call in to your organization.

Today, IT administrators frequently manage the voice mail or telephony networks and the email systems or data networks for their organizations as separate systems. Voice mail and email are located in separate inboxes that are hosted on separate servers accessed through the desktop for email and through the telephone for voice mail.

Unified Messaging makes it possible for Exchange administrators to combine voice messaging and email messaging into one mailbox so their users can listen to their voice mail messages in their Inbox or by using Outlook Voice Access from any telephone. It uses the Exchange store for both email and voice messages.

Contents

New features

Unified Messaging (UM) was first introduced in Microsoft Exchange Server 2007 and was also available in Exchange 2010. The Unified Messaging feature set in Exchange 2013 is similar to previous versions of Exchange. However, new features have been added and there have been architectural changes. Unified Messaging is now considered a component or sub feature of the voice-related features that are offered in Exchange 2013. The term *Unified Messaging* is still widely used in Exchange Management Shell cmdlets and UM-related services, and all Unified Messaging components—including dial plans, auto attendants, UM mailbox policies, and UM IP gateways—along with the ability to manage those UM components, are located within the Unified Messaging node in the navigation pane of the Exchange Administration Center (EAC).

The following topics are gateways to information about new or enhanced features found in Exchange 2013 Unified Messaging:

- Voice architecture changes
- IPv6 support in Unified Messaging
- Voice mail preview enhancements
- Unified Messaging cmdlet updates

Return to top

Unified Messaging features

The voice mail features found in Unified Messaging offer benefits for both end users and IT administrators.

Features for end users

When you deploy Unified Messaging, users can access voice mail, email, and calendar information that's located in their mailbox from an email client, for example, Outlook or Microsoft Outlook Web App, from a mobile phone with Microsoft Exchange ActiveSync set up, such as a Windows Phone, or from a telephone. Additionally, users can use the following features:

- **Access to Exchange information** UM-enabled users can access a full set of voice mail features from Internet-capable mobile phones, Microsoft Office Outlook 2007 or later versions, and Outlook Web App. These features include many voice mail configuration options and the ability to play a voice message from either the Reading Pane, using an integrated Windows Media Player, or the message list, using computer speakers.
- **Play on Phone** The Play on Phone feature lets UM-enabled users play voice messages over a telephone. If the user works in an office cubicle, is using a public computer or a computer that isn't enabled for multimedia, or is listening to a voice message that's confidential, they might not want to or be able to listen to a voice message through computer speakers. They can play the voice message using any telephone, including a home, office, or mobile telephone.
- **Voice mail form** The voice mail form resembles the default email form. It gives users an interface for performing actions such as playing, stopping, or pausing voice messages, playing voice messages on a telephone, and adding and editing notes.

The voice mail form includes the embedded Windows Media Player and an Audio notes field. The embedded Windows Media Player and notes field are displayed in either the Reading Pane when users preview a voice message or in a separate window when they open the voice message. If users aren't enabled for Unified Messaging, or if a supported email client hasn't been installed on the client computer, they view voice messages as email attachments, and the voice mail form isn't available.

- **User configuration** A user who's enabled for Unified Messaging can configure several voice mail options for Unified Messaging using Outlook Web App. For example, the user can configure telephone access numbers and the voice mail Play on Phone number, and can then reset a voice mail access PIN.
- **Call answering** Call answering includes answering incoming calls on behalf of users, playing their personal greetings, recording messages, and submitting them for delivery to their Inbox as an email message.
- **Call Answering Rules** Call Answering Rules lets users who are enabled for voice mail determine how their incoming call answering calls should be handled. The way call answering rules are applied to incoming calls is similar to the way Inbox rules are applied to incoming email messages. By default, no call answering rules are configured. If an incoming call is answered by the Mailbox server, the caller is prompted to leave a voice message for the called party. Using call answering rules, a caller can:
  - Leave a voice message for the UM-enabled user.
  - Transfer to an alternate contact of the UM-enabled user.
  - Transfer to the alternate contact's voice mail.

- Transfer to other phone numbers that the UM-enabled user has configured.
- Use the Find Me feature or locate the UM-enabled user via a transfer from an operator.

- **Voice Mail Preview** The Mailbox server uses Automatic Speech Recognition (ASR) on newly created voice mail messages. When users receive voice messages, the messages contain both a recording and text that's been created from the voice recording. Users see the voice message text displayed in an email message from within Outlook Web App or another supported email client.
- **Message Waiting Indicator** Message Waiting Indicator is a feature found in most legacy voice mail systems and can refer to any mechanism that indicates the existence of a new message. In Exchange 2007, this functionality was provided by a third-party application, which indicated receipt of a new voice message by lighting the lamp on the desk phone. This feature was added to Exchange 2010, and third-party software is no longer needed. Enabling or disabling Message Waiting Indicator is done on the user's mailbox or on a UM mailbox policy.
- **Missed call and voice mail notifications using SMS** When users are part of a hybrid or Office 365 deployment, and they configure their voice mail settings with their mobile phone number and configure call forwarding, they can receive notifications about missed calls and new voice messages on their cell phones in a text message via the Short Messaging Service (SMS). However, to receive these types of notifications, the users must first configure text messaging and also enable notifications on their account.
- **Protected Voice Mail** Protected Voice Mail is Unified Messaging functionality that enables users to send private mail. This mail is protected by Active Directory Rights Management Services (AD RMS), and users are restricted from forwarding, copying, or extracting the voice file from email. Protected Voice Mail increases the confidentiality of Unified Messaging, and lets users limit the audience for voice messages. This functionality is similar to the way private email messages were handled in Exchange 2007 but now it also applies to voice mail messages.
- **Outlook Voice Access** There are two Unified Messaging user interfaces available to UM-enabled users: the telephone user interface (TUI) and the voice user interface (VUI). These two interfaces together are called Outlook Voice Access. Outlook Voice Access users can use Outlook Voice Access when they access the voice mail system from an external or internal telephone. UM-enabled users who dial in to the voice mail system can access their mailbox using Outlook Voice Access. Using a telephone, a UM-enabled user can:
  - Access voice mail
  - Listen to, forward, or reply to email messages
  - Listen to calendar information
  - Access or dial contacts who are stored in the organization’s directory or a single contact or contact group located in their personal Contacts.
  - Accept or cancel meeting requests
  - Set a voice message to let callers know the called party is away
  - Set user security preferences and personal options
- **Group addressing using Outlook Voice Access** In Exchange 2007, users could use either the telephone user interface (TUI) or voice user interface (VUI) in Outlook Voice Access to send email and voice messages when they signed in to their mailbox. However, users could only send a single email message to a single user in their personal Contacts, to multiple recipients from the

directory by adding each recipient individually, or by adding the name of a distribution list from the directory for your organization. In Exchange 2013, when a user signs in to their mailbox using Outlook Voice Access, they can also send email and voice messages to users in a group stored in their personal Contacts.

Return to top

Administrative features

Currently, most users and IT departments manage their voice mail separately from their email. Voice mail and email exist as separate inboxes hosted on separate servers accessed through the desktop for email and through the telephone for voice mail. Unified Messaging offers an integrated store for all messages and access to content through the computer and the telephone.

Exchange administrators can manage Unified Messaging using the same interface they use to manage the rest of Exchange, using the Exchange Administration Center (EAC) and the Exchange Management Shell. They can:

- Manage voice mail and email from a single platform
- Manage Unified Messaging using scriptable commands
- Build highly available and reliable Unified Messaging infrastructures

Exchange 2013 Unified Messaging offers administrators:

- **A complete voice mail system** Unified Messaging offers a complete voice mail solution using a single store, transport, and directory infrastructure. The store is provided by a Mailbox server and forwarding of incoming calls from a VoIP gateway or IP PBX is handled by a Client Access server. All email and voice mail messages can be managed from a single management point, using a single administration interface and tool set.
- **An Exchange security model** The Microsoft Exchange Unified Messaging service on a Mailbox server and the Microsoft Exchange Unified Messaging Call Router service on a Client Access server run as a single Exchange server account.
- **Consolidation of voice mail systems** Currently, most voice messaging systems require that all the voice messaging components be installed in every physical office location in an organization. In this kind of arrangement, the voice messaging systems in branch offices are located outside the central office and must be administered onsite. This frequently results in increased administration costs and complexity. Unified Messaging lets you manage your voice mail system from a central location. To create a centralized management system for Unified Messaging, you can place some of your Exchange servers in a datacenter or other location, and the remainder of your Exchange servers on-premises and then deploy VoIP gateways, IP PBXs, or Session Border Controllers (SBCs) in each of your branch offices to replace the voice messaging system for each branch office. Deploying a centralized voice messaging system this way can result in a significant savings in hardware and administrative costs.
- **Built-in Unified Messaging administrative roles** The set of UM-specific administrative roles for managing Unified Messaging and voice mail features includes the following:
  - UM Mailboxes

    - UM Prompts
    - Unified Messaging
- **Incoming fax support** Exchange 2013 provides built-in incoming fax support for users who have a UM-enabled mailbox. They can receive fax messages via calls placed to their extension number.

Customers who require a fax solution will have to deploy a fax partner solution. Fax partner solutions are available from several fax partners. The fax partner solutions are designed to be tightly integrated with Exchange and enable UM-enabled users to receive incoming fax messages. You can find a fax partner solution by visiting Microsoft Pinpoint for Fax Partners.

- **Support for multiple languages** All available language packs contain the Text-to-Speech (TTS) engine and the prerecorded prompts for a specified language and ASR support. However, only some language packs contain support for Voice Mail Preview. The US English (en-US) language pack is included on the installation media and additional UM language packs can be downloaded from the Microsoft Download Center.
- **Auto attendant** An auto attendant is a set of voice prompts that gives external and internal users access to the voice mail system. Users can use the telephone keypad or speech inputs to move through the auto attendant menu, place a call to a user, or locate a user in your organization and then place a call to them. An auto attendant gives the administrator the ability to:
    - Create a customized menu for external users.
    - Define informational greetings, business hours greetings, and non-business hours greetings.
    - Define holiday schedules.
    - Describe how to search the organization's directory.
    - Describe how to connect to a user's extension so that external callers can call users by specifying their extension.
    - Describe how to search the organization's directory so that external callers can search the organization's directory and call a specific user.
    - Enable external users to call the operator.

Return to top

Planning and deploying UM

Unified Messaging requires that you integrate your Exchange Server deployment with the existing telephony system for your organization. A successful deployment requires you to make a careful analysis of your existing telephony infrastructure and to perform the correct planning steps to deploy and manage voice mail in Unified Messaging.

When you plan your Unified Messaging deployment, you must consider design and other issues that may affect your ability to reach your organizational goals when you deploy Unified Messaging. Generally, the simpler the Unified Messaging topology, the easier Unified Messaging is to deploy and maintain. Install as few Client Access and Mailbox servers and create as few Unified Messaging components like UM dial plans, auto attendants and UM mailbox policies as you need to support

your business and organizational goals. Large enterprises with complex network and telephony environments, multiple business units, or other complexities will require more planning than smaller organizations with relatively straightforward Unified Messaging needs.

There are many areas that you must consider and evaluate to be able to successfully deploy Unified Messaging. You must understand the different aspects of Unified Messaging and each component and feature so that you can plan your Unified Messaging infrastructure and deployment appropriately. Allocating time to plan and work through these issues will help prevent problems when you deploy Unified Messaging in your organization.The following are some of the areas that you should consider and evaluate when planning for Unified Messaging in your organization:

- The needs of your organization.
- The security requirements in your organization.
- Your existing telephony, circuit-switched network, and your current voice mail system.
- Your current packet-switched IP network design. This includes your local area network (LAN) and WAN connectivity points and devices.
- Your current Active Directory environment.
- The number of users that you'll have to support.
- The number of Client Access and Mailbox servers you'll need.
- Whether you'll be integrating UM with Microsoft Lync Server to enable Enterprise Voice.
- The placement of VoIP gateways, telephony equipment, and Client Access and Mailbox servers.
- The type of UM deployment: on-premises or hybrid.
- The storage requirements for voice mail users.

Return to top

Managing UM with the EAC and the Shell

EAC management

Exchange 2013 provides a single unified management console for your organization that includes all UM components and features. The Exchange Administration Center (EAC) provides a streamlined, optimized interface for management of on-premises, online, or hybrid deployments. The EAC in Exchange 2013 replaces the Exchange Management Console (EMC) and the Exchange Control Panel (ECP) in Exchange 2010. Some of the EAC features include:

- **List view** The list view in EAC has been designed to remove limitations that existed in ECP. ECP was limited to displaying up to 500 objects and, if you wanted to view objects that weren't listed in the details pane, you needed to use searching and filtering to find those specific objects. In Exchange 2013, the viewable limit from within the EAC list view is approximately 20,000 objects. In addition, paging has been added so that you can page to the results. You can also configure page size and export to a CSV file.
- **Add/Remove columns to the Recipient list view** You can choose which columns to view, and you can save your custom list views.
- **Secure the ECP virtual directory** You can partition access from the Internet and Intranets from within the ECP IIS virtual directory to allow or disallow management features. With this feature,

you can permit or deny access to users trying to access the EAC from the Internet outside of your organizational environment, while still allowing access to an end user's Outlook Web App Options.

- **Public Folder management** In Exchange 2010 and Exchange 2007, public folders were managed through the Public Folder administration console. Public folders are now in the EAC, and you don't need a separate tool to manage them.
- **Notifications** In Exchange 2013, the EAC now has a Notification viewer so that you can view the status of long-running processes and, if you choose, receive notification via an email message when the process completes.
- **Role Based Access Control (RBAC) user editor** In Exchange 2010 you could use the RBAC User Editor to add users to management role groups. In Exchange 2013, the RBAC User Editor functionality is now in the EAC, and you don't need a separate tool to manage RBAC.
- **Unified Messaging tools** In Exchange 2010 you could use the Call Statistics and User Call Logs tools to help provide UM statistics and information about specific calls for a UM-enabled user. In Exchange 2013, the Call Statistics and User Call Logs tools are now in the EAC, and you don't need a separate tool to manage them.

Shell management

The Exchange Management Shell, built on Windows PowerShell technology, is a powerful command-line interface that enables automation of administrative tasks. With the Shell, you can manage every aspect of Exchange. You can enable new email accounts, create Send and Receive connectors, configure database properties, manage all aspects of Unified Messaging, and more. The Shell can perform every task that can be performed by the EAC plus tasks that can't be done in the EAC. In fact, when you do something in the EAC, it's the Shell that's doing the work behind the scenes.

Unified Messaging documentation

The following table contains links to topics that will help you learn about and manage Exchange Unified Messaging.

Topic	Description
New voice mail features	Learn about new features in Microsoft Exchange 2013.
Planning for Unified Messaging	Learn about the concepts and information you need to plan a Unified Messaging deployment.
Deploying voice mail and UM	Learn about the requirements and steps involved in deploying voice mail and UM.

UM languages, prompts, and greetings	Learn about UM language packs and language settings.
Telephone system integration with UM	Learn about integrating your telephony network with UM.
Connect your voice mail system to your telephone network	Learn how to use and configure UM components to connect your telephony network to Exchange UM.
Automatically answer and route incoming calls	Learn how to create UM auto attendants and manage settings for navigation menus, greetings, and business and non-business hours.
Set up voice mail for users	Learn how to create and manage UM mailbox policies and how to enable users for UM.
Set up client voice mail features	Learn how to set up client features to enable users to access and manage their voice mail messages.
Set Outlook Voice Access PIN security	Learn how to set PIN requirements for Outlook Voice Access users.
Protect voice mail	Learn how to use UM to protect voice messages.
Run reports for voice mail calls	Learn about UM call reports.

New voice mail features

Exchange Server 2013 > Unified Messaging >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-13*

Unified Messaging (UM) in Microsoft Exchange Server 2013 includes the same feature set as Exchange 2010 and Exchange 2007, with some enhancements and architectural changes. However, Unified Messaging is no longer a separate server role. It's now a component of the voice-related features offered in Exchange 2013.

Changes in the Voice architecture

The Voice architecture in Exchange 2013 is different than it was in Exchange 2010 and Exchange 2007. In previous versions of Exchange UM, all the components for Unified Messaging were included on a server that had the UM server role installed. In Exchange 2013, the Unified Messaging components are split between a Client Access server running the Microsoft Exchange Unified Messaging Call Router service and a Mailbox server running the Microsoft Exchange Unified Messaging service. Most of the functionality, including the services and worker processes for Unified Messaging, is located on each Mailbox server. The Client Access server, running the Microsoft Exchange Unified Messaging Call Router service, proxies incoming calls to the Mailbox server. For details, see Voice architecture changes.

Support for IPv6

Internet Protocol version 6 (IPv6) is the most recent version of the Internet Protocol (IP). IPv6 is intended to correct many of the shortcomings of IPv4, which was the previous version of the IP. Just as Exchange 2010 did, Exchange 2013 Client Access and Mailbox servers fully support IPv6 networks. For details, see IPv6 support in Unified Messaging.

Support for UCMA 4.0 API

Since Exchange 2010 Service Pack 1 (SP1), the Unified Messaging role has relied on Unified Communications Managed API v2.0 (UCMA) for signaling and media. Therefore, UCMA 2.0 was a prerequisite for Exchange 2010 UM setup. UCMA 2.0 is downloaded separately and deployed manually by administrators on UM servers running Exchange 2010 SP1 or a later version.

However, UCMA 2.0 has several limitations. Many of these shortcomings are corrected by UCMA 4.0, which is required for Exchange 2013. Now that the UM server is no longer a separate server role, it's the Client Access and Mailbox servers that require UCMA 4.0.

UCMA 4.0 supports new features in Unified Messaging, such as using the same version of the Speech Engine for both Text-to-Speech (TTS) and Automatic Speech Recognition (ASR). The platform that's used for Exchange 2013, .NET 4.0, includes a single installer file and enables backward compatibility with Exchange 2010 and Exchange 2007 UM servers.

In Exchange 2010 SP2 and SP1, UCMA 2.0 installation is required prior to installing the service pack on a Unified Messaging server.

Using UCMA 4.0 offers multiple benefits:

- It incorporates hotfixes and patches.
- It supports IPv6.
- Deployment of UCMA 4.0 has been automated and simplified.
- UCMA 4.0 setup includes all prerequisites for Exchange 2013.
- UCMA 4.0 provides more accurate speech engine translations and more scalable voice platform support across multiple products.

Note:

UCMA 4.0 is installed when you're installing Exchange 2013. For details about UCMA 4.0 and setup requirements, see Exchange 2013 prerequisites. To upgrade to the most recent version of UCMA, you must first uninstall any previous versions of UCMA that are installed using Add/Remove programs.

Improvements to Voice Mail Preview

Some enhancements to speech-related services are included in Exchange Server 2013 UM via the Speech Engine 11.0 and UCMA 4.0. There have been improvements in grammar generation, core voice services, and support for multiple languages. Exchange Server 2013 UM also includes several enhancements for transcription services that are delivered to end users and increased confidence and accuracy for Voice Mail Preview. For details, see Voice mail preview enhancements.

Enhanced caller ID support

In previous releases of Exchange Unified Messaging, a UM server that received a call used caller ID to look up the possible identity of the calling party. This search extended across Active Directory and the UM user's personal contacts stored in their mailbox.

In the past, users sometimes were frustrated by the voice mail system's failure to identify Exchange or personal contacts from their caller ID. Until now, only the default contact folder in a user's Exchange mailbox has been used for this search. But Exchange Server 2013 users are likely to have contacts aggregated from external social networks or contacts they added to unique folders when organizing their contacts. In Exchange 2013, UM extends the scope of the search to include the user's other Exchange and personal contact folders that were created manually. Exchange 2013 also supports contact aggregation from external social networks, provides intelligence to link multiple contacts that refer to the same person, and uses that data to present person-centric (rather than contact-centric) views. This means that contacts that are aggregated from external social networks can be placed in the contact folder stored in the user's mailbox in Microsoft Outlook Web App and Outlook. These contacts can now also be added to any additional contact folders that users create.

Caller ID look-up is integrated with contact aggregation, so that it searches across external contacts. The **PersonID** property, where present and set to a value other than Null, improves the user experience for caller ID resolution by suppressing duplicate matches to contacts that are associated with the same person. Because the PersonID property is the same on both results, UM treats this as a match to a single contact.

Enhancements to speech platform and speech recognition

Exchange Server 2013 UM introduces some enhancements to the speech platform and speech recognition, including the following:

- Enhancements and improved accuracy for Voice Mail Preview.
- Support for the Microsoft Speech Platform – Runtime (Version 11.0).
- Speech grammar generation using the system mailbox for an organization.

Exchange Unified Messaging uses static and dynamic speech grammars to recognize commands, names of contacts in the global address list (GAL), and names of personal contacts in the user's mailbox. Today, in Exchange Server 2013, every Mailbox server running the Microsoft Exchange Unified Messaging service generates grammars for all UM languages installed on it and stores them in directories. Every Mailbox server stores every possible grammar, which it generates based on the number of dial plans, auto attendants, and the UM languages that are installed.

Grammar files are used by UM to allow callers to use speech to locate users in your organization. The files are updated each 24 hours by the Mailbox Assistant. The GGG.exe command in Exchange 2007 and Exchange 2010 made it possible to manually update the grammar files without waiting for the scheduled update. In Exchange Server 2013, to address ASR grammar generation scalability issues for UM, the speech GAL grammar generation no longer happens on the server with the Unified Messaging server role installed. Instead, it happens periodically using the Mailbox Assistant, on the Mailbox server running the Microsoft Exchange Unified Messaging service that hosts the organization's arbitration mailbox. The GAL speech grammar file is stored in the arbitration mailbox for an organization and later downloaded to all Mailbox servers in the Exchange organization. By default, the Mailbox Assistant runs every 24 hours. You can adjust the frequency by using the **Set-MailboxServer** cmdlet.

Cmdlet updates

For Exchange 2013, many UM cmdlets have been brought over from Exchange 2010. However, there have been changes in some of those cmdlets, and new cmdlets have been added for new functionality. For details, see Unified Messaging cmdlet updates.

Voice architecture changes

Exchange Server 2013 > Unified Messaging > New voice mail features >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-12-04*

The Microsoft Exchange Server 2013 architecture is different than the architecture in Exchange

Server 2007 and Exchange Server 2010. In Exchange 2007 and Exchange 2010, the types of servers were separated into multiple server roles: Client Access, Mailbox, Hub Transport, and Unified Messaging. In Exchange 2013, the server roles are combined into two types of servers, and all components or services from those server roles are run on the same physical server or on two separate servers called Client Access and Mailbox. In the new model, the Client Access server running the Microsoft Exchange Unified Messaging Call Router service redirects Session Initialization Protocol (SIP) traffic that's generated from an incoming call to a Mailbox server. Then a media (Realtime Transport Protocol (RTP) or secure RTP (SRTP)) channel is established from the VoIP gateway or IP Private Branch eXchange (PBX) to the Mailbox server that hosts the user's mailbox. In Exchange 2013, the Mailbox server has the same processes as the Unified Messaging server role in Exchange 2007 and Exchange 2010. The Mailbox server runs both the Microsoft Exchange Unified Messaging service and UM worker processes. The Client Access server runs the Microsoft Exchange Unified Messaging Call Router service, which receives an incoming call and forwards it to the Mailbox server.

Contents

Support for the new Exchange architecture

In Exchange 2013, the Client Access server is responsible for Autodiscover, Secure Sockets Layer (SSL), authentication, redirection, and proxy. The Client Access server is the entry point for any inbound calls or SIP requests for Unified Messaging (UM). The routing logic and SIP REDIRECT is implemented as a service that's automatically included in a Client Access server. This service is known as the Microsoft Exchange Unified Messaging Call Router service. It's installed and runs on each Client Access server in your organization. When a Client Access server receives a SIP INVITE for an incoming call, the Microsoft Exchange Unified Messaging Call Router service redirects the incoming call to the Mailbox server. Then a media channel (RTP or SRTP) is created between the VoIP gateway, IP PBX, or session border controller (SBC) and the Mailbox server. Although the Client Access server acts as a SIP redirector, it only handles SIP requests from VoIP gateways, IP PBXs, or SBCs. It doesn't receive any media traffic. Media traffic that uses RTP or SRTP is only passed between the Mailbox server and SIP peers such as VoIP gateways, IP PBXs, or SBCs—not to the Client Access server. When you deploy Exchange 2013 and UM, you have to configure your VoIP gateways, IP PBXs, or SBCs to point to the Client Access servers that you've installed so that incoming calls will be routed correctly for UM.

In some cases, deploying multiple Client Access servers is a requirement, and the Client Access servers are deployed separately on different physical hardware from the Mailbox servers. Client Access servers can be grouped in an array by using an L4 or L5 hardware or software load balancer.

However, there are no Active Directory Exchange object-based Client Access server arrays. Using a hardware or software load balancer in front of Client Access servers is an accepted practice in larger Exchange deployments.

When a Client Access server is installed, the Microsoft Exchange Unified Messaging Call Router service is running. The service does the following:

- When initialized, it reads a local configuration file named msexchangeumcallrouter.config.
- Performs speech grammar generation using an arbitration mailbox for an organization.
- Supports Transmission Control Protocol (TCP) and/or Transport Layer Security (TLS) connections. This setting is configurable.
- Will only stop if there's a configuration error or if it can't register the required ports.

In Exchange 2013, the Mailbox server isn't responsible for answering SIP requests from incoming calls. It's only responsible for receiving the SIP traffic from a Client Access server and then establishing an RTP or SRTP connection to the VoIP gateway, IP PBX, or SBC.

After a Client Access server redirects an incoming call to a Mailbox server, a media channel is established between the VoIP gateway, IP PBX, or SBC and the Mailbox server. After the media channel is established, the Microsoft Exchange Unified Messaging service on the Mailbox server plays the user's voice mail greeting, processes call answering rules for the user, and invites the caller to leave a voice message. The Mailbox server then records the voice message, creates a transcription of the message, and deposits it in the user's mailbox. However, if you're integrating Exchange with Office Communications Server 2007 R2 or Lync Server, both the SIP and RTP or SRTP media channels for incoming calls are handled by Lync servers and the Mailbox server. In a Lync integrated environment, you don't have VoIP gateways, IP PBXs, or SBCs. To Lync, the Mailbox server that's running the Microsoft Exchange Unified Messaging service looks just like an Exchange 2010 UM server. The Mailbox server and the Client Access server that's running the Microsoft Exchange Unified Messaging Call Router service are considered trusted peers because both servers must be added to a SIP dial plan. Lync routes the incoming call using the Inbound Routing component, which uses SIP to communicate with the Client Access server and then route the call to a Mailbox server.

Exchange 2010 UM administrators can configure a set of properties for Unified Messaging on each UM server. In Exchange 2013, UM components and configuration settings for UM are found on both Client Access and Mailbox servers. All the configuration settings that applied to a single computer running the Unified Messaging server role in Exchange 2010 are still available. However, some of those properties and configuration settings are set on a Client Access server that's running the Microsoft Exchange Unified Messaging Call Router service, and others are available on a Mailbox server that's running the Microsoft Exchange Unified Messaging service. In some cases, the same setting is available on both. The following list shows the cmdlets and parameters that are available on Client Access servers and Mailbox servers and where changes were made to a cmdlet to support deployment scenarios with previous versions of Unified Messaging.

- **Set-UMService -DialPlans <MultiValuedProperty>** Available on Exchange 2013 Mailbox servers and also works on Exchange 2007 and Exchange 2010 Unified Messaging servers.
- **Set-UMCallRouterSettings -DialPlans <MultiValuedProperty>** Available on Exchange 2013

Client Access servers but not available for Exchange 2007 and Exchange 2010 Unified Messaging servers.

- **Set-UMService -MaxCallsAllowed <Int32>** Available on Exchange 2013 Mailbox servers and also works on Exchange 2007 and Exchange 2010 Unified Messaging servers.
- **Set-UMCallRouterSettings -MaxCallsAllowed <Int32>** Not available on Exchange 2013 Client Access servers and not available for Exchange 2007 and Exchange 2010 Unified Messaging servers.
- **Set-UMService -SipTcpListeningPort <Int32>** Not configurable on Exchange 2013 Mailbox servers but works on Exchange 2007 and Exchange 2010 Unified Messaging servers.
- **Set-UMService -SipTlsListeningPort <Int32>** Not configurable on Exchange 2013 Mailbox servers but works on Exchange 2007 and Exchange 2010 Unified Messaging servers.
- **Set-UMCallRouterSettings -SipTcpListeningPort <Int32>** Available on Exchange 2013 Client Access servers but doesn't work on Exchange 2007 and Exchange 2010 Unified Messaging servers.
- **Set-UMCallRouterSettings -SipTlsListeningPort <Int32>** Available on Exchange 2013 Client Access servers but doesn't work on Exchange 2007 and Exchange 2010 Unified Messaging servers.
- **Set-UMService - Status <Enabled | Disabled | NoNewCalls>** Not available on Exchange 2013 Mailbox servers but works on Exchange 2007 and Exchange 2010 Unified Messaging servers.
- **Set-UMCallRouterSettings - Status <Enabled | Disabled | NoNewCalls>** Not available on Exchange 2013 Client Access servers and doesn't work on Exchange 2007 and Exchange 2010 Unified Messaging servers.
- **Set-UMService -UMStartupMode <TCP | TLS | Dual>** Available on Exchange 2013 Mailbox servers and works on Exchange 2007 and Exchange 2010 Unified Messaging servers.
- **Set-UMCallRouterSettings - UMStartupMode <TCP | TLS | Dual>** Available on Exchange 2013 Client Access servers but doesn't work on Exchange 2007 and Exchange 2010 Unified Messaging servers.
- **Enable-UMService** Not available on Exchange 2013 Mailbox servers but works on Exchange 2007 and Exchange 2010 Unified Messaging servers.
- **Disable-UMService** Not available on Exchange 2013 Mailbox servers but works on Exchange 2007 and Exchange 2010 Unified Messaging servers.

For the Mailbox server, you'll use the **Set/Get/Enable/Disable-UMService** cmdlets to view or configure UM properties for the Microsoft Exchange Unified Messaging service on Exchange 2013 Mailbox servers or Exchange 2007 or Exchange 2010 Unified Messaging servers. A different set of cmdlets, **Set/Get-UMCallRouterSettings**, are used to view or configure the Microsoft Exchange Unified Messaging Call Router service properties on a Client Access server. This ensures that the existing **Get-UMServer**, **Set-UMServer**, **Enable-UMServer**, and **Disable-UMServer** cmdlets from Exchange 2007 and Exchange 2010 will work in a coexistence deployment with Exchange 2013 Mailbox servers. This also ensures that the cmdlets will work when the Mailbox and Client Access servers are installed on the same or different servers.

Return to top

UM ports

The Microsoft Exchange Unified Messaging Call Router service found on a Client Access server uses SIP over either Transmission Control Protocol (TCP) or mutual Transport Layer Security (mutual TLS) to communicate with Mailbox servers that are running the Microsoft Exchange Unified Messaging service. To avoid TCP/User Datagram Protocol (UDP) port conflicts, the Microsoft Exchange Unified Messaging Call Router service and the Microsoft Exchange Unified Messaging service default to and listen on different TCP ports. They can accept both unsecured and secured connections, depending on whether mutual TLS is used with SIP and RTP traffic. By default, a Client Access server listens for SIP requests on both TCP port 5060 in Unsecured mode and TCP port 5061 in SIP Secured mode when mutual TLS is used. These ports are configurable using the **Set-UMCallRouterSettings** cmdlet. The Microsoft Exchange Unified Messaging Call Router service on the Client Access server doesn't handle media (RTP or SRTP) traffic, so only TCP ports and no UDP ports are used. By default, a Mailbox server listens for SIP requests on both TCP port 5062 in Unsecured mode and TCP port 5063 in SIP Secured mode when mutual TLS is used. These ports aren't configurable using Exchange Management Shell cmdlets. On the Mailbox server that runs the Microsoft Exchange Unified Messaging service, TCP ports can't be configured on the Exchange server either by using the Shell or by configuring settings in the registry. The Microsoft Exchange Unified Messaging service on the Mailbox server will accept connections from a Client Access server on SIP ports 5062 and 5063. After the Client Access server redirects the SIP request to a Mailbox server, an RTP or SRTP media channel is created using a VoIP gateway, IP PBX, or SBC, and the Microsoft Exchange Unified Messaging worker process on the Mailbox server.

The following table summarizes the Exchange 2013 ports and protocols, and whether the ports can be changed.

UM listening ports

Protocol	TCP port	UDP port	Can the ports be changed?
SIP (Client Access server – Microsoft Exchange Unified Messaging Call Router service)	5060 (unsecured), 5061 (secured). The service listens on both ports.	Not applicable	Yes, using the **Set-UMCallRouterSettings** cmdlet.
SIP (Mailbox server – Microsoft Exchange Unified Messaging service)	5062 (unsecured), 5063 (secured). The service listens on both ports.	Not applicable	Ports can't be changed.
SIP (Mailbox server - UM worker process)	5065 and 5067 for TCP (unsecured). 5066 and	Not applicable	Ports can't be changed.

	5068 for mutual TLS (secured). This is the case when *UMStartupMode* is set to *Dual*. If *UMStartUpMode* is set to *TCP* or *TLS*, ports 5065 and 5066 are used. The default *UMStartupMode* is *TCP*.		
RTP (Mailbox server - UM worker process)	Not applicable	Ports between 1024 and 65535.	The range of ports can be changed through the registry (however, this isn't a supported configuration): HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Microsoft Speech Server\2.0\AudioConnectionMinPort HKLM\SOFTWARE\Microsoft\Microsoft Speech Server\2.0\AudioConnectionMaxPort

Return to top

UM dial plans

Mapping or associating UM dial plans to UM servers isn't required in Exchange 2013 the way it was in Exchange 2007 and Exchange 2010. Client Access or Mailbox servers running UM services don't need to be linked to a dial plan because all Client Access and Mailbox servers are expected to

receive all incoming calls from VoIP gateways, IP PBXs, or SBCs. The exception is that SIP dial plans that are used with Lync 2013, Lync Server 2010, and Office Communications Server 2007 R2 must be associated with Client Access and Mailbox servers that you've deployed. Both types of Exchange servers must be added to each SIP dial plan to be included as trusted peers from Communications Server 2007 R2 or Lync Server. Otherwise, Communications Server 2007 R2 or Lync Server will reject outbound calls from users.

The following table summarizes the relationship between Client Access and Mailbox servers and UM dial plans.

Linking UM dial plans

Topology	Dial plan
Client Access and Mailbox on the same server (without Communications Server 2007 R2 or Lync Server 2010 non-SIP dial plans)	Dial plans are no longer required to be associated with a Client Access or Mailbox server. You aren't allowed to add the Client Access or Mailbox servers to a dial plan. If you run the **Set-UMService** cmdlet, it will generate an error if you try to associate a Mailbox server with a non-SIP dial plan.
Client Access and Mailbox on different servers (without Communications Server 2007 R2 or Lync Server 2010 non-SIP dial plans)	Dial plans are no longer required to be associated with Client Access or Mailbox servers. You aren't allowed to add Client Access or Mailbox servers to a dial plan. If you run the **Set-UMService** cmdlet, it will generate an error if you try to associate a Mailbox server with a non-SIP dial plan.
Client Access and Mailbox server on the same physical server (with Communications Server 2007 R2 and Lync Server 2010 with SIP dial plans)	For a single SIP dial plan, add all Client Access and Mailbox servers to the SIP dial plan. For multiple SIP dial plans, add all Client Access and Mailbox servers to each SIP dial plan. This will make both servers trusted peers of Office Communications Server 2007 R2 or Lync Server. You must use the same certificate in your Office Communications Server 2007 R2 or Lync Server deployment as you do on each

	Client Access and Mailbox server.
Client Access and Mailbox server on different physical servers (with Communications Server 2007 R2 and Lync Server 2010 with SIP dial plans)	For a single SIP dial plan, add all Client Access and Mailbox servers to the SIP dial plan. For multiple SIP dial plans, add all Client Access and Mailbox servers to each SIP dial plan. This will make both servers trusted peers of Office Communications Server 2007 R2 or Lync Server. If the certificates being used on the Client Access and Mailbox servers are different, you must use the same certificate in your Office Communications Server 2007 R2 or Lync Server deployment as you do on each Client Access and Mailbox server in your organization.

Return to top

UM Call Router performance counters

Past versions of Exchange included the Unified Messaging server role, which ran the Microsoft Exchange Unified Messaging service. Because of the architecture changes in Exchange 2013, the Client Access server runs the Microsoft Exchange Unified Messaging Call Router service and the Mailbox server runs the Microsoft Exchange Unified Messaging service. The same performance counters for the Microsoft Exchange Unified Messaging service are available to administrators as in earlier versions of Exchange UM. However, there are also additional performance counters that you can use on the Client Access server to verify the status of the Microsoft Exchange Unified Messaging Call Router service and for troubleshooting.

To support the new Client Access Unified Messaging Call Router service in Exchange 2013, the following performance counters are now available.

Performance counters

Performance counter category	Counter name	Description	Threshold
MSExchangeUMRouter Availability	% of Inbound Calls Rejected by the Microsoft Exchange	Shows the percentage of inbound calls that were rejected by the	Should always be less than 5 percent, but should be 0 at all times.

	Unified Messaging Call Router Service over the Last Hour	Microsoft Exchange Unified Messaging Call router service over the last hour.	
MSExchangeUMRouter Availability	Calls Disconnected on Irrecoverable Internal Error for the Microsoft Exchange Unified Messaging Call Router Service	Shows the number of calls disconnected after an internal system error occurred.	Should be 0 at all times.
MSExchangeUMRouter Availability	Total Inbound Calls Rejected by the Microsoft Exchange Unified Messaging Call Router Service	Shows the total number of inbound calls that were rejected by the Microsoft Exchange Unified Messaging Call Router service since the service was started.	Should be 0 at all times.
MSExchangeUMRouter Availability	Total number of calls received by the Microsoft Exchange Unified Messaging Call Router Service	Shows the total number of inbound calls that were received by the Microsoft Exchange Unified Messaging Call Router service since the service was started.	Should be 0 or greater.
MSExchangeUMRouter Availability	% of Inbound Calls Rejected by the Microsoft Exchange Unified Messaging Call Router Service Over	Shows the percentage of inbound calls that were rejected by the Microsoft Exchange Unified Messaging Call	Should be less than 5 percent.

	the Last Hour	Router service over the last hour.

IPv6 support in Unified Messaging

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-12*

Internet Protocol version 6 (IPv6) is the most recent version of the Internet Protocol (IP). IPv6 is intended to correct many of the shortcomings of IPv4, which was the previous version of the IP. In Microsoft Exchange Server 2010, IPv6 is supported only when IPv4 is also used. A pure IPv6 Exchange environment isn't supported. The use of IPv6 addresses and IP address ranges is supported only when both IPv6 and IPv4 are enabled on the computer running Exchange 2010 and the network supports both IP address versions. However, because IPv4 and IPv6 are completely different protocols, an IPv4 network can't communicate directly with an IPv6 network, and vice versa. To handle this shortcoming, network administrators are required to deploy devices, such as routers, that can route information between IPv4 networks and IPv6 networks. If Exchange 2010 is deployed using both IPv4 and IPv6, all server roles except Unified Messaging (UM) can send data to and receive data from devices, servers, and clients that use IPv6 addresses. With Exchange 2013, Unified Messaging is no longer a separate server role like the Transport, Client Access, and Mailbox server roles in Exchange 2007 and Exchange 2010. UM-related components and speech services run on only Client Access and Mailbox servers.

In Exchange 2013, because UM architecture has changed and now requires Unified Communications Managed API (UCMA) v4.0 to support both IPv4 and IPv6 as well as other Exchange features, both Client Access and Mailbox servers that have Unified Messaging components and services will fully support IPv6 networks.

IPv6 support

Starting with Exchange 2010 Service Pack 1 (SP1), the Unified Messaging server role relied on UCMA 2.0 for its underlying Session Initiation Protocol (SIP) signaling and speech processing. UCMA 2.0 is the main component for speech features in UM. UCMA 2.0 contains a SIP stack, a media stack, and speech engines for Automatic Speech Recognition (ASR), in addition to speech synthesis that's generated by Text-to-Speech (TTS).

In Exchange 2010, running a dual stack (IPv4 and IPv6) was required by all server roles except for

UM because UM required UCMA 2.0 but supported only IPv4, not IPv6. For Exchange 2013, UCMA 4.0 is used by UM and is required for installing Exchange 2013 on Client Access and Mailbox servers. UCMA 4.0 is required to support new features and to support IPv6.

Some of the reasons why UM now uses UCMA 4.0 to support the new features in Exchange 2013, including IPv6, are as follows:

- Some government agencies require IPv6 support for products that they use.
- UM now requires compatibility with hardware devices such as routers, IP gateways, IP PBXs, and session border controllers (SBCs) that run either a dual stack (IPv4 and IPv6) or IPv6 only.
- In Exchange 2013, the Microsoft Exchange Unified Messaging service runs on the Mailbox server and the Microsoft Exchange Unified Messaging Call Router service runs on the Client Access server. The Mailbox and Client Access server roles in Exchange 2013 require both IPv4 and IPv6.
- Online services allow clients to connect to their service using either IPv4 orIPv6.
- Public IPv4 address space is running out. For Exchange Server 2013 Enterprise, this isn't really an issue for UM, since UM always communicates with internal SIP peers that can be deployed with a private IPv4 address space. However, for hosted Exchange UM, the customer's equipment must support hosted UM using IPv4 and IPv6.

With the exception of UM and a small part of Transport, Exchange 2013 can connect to Exchange 2010 servers in an organization when either a Client Access or Mailbox server runs in dual-stack mode with IPv4 and IPv6 enabled. This means that customers can install Exchange 2013 on computers that are running with both IPv4 and IPv6 stack addresses configured. This allows IPv6 clients and other Exchange servers, including Exchange Server 2010, to connect directly to Exchange 2013.

UM works on Windows servers running in dual-stack mode. This is because protocols such as HTTP ignore the transport type, and UM uses voice over IP (VoIP) protocols (including SIP/RTP/STUN/TURN/ICE), which aren't dependent on one another. This includes media negotiation (RTP/SRTP), in which UM advertises and communicates a list of IP addresses to SIP peers, such as IP gateways, IP PBXs, or SBCs.

What does it mean to support IPv6 for UM?

To enable Exchange 2013 UM to support IPv6, both enterprise and online UM administrators must be able to take advantage of IPv6 when they connect UM to IPv6-capable devices, including devices such as routers, IP gateways, IP PBXs, and Office Communications Server 2007 R2 and Microsoft Lync servers. However, if IPv6 isn't available for interoperability and backward compatibility with previous versions of Exchange, administrators don't need to make additional configuration changes, and IPv4 can be used instead.

For Exchange 2013 Enterprise, UM must communicate directly with SIP peers (IP gateways, IP PBXs, and SBCs) that may not support IPv6 in their software or firmware. Therefore, UM must be able to communicate directly with SIP peers that support IPv4 and, more important, with IPv6. For hosted Exchange 2013, UM communicates with customer equipment through SBCs or Lync Server 2010 or

Lync Server 15. In hosted Exchange 2013 environments, IPv6 SIP-aware clients such as SBCs and Lync servers can potentially be deployed and thus handle the IPv6-to-IPv4 conversion process.

UM device support for IPv6

Because Exchange 2013 Mailbox and Client Access servers that run UM components and services support IPv6, IP gateway, IP PBX, and SBC vendors must also be able to support IPv6. There are several issues that affect device support for IPv6:

- There are IP gateways, IP PBXs, and SBCs that may be able to support IPv6 but haven't yet been tested with IPv6 and UM. This support may be added in the future, but it's dependent on the hardware vendor.
- Some IP gateways currently have no IPv6 support.
- Some SBCs have IPv4-IPv6 functionality, but they don't currently work for UM because they don't support SRTP (Secure Real-time Transport Protocol)/SDES (Session Description Protocol Security).
- There are IP PBXs that don't support a dual stack and pure IPv6, but these devices haven't been tested to work with Exchange 2013.

Currently UCMA 4.0 is IPv6-enabled, meaning that it can accept IPv6 connections but that IPv4 also can be accepted, when operating in dual mode or when making outbound connections. Running in dual mode allows IPv4 connections to be made when they're needed to connect to previous versions of Exchange UM. For Lync installations, this is done by Lync Server, which obtains the version information from Active Directory for the latest version of Exchange Server. For traditional telephony devices—including IP gateways, IP PBXs, and SBCs—to support IPv6 connections along with IPv4, they must listen for both types of connections. This is because each SIP peer must be able to accept both types of connections for backward compatibility with previous versions of Exchange UM. This is also necessary to support outdialing for both types of connections.

UM configuration for supporting IPv6

After you install your Client Access and Mailbox servers, you need to create Unified Messaging dial plans, auto attendants, IP gateways, and hunt groups. To allow UM to support IPv6, you must:

- Create a new UM IP gateway or configure an existing UM IP gateway with an IPv6 address for each of the IP gateways, IP PBXs, or SBCs on your network. When you're creating and configuring the required UM IP gateways, you must add the IPv6 address or the Fully Qualified Domain Name (FQDN) for the UM IP gateway. If you're adding the FQDN to the UM IP gateway, you must have created the correct DNS records to resolve the UM IP gateway FQDN to the IPv6 address. If you have an existing UM IP gateway, you can use the **Set-UMIPgateway** cmdlet to configure the IPv6 address or FQDN. After you create or configure the UM IP gateways, you can use the **Get-UMIPgateway** cmdlet to view the properties of the UM IP gateway to ensure that the IPv6 settings are correct.
- Configure the *IPAddressFamily* parameter on each UM IP gateway. To enable the IP gateway to accept IPv6 packets, you must set the UM IP gateway to either accept both IPv4 and IPv6

connections, or accept only IPv6 connections, by using the **Set-UMIPgateway** cmdlet and setting the *IPAddressFamily* parameter to one of the following:
  - *IPv4* – This is the default and is used if no other value is configured.
  - *IPv6* - This enables IPv6 to be used. However, IPv4 isn't used.
  - *Any* – This allows IPv6 to be used, but if the device doesn't support IPv6, then IPv4 is used instead.
- After you've configured your UM IP gateways, you must also configure the IP gateways, IP PBXs, and SBCs on your network to support IPv6. For details, see your hardware vendor for a list of devices that support IPv6 and how to correctly configure them.
- Optionally, you may need to set the Client Access and Mailbox servers to accept IPv6 traffic if either of the servers are only set to receive IPv4 traffic. However, the default setting is for both Client Access servers running the Microsoft Exchange Unified Messaging Call Router service and Mailbox servers running the Microsoft Exchange Unified Messaging service to accept IPv4 and IPv6 traffic. For details about configuring the IPv6 settings on Client Access and Mailbox servers, see Set-UMCallRouterSettings and Set-UMService.

There are two parameters that may need to be configured on Client Access and Mailbox servers to support IPv6: *IPAddressFamily* and *IPAddressFamilyConfigurable*. To enable a Client Access and a Mailbox server to accept IPv6 packets, you must set the Client Access and Mailbox server either to accept both IPv4 and IPv6 connections, or accept only IPv6 connections. To configure the *IPAddressFamily* parameter, the *IPAddressFamilyConfigurable* parameter must be set to `$true`.

UM IP addressing logic

The logic behind IPv6 support for UM in Exchange 2013 is as follows:

- Client Access and Mailbox servers listen on both IPv4 and IPv6 interfaces when the dual stack is enabled and the Client Access and Mailbox servers are set to *IPv6* or *Any*. Otherwise, only IPv4 is used.
- For outgoing calls, UM uses dual mode if the *IPAddressFamily* parameter for the UM IP gateways, Client Access servers, and Mailbox servers is set to *IPv6* or *Any*. Otherwise, only IPv4 is used.

When making outgoing calls in dual mode, if the *IPAddressFamily* parameter is set to *IPv6* or *Any*:

- UCMA will obtain a list of addresses in the FQDN for a SIP peer that it's trying to reach.
- UCMA will try all IPv6 addresses, if any.
- If UCMA determines that an address isn't available, it will include the address in a list and not try it again based on a configured interval. This prevents UM from needlessly retrying known bad addresses.
- If no IPv6 addresses are available, UCMA will fall back to IPv4 addresses in the list of addresses for SIP peers.

Voice mail preview enhancements

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-07-05*

Voice Mail Preview is a feature that's available to users who receive their voice mail messages using Microsoft Exchange Server 2010 or Exchange Server 2013 Unified Messaging (UM). Voice Mail Preview enhances UM voice mail functionality by providing a text version of audio recordings. The voice mail text is displayed in an email message within Microsoft Office Outlook Web App, Outlook 2010, and other email programs.

Voice Mail Preview enhancements

In Exchange 2013, UM includes several enhancements to the user interface for Outlook Web App and Outlook clients and improvements to increase confidence and accuracy for Voice Mail Preview. Also, some enhancements to the speech-related services are offered through the Microsoft Speech Platform (Version 11.0) and Unified Communications Managed API (UCMA) 4.0 to enhance grammar generation and language support.

Unified Messaging introduced the Voice Mail Preview feature in Exchange 2010. Voice Mail Preview uses automatic speech recognition (ASR) to add a text version of a voice mail audio file to a voice message. ASR isn't entirely accurate, especially when it's used to record audio over a phone that includes unknown voices and noises.

Some organizations require consistently error-free or near-error-free transcripts of voice mail messages for some, if not all, of their users. The Voice Mail Preview Partner Program helps such organizations meet those requirements. The Voice Mail Preview Partner Program was designed for Exchange 2010 to improve Voice Mail Preview results, but it wasn’t used by Exchange 2010 customers because of the overhead and cost. To address these issues, Exchange 2013 includes the following enhancements for Voice Mail Preview:

- **Improved audio normalization** Audio normalization is the process of uniformly increasing (or decreasing) the amplitude of an entire audio signal so that the resulting peak amplitude matches a specified target or the norm. UM normalizes the audio recording before compressing it and sending to the user.
- **Enhanced speech recognition** By collecting voice mail messages (only if the Exchange customer chooses to share this information), the results of the voice mail previews can be used to add words and phrases to the speech engine. This is done by setting the *VoiceMailAnalysisEnabled* parameter to `$true` using the **Set-UMMailbox** cmdlet or by setting the *AllowVoiceMailAnalysis* parameter to `$true` on the **Set-UMMailboxPolicy** cmdlet. Also, Exchange 2013 UM uses information more efficiently from email threads created by a user using Outlook Voice Access. This includes information about the participant’s (Active Directory or personal contact) information (country, city, company), and the phone number of the Outlook Voice Access user.
- **Voice Mail Preview confidence** The confidence score is the number assigned by Unified Messaging that is directly related to the overall accuracy of the transcription. The confidence calculations that are used by UM have been adjusted to be more accurate and represent the actual accuracy of a transcribed message.

- **Filtering** Offensive words are detected and filtered and the results are cached and stored in the user's mailbox.
- **Hiding the text preview** If the confidence score of a voice mail preview is below a given threshold, the Voice Mail Preview text will be hidden. If the text is hidden, the voice message will include text stating that the confidence of the voice mail was too low for results to be displayed.
- **Transcription performance** Voice Mail Preview is a CPU-intensive operation that requires roughly twice the time it takes to process an audio file. If generating the voice mail preview text takes too long, CPU throttling stops processing the preview. In Exchange 2010, UM didn't try to transcribe any voice message that was longer than 75 seconds. In Exchange 2013, the entire voice message is transcribed, but the text for the message isn't included if it extends past 75 seconds.
- **Color schemes** Because of the confusion over the colors that were used to distinguish between low, medium, and high confidence for a voice mail preview, the color scheme has been removed in Exchange 2013 for Outlook Web App and Outlook.

Unified Messaging cmdlet updates

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-10-03*

Many of the Unified Messaging (UM) cmdlets that existed in Exchange Server 2010 have been brought over for Exchange Server 2013, but there have been changes to some of those cmdlets. In addition, new cmdlets were added for Exchange 2013.

Updated parameters and new UM cmdlets

The following is a list of the updated parameters and new cmdlets for Exchange 2013.

Cmdlet	Parameters
New-UMIPGateway	`[-IPAddressFamily <IPv4Only | IPv6Only | Any>]`
Set-UMIPGateway	`[-IPAddressFamily <IPv4Only | IPv6Only | Any>]`
Get-UMMailbox	`[-AccountPartition <AccountPartitionIdParameter>]`
Set-UMMailbox	`[-ImListMigrationCompleted <$true | $false> -VoiceMailAnalysisEnabled <$true | $false>]`
Test-Connectivity	`[-CallRouter <SwitchParameter>]`
New-UMCallAnsweringRule	`[-Name <String> [-CallerIds <MultiValuedProperty>] [-`

	CallersCanInterruptGreeting <$true | $false>] [-CheckAutomaticReplies <$true | $false>] [-Confirm [<SwitchParameter>]] [-DomainController <Fqdn>] [-ExtensionsDialed <MultiValuedProperty>] [-KeyMappings <MultiValuedProperty>] [-Mailbox <MailboxIdParameter>] [-Organization <OrganizationIdParameter>] [-Priority <Int32>] [-ScheduleStatus <Int32>] [-TimeOfDay <TimeOfDay>] [-WhatIf [<SwitchParameter>]]
Remove-UMCallAnsweringRule	[-Identity <UMCallAnsweringRuleIdParameter> [-Confirm [<SwitchParameter>]] [-DomainController <Fqdn>] [-Mailbox <MailboxIdParameter>] [-WhatIf [<SwitchParameter>]]
Get-UMCallAnsweringRule	[-Identity <UMCallAnsweringRuleIdParameter>] [-DomainController <Fqdn>] [-Mailbox <MailboxIdParameter>]
Set-UMCallAnsweringRule	[-Identity <UMCallAnsweringRuleIdParameter> [-CallerIds <MultiValuedProperty>] [-CallersCanInterruptGreeting <$true | $false>] [-CheckAutomaticReplies <$true | $false>] [-Confirm [<SwitchParameter>]] [-DomainController <Fqdn>] [-ExtensionsDialed <MultiValuedProperty>] [-KeyMappings <MultiValuedProperty>] [-Mailbox <MailboxIdParameter>] [-Name <String>] [-Priority <Int32>] [-ScheduleStatus <Int32>] [-TimeOfDay <TimeOfDay>] [-WhatIf [<SwitchParameter>]]
Enable-UMCallAnsweringRule	[-Identity <UMCallAnsweringRuleIdParameter> [-Confirm [<SwitchParameter>]] [-DomainController <Fqdn>] [-Mailbox <MailboxIdParameter>] [-WhatIf [<SwitchParameter>]]
Disable-UMCallAnsweringRule	[-Identity <UMCallAnsweringRuleIdParameter> [-Confirm [<SwitchParameter>]] [-DomainController <Fqdn>] [-Mailbox <MailboxIdParameter>] [-WhatIf [<SwitchParameter>]]
Get-UMCallRouterSettings	[-DomainController <Fqdn>] [-Server <ServerIdParameter>]
Set-UMCallRouterSettings	Set-UMCallRouterSettings [-Confirm [<SwitchParameter>]] [-DialPlans <MultiValuedProperty>] [-DomainController <Fqdn>] [-IPAddressFamily <IPv4Only | IPv6Only | Any>] [-IPAddressFamilyConfigurable <$true | $false>] [-Server <ServerIdParameter>] [-SipTcpListeningPort <Int32>] [-SipTlsListeningPort <Int32>] [-UMPodRedirectTemplate <String>] [-UMStartupMode <TCP | TLS | Dual>] [-WhatIf [<SwitchParameter>]]

Disable-UMService	`-Identity <UMServerIdParameter> [-Confirm [<SwitchParameter>]] [-DomainController <Fqdn>] [-Immediate <$true | $false>] [-WhatIf [<SwitchParameter>]]` **Note:** This cmdlet only works with Exchange 2007 and 2010 UM servers.
Enable-UMService	`-Identity <UMServerIdParameter> [-Confirm [<SwitchParameter>]] [-DomainController <Fqdn>] [-WhatIf [<SwitchParameter>]]` **Note:** This cmdlet only works with Exchange 2007 and 2010 UM servers.
Get-UMService	`[-Identity <UMServerIdParameter>] [-DomainController <Fqdn>]`
Set-UMService	`Set-UMService -Identity <UMServerIdParameter> [-Confirm [<SwitchParameter>]] [-DialPlans <MultiValuedProperty>] [-DomainController <Fqdn>] [-GrammarGenerationSchedule <ScheduleInterval[]>] [-IPAddressFamily <IPv4Only | IPv6Only | Any>] [-IPAddressFamilyConfigurable <$true | $false>] [-IrmLogEnabled <$true | $false>] [-IrmLogMaxAge <EnhancedTimeSpan>] [-IrmLogMaxDirectorySize <Unlimited>] [-IrmLogMaxFileSize <ByteQuantifiedSize>] [-IrmLogPath <LocalLongFullPath>] [-MaxCallsAllowed <Int32>] [-SIPAccessService <ProtocolConnectionSettings>] [-UMStartupMode <TCP | TLS | Dual>] [-WhatIf [<SwitchParameter>]]`

For details about all UM cmdlets, see Unified Messaging cmdlets.

Planning for Unified Messaging

Exchange Server 2013 > Unified Messaging >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-10*

When you plan your Unified Messaging (UM) deployment, there are many factors that you must consider to be able to successfully deploy UM. You must understand the different elements of Unified Messaging and each component and feature so that you can plan your Unified Messaging infrastructure and deployment appropriately. Allocating time to plan and work through these issues will help prevent problems when you deploy Unified Messaging in your organization.

You may be deploying Unified Messaging in a new Exchange organization or upgrading from a legacy or third-party voice mail solution. If you're upgrading, you need to decide whether to convert the devices that are accepting telephony circuit-based protocols to a data network using IP or whether to deploy an Enterprise Voice solution like Microsoft Lync Server. This is just the first step in preparing yourself to understand and deploy UM for your organization.

Planning your voice mail system

UM provides voice mail, fax, and email messaging in one store that can be accessed from a telephone, a user's computer, or a mobile device. Users can access voice messages, email, calendar information, and personal contacts that are located in their Exchange mailbox from email clients such as Outlook and Outlook Web App.

Client Access servers running the Microsoft Exchange Unified Messaging Call Router service and Mailbox servers running the Microsoft Exchange Unified Messaging service are designed to provide voice mail features for users in your organization.

Mailbox servers rely on Client Access servers to forward SIP traffic from incoming calls and then establish a connection with a VoIP gateway, IP PBX, or Session Border Controller (SBC) and accept the RTP/SRTP media traffic. All voice mail and fax messages are submitted from the Microsoft Exchange Unified Messaging service on a Mailbox server to be delivered to the user's mailbox. For a user to use the voice mail features with Unified Messaging, they must have an Exchange mailbox.

Planning your UM deployment

Generally, the simpler the Unified Messaging topology, the easier UM is to deploy and maintain. Install as few Client Access and Mailbox servers and create as few Unified Messaging components —like UM dial plans, auto attendants, and UM mailbox policies—as you need to support your business and organizational goals. Large enterprises with complex network and telephony environments, multiple business units, or other complexities will require more planning than smaller organizations with relatively straightforward Unified Messaging needs.

The following are some of the areas that you should consider when planning for Unified Messaging in your organization:

- **Organizational requirements** Evaluate your business needs, the usefulness of deploying a voice mail system, your physical network and business topology, and security requirements for your organization.
- **Telephony requirements** Review your existing telephony, circuit-switched network, and voice mail system.
- **Network requirements** Analyze your network topology, your current packet-switched IP network design including your LAN and WAN connectivity points, and devices.
- **Active Directory (directory service)** Inspect your current implementation and design and think about how to integrate UM.
- **Deployment model** Decide whether you want to have a hybrid, online-only, or on-premises UM

deployment.

- **Exchange requirements** Determine the following:
  - How many users will be using voice mail.
  - Which UM features and services you want to deploy, such as concurrent calls, internal and external access for users, incoming faxing, Voice Mail Preview, and so on.
  - The number of Client Access and Mailbox servers you'll need to deploy.
  - The storage requirements and quotas for voice mail users.
  - The best design for high availability and site resiliency. This includes UM system requirements, providing a highly available and scalable UM deployment, and system hardware requirements to ensure performance.
- **Integration with telephony components and devices** Decide whether to use traditional telephony equipment or Microsoft Lync Server. Consider where to place VoIP gateways, telephony equipment, and Client Access and Mailbox servers, and whether you want to enable Enterprise Voice in your organization.

Connecting your telephony network

Unified Messaging requires that you integrate your Exchange Server deployment with your existing telephony system or integrate it with Microsoft Lync Server. You need to make a careful analysis of your existing telephony infrastructure and Microsoft Lync Server, and then follow the correct planning steps so you can deploy and manage UM voice mail successfully.

VoIP gateways Choosing the correct VoIP gateway, IP PBX, SIP-enabled PBX, or SBC is just the first step in integrating your telephony network with UM. You must configure those devices to work with UM, deploy the required Client Access and Mailbox servers, and create and configure all necessary UM components. These components allow you to make the connection from your circuit-based protocol network to your IP data network and enable voice mail for your users.

Microsoft Lync Server Unified Messaging can use Microsoft Lync Server to combine voice messaging, instant messaging, enhanced presence, audio/video conferencing, and email into a familiar, integrated communications experience. Integrating UM and Microsoft Lync Server has the following benefits:

- Enhanced presence notifications across a variety of applications that keep users informed of the availability of contacts.
- Integration of instant messaging, voice messaging, conferencing, email, and other communication methods, which enables users to select the most appropriate method for the task. Users can also switch from one method to another as needed.
- Availability of communications alternatives from any location where an Internet connection is available.
- A smart client (Microsoft Lync) for telephony, instant messaging, and conferencing.
- Continuity of the user experience across multiple devices.

For more information about Microsoft Lync Server, see Microsoft Lync Server.

Note:

Planning and deploying Unified Messaging can pose certain challenges. Depending on your technical experience with Exchange and voice mail systems, you might want to obtain the assistance of a Unified Messaging specialist. An Exchange Unified Messaging specialist will help make sure that there's a smooth transition from a legacy or third-party voice mail system to Exchange Unified Messaging. Performing a new deployment or upgrading a legacy voice mail system requires significant knowledge about VoIP gateways, PBXs, and Unified Messaging. For more information about how to contact a Unified Messaging specialist, see Microsoft Exchange Server 2013 Unified Messaging (UM) Specialists.

Deployment steps

Many deployment options are available for Unified Messaging. Each option has several steps in common that are required to create a scalable and highly-available system to support large numbers of users. These steps are as follows:

1. Deploy and configure your telephony components or Microsoft Lync Server with Unified Messaging.
2. Verify that you've correctly installed the Client Access and Mailbox servers that are required by Unified Messaging.
3. Create and configure the required Unified Messaging components, including UM dial plans, UM IP gateways, UM hunt groups, and UM mailbox policies.
4. Perform post-deployment tasks, including obtaining certificates for mutual TLS, creating UM auto attendants, and configuring faxing.

For details about deploying Unified Messaging, see Deploy Exchange 2013 UM.

If you're integrating your Unified Messaging environment with Microsoft Lync Server, there are additional planning considerations. For details, see Deploying Exchange 2013 UM and Lync Server overview.

Deploying voice mail and UM

Exchange Server 2013 > Unified Messaging >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-08-05*

Exchange Unified Messaging (UM) enables you to provide voice mail services to users in your organization. When you deploy Unified Messaging, you must either integrate your Exchange Server deployment with the existing telephony system for your organization or integrate it with Microsoft Lync Server. A successful deployment requires you to make a careful analysis of your existing telephony infrastructure and perform the correct planning steps to deploy and manage voice mail in Unified Messaging. If you’re integrating Exchange with Lync Server, you must also familiarize

yourself with that product.

When you're deploying Unified Messaging, you have multiple options depending on the telephony hardware found in your organization. If you're connecting UM to your telephony network, you may have one of the following telephony configurations in your organization:

- One or multiple VoIP gateways with one or multiple PBXs
- One or multiple IP PBXs
- One or multiple SIP-enabled PBXs
- Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server 2010 or 2013

⚠**Warning:**
When you're deploying Exchange UM in a hosted or hybrid environment, you must deploy session border controllers (SBCs). SBCs don't enable UM to connect to a telephony network or provide a dial tone for an organization. However, they do connect your on-premises UM deployment to a datacenter using the IP protocol over a public or private WAN.

Telephony Hardware Choosing the correct VoIP gateway, IP PBX, or SBC is only the first step in integrating your telephony network with UM. You must configure those devices to work with UM, deploy the required Client Access and Mailbox servers, and create and configure all needed UM components. These components allow you to connect your circuit-based protocol network to your IP data network and enable voice mail for users in your organization. For details, see Telephony advisor for Exchange 2013.

Microsoft Lync Server Unified Messaging can use Microsoft Lync Server to combine voice messaging, instant messaging, enhanced presence, audio/video conferencing, and email into a familiar, integrated communications experience. Integrating UM and Lync Server has the following benefits:

- Enhanced presence notifications across a variety of applications that keep users informed of the availability of contacts.
- Integration of instant messaging, voice messaging, conferencing, email, and other communication methods to enable users to select the most appropriate method for the task. Users can also switch from one method to another as needed.
- Availability of communications alternatives from any location where an Internet connection is available.
- A smart client (Microsoft Lync) for telephony, instant messaging, and conferencing.
- Continuity of the user experience across multiple devices.

For more information about Lync Server, see Microsoft Lync Server.

Deployment steps

Many deployment options are available for Unified Messaging. Each option has several steps in common that are required to create a scalable and highly available system to support large numbers of users. These steps are as follows:

1. Deploy and configure your telephony components or Microsoft Lync Server with Unified

Messaging.

2. Verify that you've correctly installed the Client Access and Mailbox servers that are required by Unified Messaging.

⚠**Warning:**
You must deploy at least one Exchange 2013 Mailbox server in your organization before you configure the VoIP gateways or IP PBXs to send UM SIP and RTP traffic to the Exchange 2013 Client Access servers.

3. Create and configure the required Unified Messaging components including UM dial plans, UM IP gateways, UM hunt groups, and UM mailbox policies.
4. Perform post-deployment tasks including deploying certificates for mutual TLS, creating UM auto attendants, and client features.

For details about deploying Unified Messaging, see Deploy Exchange 2013 UM.

If you're integrating your Unified Messaging environment with Microsoft Lync Server, there are additional planning considerations. For details, see Deploying Exchange 2013 UM and Lync Server overview.

Deploy Exchange 2013 UM

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-08-05*

Unified Messaging (UM) requires that you integrate your Exchange Server deployment with the existing telephony system for your organization. A successful deployment requires you to make a careful analysis of your existing telephony infrastructure and perform the correct planning steps to deploy and manage voice mail in Unified Messaging.

Contents

Before you deploy

Before you deploy Unified Messaging, we recommend that you familiarize yourself with the concepts in the following topics:

- UM dial plans
- UM IP gateways

- UM services
- UM hunt groups
- Automatically answer and route incoming calls
- UM mailbox policies
- Voice mail for users

Deploying Unified Messaging

Whether you're deploying UM using IP Private Branch eXchanges (IP PBXs), VoIP gateways, or Microsoft Lync Server, all the deployment options for Unified Messaging have several steps in common. These steps are required to create a scalable and highly available system to support large numbers of Unified Messaging users. These steps are as follows:

1. Deploy and configure your telephony components for Unified Messaging.
2. Verify that you've correctly installed the Client Access server running the Microsoft Exchange Unified Messaging Call Router service and the Mailbox server running the Microsoft Exchange Unified Messaging service.
3. Create and configure the required Unified Messaging components.
4. Perform any post-deployment tasks for Unified Messaging.

Deploy and configure telephony components

To successfully deploy Unified Messaging in an Exchange organization, the Exchange administrator needs to become knowledgeable about data networking concepts and telephony terminology and concepts and be able to correctly configure the telephony components that UM requires. Performing a new deployment or upgrading a legacy voice mail system requires significant knowledge about telephony networks and Unified Messaging.

Generally, you need to complete three tasks to successfully configure the telephony components that UM requires:

1. **Provision PBX lines** The first step in deploying a scalable UM solution is to provision PBX lines.
2. **Organize channels** After you provision PBX-based voice channels, you can organize the channels into hunt groups.
3. **Deploy VoIP gateways** After you organize your voice channels as hunt groups, you need to end these channels at VoIP gateways. VoIP gateways are used with a legacy PBX to convert the circuit-switched protocols found on a telephony network to IP-based packet-switched protocols.

When you integrate your organization's telephony and data networks during the deployment of Unified Messaging, you need to configure the telephony and data networking components correctly. You also need to configure the following components or interfaces to successfully deploy Unified Messaging:

- **Configure the connection from the PBXs in your organization to communicate with your VoIP gateways.** For details, see Connect a VoIP gateway to communicate with a PBX.
- **Configure the connection from the VoIP gateway interface to the PBX.** For more information about how to configure your PBX interface to communicate with your supported

VoIP gateway, see the product documentation that's specific to your PBX or see Connect a VoIP gateway to communicate with a PBX.

- **Configure the connection from the VoIP gateway interface to the Client Access and Mailbox servers.** For details, see Connect a VoIP gateway, IP PBX, or session border controller to UM.
- **Configure the connection from Client Access and Mailbox servers to the VoIP gateway interface.** For details, see Connect UM to a supported VoIP gateway.

Return to top

Install the Mailbox and Client Access servers

Different deployment paths are available for organizations that plan to deploy Exchange Unified Messaging. Although these paths all lead to the same end—a successful deployment of Unified Messaging—each path is slightly different because each customer's needs and starting points are different. However, generally there are common starting points and paths that cover all supported deployment scenarios, including new installations and upgrades. Follow these steps to deploy your Client Access and Mailbox servers:

1. Verify that your existing infrastructure meets certain prerequisites. For details, see Exchange 2013 prerequisites.
2. Deploy your new Exchange 2013 organization. For details, see Install Exchange 2013 using the Setup wizard.

⚠**Warning:**
You must deploy at least one Exchange 2013 Mailbox server in your organization before you configure the VoIP gateways or IP PBXs to send UM SIP and RTP traffic to the Exchange 2013 Client Access servers.

3. Verify that you've correctly installed the Client Access and Mailbox servers. After you install the servers, we recommend that you verify the installation and review the server setup logs. For details, see Verify an Exchange 2013 installation.

Add the required UM language packs

UM language packs enable callers and Outlook Voice Access users to interact with the voice mail system in multiple languages. After you install an additional language pack on a Mailbox server, callers and Outlook Voice Access users can hear email messages and interact with the voice mail system in that language.

When you first install Exchange, U.S. English will be the default language, and the only available language option for your dial plan. After you install a UM language pack on a Mailbox server, the language associated with the language pack will be listed as an available option when you configure the default language for the dial plan. By default, because UM auto attendants are associated with a UM dial plan when they're created, they use the default language setting of the associated UM dial plan. However, this setting can be changed after the UM auto attendant is created.

You can add UM language packs by using the Setup.exe command or by running the *<UMLanguagePack>*.exe installation program after you've downloaded the UM language pack from Exchange Server 2013 UM Language Packs. However, you have to use the Setup.exe command to remove a UM language pack. There's no Exchange Management Shell cmdlet that you can use to add or remove languages from a Mailbox server. For more information about how to install a UM language pack, see Install a UM language pack.

Note:
By default, when you install a Mailbox server, the U.S. English language (en-US) is installed. It can't be removed unless you remove the Mailbox server from the computer.

Return to top

Create and configure UM components

Several UM components are required for the deployment and operation of Unified Messaging. Unified Messaging components connect the telephony infrastructure with the Unified Messaging environment. After you've successfully installed the Client Access and Mailbox servers, follow these steps.

Step 1: Create and configure UM dial plans

UM dial plans are important to the operation of Unified Messaging and are required to successfully deploy Unified Messaging on your network. After you've successfully installed your Client Access and Mailbox servers, a UM dial plan will be the first component that you'll create.

By default, UM dial plans and Client Access and Mailbox servers that are associated with the dial plan send and receive data without using encryption. In Unsecured mode, the VoIP and SIP traffic won't be encrypted. When you create the dial plan or after you've created the dial plan, you can configure the dial plan to encrypt the VoIP and SIP traffic by using Mutual Transport Layer Security (mutual TLS). If you will be using mutual TLS, you will set the dial plan to SIP secured or Secured, set the UM start mode to TLS or Dual, and create and distribute a trusted certificate be the Exchange servers and the VoIP gateways, IP PBXs or session border controllers (SBCs). After you configure the VoIP security setting, you'll have to configure the startup mode for the Client Access and Mailbox servers. For details, see Configure the startup mode on a Mailbox server or Configure the startup mode on a Client Access server.

Perform the following procedure to create a new UM dial plan.

Create a UM dial plan

1. In the Exchange admin center (EAC), navigate to **Unified Messaging** > **UM dial plans**, and then click **Add +**.
2. On the **New UM Dial Plan** page, complete the following boxes:
   - **Name** Type the name of the dial plan. A UM dial plan name is required and must be unique. The name you type is used only for display purposes in the EAC and the Shell. The maximum length of a UM dial plan name is 64 characters, and it can include spaces. However, it can't

include any of the following characters: " / \ [ ] : ; | = , + * ? < >.

Important:

Although the box for the name of the dial plan can accept 64 characters, the name of the dial plan can't be longer than 49 characters. This is because, when you create a dial plan, a default UM mailbox policy is also created that has the name <*DialPlanName*> Default Policy. The *name* parameter for both the UM dial plan and UM mailbox policy can be 64 characters long.

- **Extension length (digits)** Enter the number of digits for extension numbers in the dial plan. The number of digits for extension numbers is based on the telephony dial plan created on a PBX. For example, if a user associated with a telephony dial plan dials a four-digit extension to call another user in the same telephony dial plan, you select 4 as the number of digits in the extension.

This is a required box that has a value range from 1 through 20. The typical extension length is from 3 through 7 numbers. If your existing telephony environment includes extension numbers, you must specify a number of digits that matches the number of digits in those extensions.

When you create a Telephone extension dial plan, you're required to enter an extension number for the user when they're linked to a Telephone extension dial plan. An extension number is also required with Session Initiation Protocol (SIP) dial plans or E.164 dial plans when a UM-enabled user is linked to a SIP URI or E.164 dial plan. This extension number is used by Outlook Voice Access users when they access their Exchange mailbox.

- **Dial plan type** A Uniform Resource Identifier (URI) is a string of characters that identifies or names a resource. The main purpose of this identification is to enable VoIP devices to communicate with other devices over a network using specific protocols. URIs are defined in schemes that define a specific syntax and format and the protocols for the call. In simple terms, this format is passed from the IP PBX or PBX. After you create a UM dial plan, you won't be able to change the URI type without deleting the dial plan, and then re-creating the dial plan to include the correct URI type. You can select one of the following URI types for the dial plan:
  - **Telephone extension** This is the most common URI type. The calling and called party information from the VoIP gateway or IP Private Branch eXchange (PBX) is listed in one of the following formats: Tel:512345 or 512345@<*IP address*>. This is the default URI type for dial plans.
  - **SIP URI** Use this URI type if you must have a Session Initiation Protocol (SIP) URI dial plan such as an IP PBX that supports SIP routing or if you're integrating Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server and Unified Messaging. The calling and called party information from the VoIP gateway. IP PBX, or Communications Server 2007 R2 or Lync Server is listed as a SIP address in the following format: sip:<*username*>@<*domain* or *IP address*>:Port.
  - **E.164** E.164 is an international numbering plan for public telephone systems in which each assigned number contains a country code, a national destination code, and a subscriber number. The calling and called party information sent from the VoIP gateway or IP PBX is listed in the following format: Tel:+14255550123.

Warning:

After you create a dial plan, you will be unable to change the URI type without deleting the dial plan, and then re-creating the dial plan to include the correct URI type.

- **VoIP security mode** Use this drop-down list to select the VoIP security setting for the UM dial plan. You can select one of the following security settings for the dial plan:
  - **Unsecured** By default, when you create a UM dial plan, it is set to not encrypt the SIP signaling or RTP traffic. In unsecured mode, the Client Access and Mailbox servers associated the UM dial plan send and receive data from VoIP gateways, IP PBXs, SBCs and other Client Access and Mailbox servers using no encryption. In unsecured mode, neither the Realtime Transport Protocol (RTP) media channel nor the SIP signaling information is encrypted.
  - **SIP secured** When you select **SIP secured**, only the SIP signaling traffic is encrypted, and the RTP media channels still use TCP, which isn't encrypted. With SIP secured, Mutual Transport Layer Security (TLS) is used to encrypt the SIP signaling traffic and VoIP data.
  - **Secured** When you select **Secured**, both the SIP signaling traffic and the RTP media channels are encrypted. Both the secure signaling media channel that uses Secure Realtime Transport Protocol (SRTP) and the SIP signaling traffic use mutual TLS to encrypt the VoIP data.
- **Country/Region code** Use this box to type the country/region code number to be used for outgoing calls. This number will automatically be prepended to the telephone number that's dialed. This box accepts from 1 through 4 digits. For example, in the United States, the country/region code is 1. In the United Kingdom, it's 44.

3. Click **Save**.

Important:

In previous versions of Exchange, the Unified Messaging server had to be added to a UM dial plan. In Exchange 2013, Client Access and Mailbox servers can’t be associated with a Telephone extension or E.164 dial plan. Client Access and Mailbox servers will answer all incoming calls for all types of dial plans. However, if you’re integrating UM with Microsoft Lync Server, you must add all Client Access and Mailbox servers to all SIP URI dial plans to enable call routing to work correctly with Lync Server.

Return to top

Step 2: Create and configure your UM IP gateways

A UM IP gateway represents either a VoIP gateway hardware device or an IP PBX. The combination of the UM IP gateway and a UM hunt group establishes a link between a VoIP gateway or IP PBX and a UM dial plan.

If you've created or enabled VoIP security on a dial plan, the UM IP gateway that you create by using one of the following procedures will be associated with a UM dial plan that uses VoIP security. In that case, you must use a fully qualified domain name (FQDN) to create the UM IP gateway, and not an IP address. You must also configure the UM IP gateway to listen on TCP port 5061. To configure a UM IP gateway to listen on TCP port 5061, run the following command: `Set-`

`UMIPGateway -identity MyUMIPGateway -Port 5061`. You must also verify that any VoIP gateways or IP PBXs have also been configured to listen on port 5061 for mutual TLS.

Perform the following procedure to create a new UM IP gateway.

Create a UM IP gateway

1. In the EAC, navigate to **Unified Messaging** > **UM IP Gateways**, and then click **Add +**.
2. On the **New UM IP gateway** page, enter the following information:
   - **Name** Use this box to specify a unique name for the UM IP gateway. This is a display name that appears in the EAC. If you have to change the display name of the UM IP gateway after it's been created, you must first delete the existing UM IP gateway, and then create another UM IP gateway that has the appropriate name. The UM IP gateway name is required, but it's used for display purposes only. Because your organization may use multiple UM IP gateways, we recommend that you use meaningful names for your UM IP gateways. The maximum length of a UM IP gateway name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.
   - **Address** You can configure a UM IP gateway with either an IP address or a fully qualified domain name (FQDN). Use this box to specify the IP address configured on the VoIP gateway, SIP-enabled PBX, IP PBX, or SBC, or an FQDN. This box accepts only FQDNs that are valid and formatted correctly.

You can enter alphabetical and numeric characters in this box. IPv4 addresses, IPv6 addresses, and FQDNs are supported. If you want to use mutual TLS between a UM IP gateway and a dial plan operating in either SIP secured or Secured mode, you must configure the UM IP gateway with an FQDN. You must also configure it to listen on port 5061 and verify that any VoIP gateways or IP PBXs have also been configured to listen for mutual TLS requests on port 5061. To configure a UM IP gateway, run the following command: `Set-UMIPGateway -identity MyUMIPGateway -Port 5061`.
If you use an FQDN, you must also make sure that you've correctly configured a DNS host record for the VoIP gateway so that the host name will be correctly resolved to an IP address. Also, if you use an FQDN instead of an IP address, and the DNS configuration for the UM IP gateway is changed, you must disable and then enable the UM IP gateway to make sure that configuration information for the UM IP gateway is updated correctly

   - **UM dial plan** Click **Browse** to select the UM dial plan that you want to associate with the UM IP gateway. When you select a UM dial plan to associate with a UM IP gateway, a default UM hunt group is also created and associated with the UM dial plan that you selected. If you don't select a UM dial plan, you must manually create a UM hunt group and then associate that UM hunt group with the UM IP gateway that you create.
3. Click **Save**.

Step 3: Create and configure your UM hunt groups (optional)

Hunt group is a term that's used to describe a group of PBX or IP PBX resources or extension numbers that are shared by users. Hunt groups are used to efficiently distribute calls into or out of a given business unit.

If you've created a UM IP gateway and associated the UM IP gateway with a UM dial plan, a default UM hunt group has been created. You can associate another UM hunt group with the same or a different UM IP gateway, depending on the number of UM IP gateways that you've created.

When you create a UM hunt group, you enable all Mailbox servers that are specified within the UM dial plan to communicate with a VoIP gateway. For details, see UM hunt groups.

Create a UM hunt group

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**. In the list view, select the UM dial plan you want to change, and then click **Edit** ✎.
2. On the **UM Dial Plan** page, under **UM Hunt Groups**, click **Add +**.
3. On the **New UM Hunt Group** page, complete the following boxes:
   - **Associated UM IP gateway** This display-only box shows the name of the UM IP gateway that will be associated with the UM hunt group.
   - **Name** Use this box to create the display name for the UM hunt group. A UM hunt group name is required and must be unique, but it's used only for display purposes in the EAC and the Shell. If you have to change the display name of the hunt group after it's been created, you must first delete the existing hunt group and then create another hunt group that has the appropriate name.

If your organization uses multiple hunt groups, we recommend that you use meaningful names for your hunt groups. The maximum length of a UM hunt group name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.

   - **Dial plan** Click **Browse** to select the dial plan that will be associated with the UM hunt group. Associating a hunt group with a dial plan is required. A UM hunt group can be associated with only one UM IP gateway and one UM dial plan.
   - **Pilot identifier** Use this box to specify a string that uniquely identifies the pilot identifier or pilot ID configured on the PBX or IP PBX.

An extension number or a Session Initiation Protocol (SIP) Uniform Resource Identifier (URI) can be used in this box. Alphanumeric characters are accepted in this box. For legacy PBXs, a numeric value is used as a pilot identifier. However, some IP PBXs can use SIP URIs.

4. Click **Save**.

Return to top

Step 4: Create and configure a UM mailbox policy

UM mailbox policies are required when you enable users for Unified Messaging. The mailbox of each UM-enabled user must be linked to a single UM mailbox policy. After you create a UM mailbox policy, you link one or more UM-enabled mailboxes to the UM mailbox policy. This lets you control PIN security settings such as the minimum number of digits in a PIN or the maximum number of failed sign-in attempts for the UM-enabled users who are associated with the UM mailbox policy.

Every time that you create a UM dial plan, a UM mailbox policy is also created. The UM mailbox policy will be named <*DialPlanName*> Default Policy. However, if you have to create a new UM

mailbox policy, perform the following procedure.

Create a UM mailbox policy

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**. In the list view, select the UM dial plan you want to modify, and then click **Edit** ✎.
2. On the **UM dial plan** page, under **UM Mailbox Policies**, click **Add +**.
3. On the **New UM Mailbox Policy** page, in the **Name** text box, enter the name of the new UM mailbox policy.

Use this box to specify a unique name for the UM mailbox policy. This is a display name that appears in the EAC. If you must change the display name of the UM mailbox policy after it's been created, you must first delete the existing UM mailbox policy, and then create another UM mailbox policy that has the appropriate name. You can't delete a UM mailbox policy if any UM-enabled users are associated with it.

The UM mailbox policy name is required, but it is used for display purposes only. Because your organization may use multiple UM mailbox policies, we recommend that you use meaningful names for your UM mailbox policies. The maximum length of a UM mailbox policy name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.

4. Click **Save** to save the new UM mailbox policy. When you save the UM mailbox policy, all of the default settings including PIN policies, voice mail features, and Protected Voice Mail settings are enabled. If you want to customize or change any default settings, use the **Set-UMMailbox** cmdlet to change the settings for the UM mailbox policy you just created.

Step 5: Create and configure UM auto attendants (optional)

Unified Messaging enables you to create one or more UM auto attendants, depending on the needs of your organization. When you create a UM auto attendant, you create a voice menu system for your organization. Callers from outside or inside your organization can then move through the menu system to locate and place or transfer calls to users or departments in your organization.

Callers can move through the menu system by using dual tone multi-frequency (DTMF), also known as touchtone, or voice inputs. For Automatic Speech Recognition (ASR) to work, so users can use voice inputs, you must speech-enable the UM auto attendant.

Creating and using auto attendants is optional in Unified Messaging. However, if you want to create a new UM auto attendant, perform the following procedure.

Create a UM auto attendant

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**, select the UM dial plan for which you want to add an auto attendant, and then click **Edit** ✎.
2. On the **UM Dial Plan** page, under **UM Auto Attendants**, click **Add +**.
3. On the **New UM auto attendant** page, complete the following boxes:
   - **Name** Use this box to create the display name for the UM auto attendant. A UM auto attendant name is required and must be unique. However, it's used only for display purposes in the EAC and the Shell.

If you have to change the display name of the auto attendant after it's created, you must first delete the existing UM auto attendant and then create another auto attendant that has the appropriate name. If your organization uses multiple UM auto attendants, we recommend that you use meaningful names for your UM auto attendants. The maximum length of a UM auto attendant name is 64 characters, and it can include spaces.

Although you can name a new UM auto attendant to include spaces, if you integrate Unified Messaging with Office Communications Server 2007 R2 or Microsoft Lync Server, the name of the auto attendant can't include spaces. Therefore, if you created an auto attendant that has spaces in the display name and you're integrating with Office Communications Server 2007 R2 or Lync Server, you must first delete that auto attendant and then create another auto attendant that doesn't include spaces in the display name.

- **Create this auto attendant as enabled** Select this check box to enable the auto attendant to answer incoming calls when you finish creating the UM auto attendant. By default, a new auto attendant is created as disabled.

If you decide to create the UM auto attendant as disabled, you can use the EAC or the Shell to enable the auto attendant after you finish creating the auto attendant.

- **Set the auto attendant to respond to voice commands** Select this check box to speech-enable the UM auto attendant. If the auto attendant is speech-enabled, callers can respond to the system or custom prompts used by the UM auto attendant using touchtone or voice inputs. By default, the auto attendant won't be speech-enabled when it's created.

For callers to use a speech-enabled auto attendant in a language other than U.S. English (en-US), you must install the appropriate UM language pack and configure the properties of the auto attendant to use this language. The en-US UM language pack is installed by default when you install a Mailbox server.

- **Access numbers** Use this box to enter the extension or telephone numbers that callers will use to reach the auto attendant. Type an extension number or telephone number in the box, and then click **Add +** to add the number to the list. The number of digits in the extension number or telephone number that you provide doesn't have to match the number of digits for an extension number configured on the associated UM dial plan. This is because direct calls are allowed to UM auto attendants.

The number of extension numbers or pilot identifiers you can enter is unlimited. However, you may create a new auto attendant without listing an extension number or telephone number. An extension number or telephone number isn't required.

You can edit or remove an existing extension number or pilot identifier. To edit an existing extension number or telephone number, click **Edit** ✎. To remove an existing extension number or telephone number from the list, click **Remove −**.

4. Click **Save**.

Return to top

Post-deployment tasks for Unified Messaging

After you complete a new installation of the Client Access and Mailbox servers and have successfully deployed Unified Messaging, you should complete the post-deployment tasks. The post-deployment tasks will help you enable users for Unified Messaging, secure your UM deployment, and deploy incoming faxing for UM-enabled users.

Enable users for voice mail

After you've deployed your VoIP gateways or IP PBXs, installed the Client Access and Mailbox servers, and created the components required for Unified Messaging, you need to enable your users for Unified Messaging. For details, see Enable a user for voice mail.

Protect voice mail

Unified Messaging can be configured to use Active Directory Rights Management Services (AD RMS) to protect voice messages for an organization. This feature is known as Protected Voice Mail. When a voice message is protected, the recipient is not only blocked from forwarding the message, but UM also assures that only the intended recipient or recipients of the message can access its content. Protected voice messages can be accessed by using Microsoft Outlook 2010 or later, Outlook Web App, or Outlook Voice Access. For details, see Protect voice mail.

Mutual TLS for UM

To use mutual TLS to encrypt SIP and Realtime Transport Protocol (RTP) traffic that's sent and received by your Client Access and Mailbox servers, perform the following tasks:

- Run the Exchange Certificate wizard. For details, see Deploying certificates for UM.
- Import the certificate on the Client Access and Mailbox servers.
- Import the required certificates on the VoIP gateways and the IP PBX and Client Access and Mailbox servers in your organization.
- Configure VoIP security on the UM dial plans. For details, see Configure the VoIP security setting.
- Configure the startup mode on the Client Access and Mailbox servers. For details, see Configure the startup mode on a Mailbox server and Configure the startup mode on a Client Access server.
- Configure the UM IP gateways to listen on port 5061. For details, see Configure the listening port.

PIN policies for UM-enabled users

In Unified Messaging, PIN policies are defined and configured on a UM mailbox policy. When you enable a user for Unified Messaging, you associate the user with an existing UM mailbox policy. The UM PIN policies that are configured on the UM mailbox policy should be based on the security requirements of your organization. For more information about how to configure PIN settings for UM-enabled users, see Set Outlook Voice Access PIN security.

Set up client voice mail features

After you've deployed your servers and the required UM components, there are several optional

voice mail-related features that you can configure. For more information, see the following:

- Setting up Outlook Voice Access
- Allow voice mail users to forward calls
- Allow users to see a voice mail transcript
- Enable voice mail users to receive faxes

Important:
If you're integrating your Unified Messaging environment with Microsoft Lync Server, there are additional planning considerations. For details, see Deploying Exchange 2013 UM and Lync Server overview.

Checklist: Deploy Exchange 2013 UM

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-08-05*

Use this checklist to help you install and deploy Unified Messaging (UM) in your organization.

Before you start working with this checklist, make sure you're familiar with the concepts in:

- Unified Messaging
- New voice mail features
- Planning for Unified Messaging

For step-by-step guidance about how to deploy UM and Microsoft Lync Server, see Checklist: Integrate Exchange 2013 UM with Lync Server.

Checklist for deploying Unified Messaging

Done?	Tasks	Topic
	Deploy and configure telephony components.	Connect UM to your telephone system
	Review the system requirements before installing Exchange 2013.	Exchange 2013 system requirements
	Verify that you meet the prerequisites for installation.	Exchange 2013 prerequisites

	Install the required Client Access and Mailbox servers. **⚠Warning:** You must deploy at least one Exchange 2013 Mailbox server in your organization before you configure the VoIP gateways or IP PBXs to send UM SIP and RTP traffic to the Exchange 2013 Client Access servers.	Install Exchange 2013 using the Setup wizard
	Verify the installation and review the server setup logs.	Verify an Exchange 2013 installation
	If required, install the required UM language packs.	Install a UM language pack
	Create the number of dial plans required for your organization.	Create a UM dial plan
	Configure the dial plan security setting.	Configure the VoIP security setting
	Configure the UM startup mode for each Client Access and Mailbox server.	Configure the startup mode on a Mailbox server Configure the startup mode on a Client Access server
	Configure the number of concurrent calls on your Mailbox servers.	Configure the number of incoming calls on a Mailbox server
	Configure Outlook Voice Access numbers and other settings.	Manage a UM dial plan
	Configure outbound dialing for Unified Messaging.	Authorize calls using dialing rules Authorize calls for users in a

		dial plan Authorize calls for a group of users
	Create the required number of auto attendants.	Create a UM auto attendant
	Set up and configure each of the UM auto attendants.	Set up a UM auto attendant
	Create, import, and enable a new Exchange certificate for UM or enable a mutually-trusted third-party certificate. Also, import the certificate on all VoIP gateways, IP PBXs, and SBCs.	Add Mailbox and Client Access servers to a SIP URI dial plan
	Restart the Microsoft Exchange Unified Messaging service and the Unified Messaging Call Router service on all Exchange servers to load the required certificates.	Stop the Microsoft Exchange Unified Messaging service Start the Microsoft Exchange Unified Messaging service Stop the Microsoft Exchange Unified Messaging Call Router service Start the Microsoft Exchange Unified Messaging Call Router service
	Create a UM mailbox policy or configure the default UM mailbox policy.	Create a UM mailbox policy Manage a UM mailbox policy
	Enable users for Unified Messaging with an extension number and an E.164 number, if	Enable a user for voice mail

	required.	
	Enable incoming faxing (Optional).	Enable voice mail users to receive faxes
	Set up Protected Voice Mail (Optional).	Protect voice mail

Upgrade Exchange 2010 UM to Exchange 2013 UM

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-04-04*

When you're upgrading a Microsoft Exchange 2010 organization with Unified Messaging (UM) to Exchange 2013 Unified Messaging, there are steps that are required and other steps that were already completed as part of your Exchange 2010 UM deployment. Depending on your telephony environment and the UM components that were created and configured to support Unified Messaging in Exchange 2010, you may need to deploy additional telephony equipment including Voice over IP (VoIP) gateways, IP Private Branch eXchanges (PBXs), or traditional or SIP-enabled PBXs and then create and configure any additional UM components that will be required for Exchange 2013 UM.

What do you need to know before you begin?

- Estimated time to complete this task: 45-90 minutes.
- Verify that you have the appropriate permissions in the Exchange 2010 and Exchange 2013 organization to create and configure all the required components.
- Verify that you've deployed and correctly configured your telephony components, including VoIP gateways and PBXs, IP PBXs, or Session Initiation Protocol (SIP)-enabled PBXs.
- Verify that you've correctly installed and configured the Client Access servers running the Microsoft Exchange Unified Messaging Call Router (UM Call Router) service and Mailbox servers running the Microsoft Exchange Unified Messaging (UM) service. To learn more about UM services, see UM services.

Warning:

You must deploy at least one Exchange 2013 Mailbox server in your organization before you configure the VoIP gateways or IP PBXs to send UM SIP and RTP traffic to the Exchange 2013 Client Access servers.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

How do you do this?

Step 1: Download and install the required UM language packs

UM language packs enable callers and Outlook Voice Access users to interact with the voice mail system in multiple languages. After you install an additional language on an Exchange 2013 Mailbox server, callers and Outlook Voice Access users can hear email messages and interact with the voice mail system in that language. However, to make the language available for all incoming calls, you must install the required UM language packs on all Exchange 2013 Mailbox servers. This is because every Exchange 2013 Mailbox server can answer incoming calls for Unified Messaging.

By default, when you install an Exchange 2013 Mailbox server, the U.S. English (en-US) language pack is installed. It's the only available language option for your dial plan unless you install another UM language pack. (U. S. English can't be removed unless you remove the Mailbox server from the computer.) After you install a UM language pack on an Exchange 2013 Mailbox server, the language associated with the language pack will be listed as an available option when you configure the default language for the dial plan. By default, because a UM auto attendant is linked to a UM dial plan when the auto attendant is created, it uses the default language setting of the linked UM dial plan. However, this setting can be changed after the UM auto attendant is created.

Note:

If U.S. English is the only language that you want to provide for your dial plan, you can skip this step and go to step 2.

You can add UM language packs by using the setup.exe command or by running the *<UMLanguagePack>*.exe installation program after you've downloaded the UM language pack from Exchange Server 2013 UM Language Packs. For more information, see Install a UM language pack.

This example uses setup.exe to install the Japanese (ja-JP) UM language pack.

```
setup.exe /AddUmLanguagePack:ja-JP /s:d:\Exchange
\UMLanguagePacks /IAcceptExchangeServerLicenseTerms
```

Step 2: Move the Exchange 2010 system mailbox used for UM custom greetings, announcements, menus, and prompts to Exchange 2013

Custom greetings, announcements, menus, and prompts are used by Unified Messaging dial plans and auto attendants. The system mailbox named {e0dc1c29-89c3-4034-b678-e6c29d823ed9} is created when you install Exchange 2010 or Exchange 2013 and is used to support features such as Message Approval and Multi-Mailbox Search. This system mailbox is also used to store dial plan and auto attendant custom greetings, announcements, menus, and prompts. If the system mailbox doesn't exist, you can use the **Setup /PrepareAD** command to create it.

By default, system mailboxes aren't visible in the Exchange admin center (EAC). You can get a list of the system mailboxes by running one the following:

This command returns a list of all the system mailboxes.

```
Get-Mailbox -Arbitration
```

This command returns a list of system mailboxes and their individual properties or settings.

```
Get-Mailbox -Arbitration |fl
```

By using this system mailbox, custom greetings, announcements, menus, and prompts can be backed up and restored along with other mailboxes in a database. This reduces the amount of resources that are needed. Storing custom greetings, announcements, menus, and prompts in a system mailbox removes any possible inconsistencies that may have occurred. To learn more about mailbox moves, see Mailbox moves in Exchange 2013.

Optional: Manually export and import dial plan and auto attendant custom greetings, announcements, menus, and prompts

There could be situations that the Exchange 2010 system mailbox has been moved and you still need to export and import the custom greetings, announcements, menus, and prompts that are used with UM dial plans and auto attendants from the Exchange 2010 system mailbox to the Exchange 2013 system mailbox. The system mailbox in both versions is named {e0dc1c29-89c3-4034-b678-e6c29d823ed9}.

Custom greetings, announcements, menus, and prompts are audio files (in .wav or .wma format) that are used by UM for the following purposes:

- On UM dial plans, the audio files are used for customized welcome greetings and informational announcements. They're played when Outlook Voice Access users call in to an Outlook Voice Access number.
- On UM auto attendants, the audio files are used for customized non-business and business hours greetings, informational announcements, menu prompts, and navigation menus. They're played when callers call in to a UM auto attendant.

When you're exporting and importing custom greetings, announcements, menus, and prompts from Exchange 2010 to Exchange 2013, you must use the **Export-UMPrompt** and **Import-UMPrompt** cmdlets. You can't use the EAC to export or import custom prompts. On an Exchange 2010 server, use the **Export-UMPrompt** cmdlet to export the Exchange 2010 dial plan and auto attendant prompts. After you've exported the prompts, you can import them to the Exchange 2013 Mailbox server. When you run the **Export-UMPrompt** cmdlet from your Exchange 2010 server, the command performs a GUID or object identifier lookup for the dial plan or auto attendant in Active Directory and queries it to determine if there are any custom greetings, announcements, menus, or prompts. If found, the custom greetings, announcements, menus, or prompts will be saved to the directory that you specify. After you've exported all custom greetings, announcements, menus, and prompts, use the **Import-UMPrompt** cmdlet to import the prompts into your Exchange 2013 system mailbox.

This example exports the welcome greeting for the UM dial plan `MyUMDialPlan` and saves it as the file `welcomegreeting.wav`.

```
$prompt = Export-UMPrompt -PromptFileName
"customgreeting.wav" -UMDialPlan MyUMDialPlan
set-content -Path "d:\DialPlanPrompts\welcomegreeting.wav"
-Value $prompt.AudioData -Encoding Byte
```

This example imports the welcome greeting `welcomegreeting.wav` from d:\UMPrompts into the UM dial plan `MyUMDialPlan`.

```
[byte[]]$c = Get-content -Path "d:\UMPrompts
\welcomegreeting.wav" -Encoding Byte -ReadCount 0
Import-UMPrompt -UMDialPlan MyUMDialPlan -PromptFileName
"welcomegreeting.wav" -PromptFileData $c
```

This example exports a custom greeting for the UM auto attendant `MyUMAutoAttendant` and saves it to the file `welcomegreetingbackup.wav`.

```
Export-UMPrompt -PromptFileName "welcomegreeting.wav" -
UMAutoAttendant MyUMAutoAttendant
```

```
set-content -Path "e:\UMPromptsBackup\welcomegreeting.wav"
-Value $prompt.AudioData -Encoding Byte
```

This example imports the welcome greeting `welcomegreeting.wav` from d:\UMPrompts into the UM auto attendant `MyUMAutoAttendant`.

```
[byte[]]$c = Get-content -Path "d:\UMPrompts
\welcomegreeting.wav" -Encoding Byte -ReadCount 0
Import-UMPrompt -UMAutoAttendant MyUMAutoAttendant -
PromptFileName "welcomegreeting.wav" -PromptFileData $c
```

To learn more about custom prompts for UM, see:

- Import and export custom greetings, announcements, menus, and prompts
- Import-UMPrompt
- Export-UMPrompt
- UM languages, prompts, and greetings

Step 4: Export and import certificates

If you're using SIP secured or Secured dial plans in your Exchange 2010 organization, you'll need to export and import the certificates that were used to your Exchange 2013 Client Access and Mailbox servers. Mutual Transport Layer Security (mutual TLS) is used to encrypt data sent between your Exchange 2013 servers and the VoIP gateways, IP PBXs, and SIP-enabled PBXs. Certificates bind the identity of the certificate owner to a pair of electronic keys (public and private) that are used to encrypt and sign information digitally. You can use one of the following certificates for the UM and UM Call Router services:

- A self-signed (Exchange) certificate
- An internal public key infrastructure (PKI) certificate
- A third-party commercial certificate

By default, when you install Exchange 2013, two self-signed certificates are created: **Microsoft Exchange Server Auth Certificate** and **Microsoft Exchange**. The **Microsoft Exchange** self-signed certificate can be used for UM to encrypt data, but you must assign the certificate to the UM and UM Call Router services. This self-signed certificate can be copied and then imported on the VoIP gateways, IP PBXs, and SIP-enabled PBXs. However, it can't be used when you're integrating UM with Microsoft Lync Server.

To enable UM to encrypt data that's sent between your Exchange 2013 servers and VoIP gateways, IP PBXs, and SIP-enabled PBXs, you need to do the following:

- Use an existing self-signed UM certificate, create a new self-signed Exchange certificate, submit a certificate request to an internal certification authority for a PKI certificate, or purchase a third-party commercial certificate that you can use for mutual TLS between your Exchange 2013 Mailbox and Client Access servers and VoIP gateways, IP PBXs, and SIP-enabled PBXs.

Create an Exchange self-signed certificate by using the EAC, as follows:

1. In the EAC, navigate to **Servers** > **Certificates**, and then click **Add +**.
2. On the **New Exchange certificate** page, choose **Create a self-signed certificate**, and then select **Next**.
3. Enter a friendly name for the certificate, and then select **Next**.
4. Click **Add +** to select the Exchange servers that you want to apply this certificate to, and then select **Next**.
5. Specify the domains that you want to be included in your certificate, and then select **Next**. If you want to add a domain for a service, click **Edit** ✎.
6. Verify that the domains you included are correct, and then select **Finish**.

Important:

When you use the EAC to create a certificate, you won't be prompted to enable the services for the certificate. After the certificate has been created, you can use the EAC to enable the services. For more information about how to enable a certificate for services, see Assign a certificate to the UM and UM Call Router services.

Create an Exchange self-signed certificate by running the following command in the Shell.

```
New-ExchangeCertificate -Services 'UM, UMCallRouter' -
DomainName '*.northwindtraders.com' -FriendlyName
'UMSelfSigned' -SubjectName
'C=US,S=WA,L=Redmond,O=Northwindtraders,OU=Servers,CN=
Northwindtraders.com' -PrivateKeyExportable $true
```

Note:

If you specify the services you want to enable by using the *Services* parameter, you will be prompted to enable the services for the certificate you created. In this example, you will be prompted to enable the certificate for the Unified Messaging and Unified Messaging Call Router services. For more information about how to enable a certificate for services, see Assign a certificate to the UM and UM Call Router services.

- Import the certificate that will be used on all Exchange 2013 Client Access and Mailbox servers in your organization. If you use the Exchange 2013 self-signed certificate, you'll need to copy the certificate, then import it on the VoIP gateways, IP PBXs, or SIP-enabled PBXs. If you use the self-signed certificate from Exchange 2010, the Subject Alternative Name (SAN) must contain the machine names of all the Exchange 2013 servers. If you have Exchange 2010 Unified Messaging servers in your organization, you can use the Exchange 2013 self-signed certificate, but you must add the machine names of the Exchange 2010 UM servers to the SAN in the Exchange 2013 certificate.
- Enable or assign the certificate to be used to the UM and UM Call Router services on the Client Access and Mailbox servers in your organization.

Enable the UM service and UM Call Router service on all Exchange 2013 servers to use the Exchange self-signed certificate by using the EAC, as follows:

1. In the EAC, navigate to **Servers** > **Certificates**, select the certificate you want to enable services on, and then click **Edit** ✎.

2. On the **Procedure** page, select **Services**, select **Unified Messaging**, and then select **Unified Messaging call router**.

Enable an Exchange self-signed certificate by running the following command in the Shell.

```
Enable-ExchangeCertificate -Thumbprint
5113ae0233a72fccb75b1d0198628675333d010e -Services 'UM,
UMCallRouter'
```

- Configure any new or existing UM dial plans as SIP secured or Secured.
- Configure the UM startup mode to TLS or Dual on the Client Access and Mailbox servers in your organization.
- Create and configure new or existing UM IP gateways with a fully qualified domain name (FQDN).
- Configure the listening port on the UM IP gateways to use TLS port 5061.
- Restart the UM Call Router service on all Exchange 2013 Client Access servers and restart the UM service on all Exchange 2013 Mailbox servers. To learn more about UM services, see UM services.

Step 5: Configure the UM startup mode on all Exchange 2013 Client Access servers

If you're using SIP secured or Secured dial plans, you must configure the UM startup mode on your Exchange 2013 Client Access servers. You can specify the UM startup mode for the UM Call Router service on an Exchange 2013 Client Access server by using the EAC or the Exchange Management Shell. By default, the Client Access server will start up in TCP mode, but if you're using Transport Layer Security (TLS) to encrypt Voice over IP (VoIP) traffic, you must configure the Exchange 2013 Client Access server to use TLS or Dual mode. We recommend that all Exchange 2013 Client Access servers be configured to use Dual as the UM startup mode. This is because all Exchange 2013 Client Access servers can answer incoming calls for all UM dial plans, and those dial plans can have different security settings. If you change the UM startup mode, you must restart the UM Call Router service for the change to take effect. To learn more about UM services, see UM services.

Configure the UM startup mode on an Exchange 2013 Client Access server by using the EAC, as follows:

1. In the EAC, navigate to **Servers** > **Servers**.
2. In the list view, select the Exchange server that you want to modify, and then click **Edit** ✎.
3. On the **Exchange Server** page, click **Unified Messaging**.
4. Under **UM Call Router settings** > **UM startup mode**, select one of the following from the drop-down list:
   - **TCP** Use this option if you aren't using mTLS and are using only Unsecured dial plans.
   - **TLS** Use this option if you're using mTLS and are using only SIP Secured or Secured dial plans.
   - **DUAL** Use this option if you're using mTLS and are using Unsecured, SIP Secured, and Secured dial plans.
5. After you select the UM startup mode, click **Save**.

Configure the UM startup mode on an Exchange 2013 Client Access server by running the following command in the Shell.

```
Set-UMCallRouterSettings -Server
MyUMCallRouter.northwindtraders.com -UMStartupMode Dual
```

Step 6: Configure the UM startup mode on all Exchange 2013 Mailbox servers

If you're using SIP secured or Secured dial plans, you must configure the UM startup mode on your Exchange 2013 Mailbox servers. You can specify the UM startup mode for the UM service on an Exchange 2013 Mailbox server by using the EAC or the Shell. By default, an Exchange 2013 Mailbox server will start up in TCP mode, but if you're using Transport Layer Security (TLS) to encrypt Voice over IP (VoIP) traffic, you must configure the Exchange 2013 Mailbox server to use TLS or Dual mode. We recommend that all Exchange 2013 Mailbox servers be configured to use Dual as the UM startup mode. This is because all Exchange 2013 Mailbox servers can answer incoming calls for all UM dial plans, and those dial plans can have different security settings. If you change the UM startup mode, you must restart the UM service for the change to take effect. To learn more about UM services, see UM services.

Configure the UM startup mode on an Exchange 2013 Mailbox server by using the EAC, as follows:

1. In the EAC, navigate to **Servers** > **Servers**.
2. In the list view, select the Exchange server that you want to modify, and then click **Edit** ✎.
3. On the **Exchange Server** page, click **Unified Messaging**.
4. Under **UM Service settings** > **UM startup mode**, select one of the following from the drop-down list:
   - **TCP** Use this option if you aren't using mTLS and are using only Unsecured dial plans.
   - **TLS** Use this option if you're using mTLS and are using only SIP Secured or Secured dial plans.
   - **DUAL** Use this option if you're using mTLS and are using Unsecured, SIP Secured, and Secured dial plans.
5. After you select the UM startup mode, click **Save**.

Configure the UM startup mode on an Exchange 2013 Mailbox server by running the following command in the Shell.

```
Set-UMService -Identity MyUMServer -ExternalHostFqdn
host.external.contoso.com -IPAddressFamily Any -
UMStartupMode Dual
```

Step 7: Create or configure existing UM dial plans

Depending on your existing Exchange 2010 deployment, you may be required to create new UM

dial plans or configure your existing dial plans. A UM dial plan represents a set of traditional or SIP-enabled Private Branch eXchanges (PBXs) or IP PBXs that share common user extension numbers. All users' extensions hosted on traditional or SIP-enabled PBXs or IP PBXs within a dial plan contain the same number of digits. Users can dial one another's telephone extensions without appending a special number to the extension or dialing a full telephone number.

UM dial plans are used in Unified Messaging to make sure that user telephone extensions are unique. In some telephony networks, multiple PBXs or IP PBXs exist. In these telephony networks, there could be two users who have the same telephone extension number. UM dial plans resolve this situation. Putting the two users into two separate UM dial plans makes their extensions unique. For more information, see UM dial plans.

If required, you can create a UM dial plan by using the EAC:

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**, and then click **New +**.
2. On the **New UM Dial Plan** page, complete the following boxes:
   - **Name** Type the name of the dial plan. A UM dial plan name is required and must be unique. However, the name you type is used only for display purposes in the EAC and the Shell. The maximum length of a UM dial plan name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.

Although the box for the name of the dial plan can accept 64 characters, the name of the dial plan can't be longer than 49 characters. If you try to create a dial plan name that contains more than 49 characters, you'll receive an error message. The message will say that the UM mailbox policy couldn't be generated because the UM dial plan name is too long. This happens because, when you create a dial plan a default UM mailbox policy named <*DialPlanName*> **Default Policy** is also created. When the 15 characters in the default policy are added to the name of the dial plan, the total characters exceed the limit. The *name* parameter for both the UM dial plan and UM mailbox policy can be 64 characters. However, if the name of the dial plan is longer than 49 characters, the name of the default UM mailbox policy will be longer than 64 characters, and this isn't allowed by the system.

   - **Extension length (digits)** Enter the number of digits for extension numbers in the dial plan. The number of digits for extension numbers is based on the telephony dial plan created on a PBX. For example, if a user associated with a telephony dial plan dials a four-digit extension to call another user in the same telephony dial plan, you select 4 as the number of digits in the extension.

This is a required box that has a value range from 1 through 20. The typical extension length is from 3 through 7 numbers. If your existing telephony environment includes extension numbers, you must specify a number of digits that matches the number of digits in those extensions.

When you create a Telephone extension dial plan, you're required to enter an extension number for the user if they're linked to a Telephone extension dial plan. An extension number is also required with Session Initiation Protocol (SIP) dial plans or E.164 dial plans when a UM-enabled user is linked to a SIP URI or E.164 dial plan. The extension number is used by Outlook Voice Access users when they access their Exchange mailbox.

   - **Dial plan type** A Uniform Resource Identifier (URI) is a string of characters that identifies or

names a resource. The main purpose of this identification is to enable VoIP devices to communicate with other devices over a network using specific protocols. URIs are defined in schemes that define a specific syntax and format and the protocols for the call. In simple terms, this format is passed from the IP PBX or PBX. After you create a UM dial plan, you won't be able to change the URI type without deleting the dial plan, and then re-creating the dial plan to include the correct URI type. You can select one of the following URI types for the dial plan:

- **Telephone extension** This is the most common URI type. The calling and called party information from the VoIP gateway or IP Private Branch eXchange (PBX) is listed in one of the following formats: Tel:512345 or 512345@<*IP address*>. This is the default URI type for dial plans.
- **SIP URI** Use this URI type if you must have a Session Initiation Protocol (SIP) URI dial plan such as an IP PBX that supports SIP routing or if you're integrating Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server and Unified Messaging. The calling and called party information from the VoIP gateway. IP PBX, or Communications Server 2007 R2 or Lync Server is listed as a SIP address in the following format: sip:<*username*>@<*domain* or *IP address*>:Port.
- **E.164** E.164 is an international numbering plan for public telephone systems in which each assigned number contains a country code, a national destination code, and a subscriber number. The calling and called party information sent from the VoIP gateway or IP PBX is listed in the following format: Tel:+14255550123.

⚠Warning:

After you create a dial plan, you will be unable to change the URI type without deleting the dial plan, and then re-creating the dial plan to include the correct URI type.

- **VoIP security mode** Use this drop-down list to select the VoIP security setting for the UM dial plan. You can select one of the following security settings for the dial plan:
  - **Unsecured** By default, when you create a UM dial plan, it is set to not encrypt the SIP signaling or RTP traffic. In unsecured mode, the Client Access and Mailbox servers associated the UM dial plan send and receive data from VoIP gateways, IP PBXs, SBCs and other Client Access and Mailbox servers using no encryption. In unsecured mode, neither the Realtime Transport Protocol (RTP) media channel nor the SIP signaling information is encrypted.
  - **SIP secured** When you select **SIP secured**, only the SIP signaling traffic is encrypted, and the RTP media channels still use TCP, which isn't encrypted. With SIP secured, Mutual Transport Layer Security (TLS) is used to encrypt the SIP signaling traffic and VoIP data.
  - **Secured** When you select **Secured**, both the SIP signaling traffic and the RTP media channels are encrypted. Both the secure signaling media channel that uses Secure Realtime Transport Protocol (SRTP) and the SIP signaling traffic use mutual TLS to encrypt the VoIP data.
- **Country/Region code** Use this box to type the country/region code number to be used for outgoing calls. This number will automatically be prepended to the telephone number that's dialed. This box accepts from 1 through 4 digits. For example, in the United States, the

country/region code is 1. In the United Kingdom, it's 44.

3. Click **Save**.

If required, you can create a UM dial plan by running the following command in the Shell.

```
New-UMDialplan -Name MyUMDialPlan -URIType E164 -
NumberOfDigitsInExtension 5 -VoIPSecurity Secured
```

If required, you can configure an existing UM dial plan by using the EAC, as follows:

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**.
2. In the list view, select the UM dial plan you want to view or modify, and then click **Edit** ✎.
3. On the **UM Dial Plan** page, click **Configure**. Use the configuration options to view specific dial plan settings and to enable or disable features.

If required, you can configure an existing UM dial plan by using the Shell:

```
Set-UMDialplan -Identity MyDialPlan -AccessTelephoneNumbers
4255551234 -AudioCodec Wma -CallAnsweringRulesEnabled
$false -OutsideLineAccessCode 9 -VoIPSecurity SIPSecured
```

When you deployed Exchange 2010 Unified Messaging, you were required to add a Unified Messaging server to a UM dial plan for it to answer incoming calls. This is no longer required. In Exchange 2013, Client Access and Mailbox servers can't be linked with a Telephone extension or E.164 dial plan, but must be linked to SIP URI dial plans. Client Access and Mailbox servers will answer all incoming calls for all types of dial plans.

Step 8: Create or configure existing UM IP gateways

Depending on your existing Exchange 2010 deployment, you may be required to create new UM IP gateways or configure your existing ones. If you're using SIP secured or Secured dial plans, you must create a UM IP gateway with an FQDN and use the Shell to configure it to listen on port 5061. For existing UM IP gateways, verify that they're configured with an FQDN and are listening on port 5061. If the UM IP gateway doesn't use an FQDN, use the EAC or the Shell to change the address. If the UM IP gateway doesn't use port 5061, use the Shell to change the port. You can view the settings of a UM IP gateway by using the **Get-UMIPGateway** cmdlet.

A UM IP gateway represents a physical Voice over IP (VoIP) gateway, IP PBX, or SIP-enabled PBX. Before a VoIP gateway, IP PBX, or SIP-enabled PBX can be used to answer incoming calls and send outgoing calls for voice mail users, a UM IP gateway must be created in the directory service.

The combination of the UM IP gateway and a UM hunt group establishes a link between a VoIP gateway, IP PBX, or SIP-enabled PBX and a UM dial plan. By creating multiple UM hunt groups, you can associate a single UM IP gateway with multiple UM dial plans. For more information, see UM IP gateways.

If required, you can create a UM IP gateway by using the EAC, as follows:

1. In the EAC, navigate to **Unified Messaging** > **UM IP gateways**, and then click **Add +**.
2. On the **New UM IP Gateway** page, enter the following information:
   - **Name** Use this box to specify a unique name for the UM IP gateway. This is a display name that appears in the EAC. If you have to change the display name of the UM IP gateway after it's been created, you must first delete the existing UM IP gateway, and then create another UM IP gateway that has the appropriate name. The UM IP gateway name is required, but it's used for display purposes only. Because your organization may use multiple UM IP gateways, we recommend that you use meaningful names for your UM IP gateways. The maximum length of a UM IP gateway name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.
   - **Address** You can configure a UM IP gateway with either an IPv4 or IPv6 address or an FQDN. Use this box to specify the IP address or FQDN configured on the VoIP gateway, IP PBX, or SIP-enabled PBX. This box accepts only FQDNs that are valid and formatted correctly.

You can enter alphabetical and numeric characters. IPv4 addresses, IPv6 addresses, and FQDNs are supported. If you want to use mutual TLS between a UM IP gateway and a dial plan operating in either SIP secured or Secured mode, you must configure the UM IP gateway with an FQDN. You must also configure it to listen on port 5061 and verify that any VoIP gateways or IP PBXs have also been configured to listen for mutual TLS requests on port 5061. To configure a UM IP gateway, run the following command in the Shell: `Set-UMIPGateway -identity MyUMIPGateway -Port 5061`

If you use an FQDN, you must also make sure that you've correctly configured a DNS host record for the VoIP gateway, IP PBX, or SIP-enabled PBX so that the host name will be correctly resolved to an IP address. Also, if you use an FQDN instead of an IP address, and the DNS configuration for the UM IP gateway is changed, you must disable and then enable the UM IP gateway to make sure that configuration information for the UM IP gateway is updated correctly.

   - **UM Dial Plan** Click **Browse** to select the UM dial plan that you want to associate with the UM IP gateway. When you select a UM dial plan to associate with a UM IP gateway, a default UM hunt group is also created and associated with the UM dial plan that you selected. If you don't select a UM dial plan, you must manually create a UM hunt group and then associate that UM hunt group with a UM IP gateway that you have created.
3. Click **Save**.

If required, you can create a UM IP gateway by run the following command.

```
New-UMIPGateway -Identity MyUMIPGateway -Address
"MyUMIPGateway.contoso.com"
```

To configure an existing UM IP gateway by using the EAC:

1. In the EAC, navigate to **Unified Messaging** > **UM IP gateways**, and then click **Edit** ✎.
2. On the **UM IP gateway** page, click **Configure**. Use the configure options to view specific UM IP gateway settings and to enable or disable features.

To configure an existing UM IP gateway in the Shell, running the following command in the Shell.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address
```

```
fe80::39bd:88f7:6969:d223%11 -IPAddressFamily Any -Status
Disabled -OutcallsAllowed $false
```

Step 9: Create a UM hunt group

Depending on your existing Exchange 2010 deployment, you may be required to create new UM hunt groups. A telephony hunt group provides a way to distribute telephone calls from a single number to multiple extensions or telephone numbers. In Unified Messaging, a UM hunt group is a logical representation of a telephony hunt group, and it links a UM IP gateway to a UM dial plan.

You need to have at least one UM hunt group for every IP PBX or PBX hunt group. When you complete the following procedure, one UM hunt group is created by default. If you have more than one IP PBX or PBX hunt group, you need to create additional UM hunt groups. To learn more about UM hunt groups, see UM hunt groups.

If required, you can To create a UM hunt group by using the EAC, as follows:

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**. In the list view, select the UM dial plan you want to modify, and then click **Edit** ✎.
2. On the **UM Dial Plan** page, under **UM Hunt Groups**, click **New +**.
3. On the **New UM Hunt Group** page, enter the following information:
   - **Name** Use this box to create the display name for the UM hunt group. A UM hunt group name is required and must be unique, but it's used only for display purposes in the EAC and the Shell. If you have to change the display name of the hunt group after it's been created, you must first delete the existing hunt group and then create another hunt group that has the appropriate name. If your organization uses multiple hunt groups, we recommend that you use meaningful names for your hunt groups. The maximum length of a UM hunt group name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.
   - **UM IP Gateway** Use this box to select a UM IP gateway. This box shows the name of the UM IP gateway that will be linked with the UM hunt group. To link a UM IP gateway to the UM hunt group, click **Browse**.
   - **Pilot Identifier** Use this box to specify a string that uniquely identifies the pilot identifier configured on the PBX or IP PBX. An extension number or a SIP Uniform Resource Identifier (URI) can be used in this box. Alphanumeric characters are accepted in this box. For legacy PBXs, a numeric value is used as a pilot identifier. However, some IP PBXs and SIP-enabled PBXs can use SIP URIs.
4. Click **Save**.

If required, you can create a UM hunt group by running the following command in the Shell.

```
New-UMHuntGroup -Name MyUMHuntGroup -PilotIdentifier
5551234,55555 -UMDialPlan MyUMDialPlan -UMIPGateway
MyUMIPGateway
```

Tip:

You can't configure or change settings for a UM hunt group. If you want to change the configuration settings for a UM hunt group, you must delete it and add a new UM hunt group with the correct settings.

Step 10: Create or configure UM auto attendants

Depending on your existing Exchange 2010 deployment, you may be required to create new UM auto attendants. You can use UM auto attendants to create a voice menu system that lets external and internal callers use the UM auto attendant menu system to locate people and place or transfer calls to company users or departments in an organization. For more information, see Automatically answer and route incoming calls.

In smaller deployments you may only want to deploy UM so that callers can leave voice mail for users. In these deployments, creating an auto attendant isn't required. However, in most cases, using auto attendants is very useful for external callers when they call in to your organization.

If required, you can create a UM auto attendant by using the EAC, as follows:

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**. Select the UM dial plan for which you want to add an auto attendant, and then click **Edit** ✎.
2. On the **UM dial plan** page, under **UM Auto Attendants**, click **Add +**.
3. On the **New UM Auto Attendant** page, complete the following boxes:
   - **Name** Use this box to create the display name for the UM auto attendant. A UM auto attendant name is required and must be unique. However, it's used only for display purposes in the EAC and the Shell. If you have to change the display name of the auto attendant after it's created, you must first delete the existing UM auto attendant and then create another auto attendant that has the appropriate name. If your organization uses multiple UM auto attendants, we recommend that you use meaningful names for your UM auto attendants. The maximum length of a UM auto attendant name is 64 characters, and it can include spaces.

Although you can name a new UM auto attendant to include spaces, if you integrate Unified Messaging with Lync Server, the name of the auto attendant can't include spaces. Therefore, if you created an auto attendant that has spaces in the display name and you're integrating with Lync Server, you must first delete that auto attendant and then create another auto attendant that doesn't include spaces in the display name.

   - **Create this auto attendant as enabled** Select this check box to enable the auto attendant to answer incoming calls when you finish creating the UM auto attendant. By default, a new auto attendant is created as disabled. If you decide to create the UM auto attendant as disabled, you can use the EAC or the Shell to enable the auto attendant after you finish creating it.
   - **Set the auto attendant to respond to voice commands** Select this check box to speech-enable the UM auto attendant. If the auto attendant is speech-enabled, callers can respond to the system or custom prompts used by the UM auto attendant using touchtone or voice inputs. By default, the auto attendant isn't speech-enabled when it's created. For callers to use a speech-enabled auto attendant in a language other than U.S. English (en-US), you must install

the appropriate UM language pack and configure the properties of the auto attendant to use this language. The en-US UM language pack is installed by default when you install an Exchange 2013 Mailbox server.

- **Access numbers** Enter the extension or telephone numbers that callers will use to reach the auto attendant. Type an extension number or telephone number in the box, and then click **Add** to add the number to the list. The number of digits in the extension number or telephone number that you provide doesn't have to match the number of digits for an extension number configured on the associated UM dial plan. This is because direct calls are allowed to UM auto attendants.

The number of extension or access numbers you can enter is unlimited. However, you may create a new auto attendant without listing an extension number or telephone number. An extension number or telephone number isn't required. You can edit or remove an existing extension number or pilot identifier. To edit an existing extension number or telephone number, click **Edit**. To remove an existing extension number or telephone number from the list, click **Remove**.

4. Click **Save**.

If required, you can create a UM auto attendant by running the following command in the Shell.

```
New-UMAutoAttendant -Name MyUMAutoAttendant -UMDialPlan
MyUMDialPlan -PilotIdentifierList 56000,56100 -
SpeechEnabled $true -Status Enabled
```

If required, you can configure an existing auto attendant by using the EAC, as follows:

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**, and then click **Edit** ✎.
2. On the **UM dial plan** page, under **UM Auto Attendants**, select the UM auto attendant that you want to view or configure, and then click **Edit** ✎. Use the configuration options to view specific auto attendant settings and to enable or disable features.

If required, you can configure an existing auto attendant by running the following command in the Shell.

```
Set-UMAutoAttendant -Identity MySpeechEnabledAA -
DTMFFallbackAutoAttendant MyDTMFAA -OperatorExtension 50100
-AfterHoursTransferToOperatorEnabled $true -
StaroutToDialPlanEnabled $true
```

Step 11: Create or configure UM mailbox policies

Depending on your existing Exchange 2010 deployment, you may be required to create new UM mailbox policies or configure existing UM mailbox policies. UM mailbox policies are required when you enable users for Unified Messaging. The mailbox of each UM-enabled user must be linked to a single UM mailbox policy. After you create a UM mailbox policy, you link one or more UM-enabled mailboxes to the UM mailbox policy. This lets you control PIN security settings such as the minimum number of digits in a PIN or the maximum number of logon attempts for the UM-enabled users

who are linked to the UM mailbox policy. For more information, see UM mailbox policies.

If required, you can create a UM mailbox policy by using the EAC:

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**. In the list view, select the UM dial plan that you want to modify, and then click **Edit** .
2. On the **UM dial plan** page, under **UM Mailbox Policies**, click **Add** .
3. On the **New UM Mailbox Policy** page, in the **Name** box, enter the name of the new UM mailbox policy.

Note:

Use this box to specify a unique name for the UM mailbox policy. This is a display name that appears in the EAC. If you must change the display name of the UM mailbox policy after it's been created, you must first delete the existing UM mailbox policy, and then create another UM mailbox policy that has the appropriate name. You can't delete a UM mailbox policy if any UM-enabled users are associated with it.The UM mailbox policy name is required, but it's used for display purposes only. Because your organization may use multiple UM mailbox policies, we recommend that you use meaningful names for your UM mailbox policies. The maximum length of a UM mailbox policy name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.

4. Click **Save**.

Note:

When you save the UM mailbox policy, all the default settings including PIN policies, voice mail features, and Protected Voice Mail settings are enabled. If you want to customize or change any default settings for the UM mailbox policy you just created, use the **Set-UMMailbox** cmdlet or the EAC.

If required, you can create a UM mailbox policy by running for following command in the Shell.

```
New-UMMailboxPolicy -Name MyUMMailboxPolicy -UMDialPlan
MyUMDialPlan
```

If required, you can configure an existing UM mailbox policy by using the EAC:

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**, and then click **Edit** .
2. On the **UM dial plan** page, under **UM Mailbox Policies**, select the UM mailbox policy you want to view or configure, and then click **Edit** . Use the configuration options to view specific UM mailbox policy settings and to enable or disable features.

If required, you can configure an existing UM mailbox policy by running the following command in the Shell.

```
Set-UMMailboxPolicy -Identity MyUMMailboxPolicy -
LogonFailuresBeforePINReset 8 -MaxLogonAttempts 12 -
MinPINLength 8 -PINHistoryCount 10 -PINLifetime 60 -
ResetPINText "The PIN used to allow you access to your
mailbox using Outlook Voice Access has been reset."
```

Step 12: Move existing UM-enabled mailboxes to Exchange 2013

In Exchange 2010 Unified Messaging, after you've enabled users within the organization to use voice mail, a default set of UM properties is applied to the user so they can use UM features. Learn more at Voice mail for users.

During the process of upgrading, there will be a period of time during which you'll have mailboxes that are UM enabled both on Exchange 2010 Mailbox servers and on Exchange 2013 Mailbox servers. However, if you're moving all UM-enabled users over to Exchange 2013 Mailbox servers, you must use the EAC or the **New-MoveRequest** cmdlet in the Shell from an Exchange 2013 server to retain all of the properties and settings, including the user's PIN.

A move request is the process of moving a mailbox from one mailbox database to another. A local move request is a mailbox move that occurs within a single forest. For more information about mailbox moves, see:

- Mailbox moves in Exchange 2013
- New-MoveRequest
- New-MigrationBatch
- Managing Move Requests

To move an Exchange 2010 mailbox to an Exchange 2013 Mailbox server by using the EAC:

1. In the EAC, click **Recipients** > **Migration**, and then click **Add** .
2. In the **New local mailbox move** wizard, select the user you want to move, click **OK**, and then click **Next**.
3. On the **Move configuration** page, specify a name for the new batch. Select which options you want for the archive mailbox and the mailbox database location, and then click **New**.

To move an Exchange 2010 mailbox to an Exchange 2013 Mailbox server by using the Shell, run the following command.

```
New-MoveRequest -Identity 'tony@alpineskihouse.com' -
TargetDatabase "DB01"
```

Step 13: Enable new users for UM or configure settings for an existing UM-enabled user

A user must have a mailbox before they can be enabled for Unified Messaging. But, by default, a user who has a mailbox isn't enabled for UM. After the user is UM-enabled, you can manage, modify, and configure the UM properties and voice mail features for them. You can enable a user for UM by using the EAC or the Shell. Learn more at Voice mail for users.

When you enable a user for UM, you must define at least one extension number that UM will use

when voice mail is submitted to the user's mailbox and to allow the user to use Outlook Voice Access. After you enable the user for UM, you can add secondary extension numbers to the user's mailbox, modify or remove them by configuring the Exchange Unified Messaging (EUM) proxy address on the user's mailbox, or add or remove additional or secondary extensions for the user in the EAC. To add, modify, or remove extension numbers, E.164 numbers, or SIP addresses, see Voice mail-enabled user procedures.

To enable a user for Unified Messaging by using the EAC:

1. In the EAC, click **Recipients**.
2. In the list view, select the user whose mailbox you want to enable for Unified Messaging.
3. In the Details pane, under **Phone and Voice Features**, click **Enable**.
4. On the **Enable UM mailbox** page, click the **Browse** button next to **UM mailbox policy**, locate the UM mailbox policy to assign the user from the list, and then click **OK**.
5. On the **Enable UM mailbox** page, complete the following boxes:
   - **SIP address or E.164 number** Enter the SIP address or E.164 number for the user. These options are available if the user that you enable for Unified Messaging is assigned to a UM mailbox policy that's linked to either a SIP URI or an E.164 dial plan. Adding a SIP address or E.164 number for a user isn't available if the user is associated with a telephone extension dial plan. When you assign the user to a UM mailbox policy that's linked to a SIP URI or E.164 dial plan, you must still also enter an extension number for the user. This extension number is used when users access their mailbox using Outlook Voice Access. The number of digits that you configure in this box must match the number of digits configured on the SIP URI or E.164 dial plan.
   - **Extension number** Enter the extension number for the user you're enabling for UM.

You must provide a valid extension number for the user, and it must match the number of digits specified on the dial plan. You can only enter numeric characters or digits from 1 through 20. The typical extension number is 3 to 7 digits long. The number of digits in the extension is set on the dial plan that's linked to the UM mailbox policy that's assigned to the user.

   - Under **PIN settings**, complete the following:
     - **Automatically generate PIN** Click this button to automatically generate a PIN for the UM-enabled user to use for voice mail access via Outlook Voice Access. This is the default setting. When you click this button, a PIN is automatically generated based on the PIN policies configured on the UM mailbox policy assigned to the user. We recommend that you use this setting to help protect the user's PIN. The PIN is sent to the user in the welcome message they receive after they're enabled for UM. By default, they'll have to change this PIN when they first sign in to their mailbox to get their voice mail.
     - **Type a PIN** Click this button to manually specify a PIN that the user will use to access the voice mail system.The PIN must comply with the PIN policy settings configured on the UM mailbox policy associated with this UM-enabled user. For example, if the UM mailbox policy is configured to accept only PINs that contain seven or more digits, the PIN you enter in this box must be at least seven digits long.
     - **Require the user to reset their PIN the first time they sign in** Select this check box to

force the user to reset their voice mail PIN when they access the voice mail system from a telephone using Outlook Voice Access for the first time. They will be prompted to enter a PIN that's more familiar to them.It's a security best practice to force UM-enabled users to change their PIN when they first sign in to help protect against unauthorized access to their data and Inbox. This check box is selected by default.

6. On the **Enable UM mailbox** page, review your settings. Click **Finish** to enable the user for Unified Messaging. Click **Back** to make configuration changes.

To enable a user for Unified Messaging by using the Shell, run the following command.

```
Enable-UMMailbox -Identity tonysmith@contoso.com -
UMMailboxPolicy MyUMMailboxPolicy -Extensions 51234 -PIN
5643892 -NotifyEmail administrator@contoso.com -PINExpired
$true
```

If required, you can configure a user that's been enabled for UM by using the EAC:

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list view, select the mailbox for which you want to change the UM mailbox policy.
3. In the details pane, under **Phone and Voice Features** > **Unified Messaging**, click **View details**.
4. On the **UM Mailbox** page, click **UM mailbox settings** to view or change the following UM properties for an existing UM-enabled user:
   - **PIN Status** This display-only box shows the status of the user's mailbox. By default, when a user is UM-enabled, the PIN status is listed as **Not locked out**. However, if the user has input an incorrect Outlook Voice Access PIN multiple times, the status is listed as **Locked Out**.
   - **UM mailbox policy** This box shows the name of the UM mailbox policy associated with the UM-enabled user. You can click **Browse** to locate and specify the UM mailbox policy to be associated with this UM mailbox.
   - **Personal operator extension** Use this box to specify the operator extension number for the user. By default, an extension number isn't configured. The length of the extension number can be from 1 through 20 characters. This enables incoming calls for the UM-enabled user to be forwarded to the extension number that you specify in this box.

You can configure other types of operator extension numbers on dial plans and auto attendants. However, those extensions are generally meant for company-wide receptionists or operators. The personal operator extension setting could be used when an administrative assistant or personal assistant answers incoming calls for a specific user.

5. On the **UM Mailbox** page, under **Other extensions**, you can add, change, and view extension numbers for the user.
   - To add an extension number, click **Add +**. On the **Add another extension** page, use **Browse** to select the UM dial plan, and then enter the extension number in the **Extension number** box.
   - To remove an extension number, select the extension number you want to remove, and then click **Remove −**.
6. If you make any changes, click **Save**.

If required, you can configure a user that's been enabled for UM in the Shell by running the

following command.

```
Set-UMMailbox -Identity tony@contoso.com -
CallAnsweringAudioCodec Wma -CallAnsweringRulesEnabled
$false -FaxEnabled $false -UMSMSNotificationOption
VoiceMail
```

Step 14: Configure your VoIP gateways, IP PBXs, and SIP-enabled PBXs to send all incoming calls to the Exchange 2013 Client Access servers

When Exchange 2013 Client Access and Mailbox servers are installed, they're automatically enabled so they can answer incoming and outgoing voice calls and route voice mail messages to the intended recipients. When you're installing your Exchange 2013 Client Access and Mailbox servers and deploying Unified Messaging, you don't have to link or add Exchange 2013 Client Access or Mailbox servers to UM dial plans. Exchange 2013 Client Access and Mailbox servers answer all incoming calls and then use the UM dial plans to locate users.

The Exchange 2013 Client Access server is the entry point for any inbound calls or Session Initiation Protocol (SIP) requests for Unified Messaging. The service that handles the SIP requests on an Exchange 2013 Client Access server is the UM Call Router service and it runs on each Exchange 2013 Client Access server in your organization.

When you're upgrading to Exchange 2013 UM, you should have already installed and configured single or multiple VoIP gateways to connect to the PBXs in your telephony network, or installed and configured Session Initiation Protocol (SIP)-enabled PBXs or IP PBXs.

The last step in the process of upgrading to Exchange 2013 UM is to configure the VoIP gateways, IP PBXs, or SIP-enabled PBXs to send incoming calls—including callers who want to leave voice mail for a user, calls from UM-enabled users calling in to Outlook Voice Access, and calls from callers that dial in to a UM auto attendant—to your Exchange 2013 Client Access servers. All these calls are received first by a VoIP gateway, IP PBX, or SIP-enabled PBX and then forwarded on to the Exchange 2013 Client Access servers in your Exchange 2013 organization. For more information, see the following resources:

UM services

Configuration notes for supported VoIP gateways, IP PBXs, and PBXs

Telephony advisor for Exchange 2013

Step 15: Disable call answering on an Exchange 2010 Unified Messaging server

You can disable call answering by disabling UM on an Exchange 2010 Unified Messaging server or by removing the UM server from a dial plan. When you disable UM, you prevent the UM server from answering incoming calls. You can choose to disconnect all calls immediately or wait for existing calls to be processed before disabling the Unified Messaging server. You'll want to disable call answering before removing the server from a dial plan so that it will finish processing any incoming calls.

To disable Unified Messaging on an Exchange 2010 UM server by using the Exchange Management Console:

1. In the console tree of the EMC, navigate to **Server Configuration** > **Unified Messaging**.
2. In the result pane, select the Unified Messaging server to disable.
3. In the action pane, click one of the following:
   - When you select the **Disable Immediately** option, the Unified Messaging server disconnects all calls connected to the Unified Messaging server.
   - When you select the **Disable After Completing Calls** option, the Unified Messaging server won't accept new calls and won't be disabled until all calls have been processed.
4. In the confirmation dialog box, click **Yes** to continue.

To disable Unified Messaging on an Exchange 2010 UM server by using the Shell, run the following command.:

```
Disable-UMServer -Identity MyUMServer -Immediate $true
```

Tip:

You can use the **Disable-UMServer** cmdlet from an Exchange 2010 UM server or the **Disable-UMService** cmdlet from an Exchange 2013 Mailbox server to disable call answering.

Step 16: Remove an Exchange 2010 Unified Messaging server from a dial plan

To process calls, an Exchange 2010 UM server must be added to at least one UM dial plan. A UM server can be added to multiple UM dial plans. You can remove an Exchange 2010 UM server from a UM dial plan. When you remove a UM server from a dial plan, the UM server will no longer answer calls or process UM calls for UM-enabled users.

To remove an Exchange 2010 UM server from a dial plan by using the Exchange Management Console:

1. In the console tree of the EMC, navigate to **Server Configuration** > **Unified Messaging**.
2. In the result pane, select the Unified Messaging server.

3. In the action pane, click **Properties**.
4. On the **UM Settings** tab, in the **Associated Dial Plans** section, click **Remove**.
5. In the confirmation dialog box, click **Yes** to confirm the deletion of the Exchange 2010 server from the UM dial plan.
6. Click **OK** to close the properties window.

To remove an Exchange 2010 UM server from a dial plan using the Shell, run the following command.

```
$dp= Get-UMDialPlan "MySIPDialPlan"
$s=Get-UMServer -id MyUMServer
$s.dialplans-=$dp.identity
Set-UMServer -id MyUMServer -dialplans:$s.dialplans
```

In this example, there are three SIP URI dial plans: SipDP1, SipDP2 and SipDP3. This example removes the UM server named `MyUMServer` from the SipDP3 dial plan.

```
Set-UMServer -id MyUMServer -DialPlans SipDP1,SipDP2
```

In this example, there are two SIP URI dial plans: SipDP1 and SipDP2. This example removes the UM server named `MyUMServer` from the SipDP2 dial plan.

```
Set-UMServer -id MyUMServer -DialPlans SipDP1
```

Tip:

You can use the **Set-UMServer** cmdlet in the Shell on an Exchange 2010 Unified Messaging server or the **Set-UMService** cmdlet on an Exchange 2013 Mailbox server to remove an Exchange 2010 UM server from a single or multiple dial plans. For example, to remove a UM server from all dial plans, run the following command: `Set-UMServer -identity MyUMServer -DialPlans $null`

How do you know this worked?

After you've set up Unified Messaging, verify the following to ensure it's working correctly:

- A user you've enabled for voice mail can sign in to Outlook Web App or Outlook and see a Welcome Message for Unified Messaging.
- UM users can receive voice messages.
- UM users can call in to an Outlook Voice Access number to listen to email, calendar items, and voice mail.
- UM is routing calls from outside of your organization, and you can place a call.

Checklist: Upgrade Exchange 2010 UM

to Exchange 2013 UM

Topic Last Modified: *2014-04-04*

Use this checklist to help you upgrade Exchange 2010 Unified Messaging (UM) to Exchange 2013 UM. Be sure to refer to this information when you're upgrading your Exchange 2010 organization and your UM deployment to Exchange 2013. For step-by-step instructions for upgrading to Exchange 2013 UM, see Upgrade Exchange 2010 UM to Exchange 2013 UM.

Before you start working with this checklist, make sure you're familiar with the concepts in:

- Planning for Unified Messaging
- Telephone system integration with UM
- Connect your voice mail system to your telephone network

For step-by-step guidance about how to upgrade from Exchange 2007 UM to Exchange 2013 UM, see Upgrade Exchange 2007 UM to Exchange 2013 UM.

Checklist for upgrading Exchange 2010 UM to Exchange 2013 UM

Done?	Tasks	Topic
	Deploy and configure telephony components.	Connect UM to your telephone system
	Review the system requirements before installing Exchange 2013.	Exchange 2013 system requirements
	Verify that you meet the prerequisites for installation.	Exchange 2013 prerequisites
	Install the required Client Access and Mailbox servers. **⚠Warning:** You must deploy at least one Exchange 2013 Mailbox server in your organization before you configure the VoIP gateways or IP PBXs to send UM SIP and RTP	Install Exchange 2013 using the Setup wizard

	traffic to the Exchange 2013 Client Access servers.	
	Verify the installation and review the server setup logs.	Verify an Exchange 2013 installation
	If required, install the required UM language packs.	Install a UM language pack
	Move the Exchange 2010 system mailbox used for UM custom prompts to Exchange 2013.	Mailbox moves in Exchange 2013 **Note:** If the system mailbox has already been moved, you can still manually import/export custom prompts from Exchange 2010 using Import and export custom greetings, announcements, menus, and prompts.
	Export and import certificates.	Deploying certificates for UM
	Configure the UM startup mode on all Exchange 2013 Client Access servers.	Configure the startup mode on a Client Access server

Upgrade Exchange 2007 UM to Exchange 2013 UM

Exchange Server 2013 > Unified Messaging > Deploying voice mail and UM >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-04-19*

When you're upgrading a Microsoft Exchange 2007 organization with Unified Messaging (UM) to Exchange 2013 Unified Messaging, there are steps that are required and other steps that were already completed as part of your Exchange 2007 UM deployment. Depending on your telephony environment and the UM components that were created and configured to support Unified

Messaging in Exchange 2007, you may need to deploy additional telephony equipment including Voice over IP (VoIP) gateways, IP Private Branch eXchanges (PBXs), or traditional or SIP-enabled PBXs and then create and configure any additional UM components that will be required for Exchange 2013 UM.

What do you need to know before you begin?

- Estimated time to complete this task: 45-90 minutes.
- Verify that you have the appropriate permissions in the Exchange 2007 and Exchange 2013 organization to create and configure all the required components.
- Verify that you've deployed and correctly configured your telephony components, including VoIP gateways and PBXs, IP PBXs, or Session Initiation Protocol (SIP)-enabled PBXs.
- Verify that you've correctly installed and configured the Client Access servers running the Microsoft Exchange Unified Messaging Call Router (UM Call Router) service and Mailbox servers running the Microsoft Exchange Unified Messaging (UM) service. To learn more about UM services, see UM services.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

How do you do this?

Step 1: Download and install the required UM language packs

UM language packs enable callers and Outlook Voice Access users to interact with the voice mail system in multiple languages. After you install an additional language on an Exchange 2013 Mailbox server, callers and Outlook Voice Access users can hear email messages and interact with the voice mail system in that language. However, to make the language available for all incoming calls, you must install the required UM language packs on all Exchange 2013 Mailbox servers. This is because every Exchange 2013 Mailbox server can answer incoming calls for Unified Messaging.

By default, when you install an Exchange 2013 Mailbox server, the U.S. English (en-US) language pack is installed. It's the only available language option for your dial plan unless you install another UM language pack. (U. S. English can't be removed unless you remove the Mailbox server from the computer.) After you install a UM language pack on an Exchange 2013 Mailbox server, the language associated with the language pack will be listed as an available option when you configure the default language for the dial plan. By default, because a UM auto attendant is linked to a UM dial plan when the auto attendant is created, it uses the default language setting of the

linked UM dial plan. However, this setting can be changed after the UM auto attendant is created.

Note:
If U.S. English is the only language that you want to provide for your dial plan, you can skip this step and go to step 2.

You can add UM language packs by using the setup.exe command or by running the *<UMLanguagePack>*.exe installation program after you've downloaded the UM language pack from Exchange Server 2013 UM Language Packs. For more information, see Install a UM language pack.

This example uses setup.exe to install the Japanese (ja-JP) UM language pack.

```
setup.exe /AddUmLanguagePack:ja-JP /s:d:\Exchange
\UMLanguagePacks /IAcceptExchangeServerLicenseTerms
```

Step 2: Move the Exchange 2007 custom greetings, announcements, menus, and prompts to the Exchange 2013 system mailbox

Custom greetings, announcements, menus, and prompts are used by Unified Messaging dial plans and auto attendants. The system mailbox named {e0dc1c29-89c3-4034-b678-e6c29d823ed9} is created when you install Exchange 2007 or Exchange 2013 and is used to support features such as Message Approval and Multi-Mailbox Search. This system mailbox is also used to store dial plan and auto attendant custom greetings, announcements, menus, and prompts. If the system mailbox doesn't exist, you can use the **Setup /PrepareAD** command to create it.

By default, system mailboxes aren't visible in the Exchange admin center (EAC). You can get a list of the system mailboxes by running one the following:

This command returns a list of all the system mailboxes.

```
Get-Mailbox -Arbitration
```

This command returns a list of system mailboxes and their individual properties or settings.

```
Get-Mailbox -Arbitration |fl
```

When you're importing custom greetings, announcements, menus, and prompts from Exchange 2007 to Exchange 2013, you must use the MigrateUMCustomPrompts.ps1 script. You can't use the EAC to import custom greetings, announcements, menus, and prompts. The MigrateUMCustomPrompts.ps1 script migrates a copy of all Exchange Server 2007 UM custom greetings, announcements, menus, and prompts to Exchange 2013 UM. By default, the MigrateUMCustomPrompts.ps1 script is located in the *<Program Files>*\Microsoft\Exchange Server

\V15\Scripts folder on an Exchange 2013 Mailbox server and must be run from an Exchange 2013 Mailbox server. To run the script:

1. Click **Start** > **All Programs** > **Microsoft Exchange Server 2013** > **Exchange Management Shell**.
2. In the Exchange Management Shell, at the prompt, type the path to the script. For example, type **cd "D:\Program Files\Microsoft\Exchange Server\V15\Scripts"**, and then press Enter.
3. At the Shell prompt, type **".\MigrateUMCustomPrompts"**, and then press Enter.

Note:
Custom prompts can also be imported individually by using the **Import-UMPrompt** cmdlet. The Exchange 2007 UM **Copy-UMCustomPrompt** cmdlet isn't supported for copying custom prompts to Exchange 2013 UM.

When you run the MigrateUMCustomPrompts.ps1 script from your Exchange 2013 server, the script performs a GUID or object identifier lookup for the dial plan or auto attendant in Active Directory and queries it to determine if there are any custom greetings, announcements, menus, or prompts. If found, the custom greetings, announcements, menus, and prompts will be imported into the system mailbox named {e0dc1c29-89c3-4034-b678-e6c29d823ed9}.

By using this system mailbox, custom greetings, announcements, menus, and prompts can be backed up and restored along with other mailboxes in a database. This reduces the amount of resources that are needed. Storing custom greetings, announcements, menus, and prompts in a system mailbox removes any possible inconsistencies that may have occurred. To learn more about mailbox moves, see Mailbox moves in Exchange 2013.

Step 3: Export and import certificates

If you're using SIP secured or Secured dial plans in your Exchange 2007 organization, you'll need to export and import the certificates that were used to your Exchange 2013 Client Access and Mailbox servers. Mutual Transport Layer Security (mutual TLS) is used to encrypt data sent between your Exchange 2013 servers and the VoIP gateways, IP PBXs, and SIP-enabled PBXs. Certificates bind the identity of the certificate owner to a pair of electronic keys (public and private) that are used to encrypt and sign information digitally. You can use one of the following certificates for the UM and UM Call Router services:

- A self-signed (Exchange) certificate
- An internal public key infrastructure (PKI) certificate
- A third-party commercial certificate

By default, when you install Exchange 2013, two self-signed certificates are created: **Microsoft Exchange Server Auth Certificate** and **Microsoft Exchange**. The **Microsoft Exchange** self-signed certificate can be used for UM to encrypt data, but you must assign the certificate to the UM and UM Call Router services. This self-signed certificate can be copied and then imported on the VoIP gateways, IP PBXs, and SIP-enabled PBXs. However, it can't be used when you're integrating UM with Microsoft Lync Server.

To enable UM to encrypt data that's sent between your Exchange 2013 servers and VoIP gateways, IP PBXs, and SIP-enabled PBXs, you need to do the following:

- Use an existing self-signed UM certificate, create a new self-signed Exchange certificate, submit a certificate request to an internal certification authority for a PKI certificate, or purchase a third-party commercial certificate that you can use for mutual TLS between your Exchange 2013 Mailbox and Client Access servers and VoIP gateways, IP PBXs, and SIP-enabled PBXs.

Create an Exchange self-signed certificate by using the EAC, as follows:

1. In the EAC, navigate to **Servers** > **Certificates**, and then click **Add +**.
2. On the **New Exchange certificate** page, choose **Create a self-signed certificate**, and then select **Next**.
3. Enter a friendly name for the certificate, and then select **Next**.
4. Click **Add +** to select the Exchange servers that you want to apply this certificate to, and then select **Next**.
5. Specify the domains that you want to be included in your certificate, and then select **Next**. If you want to add a domain for a service, click **Edit** .
6. Verify that the domains you included are correct, and then select **Finish**.

Important:

When you use the EAC to create a certificate, you won't be prompted to enable the services for the certificate. After the certificate has been created, you can use the EAC to enable the services. For more information about how to enable a certificate for services, see Assign a certificate to the UM and UM Call Router services.

Create an Exchange self-signed certificate by running the following command in the Shell.

```
New-ExchangeCertificate -Services 'UM, UMCallRouter' -
DomainName '*.northwindtraders.com' -FriendlyName
'UMSelfSigned' -SubjectName
'C=US,S=WA,L=Redmond,O=Northwindtraders,OU=Servers,CN=
Northwindtraders.com' -PrivateKeyExportable $true
```

Tip:

If you specify the services you want to enable by using the *Services* parameter, you will be prompted to enable the services for the certificate you created. In this example, you will be prompted to enable the certificate for the Unified Messaging and Unified Messaging Call Router services. For more information about how to enable a certificate for services, see Assign a certificate to the UM and UM Call Router services.

- Import the certificate that will be used on all Exchange 2013 Client Access and Mailbox servers in your organization. If you use the Exchange 2013 self-signed certificate, you'll need to copy the certificate, then import it on the VoIP gateways, IP PBXs, or SIP-enabled PBXs. If you use the self-signed certificate from Exchange 2007, the Subject Alternative Name (SAN) must contain the machine names of all the Exchange 2013 servers. If you have Exchange 2007 Unified Messaging servers in your organization, you can use the Exchange 2013 self-signed certificate, but you must add the machine names of the Exchange 2007 UM servers to the SAN in the Exchange 2013

certificate.

- Enable or assign the certificate to be used to the UM and UM Call Router services on the Client Access and Mailbox servers in your organization.

Enable the UM service and the UM Call Router service on all Exchange 2013 servers to use the Exchange self-signed certificate by using the EAC, as follows:

1. In the EAC, navigate to **Servers** > **Certificates**, select the certificate you want to enable services on, and then click **Edit** ✎.
2. On the **Procedure** page, select **Services**, select **Unified Messaging**, and then select **Unified Messaging call router**.

Enable an Exchange self-signed certificate by running the following command in the Shell.

```
Enable-ExchangeCertificate -Thumbprint
5113ae0233a72fccb75b1d0198628675333d010e -Services 'UM,
UMCallRouter'
```

- Configure any new or existing UM dial plans as SIP secured or Secured.
- Configure the UM startup mode to TLS or Dual on the Client Access and Mailbox servers in your organization.
- Create and configure new or existing UM IP gateways with a fully qualified domain name (FQDN).
- Configure the listening port on the UM IP gateways to use TLS port 5061.
- Restart the UM Call Router service on all Exchange 2013 Client Access servers and restart the UM service on all Exchange 2013 Mailbox servers. To learn more about UM services, see UM services.

Step 4: Configure the UM startup mode on all Exchange 2013 Client Access servers

If you're using SIP secured or Secured dial plans, you must configure the UM startup mode on your Exchange 2013 Client Access servers. You can specify the UM startup mode for the UM Call Router service on an Exchange 2013 Client Access server by using the EAC or the Shell. By default, the Exchange 2013 Client Access server will start up in TCP mode, but if you're using Transport Layer Security (TLS) to encrypt Voice over IP (VoIP) traffic, you must configure the Exchange 2013 Client Access server to use TLS or Dual mode. We recommend that all Exchange 2013 Client Access servers be configured to use Dual as the UM startup mode. This is because all Exchange 2013 Client Access servers can answer incoming calls for all UM dial plans, and those dial plans can have different security settings. If you change the UM startup mode, you must restart the UM Call Router service for the change to take effect. To learn more about UM services, see UM services.

Configure the UM startup mode on an Exchange 2013 Client Access server by using the EAC, as follows:

1. In the EAC, navigate to **Servers** > **Servers**.
2. In the list view, select the Exchange server that you want to modify, and then click **Edit** ✎.
3. On the **Exchange Server** page, click **Unified Messaging**.

4. Under **UM Call Router settings** > **UM startup mode**, select one of the following from the drop-down list:
   - **TCP** Use this option if you aren't using mTLS and are using only Unsecured dial plans.
   - **TLS** Use this option if you're using mTLS and are using only SIP secured or Secured dial plans.
   - **DUAL** Use this option if you're using mTLS and are using Unsecured, SIP secured, and Secured dial plans.
5. After you select the UM startup mode, click **Save**.

Configure the UM startup mode on an Exchange 2013 Client Access server by running the following command in the Shell.

```
Set-UMCallRouterSettings -Server
MyUMCallRouter.northwindtraders.com -UMStartupMode Dual
```

Step 5: Configure the UM startup mode on all Exchange 2013 Mailbox servers

If you're using SIP secured or Secured dial plans, you must configure the UM startup mode on your Exchange 2013 Mailbox servers. You can specify the UM startup mode for the UM service on an Exchange 2013 Mailbox server by using the EAC or the Shell. By default, an Exchange 2013 Mailbox server will start up in TCP mode, but if you're using Transport Layer Security (TLS) to encrypt Voice over IP (VoIP) traffic, you must configure the Exchange 2013 Mailbox server to use TLS or Dual mode. We recommend that all Exchange 2013 Mailbox servers be configured to use Dual as the UM startup mode. This is because all Exchange 2013 Mailbox servers can answer incoming calls for all UM dial plans, and those dial plans can have different security settings. If you change the UM startup mode, you must restart the UM service for the change to take effect. To learn more about UM services, see UM services.

Configure the UM startup mode on an Exchange 2013 Mailbox server by using the EAC, as follows:

1. In the EAC, navigate to **Servers** > **Servers**.
2. In the list view, select the Exchange server that you want to modify, and then click **Edit** ✎.
3. On the **Exchange Server** page, click **Unified Messaging**.
4. Under **UM Service settings** > **UM startup mode**, select one of the following from the drop-down list:
   - **TCP** Use this option if you aren't using mTLS and are using only Unsecured dial plans.
   - **TLS** Use this option if you're using mTLS and are using only SIP secured or Secured dial plans.
   - **DUAL** Use this option if you're using mTLS and are using Unsecured, SIP secured, and Secured dial plans.
5. After you select the UM startup mode, click **Save**.

Configure the UM startup mode on an Exchange 2013 Mailbox server by running the following command in the Shell.

```
Set-UMService -Identity MyUMServer -ExternalHostFqdn
host.external.contoso.com -IPAddressFamily Any -
UMStartupMode Dual
```

Step 6: Create or configure existing UM dial plans

Depending on your existing Exchange 2007 deployment, you may be required to create new UM dial plans or configure your existing dial plans. A UM dial plan represents a set of traditional or SIP-enabled Private Branch eXchanges (PBXs), IP PBXs, or SIP-enabled PBXs that share common user extension numbers. All users' extensions hosted on traditional or SIP-enabled PBXs or IP PBXs within a dial plan contain the same number of digits. Users can dial one another's telephone extensions without appending a special number to the extension or dialing a full telephone number.

UM dial plans are used in Unified Messaging to make sure that user telephone extensions are unique. In some telephony networks, multiple IP PBXs, traditional PBXs, or SIP-enabled PBXs exist. In these telephony networks, there could be two users who have the same telephone extension number. UM dial plans resolve this situation. Putting the two users into two separate UM dial plans makes their extensions unique. For more information, see UM dial plans.

If required, you can create a UM dial plan by using the EAC:

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**, and then click **New +**.
2. On the **New UM Dial Plan** page, complete the following:
   - **Name** Type the name of the dial plan. A UM dial plan name is required and must be unique. However, the name you type is used only for display purposes in the EAC and the Shell. The maximum length of a UM dial plan name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.

Although the box for the name of the dial plan can accept 64 characters, the name of the dial plan can't be longer than 49 characters. If you try to create a dial plan name that contains more than 49 characters, you'll receive an error message. The message will say that the UM mailbox policy couldn't be generated because the UM dial plan name is too long. This happens because, when you create a dial plan a default UM mailbox policy named <*DialPlanName*> **Default Policy** is also created. When the 15 characters in the default policy are added to the name of the dial plan, the total characters exceed the limit. The *name* parameter for both the UM dial plan and UM mailbox policy can be 64 characters. However, if the name of the dial plan is longer than 49 characters, the name of the default UM mailbox policy will be longer than 64 characters, and this isn't allowed by the system.

   - **Extension length (digits)** Enter the number of digits for extension numbers in the dial plan. The number of digits for extension numbers is based on the telephony dial plan created on a PBX. For example, if a user associated with a telephony dial plan dials a four-digit extension to call another user in the same telephony dial plan, you select 4 as the number of digits in the extension.

This is a required box that has a value range from 1 through 20. The typical extension length is from 3 through 7 numbers. If your existing telephony environment includes extension numbers, you must

specify a number of digits that matches the number of digits in those extensions.

When you create a Telephone extension dial plan, you're required to enter an extension number for the user if they're linked to a Telephone extension dial plan. An extension number is also required with Session Initiation Protocol (SIP) dial plans or E.164 dial plans when a UM-enabled user is linked to a SIP URI or E.164 dial plan. The extension number is used by Outlook Voice Access users when they access their Exchange mailbox.

- **Dial plan type** A Uniform Resource Identifier (URI) is a string of characters that identifies or names a resource. The main purpose of this identification is to enable VoIP devices to communicate with other devices over a network using specific protocols. URIs are defined in schemes that define a specific syntax and format and the protocols for the call. In simple terms, this format is passed from the IP PBX or PBX. After you create a UM dial plan, you won't be able to change the URI type without deleting the dial plan, and then re-creating the dial plan to include the correct URI type. You can select one of the following URI types for the dial plan:
  - **Telephone extension** This is the most common URI type. The calling and called party information from the VoIP gateway or IP Private Branch eXchange (PBX) is listed in one of the following formats: Tel:512345 or 512345@<*IP address*>. This is the default URI type for dial plans.
  - **SIP URI** Use this URI type if you must have a Session Initiation Protocol (SIP) URI dial plan such as an IP PBX that supports SIP routing or if you're integrating Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server and Unified Messaging. The calling and called party information from the VoIP gateway. IP PBX, or Communications Server 2007 R2 or Lync Server is listed as a SIP address in the following format: sip:<*username*>@<*domain* or *IP address*>:Port.
  - **E.164** E.164 is an international numbering plan for public telephone systems in which each assigned number contains a country code, a national destination code, and a subscriber number. The calling and called party information sent from the VoIP gateway or IP PBX is listed in the following format: Tel:+14255550123.

⚠Warning:

After you create a dial plan, you will be unable to change the URI type without deleting the dial plan, and then re-creating the dial plan to include the correct URI type.

- **VoIP security mode** Use this drop-down list to select the VoIP security setting for the UM dial plan. You can select one of the following security settings for the dial plan:
  - **Unsecured** By default, when you create a UM dial plan, it is set to not encrypt the SIP signaling or RTP traffic. In unsecured mode, the Client Access and Mailbox servers associated the UM dial plan send and receive data from VoIP gateways, IP PBXs, SBCs and other Client Access and Mailbox servers using no encryption. In unsecured mode, neither the Realtime Transport Protocol (RTP) media channel nor the SIP signaling information is encrypted.
  - **SIP secured** When you select **SIP secured**, only the SIP signaling traffic is encrypted, and the RTP media channels still use TCP, which isn't encrypted. With SIP secured, Mutual Transport Layer Security (TLS) is used to encrypt the SIP signaling traffic and VoIP data.

        - **Secured** When you select **Secured**, both the SIP signaling traffic and the RTP media channels are encrypted. Both the secure signaling media channel that uses Secure Realtime Transport Protocol (SRTP) and the SIP signaling traffic use mutual TLS to encrypt the VoIP data.
    - **Country/Region code** Use this box to type the country/region code number to be used for outgoing calls. This number will automatically be prepended to the telephone number that's dialed. This box accepts from 1 through 4 digits. For example, in the United States, the country/region code is 1. In the United Kingdom, it's 44.
3. Click **Save**.

If required, you can create a UM dial plan by running the following command in the Shell.

```
New-UMDialplan -Name MyUMDialPlan -URIType E164 -
NumberOfDigitsInExtension 5 -VoIPSecurity Secured
```

If required, you can configure an existing UM dial plan by using the EAC:

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**.
2. In the list view, select the UM dial plan you want to view or modify, and then click **Edit** ✎.
3. On the **UM Dial Plan** page, click **Configure**. Use the configuration options to view specific dial plan settings and to enable or disable features.

If required, you can configure an existing UM dial plan by running the following command in the Shell.

```
Set-UMDialplan -Identity MyDialPlan -AccessTelephoneNumbers
4255551234 -AudioCodec Wma -CallAnsweringRulesEnabled
$false -OutsideLineAccessCode 9 -VoIPSecurity SIPSecured
```

When you deployed Exchange 2007 Unified Messaging, you were required to add a Unified Messaging server to a UM dial plan for it to answer incoming calls. This is no longer required. In Exchange 2013, Client Access and Mailbox servers can’t be linked with a Telephone extension or E.164 dial plan, but must be linked to SIP URI dial plans. Client Access and Mailbox servers will answer all incoming calls for all types of dial plans.

Step 7: Create or configure existing UM IP gateways

Depending on your existing Exchange 2007 deployment, you may be required to create new UM IP gateways or configure your existing ones. If you’re using SIP secured or Secured dial plans, you must create a UM IP gateway with an FQDN and use the Shell to configure it to listen on port 5061. For existing UM IP gateways, verify that they’re configured with an FQDN and are listening on port 5061. If the UM IP gateway doesn’t use an FQDN, use the EAC or the Shell to change the address. If the UM IP gateway doesn’t use port 5061, use the Shell to change the port. You can view the settings of a UM IP gateway by using the **Get-UMIPGateway** cmdlet.

A UM IP gateway represents a physical Voice over IP (VoIP) gateway, IP PBX, or SIP-enabled PBX.

Before a VoIP gateway, IP PBX, or SIP-enabled PBX can be used to answer incoming calls and send outgoing calls for voice mail users, a UM IP gateway must be created in the directory service.

The combination of the UM IP gateway and a UM hunt group establishes a link between a VoIP gateway, IP PBX, or SIP-enabled PBX and a UM dial plan. By creating multiple UM hunt groups, you can associate a single UM IP gateway with multiple UM dial plans. For more information, see UM IP gateways.

If required, you can create a UM IP gateway by using the EAC, as follows:

1. In the EAC, navigate to **Unified Messaging** > **UM IP gateways**, and then click **Add +**.
2. On the **New UM IP Gateway** page, enter the following information:
   - **Name** Use this box to specify a unique name for the UM IP gateway. This is a display name that appears in the EAC. If you have to change the display name of the UM IP gateway after it's been created, you must first delete the existing UM IP gateway, and then create another UM IP gateway that has the appropriate name. The UM IP gateway name is required, but it's used for display purposes only. Because your organization may use multiple UM IP gateways, we recommend that you use meaningful names for your UM IP gateways. The maximum length of a UM IP gateway name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.
   - **Address** You can configure a UM IP gateway with either an IPv4 or IPv6 address or an FQDN. Use this box to specify the IP address or FQDN configured on the VoIP gateway, IP PBX, or SIP-enabled PBX. This box accepts only FQDNs that are valid and formatted correctly.

You can enter alphabetical and numeric characters. IPv4 addresses, IPv6 addresses, and FQDNs are supported. If you want to use mutual TLS between a UM IP gateway and a dial plan operating in either SIP secured or Secured mode, you must configure the UM IP gateway with an FQDN. You must also configure it to listen on port 5061 and verify that any VoIP gateways or IP PBXs have also been configured to listen for mutual TLS requests on port 5061. To configure a UM IP gateway, run the following command in the Shell: `Set-UMIPGateway -identity MyUMIPGateway -Port 5061`

If you use an FQDN, you must also make sure that you've correctly configured a DNS host record for the VoIP gateway, IP PBX, or SIP-enabled PBX so that the host name will be correctly resolved to an IP address. Also, if you use an FQDN instead of an IP address, and the DNS configuration for the UM IP gateway is changed, you must disable and then enable the UM IP gateway to make sure that configuration information for the UM IP gateway is updated correctly.

   - **UM Dial Plan** Click **Browse** to select the UM dial plan that you want to associate with the UM IP gateway. When you select a UM dial plan to associate with a UM IP gateway, a default UM hunt group is also created and associated with the UM dial plan that you selected. If you don't select a UM dial plan, you must manually create a UM hunt group and then associate that UM hunt group with a UM IP gateway that you have created.
3. Click **Save**.

If required, you can create a UM IP gateway by running the following command in the Shell.

```
New-UMIPGateway -Identity MyUMIPGateway -Address
```

```
"MyUMIPGateway.contoso.com"
```

If required, you can configure an existing UM IP gateway by using the EAC:

1. In the EAC, navigate to **Unified Messaging** > **UM IP gateways**, and then click **Edit** ✎.
2. On the **UM IP gateway** page, click **Configure**. Use the configure options to view specific UM IP gateway settings and to enable or disable features.

If required, you can configure an existing UM IP gateway by running the following command in the Shell.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address
fe80::39bd:88f7:6969:d223%11 -IPAddressFamily Any -Status
Disabled -OutcallsAllowed $false
```

Step 8: Create a UM hunt group

Depending on your existing Exchange 2007 deployment, you may be required to create new UM hunt groups. A telephony hunt group provides a way to distribute telephone calls from a single number to multiple extensions or telephone numbers. In Unified Messaging, a UM hunt group is a logical representation of a telephony hunt group, and it links a UM IP gateway to a UM dial plan.

You need to have at least one UM hunt group for every IP PBX or PBX hunt group. When you complete the following procedure, one UM hunt group is created by default. If you have more than one IP PBX or PBX hunt group, you need to create additional UM hunt groups. To learn more about UM hunt groups, see UM hunt groups.

If required, you can create a UM hunt group by using the EAC:

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**. In the list view, select the UM dial plan that you want to modify, and then click **Edit** ✎.
2. On the **UM Dial Plan** page, under **UM Hunt Groups**, click **New +**.
3. On the **New UM Hunt Group** page, enter the following information:
   - **Name** Use this box to create the display name for the UM hunt group. A UM hunt group name is required and must be unique, but it's used only for display purposes in the EAC and the Shell. If you have to change the display name of the hunt group after it's been created, you must first delete the existing hunt group and then create another hunt group that has the appropriate name. If your organization uses multiple hunt groups, we recommend that you use meaningful names for your hunt groups. The maximum length of a UM hunt group name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.
   - **UM IP Gateway** Use this box to select a UM IP gateway. This box shows the name of the UM IP gateway that will be linked with the UM hunt group. To link a UM IP gateway to the UM hunt group, click **Browse**.
   - **Pilot Identifier** Use this box to specify a string that uniquely identifies the pilot identifier configured on the PBX or IP PBX. An extension number or a SIP Uniform Resource Identifier

(URI) can be used in this box. Alphanumeric characters are accepted in this box. For legacy PBXs, a numeric value is used as a pilot identifier. However, some IP PBXs and SIP-enabled PBXs can use SIP URIs.

4. Click **Save**.

If required, you can create a UM hunt group by running the following command in the Shell.

```
New-UMHuntGroup -Name MyUMHuntGroup -PilotIdentifier
5551234,55555 -UMDialPlan MyUMDialPlan -UMIPGateway
MyUMIPGateway
```

Tip:

You can't configure or change settings for a UM hunt group. If you want to change the configuration settings for a UM hunt group, you must delete it and add a new UM hunt group with the correct settings.

Step 9: Create or configure UM auto attendants

Depending on your existing Exchange 2007 deployment, you may be required to create new UM auto attendants. You can use UM auto attendants to create a voice menu system that lets external and internal callers use the UM auto attendant menu system to locate people and place or transfer calls to company users or departments in an organization. For more information, see Automatically answer and route incoming calls.

In smaller deployments, you may only want to deploy UM so that callers can leave voice mail for users. In these deployments, creating an auto attendant isn't required. However, in most cases, using auto attendants is very useful for external callers when they call in to your organization.

If required, you can create a UM auto attendant by using the EAC, as follows:

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**. Select the UM dial plan for which you want to add an auto attendant, and then click **Edit** ✎.
2. On the **UM dial plan** page, under **UM Auto Attendants**, click **Add +**.
3. On the **New UM Auto Attendant** page, complete the following boxes:
   - **Name** Use this box to create the display name for the UM auto attendant. A UM auto attendant name is required and must be unique. However, it's used only for display purposes in the EAC and the Shell. If you have to change the display name of the auto attendant after it's created, you must first delete the existing UM auto attendant and then create another auto attendant that has the appropriate name. If your organization uses multiple UM auto attendants, we recommend that you use meaningful names for your UM auto attendants. The maximum length of a UM auto attendant name is 64 characters, and it can include spaces.

Although you can name a new UM auto attendant to include spaces, if you integrate Unified Messaging with Lync Server, the name of the auto attendant can't include spaces. Therefore, if you created an auto attendant that has spaces in the display name and you're integrating with Lync Server, you must first delete that auto attendant and then create another auto attendant that doesn't include spaces in the display name.

- **Create this auto attendant as enabled** Select this check box to enable the auto attendant to answer incoming calls when you finish creating the UM auto attendant. By default, a new auto attendant is created as disabled. If you decide to create the UM auto attendant as disabled, you can use the EAC or the Shell to enable the auto attendant after you finish creating it.
- **Set the auto attendant to respond to voice commands** Select this check box to speech-enable the UM auto attendant. If the auto attendant is speech-enabled, callers can respond to the system or custom prompts used by the UM auto attendant using touchtone or voice inputs. By default, the auto attendant isn't speech-enabled when it's created. For callers to use a speech-enabled auto attendant in a language other than U.S. English (en-US), you must install the appropriate UM language pack and configure the properties of the auto attendant to use this language. The en-US UM language pack is installed by default when you install an Exchange 2013 Mailbox server.
- **Access numbers** Enter the extension or telephone numbers that callers will use to reach the auto attendant. Type an extension number or telephone number in the box, and then click **Add** to add the number to the list. The number of digits in the extension number or telephone number that you provide doesn't have to match the number of digits for an extension number configured on the associated UM dial plan. This is because direct calls are allowed to UM auto attendants.

The number of extension or access numbers you can enter is unlimited. However, you may create a new auto attendant without listing an extension number or telephone number. An extension number or telephone number isn't required. You can edit or remove an existing extension number or pilot identifier. To edit an existing extension number or telephone number, click **Edit**. To remove an existing extension number or telephone number from the list, click **Remove**.

4. Click **Save**.

If required, you can create a UM auto attendant by running the following command in the Shell.

```
New-UMAutoAttendant -Name MyUMAutoAttendant -UMDialPlan
MyUMDialPlan -PilotIdentifierList 56000,56100 -
SpeechEnabled $true -Status Enabled
```

If required, you can configure an existing auto attendant by using the EAC:

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**, and then click **Edit** ✎.
2. On the **UM dial plan** page, under **UM Auto Attendants**, select the UM auto attendant that you want to view or configure, and then click **Edit** ✎. Use the configuration options to view specific auto attendant settings and to enable or disable features.

If required, you can configure an existing auto attendant by running the following command in the Shell.

```
Set-UMAutoAttendant -Identity MySpeechEnabledAA -
DTMFFallbackAutoAttendant MyDTMFAA -OperatorExtension 50100
-AfterHoursTransferToOperatorEnabled $true -
```

```
StaroutToDialPlanEnabled $true
```

Step 10: Create or configure UM mailbox policies

Depending on your existing Exchange 2007 deployment, you may be required to create new UM mailbox policies or configure existing UM mailbox policies. UM mailbox policies are required when you enable users for Unified Messaging. The mailbox of each UM-enabled user must be linked to a single UM mailbox policy. After you create a UM mailbox policy, you link one or more UM-enabled mailboxes to the UM mailbox policy. This lets you control PIN security settings such as the minimum number of digits in a PIN or the maximum number of logon attempts for the UM-enabled users who are linked to the UM mailbox policy. For more information, see UM mailbox policies.

If required, you can create a UM mailbox policy by using the EAC:

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**. In the list view, select the UM dial plan that you want to modify, and then click **Edit** .
2. On the **UM dial plan** page, under **UM Mailbox Policies**, click **Add** .
3. On the **New UM Mailbox Policy** page, in the **Name** box, enter the name of the new UM mailbox policy.

Note:

Use this box to specify a unique name for the UM mailbox policy. This is a display name that appears in the EAC. If you must change the display name of the UM mailbox policy after it's been created, you must first delete the existing UM mailbox policy, and then create another UM mailbox policy that has the appropriate name. You can't delete a UM mailbox policy if any UM-enabled users are associated with it.The UM mailbox policy name is required, but it's used for display purposes only. Because your organization may use multiple UM mailbox policies, we recommend that you use meaningful names for your UM mailbox policies. The maximum length of a UM mailbox policy name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.

4. Click **Save**.

Note:

When you save the UM mailbox policy, all the default settings, including PIN policies, voice mail features, and Protected Voice Mail settings, are enabled. If you want to customize or change any default settings for the UM mailbox policy you just created, use the **Set-UMMailbox** cmdlet or the EAC.

If required, you can create a UM mailbox policy in the Shell by running the following command.

```
New-UMMailboxPolicy -Name MyUMMailboxPolicy -UMDialPlan
MyUMDialPlan
```

If required, you can configure an existing UM mailbox policy by using the EAC:

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**, and then click **Edit** .
2. On the **UM dial plan** page, under **UM Mailbox Policies**, select the UM mailbox policy you want to view or configure, and then click **Edit** . Use the configuration options to view specific UM

mailbox policy settings and to enable or disable features.

If required, you can configure an existing UM mailbox policy by running the following command in the Shell.

```
Set-UMMailboxPolicy -Identity MyUMMailboxPolicy -
LogonFailuresBeforePINReset 8 -MaxLogonAttempts 12 -
MinPINLength 8 -PINHistoryCount 10 -PINLifetime 60 -
ResetPINText "The PIN used to allow you access to your
mailbox using Outlook Voice Access has been reset."
```

Step 11: Move existing UM-enabled mailboxes to Exchange 2013

In Exchange 2007 Unified Messaging, after you've enabled users within the organization to use voice mail, a default set of UM properties is applied to the user so they can use UM features. For more information, see Voice mail for users.

During the process of upgrading, there will be a period of time during which you'll have mailboxes that are UM enabled both on Exchange 2007 Mailbox servers and on Exchange 2013 Mailbox servers. However, if you're moving all UM-enabled users over to Exchange 2013 Mailbox servers, you must use the EAC or the **New-MoveRequest** cmdlet in the Shell from an Exchange 2013 server to retain all of the properties and settings, including the user's PIN.

A move request is the process of moving a mailbox from one mailbox database to another. A local move request is a mailbox move that occurs within a single forest. For more information about mailbox moves, see:

- Mailbox moves in Exchange 2013
- New-MoveRequest
- New-MigrationBatch
- Moving Mailboxes

To move an Exchange 2007 mailbox to an Exchange 2013 Mailbox server by using the EAC:

1. In the EAC, click **Recipients** > **Migration**, and then click **Add** .
2. In the **New local mailbox move** wizard, select the user you want to move, click **OK**, and then click **Next**.
3. On the **Move configuration** page, specify a name for the new batch. Select which options you want for the archive mailbox and the mailbox database location, and then click **New**.

To move an Exchange 2007 mailbox to an Exchange 2013 Mailbox server by using the Shell, run the following command.

```
New-MoveRequest -Identity 'tony@alpineskihouse.com' -
TargetDatabase "DB01"
```

Step 12: Enable new users for UM or configure settings for an existing UM-enabled user

A user must have a mailbox before they can be enabled for Unified Messaging. But, by default, a user who has a mailbox isn't enabled for UM. After the user is UM-enabled, you can manage, modify, and configure the UM properties and voice mail features for them. You can enable a user for UM by using the EAC or the Shell. Learn more at Voice mail for users.

When you enable a user for UM, you must define at least one extension number that UM will use when voice mail is submitted to the user's mailbox and to allow the user to use Outlook Voice Access. After you enable the user for UM, you can add secondary extension numbers to the user's mailbox, modify or remove them by configuring the Exchange Unified Messaging (EUM) proxy address on the user's mailbox, or add or remove additional or secondary extensions for the user in the EAC. To add, modify, or remove extension numbers, E.164 numbers, or SIP addresses, see Voice mail-enabled user procedures.

To enable a user for Unified Messaging by using the EAC:

1. In the EAC, click **Recipients**.
2. In the list view, select the user whose mailbox you want to enable for Unified Messaging.
3. In the Details pane, under **Phone and Voice Features**, click **Enable**.
4. On the **Enable UM mailbox** page, click the **Browse** button next to **UM mailbox policy**, locate the UM mailbox policy to assign the user from the list, and then click **OK**.
5. On the **Enable UM mailbox** page, complete the following boxes:
   - **SIP address or E.164 number** Enter the SIP address or E.164 number for the user. These options are available if the user that you enable for Unified Messaging is assigned to a UM mailbox policy that's linked to either a SIP URI or an E.164 dial plan. Adding a SIP address or E.164 number for a user isn't available if the user is associated with a telephone extension dial plan. When you assign the user to a UM mailbox policy that's linked to a SIP URI or E.164 dial plan, you must also enter an extension number for the user. This extension number is used when users access their mailbox using Outlook Voice Access. The number of digits that you configure in this box must match the number of digits configured on the SIP URI or E.164 dial plan.
   - **Extension number** Enter the extension number for the user you're enabling for UM.

You must provide a valid extension number for the user, and it must match the number of digits specified on the dial plan. You can only enter numeric characters or digits from 1 through 20. The typical extension number is 3 to 7 digits long. The number of digits in the extension is set on the dial plan that's linked to the UM mailbox policy that's assigned to the user.

   - Under **PIN settings**, complete the following:
     - **Automatically generate PIN** Click this button to automatically generate a PIN for the UM-enabled user to use for voice mail access via Outlook Voice Access. This is the default setting. When you click this button, a PIN is automatically generated based on the PIN policies configured on the UM mailbox policy assigned to the user. We recommend that you

use this setting to help protect the user's PIN. The PIN is sent to the user in the welcome message they receive after they're enabled for UM. By default, they'll have to change this PIN when they first sign in to their mailbox to get their voice mail.

- **Type a PIN** Click this button to manually specify a PIN that the user will use to access the voice mail system.The PIN must comply with the PIN policy settings configured on the UM mailbox policy associated with this UM-enabled user. For example, if the UM mailbox policy is configured to accept only PINs that contain seven or more digits, the PIN you enter in this box must be at least seven digits long.
- **Require the user to reset their PIN the first time they sign in** Select this check box to force the user to reset their voice mail PIN when they access the voice mail system from a telephone using Outlook Voice Access for the first time. They will be prompted to enter a PIN that's more familiar to them.It's a security best practice to force UM-enabled users to change their PIN when they first sign in to help protect against unauthorized access to their data and Inbox. This check box is selected by default.

6. On the **Enable UM mailbox** page, review your settings. Click **Finish** to enable the user for Unified Messaging. Click **Back** to make configuration changes.

Enable a user for Unified Messaging in the Shell, run the following command.

```
Enable-UMMailbox -Identity tonysmith@contoso.com -
UMMailboxPolicy MyUMMailboxPolicy -Extensions 51234 -PIN
5643892 -NotifyEmail administrator@contoso.com -PINExpired
$true
```

If required, you can configure a user that's been enabled for UM by using the EAC:

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list view, select the mailbox for which you want to change the UM mailbox policy.
3. In the details pane, under **Phone and Voice Features** > **Unified Messaging**, click **View details**.
4. On the **UM Mailbox** page, click **UM mailbox settings** to view or change the following UM properties for an existing UM-enabled user:
   - **PIN Status** This display-only box shows the status of the user's mailbox. By default, when a user is UM-enabled, the PIN status is listed as **Not locked out**. However, if the user has input an incorrect Outlook Voice Access PIN multiple times, the status is listed as **Locked Out**.
   - **UM mailbox policy** This box shows the name of the UM mailbox policy associated with the UM-enabled user. You can click **Browse** to locate and specify the UM mailbox policy to be associated with this UM mailbox.
   - **Personal operator extension** Use this box to specify the operator extension number for the user. By default, an extension number isn't configured. The length of the extension number can be from 1 through 20 characters. This enables incoming calls for the UM-enabled user to be forwarded to the extension number that you specify in this box.

You can configure other types of operator extension numbers on dial plans and auto attendants. However, those extensions are generally meant for company-wide receptionists or operators. The personal operator extension setting could be used when an administrative assistant or personal

assistant answers incoming calls for a specific user.

5. On the **UM Mailbox** page, under **Other extensions**, you can add, change, and view extension numbers for the user.
   - To add an extension number, click **Add +**. On the **Add another extension** page, use **Browse** to select the UM dial plan, and then enter the extension number in the **Extension number** box.
   - To remove an extension number, select the extension number you want to remove, and then click **Remove —**.
6. If you make any changes, click **Save**.

If required, you can configure a user that's been enabled for UM in the Shell by running the following command.

```
Set-UMMailbox -Identity tony@contoso.com -
CallAnsweringAudioCodec Wma -CallAnsweringRulesEnabled
$false -FaxEnabled $false -UMSMSNotificationOption
VoiceMail
```

Step 13: Configure your VoIP gateways, IP PBXs, and SIP-enabled PBXs to send all incoming calls to the Exchange 2013 Client Access servers

When Exchange 2013 Client Access and Mailbox servers are installed, they're automatically enabled so they can answer incoming and outgoing voice calls and route voice mail messages to the intended recipients. When you're installing your Exchange 2013 Client Access and Mailbox servers and deploying Unified Messaging, you don't have to link or add Exchange 2013 Client Access or Mailbox servers to UM dial plans. Exchange 2013 Client Access and Mailbox servers answer all incoming calls and then use the UM dial plans to locate users.

The Exchange 2013 Client Access server is the entry point for any inbound calls or Session Initiation Protocol (SIP) requests for Unified Messaging. The service that handles the SIP requests on an Exchange 2013 Client Access server is the UM Call Router service and it runs on each Exchange 2013 Client Access server in your organization.

When you're upgrading to Exchange 2013 UM, you should have already installed and configured single or multiple VoIP gateways to connect to the PBXs in your telephony network, or installed and configured Session Initiation Protocol (SIP)-enabled PBXs or IP PBXs.

The last step in the process of upgrading to Exchange 2013 UM is to configure the VoIP gateways, IP PBXs, or SIP-enabled PBXs to send incoming calls—including callers who want to leave voice mail for a user, calls from UM-enabled users calling in to Outlook Voice Access, and calls from callers that dial in to a UM auto attendant—to your Exchange 2013 Client Access servers. All these calls are received first by a VoIP gateway, IP PBX, or SIP-enabled PBX and then forwarded on to the

Exchange 2013 Client Access servers in your Exchange 2013 organization. For more information, see the following resources:

UM services

Configuration notes for supported VoIP gateways, IP PBXs, and PBXs

Telephony advisor for Exchange 2013

Step 14: Disable call answering on an Exchange 2007 Unified Messaging server

You can disable call answering by disabling UM on an Exchange 2007 Unified Messaging server or by removing the UM server from a dial plan. When you disable UM, you prevent the Unified Messaging server from answering incoming calls. You can choose to disconnect all calls immediately or wait for existing calls to be processed before disabling the Unified Messaging server. You'll want to disable call answering before removing the server from a dial plan so that it will finish processing any incoming calls.

To disable Unified Messaging on an Exchange 2007 UM server by using the Exchange Management Console:

1. In the console tree of the EMC, navigate to **Server Configuration** > **Unified Messaging**.
2. In the result pane, select the Unified Messaging server to disable.
3. In the action pane, click one of the following:
   a. When you select the **Disable Immediately** option, the Unified Messaging server disconnects all calls connected to the Unified Messaging server.
   b. When you select the **Disable After Completing Calls** option, the Unified Messaging server won't accept new calls and won't be disabled until all calls have been processed.
4. In the confirmation dialog box, click **Yes** to continue.

To disable Unified Messaging on an Exchange 2007 UM server by using the Shell, run the following command.

```
Disable-UMServer -Identity MyUMServer -Immediate $true
```

Tip:
You can use the **Disable-UMServer** cmdlet from an Exchange 2007 UM server or the **Disable-UMService** cmdlet from an Exchange 2013 Mailbox server to disable call answering.

Step 15: Remove an Exchange 2007 Unified Messaging server from a dial plan

To process calls, an Exchange 2007 UM server must be added to at least one UM dial plan. A UM server can be added to multiple UM dial plans. You can remove an Exchange 2007 UM server from a UM dial plan. When you remove a UM server from a dial plan, the UM server will no longer answer calls or process UM calls for UM-enabled users.

To remove an Exchange 2007 UM server from a dial plan by using the Exchange Management Console:

1. In the console tree of the EMC, navigate to **Server Configuration** > **Unified Messaging**.
2. In the result pane, select the Unified Messaging server.
3. In the action pane, click **Properties**.
4. On the **UM Settings** tab, in the **Associated Dial Plans** section, click **Remove**.
5. In the confirmation dialog box, click **Yes** to confirm the deletion of the Exchange 2007 Unified Messaging server from the UM dial plan.
6. Click **OK** to close the properties window.

To remove an Exchange 2007 UM server from a dial plan by using the Shell, run the following command.

```
$dp= Get-UMDialPlan "MySIPDialPlan"
$s=Get-UMServer -id MyUMServer
$s.dialplans-=$dp.identity
Set-UMServer -id MyUMServer -dialplans:$s.dialplans
```

In this example, there are three SIP URI dial plans: SipDP1, SipDP2 and SipDP3. This example removes the UM server named `MyUMServer` from the SipDP3 dial plan.

```
Set-UMServer -id MyUMServer -DialPlans SipDP1,SipDP2
```

In this example, there are two SIP URI dial plans: SipDP1 and SipDP2. This example removes the UM server named `MyUMServer` from the SipDP2 dial plan.

```
Set-UMServer -id MyUMServer -DialPlans SipDP1
```

Tip:

You can use the **Set-UMServer** cmdlet in the Shell on an Exchange 2007 Unified Messaging server or the **Set-UMService** cmdlet on an Exchange 2013 Mailbox server to remove an Exchange 2007 UM server from a single or multiple dial plans. For example, to remove a UM server from all dial plans, run the following command: `Set-UMServer -identity MyUMServer -DialPlan $null`

How do you know this worked?

After you've set up Unified Messaging, verify the following to ensure it's working correctly:

- A user you've enabled for voice mail can sign in to Outlook Web App or Outlook and see a Welcome Message for Unified Messaging.

- UM users can receive voice messages.
- UM users can call in to an Outlook Voice Access number to listen to email, calendar items, and voice mail.
- UM is routing calls from outside of your organization, and you can place a call.

Checklist: Upgrade Exchange 2007 UM to Exchange 2013 UM

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-04-01*

Use this checklist to help you upgrade Exchange 2007 Unified Messaging (UM) to Exchange 2013 UM. Be sure to refer to this information when you're upgrading your Exchange 2007 organization and your UM deployment to Exchange 2013. For step-by-step instructions for upgrading to Exchange 2013 UM, see Upgrade Exchange 2007 UM to Exchange 2013 UM.

Before you start working with this checklist, make sure you're familiar with the concepts in:

- Planning for Unified Messaging
- Telephone system integration with UM
- Connect your voice mail system to your telephone network

For step-by-step guidance about how to upgrade from Exchange 2010 UM to Exchange 2013 UM, see Checklist: Upgrade Exchange 2010 UM to Exchange 2013 UM.

Checklist for upgrading Exchange 2007 UM to Exchange 2013 UM

Done?	Tasks	Topic
	Deploy and configure telephony components	Connect UM to your telephone system
	Review the system requirements before installing Exchange 2013	Exchange 2013 system requirements
	Verify that you meet the prerequisites for installation	Exchange 2013 prerequisites

	Install the required Client Access and Mailbox servers	Install Exchange 2013 using the Setup wizard
	Verify the installation and review the server setup logs	Verify an Exchange 2013 installation
	If required, install the required UM language packs	Install a UM language pack
	Import dial plan and auto attendant custom prompts	Import custom prompts from Exchange 2007 to Exchange 2013
	Export and import certificates	Deploying certificates for UM
	Configure the UM startup mode on all Exchange 2013 Client Access servers	Configure the startup mode on a Client Access server
	Configure the UM startup mode on all Exchange 2013 Mailbox servers	Configure the startup mode on a Mailbox server
	Create or configure existing UM dial plans	Create a UM dial plan Manage a UM dial plan
	Create or configure existing UM IP gateways	Create a UM IP gateway Manage a UM IP gateway
	Create a UM hunt group	Create a UM hunt group
	Create or configure UM auto attendants	Create a UM auto attendant Manage a UM auto attendant
	Create or configure UM mailbox policies	Create a UM mailbox policy Manage a UM mailbox policy

	Move existing UM-enabled mailboxes to Exchange 2013	Mailbox moves in Exchange 2013
	Enable new users for UM or configure settings for an existing UM-enabled user	Enable a user for voice mail Manage voice mail settings for a user
	Configure your VoIP gateways, IP PBXs, and SIP-enabled PBXs to send all incoming calls to the Exchange 2013 Client Access servers	Configuration notes for supported VoIP gateways, IP PBXs, and PBXs Connect a VoIP gateway, IP PBX, or session border controller to UM

Deploying Exchange 2013 UM and Lync Server overview

Exchange Server 2013 > Unified Messaging > Deploying voice mail and UM >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-06-11*

Unified Messaging (UM) and Microsoft Lync Server can be deployed together to provide voice messaging, instant messaging, enhanced user presence, audio/video conferencing, and an integrated email and messaging experience for users in your organization. Unified Messaging is used to provide call answering for voice mail, Outlook Voice Access, and auto attendant services. Microsoft Lync Server enables more advanced features found in Enterprise Voice, such as instant messaging (IM), conferencing, and inbound and outbound calling. This topic describes how to configure Unified Messaging and Microsoft Lync Server to support these features.

Tip:

Microsoft Office Communications Server 2007 R2 can also be deployed together with Unified Messaging. In this topic, "Microsoft Lync Server" refers to Microsoft Lync Server 2010 or Microsoft Lync Server 2013.

Looking for more information about Microsoft Lync Server? See Microsoft Lync Server.

Contents

Deploying Exchange UM and Lync Server overview

Unified Messaging combines voice and email messaging into a single messaging infrastructure. Microsoft Lync Server Enterprise Voice takes advantage of the UM infrastructure to provide voice mail, Outlook Voice Access, call notifications, and auto attendants.

The following list shows the simplified deployment steps for UM and Lync Server. Details about each step are included later in this topic.

1. Install Microsoft Lync Server in the same topology where the Client Access servers running the Microsoft Exchange Unified Messaging Call Router service and the Mailbox servers running the Microsoft Exchange Unified Messaging service will be installed. Confirm that at least one Lync pool is created.
2. Install a certificate that's valid and signed by a private or public certification authority (CA) and is trusted by Lync Server.
3. Install the Client Access servers and Mailbox servers. Verify installation.
4. Install a certificate that's valid and signed by the same CA as the certificate you installed on your Lync servers.
5. Create and configure a Session Initiation Protocol (SIP) URI dial plan.
6. Add all Client Access and Mailbox servers to the SIP URI dial plan. However, if you have multiple SIP URI dial plans, you must add all Client Access and Mailbox servers to all SIP URI dial plans.
7. Run the ExchUcUtil.ps1 script from the <Exchange Installation folder>\Exchange Server\Script folder on a Mailbox server.

Important:

The ExchUcUtil.ps1 script creates one or more UM IP gateways for Lync integration. You must disable outgoing calls on all UM IP gateways except one gateway that the script created. This includes disabling outgoing calls on UM IP gateways that were created before you ran the script. To disable outgoing calls on a UM IP gateway, see Disable outgoing calls on UM IP gateways.

8. Run **OcsUmUtil.exe** from the %CommonProgramFiles%\Microsoft Lync Server 2013\Support

folder on a Lync Server.

9. Deploy the Mediation Server and media gateways.
10. Install a certificate on your Mediation Server that's valid and signed by the same CA as the certificate you installed on your Lync servers.
11. Enable your users for UM and Enterprise Voice.

Certificate configuration recommendations

You must have a certificate that's trusted by both the computers running Exchange and the computers running Lync Server. In an environment that has Lync Server and Unified Messaging, use the following guidelines for deploying a trusted certificate:

- On your Lync servers, Client Access servers, Mailbox servers, Mediation Server, and media gateways, import a certificate that's valid and signed by a private or public CA. This should be a trusted third-party commercial certificate or a public key infrastructure (PKI) certificate.
- It's less complex if you import the same third-party commercial or PKI certificate to each Exchange server. Also, install this trusted certificate on each computer running Microsoft Lync Server and Mediation Server. This will make your certificate deployment less complicated and reduce the administrative overhead associated with deploying certificates. However, make sure you obtain a trusted certificate that supports subject alternative names (SANs).

When you're deploying Transport Layer Security (TLS) with UM, the certificates that are used on the Client Access server and the Mailbox server both must contain the local computer's fully qualified domain name (FQDN) in the certificate's Subject Name. To work around this issue, use a public certificate and import the certificate on all Client Access and Mailbox servers, any VoIP gateways, IP PBXs, and all the Lync servers.

If your deployment includes VoIP gateways or IP PBXs, and if you use a SIP secured or Secured dial plan, a trusted certificate is required between the Client Access and Mailbox servers and the VoIP gateways or IP PBXs. A trusted certificate is also required if a direct SIP connection is used. If you use a SIP secured or Secured dial plan, you can use the same trusted certificate on your Lync and Exchange servers that's used on your VoIP gateways or IP PBXs.

- When you connect Exchange Client Access and Mailbox servers to Microsoft Lync servers or to third-party SIP gateways or Private Branch eXchange (PBX) telephony equipment, you must use a certificate that's valid and signed by an internal or public, third-party certification authority (CA) to establish secured sessions. You can use a single certificate on all the Client Access and Mailbox servers as long as the certificate has the FQDNs of all the Client Access and Mailbox servers in its SAN list. Or, you can generate a different certificate for each Client Access and Mailbox server, with the FQDN of the local computer present in the subject common name (CN) or SAN list of the certificate for that server. Exchange UM doesn't support wildcard certificates with Microsoft Lync Server.

A non-wildcard Subject Name is required for Lync Server and Exchange to work together. UM and Lync Server use the Subject Name as a way to indicate that they're trusted SIP peers. Lync Server also needs a non-wildcard Subject Name in some call-routing scenarios. The FQDN must be used as the "Issued to" value.

For Exchange UM, it isn't supported to put a wildcard in the Certificate Name. However, you can put a wildcard in the SAN.

The following table shows the certificate requirements for installing and configuring certificates for Exchange UM.

Topology	Certificate configuration
Client Access and Mailbox on the same server (without Lync 2010 or 2013; non-SIP dial plans)	A certificate is required between Client Access and Mailbox servers. This is the same certificate that's used between the Client Access and Mailbox servers and the VoIP gateway, IP PBX, or SBC.
Client Access and Mailbox on different servers (without Lync 2010 or 2013; non-SIP dial plans)	A certificate is required. The certificate must match on the Client Access and Mailbox servers. A certificate is also required between Client Access and Mailbox servers and the VoIP gateway, IP PBX, or SBC. This can be the same or a different certificate than the certificate that is used between the Client Access and Mailbox servers.For Client Access and Mailbox servers, you can run the **Create-ExchangeCertificate** cmdlet from either server.
Client Access and Mailbox on the same server (with Lync 2010 or 2013 and SIP dial plans)	A certificate is required. The Client Access and Mailbox servers must have the same certificate as the Lync 2010 or 2013 servers.
Client Access and Mailbox on different servers (with Lync 2010 or 2013 and SIP dial plans)	A certificate is required. The Client Access and Mailbox servers must have the same certificate as the Lync 2010 or 2013 servers.

Return to top

Deployment steps

After you install the required servers in your organization, there's a recommended sequence of steps that you must perform in your Exchange Unified Messaging and Lync Server deployments to correctly deploy Enterprise Voice for your users.

For details about Microsoft Lync Server, see Microsoft Lync Server.

You must complete the following steps to configure Unified Messaging to work with the Enterprise Voice features in Lync Server:

1. Create one or more Unified Messaging SIP URI dial plans that each map to a corresponding Lync Server location profile. An Enterprise Voice location profile must be created for each Exchange UM dial plan. You can use the **Get-UMDialPlan** cmdlet to obtain the FQDN of a SIP URI dial plan. For more information about how to create a SIP URI dial plan, see Create a UM dial plan.

Important:
When you're integrating Exchange UM and Lync Server, you'll probably find it unnecessary to configure dialing rules or dialing rule groups in Exchange UM. Lync Server is designed to perform call routing and number translation for users in your organization, and will also do this when the calls are made by Unified Messaging on behalf of users.

2. Install a certificate on the Client Access and Mailbox servers that's valid and signed by a private or public CA. This is the same CA that was used on the Lync Servers.
3. Encrypt the Voice over IP (VoIP) traffic by configuring the SIP URI dial plan as SIP secured or Secured.

Caution:
If you set your security setting to SIP Secured to require encryption for SIP traffic only, this setting is insufficient on a dial plan if the Front End pool is configured to require encryption (which means that the pool requires encryption for both SIP and RTP traffic). When the dial plan and pool security settings aren't compatible, all calls to Exchange UM from the Front End pool will fail, resulting in an error indicating that you have an "Incompatible security setting".

Although a UM dial plan can be configured as SIP secured or Secured, we recommend that you configure the dial plan as Secured to enable Lync Phone Edition devices to work correctly. This is recommended because of the default encryption level settings configured in Lync Server. A Lync Phone Edition device will work only if the encryption settings are configured as shown in the following table. This table shows the relationship between the encryption settings for Lync Server and UM dial plans.

Encryption settings for Lync Phone Edition

Lync Server	UM dial plan
Encryption required (default)	Secured
Encryption optional	SIP secured/Secured
No encryption	SIP secured

4. Add all Client Access and Mailbox servers to the SIP dial plan. To enable the server to answer incoming calls, you must add all Exchange servers to a dial plan if you want them to answer calls from Lync Server.
5. Set the startup mode and the TLS listening port on the Client Access and Mailbox servers that are added to the SIP URI dial plan to Dual and then restart the Microsoft Exchange Unified Messaging service on each Mailbox server and the Microsoft Exchange Unified Messaging Call Router service on each Client Access server.

6. Create and configure a UM auto attendant. For details, see Set up a UM auto attendant.
7. When you enable users for voice mail, create a SIP address for the users who will use Enterprise Voice. In most cases, this SIP address will be the same SIP address that will be used when a user is enabled for Enterprise Voice. For details, see Enable a user for voice mail.

Important:

Users who are associated with a SIP URI dial plan can't receive incoming faxes. This is because incoming voice and fax calls are routed through a Mediation Server and faxing isn't supported when using a Mediation Server.

8. Open the Exchange Management Shell and run the exchucutil.ps1 script located in the %Program Files%\Microsoft\Exchange Server\V15\Scripts folder. The exchucutil.ps1 script does the following:
   - Grants Lync Server permission to read Exchange UM Active Directory components, specifically, the SIP URI dial plan that was created in the previous task. For details about how to configure permissions in Active Directory, see How to Use ADSI Edit to Apply Permissions.
   - Creates a UM IP gateway for each Lync Server pool or for each server running Lync Server Standard Edition that hosts users who will be enabled for Enterprise Voice. For details, see Create a UM IP gateway.
   - Create an Exchange UM hunt group for each UM IP gateway. The hunt group pilot identifier will be the name of the dial plan associated with the corresponding UM IP gateway. The hunt group must specify the UM SIP dial plan used with the UM IP gateway.
9. Enable users for voice mail. When you enable them, make sure you enter a valid SIP address for the user and link them to a SIP dial plan. For details, see Enable a user for voice mail.

You must also complete the following tasks to configure Lync Server to work with Exchange UM:

- Create location profiles or Lync dial plans. The location profile name doesn't have to match the FQDN of the corresponding UM dial plans.
- Assign location profiles to the Lync Server pools.
- Deploy and configure media gateways or Mediation Servers. You must also import a certificate from the same trusted CA as was used for the certificates on the Client Access and Mailbox servers and Lync Server.
- Define telephone usage, create and assign voice policies and outbound call routes.
- Configure the users for Enterprise Voice and add a TEL URI and SIP identifier.
- Run **ocsumutil.exe**, which creates the contact objects for Outlook Voice Access and for the auto attendants.

Note:

When you install Lync Server, the **msRTC-SIPLine** attribute is added to Active Directory. If you haven't installed Lync Server in your environment, this attribute isn't added to Active Directory, and caller ID name resolution across dial plans in a single forest and in cross-forest scenarios won't work correctly unless you configure Unified Messaging proxy addresses for users who aren't UM-enabled.

After you configure the Lync Server and the Unified Messaging servers, you must enable the user to use Lync Server and install Lync on the user's client computer.

Important:

When you're integrating Unified Messaging and Lync Server, missed call notifications aren't available to users who have a mailbox located on an Exchange 2007 or Exchange 2010 Mailbox server. A missed call notification is generated when a user disconnects before the call is sent to a Mailbox server.

Return to top

For more information

For more information about how to perform the tasks that must be completed for Microsoft Lync Server, see Microsoft Lync Server.

Configure UM to work with Lync Server

Topic Last Modified: *2013-06-11*

When you're integrating Microsoft Lync Server with Exchange Unified Messaging (UM), you have to run the ExchUcUtil.ps1 script in the Shell. The ExchUcUtil.ps1 script does the following:

- Creates a UM IP gateway for each Lync Server pool.

Important:

The ExchUcUtil.ps1 script creates one or more UM IP gateways. You must disable outgoing calls on all UM IP gateways except one gateway that the script created. This includes disabling outgoing calls on UM IP gateways that were created before you ran the script. To disable outgoing calls on a UM IP gateway, see Disable outgoing calls on UM IP gateways.

- Creates a UM hunt group for each UM IP gateway. The pilot identifier of each hunt group specifies the UM SIP URI dial plan used by the Lync Server Front End pool or Standard Edition server that's associated with the UM IP gateway.
- Grants Lync Server permission to read Active Directory UM container objects such as UM dial plans, auto attendants, UM IP gateways, and UM hunt groups.

Important:

Each UM forest must be configured to trust the forest in which Lync Server 2013 is deployed, and the forest in which Lync Server 2013 is deployed must be configured to trust each UM forest. If Exchange UM is installed in multiple forests, the Exchange Server integration steps must be performed for each UM forest or you'll have to specify the Lync Server domain. For example, *ExchUcUtil.ps1 –Forest:<lync-domain-controller-fqdn>*.

For additional management tasks related to integrating Lync Server and Unified Messaging, see Deploying Exchange 2013 UM and Lync Server overview.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Permissions Cmdlets" entry in the Exchange 2013 cmdlets topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

Use the Shell to run the ExchUcUtil.ps1 script

Run the ExchUcUtil.ps1 script on any Exchange server in your organization that's in the same topology as Microsoft Lync Server. You can run the script from a Mailbox server using the Shell or you can run the script using Remote Windows PowerShell on a Client Access server. If you run the script on a Client Access server in your organization, the Client Access server will proxy the Remote Windows PowerShell session to a Mailbox server in the organization.

Important:

The ExchUcUtil.ps1 script creates one or more UM IP gateways. You must disable outgoing calls on all UM IP gateways except one gateway that the script created. This includes disabling outgoing calls on UM IP gateways that were created before you ran the script. To disable outgoing calls on a UM IP gateway, see Disable outgoing calls on UM IP gateways.

Important:

You must have the permissions of the Exchange Organization Management role or be a member of the Exchange Organization Administrators security group to run the script.

1. Open the Exchange Management Shell.
2. At the `c:\Windows\System32` prompt, type **cd "<drive letter>\Program Files\Microsoft \Exchange Server\V15\Scripts>.ExchUcUtil.ps1"**, and then press Enter.

How do you know this worked?

To verify that the ExchUcUtul.ps1 script completed successfully, do the following:

- Use the **Get-UMIPGateway** cmdlet or the EAC to view the new UM IP gateway or gateways that were created.
- Use the **Get-UMHuntGroup** cmdlet or the EAC to view the new UM hunt group or groups that were created.

Checklist: Integrate Exchange 2013 UM with Lync Server

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-20*

Use this checklist to install and deploy Unified Messaging (UM) and Microsoft Lync Server 2013. In this topic, "Lync Server" also refers to Lync Server 2010. However, Microsoft Office Communications Server 2007 R2 can also be deployed together with Unified Messaging.

Note:

Before you start working with this checklist, make sure you're familiar with the concepts in:

- Deploying Exchange 2013 UM and Lync Server overview
- Coexistence with Office Communications Server 2007 R2 and Lync Server

For more information about how to perform the tasks that must be completed for Lync Server, see Microsoft Lync Server 2013.

Checklist for deploying Microsoft Lync Server and Unified Messaging

Done?	Tasks	Topic
	Review the system requirements before installing Exchange Server 2013.	Exchange 2013 system requirements
	Verify that you meet the prerequisites for installation.	Exchange 2013 prerequisites
	Review the prerequisites for integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013.	Prerequisites for Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013

		Tip: The Unified Communications Managed API (UCMA) 4.0 Runtime is required for Exchange 2013 and Lync Server 2010 and 2013 and is installed during installation. To download and review information about UCMA 4.0, see Unified Communications Managed API 4.0 Runtime
	Install the required Client Access and Mailbox servers.	Install Exchange 2013 using the Setup wizard
	Verify the installation and review the server setup logs.	Verify an Exchange 2013 installation
	If required, install the required UM language packs.	Install a UM language pack
	Create the number of SIP URI dial plans required for your organization.	Create a UM dial plan
	Configure the dial plan security setting.	Configure the VoIP security setting
	Configure the number of concurrent calls on your Mailbox servers.	Configure the number of incoming calls on a Mailbox server
	Configure Outlook Voice Access numbers and other settings.	Manage a UM dial plan
	Add all Client Access and Mailbox servers to each SIP URI dial plan.	Add Mailbox and Client Access servers to a SIP URI dial plan

	Configure outbound dialing for Unified Messaging. Allow all calls on the SIP URI dial plans and UM mailbox policies that are linked to those dial plans.	Authorize calls for users in a dial plan Authorize calls for a group of users

	Define, deploy, and configure any required advanced Enterprise Voice features.	Deploying Advanced Enterprise Voice Features
	Enable the users for Enterprise Voice. Enter a line URI and assign a voice policy and a Lync dial plan.	Enable Users for Enterprise Voice

Coexistence with Office Communications Server 2007 R2 and Lync Server

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-11-29*

Communications Server 2007 R2 and Lync Server provide many end-user features, including instant messaging (IM), presence, multiparty IM, and their voice mail functionality can be integrated with Exchange Unified Messaging (UM). For deployments that integrate Lync Server 2010 or 2013, users can be enabled for Enterprise Voice, which lets users who are enabled for voice mail access their voice mail by using Lync Server components.

When you integrate UM with the earlier versions of Office Communications Server or Lync Server, not all features are available. For users to take full advantage of the new enhanced end-user features such as high-resolution photos, the unified contact store, and Lync Archiving Integration, they must have user accounts on Lync Server 2013 and Exchange Server 2013, and must be using the latest version of the Lync 2013 client software. For example, the unified contact store isn't available to users who've been enabled for Enterprise Voice on Lync Server 2010. Also, high-resolution photos can't be displayed in Lync 2010.

When you're integrating Exchange UM with Office Communications Server 2007 R2 or Lync Server 2010, you may need to install additional hotfixes, rollups, cumulative updates, and service packs on the Office Communications Server 2007 R2 or Lync 2010 servers that have been deployed in your organization. What you're required to install will depend on your deployment topology and the product versions you're integrating with Exchange UM.

Required hotfixes, rollups, cumulative updates, and service packs

The following table shows the fixes that are required for each version of the products for integration with UM.

Office Communications Server 2007 R2	Office Communications Server 2007 R2 cumulative update 10 or later.

Lync Server 2010	Lync Server 2010 cumulative update 3 or later.
Lync Server 2013	No updates are required.

Deploying certificates for UM

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-04-29*

You can use mutual Transport Layer Security (mutual TLS) to enable Unified Messaging (UM) to encrypt data sent between your Microsoft Exchange 2013 servers and VoIP gateways, IP PBXs, session border controllers (SBCs), and Microsoft Lync Server. Certificates bind the identity of the certificate owner to a pair of electronic keys (public and private) that are used to encrypt and sign information digitally.

If you're using SIP secured or Secured dial plans in your Exchange 2010 organization, you'll need to import the certificates that were used to your Exchange 2013 Client Access servers running the Microsoft Exchange UM Call Router service and Mailbox servers running the Microsoft Exchange UM service. You can use one of the following certificates for the UM and UM Call Router services:

- A self-signed (Exchange) certificate
- An internal public key infrastructure (PKI) certificate
- A third-party commercial certificate

By default, when you install Unified Messaging, a self-signed certificate is created and used. This self-signed certificate can be used with VoIP gateways, IP PBXs, and SBCs, but not when you're integrating UM with Lync Server. If you're deploying certificates to be used with Lync Server, you need to use the Exchange certificate wizard or the **New-ExchangeCertificate** cmdlet to obtain a certificate that was issued by an internal or PKI certification authority (CA), or purchase a commercial or third-party certificate that is mutually trusted by Unified Messaging and Lync Server.

Deploying certificates for VoIP gateways, IP PBXs, and SBCs

To enable UM to encrypt data that's sent between VoIP gateways, IP PBXs, and SBCs you need to do the following:

- Use the self-signed UM certificate, create a new Exchange certificate request and obtain an internal PKI certificate, or purchase a third-party commercial certificate that you can use for mutual TLS between UM and VoIP gateways, IP PBXs, and SBCs.

- Import the certificate that will be used on all Client Access and Mailbox servers in your organization.
- Enable the certificate to be used by UM services.
- Import the certificate on your VoIP gateways, IP PBXs, and SBCs.
- Configure the UM dial plan as SIP secured or Secured.
- Configure the UM startup mode on Client Access and Mailbox servers in your organization.
- Create the required UM IP gateways with a fully qualified domain name (FQDN).
- Configure the listening port on the UM IP gateways to use TLS port 5061.
- Restart the Unified Messaging Call Router service on all Client Access servers and restart the Microsoft Exchange Unified Messaging service on all Mailbox servers.

Deploying certificates for Lync Server

To encrypt data that's sent between UM and Lync Server, you need to do the following:

- Create a new Exchange certificate request and obtain an internal PKI certificate, or purchase a third-party commercial certificate. The certificate must be mutually trusted by UM and Lync Server.
- Import the certificate that will be used on all Client Access and Mailbox servers in your organization.
- Enable the certificate to be used by UM services.
- Import the certificate on the computers running Lync Server.
- Configure the SIP URI UM dial plan as SIP secured or Secured.
- Configure the UM startup mode on Client Access and Mailbox servers in your organization.
- Run OcsUmUtil.exe from a Lync Server computer.
- Restart the Unified Messaging Call Router service on all Client Access servers and restart the Microsoft Exchange Unified Messaging service on all Mailbox servers in your organization. For details, see UM services procedures.
- Restart the Lync Server Front-End service on all Lync Servers that are part of an Enterprise Edition Front End pool or restart the Standard Edition Front End Servers. You can use the **Stop-CsWindowsService** cmdlet to stop Lync Server services and the **Start-CsWindowsService** cmdlet to start Lync Server services.

The **Start-CsWindowsService** and **Stop-CsWindowsService** cmdlets are similar to the generic Windows PowerShell cmdlets **Start-Service** and **Stop-Service**. If you want, you could use the **Start-Service** or **Stop-Service** cmdlets to start and stop a Lync Server service. However, the **Start-CsWindowsService Stop-CsWindowsService** cmdlets include a *ComputerName* parameter that makes it easy to stop and start a Lync Server service on a remote computer. To do this, you include the *ComputerName* parameter followed by the fully qualified domain name (FQDN) of the remote computer. The **Start-Service** and **Stop-Service** cmdlets don't have a comparable parameter.

Note:
To fully integrate UM and Lync Server, you must also run the ExchUcUtil.ps1 script on any Client Access or Mailbox server in your organization

Deploying certificates for UM procedures

Create certificates for UM

Import or export certificates for UM

Assign a certificate to the UM and UM Call Router services

Create certificates for UM

Deploying voice mail and UM > Deploying certificates for UM > Deploying certificates for UM procedures >

Topic Last Modified: *2013-04-29*

You can use the New Exchange Certificate wizard in the EAC or the Shell to create self-signed certificates or certificate requests for an internal public key infrastructure (PKI) certificate. For Unified Messaging (UM), you can use one of these certificates for both the Microsoft Exchange Unified Messaging service and the Microsoft Exchange Unified Messaging Call Router services. You can use the same certificate for both services, or a different certificate for each service. You can also purchase and import a third-party commercial certificate for UM services. If you're using a self-signed certificate for UM, you may need to include the name of your Client Access and Mailbox servers in the subject alternative name (SAN).

By default, when you install Exchange Server 2013, two self-signed certificates are created: **Microsoft Exchange Server Auth Certificate** and **Microsoft Exchange**. The **Microsoft Exchange** self-signed certificate can be used by UM to encrypt data, but you must assign the certificate to the UM and UM Call Router services. After you assign the certificate to the Unified Messaging services, it can be copied to and imported to the VoIP gateways, IP PBXs, and SIP-enabled PBXs. However, instead of using the default self-signed certificates, you may need to create another one specifically for Unified Messaging.

Caution:
Self-signed certificates can't be used when you're integrating UM with Microsoft Lync Server.

For additional management tasks related to managing certificates for Unified Messaging, see Deploying certificates for UM procedures.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Certificate management" entry in the Exchange and Shell infrastructure permissions topic and the "UM service" entry in the Unified Messaging permissions topic. You must also log on by using an account that's a member of the local Administrators group on that computer.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to create a certificate request for UM

1. In the EAC, navigate to **Servers** > **Certificates**, and then click **Add +**.
2. On the **New Exchange certificate** page, select **Create a request for a certificate from a certification authority**, and then click **Next**.
3. Enter a friendly name for the certificate, and then click **Next**.
4. If you don't need a wildcard certificate, click **Next**. If you need a wildcard certificate, select **Request a wildcard certificate. A wildcard certificate can be used to secure all sub-domains under your root domain with a single certificate**, enter the name of the root domain, and then click **Next**.
5. Under **Store certificate request on this server**, click **Browse** to go to the location where you want to store the file. You can store the certificate request on any Client Access or Mailbox server in your Exchange organization. Select the location, click **OK**, and then click **Next**.
6. If you requested a wildcard certificate, skip to step 9.
7. If you didn't request a wildcard certificate, you'll need to specify the domains you want to be included in your certificate. If you want to edit a domain, click **Edit**, and then click **Next**.
8. Under **Based on your selections, the following domains will be included in your certificate. You can add additional domains here, or make changes**, you can add, edit, remove, or check the name of domains that are listed under **Domain**. Then click **Next**.
9. Under **Specify information about your organization. This is required by the certification authority**, enter the following:
   - **Organization name**
   - **Department name**
   - **City/Locality**
   - **State/Province**

- **County/Region name** For this option, use the drop-down list to select the country or region.

10. Under **Save the certificate request to the following file**, enter the name of the certificate file, and then click **Finish**.

Use the Shell to create a certificate request for UM

This example creates a new Exchange certificate request for a Mailbox server named `MyMailboxServer` with a friendly name of `CertUM`.

```
New-ExchangeCertificate -FriendlyName 'CertUM' -
GenerateRequest -PrivateKeyExportable $true -KeySize '2048'
-DomainName '*.northwindtraders.com' -SubjectName
'C=US,S=wa,L=redmond,O=northwindtraders,OU=servers,CN=
northwindtraders.com' -Server 'MyMailboxServer'
```

Use the EAC to create a self-signed certificate for UM

1. In the EAC, navigate to **Servers** > **Certificates**, and then click **Add +**.
2. On the **New Exchange certificate** page, choose **Create a self-signed certificate**, and then select **Next**.
3. Enter a friendly name for the certificate, and then select **Next**.
4. Click **Add +** to select the Exchange servers that you want to apply this certificate to, and then select **Next**.
5. Specify the domains that you want to be included in your certificate, and then select **Next**. If you want to add a domain for a service, click **Edit** ✎.
6. Verify that the domains you included are correct, and then select **Finish**.

Important:
When you use the EAC to create a self-signed certificate, you won't be prompted to enable services for the certificate. After the certificate has been created, you can use the EAC or the **Enable-ExchangeCertificate** cmdlet in the Shell to enable the Exchange services. For more information about how to assign a certificate to UM services, see Assign a certificate to the UM and UM Call Router services.

Use the Shell to create a self-signed certificate for UM

This example creates a new Exchange self-signed certificate for a Mailbox server named `MyMailboxServer` with a friendly name of `UMCert`.

```
New-ExchangeCertificate -Services 'UM, UMCallRouter' -
DomainName '*.northwindtraders.com' -FriendlyName
'UMSelfSigned' -SubjectName
'C=US,S=WA,L=Redmond,O=Northwindtraders,OU=Servers,CN=
```

```
Northwindtraders.com' -PrivateKeyExportable $true
```

Tip:

When you specify the services you want to enable by using the *Services* parameter, you'll be prompted to assign those services. In this example, you'll be prompted to enable the certificate for the UM and UM Call Router services. For more information about how to enable a certificate for services, see Assign a certificate to the UM and UM Call Router services.

Import or export certificates for UM

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-12-18*

You can use the EAC or the Shell to import or export self-signed, internal public key infrastructure (PKI), or third-party commercial certificates. For Unified Messaging (UM), you can use one of these certificates for the Microsoft Exchange Unified Messaging service and the Microsoft Exchange Unified Messaging Call Router service. You can use the same certificate for both services, or a different certificate for each service.

Importing certificates for Exchange can be useful when you want to:

- Import a certificate that was exported to a file.
- Import a PKI certificate file that was generated by an internal certification authority.
- Import a third-party commercial certificate.

Exporting an existing certificate from the certificate store on the local Exchange server can be useful when you want to:

- Export it so that it can be imported on another Exchange server.
- Export it so that it can be imported on a VoIP gateway, IP PBX, or SIP-enabled PBX.
- Export the certificate so that you can back up the certificate and its private key.

For additional management tasks related to managing certificates for Unified Messaging, see Deploying certificates for UM procedures.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Certificate management" entry in the Exchange and Shell infrastructure permissions topic and the "UM service" entry in the Unified Messaging permissions topic. You must also log on by using an account that's a member of the local Administrators group on that computer.

- Before you export a certificate, use the **Get-ExchangeCertificate** cmdlet to verify that the *PrivateKeyExportable* attribute on the certificate is set to `$true`.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to export a certificate

1. In the EAC, click **Servers** > **Certificates** > **More options** ···, and then click **Export Exchange certificate**.
2. On the **Export Exchange certificate** page, in the **File to export to** box, enter the name of the certificate file.
3. In the **Password** box, enter the password that you want to use to protect the private key, and then click **OK**.

Use the Shell to export a certificate

This example exports the certificate with the Thumbprint A36DE2B9B62980A717EBD0C3052F5F0B08FBFFCC to a file after it prompts you for a user name and password.

```
$file = Export-ExchangeCertificate -Thumbprint
A36DE2B9B62980A717EBD0C3052F5F0B08FBFFCC -
BinaryEncoded:$true -Password (Get-Credential).password
```

This example does the following:

1. Uses the **Get-ExchangeCertificate** cmdlet to find the certificate that you want to export.
2. Uses the **Export-ExchangeCertificate** cmdlet to set the password for the certificate.
3. Outputs the certificate to a file after you input the user name and password.

```
$file = Get-ExchangeCertificate -DomainName
umcorp.northwindtraders.com | Export-ExchangeCertificate -
BinaryEncoded:$true -Password (Get-Credential).password

Set-Content -Path "d:\umcerts\selfsigned.pfx" -Value
$file.FileData =Encoding Byte
```

Use the EAC to import a certificate

1. In the EAC, click **Servers** > **Certificates** > **More options** ···, and then click **Import Exchange certificate**.
2. On the **Import Exchange certificate** page, in the **File to import from** box, enter the shared folder path and the name of the certificate file. If the certificate is protected with a password, enter the password in the **Password** box, and then click **Next**.
3. Click **Add +** to select the servers that you want to apply the certificate to, and then click **OK**. If you want to remove a server from the list view, click **Remove —**, and then click **Finish**.

Use the Shell to import a certificate

This example imports a certificate from the d:\certificates\exchange\SelfSignedUMCert.pfx certificate file after you enter a user name and password.

```
Import-ExchangeCertificate -FileData ([Byte[]]$(Get-Content -Path d:\certificates\exchange\SelfSignedUMCert.pfx -Encoding Byte -ReadCount 0)) -Password:(Get-Credential).password
```

Assign a certificate to the UM and UM Call Router services

Topic Last Modified: *2013-04-29*

You can use the EAC or the Shell to assign a self-signed, internal public key infrastructure (PKI), or third-party commercial certificate for specific Exchange services. When you use the **New-ExchangeCertificate** cmdlet to assign the certificate to Exchange services with the *Services* parameter, you're prompted to assign the certificate to Exchange services. If you use the EAC to create a certificate, the New Exchange Certificate wizard won't prompt you to assign the certificate to Exchange services. You need to edit the properties of the certificate and assign the certificate by selecting which services you want to assign it to.

Different services have different certificate requirements. For example, some services may only require a server name in the **Subject Name** or **Subject Alternative Name** boxes of a certificate and other services may require a fully qualified domain name (FQDN). Make sure that the certificate name can support the uses required by the services you enable it for.

Caution:

Self-signed certificates can't be used when you're integrating Unified Messaging (UM) with Microsoft Lync Server.

For additional management tasks related to managing certificates for Unified Messaging, see Deploying certificates for UM procedures.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Certificate management" entry in the Exchange and Shell infrastructure permissions topic and the "UM service" entry in the Unified Messaging permissions topic. You must also log on by using an account that's a member of the local Administrators group on that computer.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to assign a certificate to the Unified Messaging and UM Call Router services

1. In the EAC, navigate to **Servers** > **Certificates**.
2. In the list view, select the certificate that you want to assign to the Unified Messaging and UM Call Router services, and then click **Edit** .
3. On the *<Certificate name>* page, select **Services**, and then select **UM** and **UM call router**.
4. Click **Save**.

Use the Shell to assign a certificate to the Unified Messaging and UM Call Router services

This example assigns a certificate to the Unified Messaging and UM Call Router services.

```
Enable-ExchangeCertificate -Thumbprint
5113ae0233a72fccb75b1d0198628675333d010e -Services 'UM,
UMCallRouter'
```

UM languages, prompts, and greetings

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-22*

You can install and configure language packs to support multiple languages in Unified Messaging (UM) environments.

UM language packs enable callers and Outlook Voice Access users to interact with the voice mail system in multiple languages. After you install an additional language on a Mailbox server, callers and Outlook Voice Access users can hear email messages and interact with the voice mail system in that language.

There are several key components that rely on UM language packs to enable users and callers to interact effectively with Unified Messaging in multiple languages. Each UM language pack includes a Text-to-Speech (TTS) engine, the pre-recorded prompts and support for Automatic Speech Recognition (ASR), and Voice Mail Preview for a specific language. This topic discusses UM language packs, the UM components that use the UM language packs, and how UM language packs—after they're installed—can be used to configure UM dial plans and UM auto attendants to use other languages.

Exchange Unified Messaging language packs are version-specific and platform-specific. Since Exchange Server 2007, there have been multiple releases for UM language packs, including the RTM version of Exchange 2007, Exchange 2007 SP1, SP2, and SP3, the RTM version of Exchange Server 2010, Exchange 2010 SP1 and SP2, and Exchange 2013. For some of these versions, both 32-bit and 64-bit downloads are available, but for other releases only 64-bit downloads are available.

It's very important that you install the correct version and platform of the UM language packs on a Mailbox server. Don't install UM language packs on a Mailbox server that's running an earlier version of Exchange or that's designed for a 32-bit platform.

Contents

Overview of UM language packs

Unified Messaging language packs allow a Mailbox server to speak additional languages to callers and recognize other languages when callers use ASR or when voice messages are transcribed. UM language packs contain:

- Pre-recorded prompts in the language of the UM language pack. For example, "After the tone, please record your message. When you've finished recording, hang up, or press the # key for more options."
- Grammar files in the language of the UM language pack that are used by a Mailbox server to look up the names of given users in the directory.
- Text-to-Speech (TTS) translation so that content (email, calendar, contact information, etc.) can be read to callers in the language of the UM language pack.
- Support for Automatic Speech Recognition, which allows callers to interact with UM using the voice user interface (VUI) in the language of the UM language pack.
- Support for Voice Mail Preview, which allows users to read the transcript of voice mail messages in a specific language from within a supported email client such as Outlook or Outlook Web App.

UM language packs include pre-recorded prompts, TTS conversion support for a specific language, and in some cases, support for ASR. In multiple-language environments, you may have to install additional UM language packs because some callers prefer to be prompted in a different language, or because they receive email in more than one language. You must install multiple UM language packs to support the ability of the Mailbox server to read an email message that contains more than one language, because the TTS conversion system must be instructed which language to select based on the text of the message to be read. If the Unified Messaging language pack hasn't been installed, the email message will be illogical and incoherent when it's read back to the user. Installing the appropriate language pack enables the TTS engine to read email and calendar items to the Outlook Voice Access user by using the correct language and also provides language-specific pre-recorded prompts for Unified Messaging. In some cases, they may also provide support for ASR.

Note:

The TTS engine converts text to speech, but it doesn't convert speech to text. UM-enabled users can send an email message that has a voice file attached to another user. However, they can't create and send a text-based email message to another user.

When you install a language pack, the installation program does the following:

1. Copies the language prompts that will be used to configure UM dial plans and auto attendants.
2. Allows the TTS engine to read messages when Outlook Voice Access users access their Inbox.
3. Enables ASR for speech-enabled UM dial plans and auto attendants for the language installed.
4. Enables Voice Mail Preview for clients in other languages.

You can add UM language packs by using the **Setup.exe** command or by running the

<UMLanguagePack>.exe installation program after you've downloaded the UM language pack from Exchange Server 2013 UM Language Packs. However, you have to use the Setup.exe command to remove a UM language pack. There's no Exchange Management Shell cmdlet that you can use to add or remove languages from a Mailbox server. For more information about how to install a UM language pack, see Install a UM language pack. For more information about how to remove a UM language pack, see Remove a UM language pack.

Note:

By default, when you install a Mailbox server, the U.S. English (en-US) language pack is installed. It can't be removed unless you remove the Mailbox server from the computer.

Return to top

The following table lists the Unified Messaging language packs that are currently available. It also lists the installation file name for each UM language pack and the culture ID for the UM language.

UM language pack installation file names and culture IDs

Language	Country/Region	Culture ID	Installation file name	Availability
Catalan	Spain	ca-ES	UMLanguagePack.ca-ES	Download available
Chinese (Hong Kong)	China	zh-HK	UMLanguagePack.zh-HK	Download available
Chinese (Simplified)	China	zh-CHS	UMLanguagePack.zh-CN	Download available

UM language components and features

There are several key components and features in Unified Messaging that enable users and callers to interact with a multiple-language voice mail system. For these components and features to work correctly and enable callers to interact with the system in multiple languages, the UM language packs must be installed correctly on a Mailbox server.

Pre-recorded prompts

The Mailbox server role is installed with a set of default audio prompt files. These audio files contain the recordings for Outlook Voice Access menus, voice mail greetings, and numbers that are used by Exchange Unified Messaging. The audio files are played by a Mailbox server to incoming callers, both internal and external. Many of the audio files are default prompts that provide the users of the Telephone User Interface (TUI) and Outlook Voice Access the information they need to move through the TUI and the Voice User Interface (VUI). The prompts are located in <*Program Files*>\Microsoft\Exchange Server\V15\UnifiedMessaging\Prompts\<language>. The prompts used by the Mailbox server to help callers move through the menus shouldn't be replaced or changed.

When an additional UM language pack is installed, the pre-recorded prompts for that language will also be installed. After a UM language pack is installed, the pre-recorded prompts for that language can be used by UM dial plans and auto attendants.

TTS languages

Unified Messaging relies on a Text-to-Speech (TTS) engine. TTS functionality is provided by the Microsoft Speech Server service. The TTS engine reads and converts written text into audible output that can be heard by a caller. The TTS engine reads and converts the following items in a user's mailbox:

- Email and voice mail message bodies, subjects, and names
- Calendar item bodies, subjects, locations, and names
- Personal contact names
- Users' default voice mail greetings

Note:

After a user has recorded personalized voice mail greetings, the TTS version of the voice greetings are no longer used.

Automatic Speech Recognition

In addition to TTS, ASR support is included in Unified Messaging. ASR functionality is provided by the Microsoft Speech Server service. ASR enables callers to use voice commands to move through menus and interact with items from their individual mailboxes, including messages, personal contacts, and calendar. ASR support is included with each language pack.

Return to top

Voice Mail Preview

UM language packs also provide support for Voice Mail Preview, which allows users to quickly triage their voice messages by reading their transcripts from within a supported email client such as Outlook or Outlook Web App.

When a caller leaves a voice message for a UM-enabled user, the voice message file and a transcript of the voice message are placed in the body of the voice message that's sent to the user's mailbox.

All UM language packs are single files that can be downloaded. These language packs include the pre-recorded prompts, grammar files, Text-to-Speech (TTS) translation, and ASR. However, not all the UM language packs contain support for Voice Mail Preview.

The following UM language packs contain support for all the components and features, including Voice Mail Preview:

- English (US) - (en-US)
- English (Canada) (en-CA)
- French (France) - (fr-FR)
- Italian - (it-IT)
- Polish (pl-PL)
- Portuguese (Portugal) (pt-PT)
- Spanish (Spain) (es-ES)

By default, after you install the Mailbox server, the server will send voice mail previews to UM-enabled users if a supported UM language pack is installed.

There are Unified Messaging Voice Mail Preview partners that offer enhanced transcription support for the Voice Mail Preview feature. These partners employ people to correct voice mail transcriptions that were created using ASR. Each Voice Mail Preview partner must meet a set of requirements to be certified to interoperate with Unified Messaging.

If you find that the voice mail previews sent to your users aren't accurate enough, you can contact one of the certified Voice Mail Preview partners listed on the Microsoft Pinpoint for Unified Messaging page and sign up with them at an additional cost.

You can download the UM language packs from the Microsoft Download Center. For details, see Install a UM language pack.

Unified Messaging languages

To enable callers to use the multiple language features found in Unified Messaging, you must first install a UM language pack. Then you have the option to configure other UM components.

- Install the UM language pack on the Mailbox servers in your organization.
- If required, configure the default language for a UM dial plan. This lets Outlook Voice Access users associated with the UM dial plan use the new language when they access their mailbox. However, users can still configure their language setting in the Outlook Web App Options.
- If you need to enable multiple languages on auto attendants, configure the language setting on a UM auto attendant. By default, a UM auto attendant uses the UM dial plan language. However, you can change this setting and enable unauthenticated callers to connect to your organization and move through the auto attendant menus in the language that you've specified on the UM auto attendant.

Unified Messaging language packs

You install a UM language pack on a Mailbox server using Setup.exe. After you install the new language pack, the language associated with the language pack will be added to the list of available languages that you can use. You can view the languages that have been installed using the Get-UMService cmdlet in the Exchange Management Shell.

When you install the UM language pack, the files that are used by the TTS engine and the pre-recorded prompts for the chosen language are copied and made available for users who connect to the voice mail system. You can download the UM language packs from the Microsoft Download Center. For details, see Install a UM language pack.

UM dial plan languages

Each UM dial plan that's created contains a default language setting. The UM dial plan language

setting is needed because Unified Messaging may have to use TTS conversion or play a standard audio prompt for Outlook Voice Access users when they access their mailbox. You don't have to select a default dial plan language.

When you first install Exchange, U.S. English will be the default language, and the only available language option for your dial plan. After you install a UM language pack on a Mailbox server, the language associated with the language pack will be listed as an available option when you configure the default language for the dial plan.

The default language is important to callers. When an Outlook Voice Access user calls in to the voice mail system, the language that is used is based on the language setting in Outlook Web App that was set when the user first signed in to their mailbox. Unified Messaging compares the language set in Outlook Web App to the list of available languages on the dial plan with which the user is associated. If there is no suitable match, the default UM dial plan language will be used. For example, if you have a dial plan that contains only users from France, you may want to change the default language setting on the dial plan to French.

UM auto attendant languages

By default, because UM auto attendants are associated with a UM dial plan when they're created, they use the default language setting of the associated UM dial plan. However, this setting can be changed after the UM auto attendant is created.

The UM auto attendant language setting is needed because Unified Messaging may have to use TTS conversion or play a standard audio prompt to a caller. Unified Messaging doesn't check whether the language of custom prompts for the auto attendant matches the language setting on the auto attendant. However, as a best practice, make sure that the language setting of the auto attendant matches the language of the custom prompts. Otherwise, the caller may hear the system shift from one language to another.

Being able to change the UM auto attendant language setting is also useful if you need several different language-specific auto attendants for callers.

Client language selection process

UM language packs enable callers and Outlook Voice Access users to interact with the Unified Messaging system in multiple languages. After you install additional language packs on a Mailbox server, callers and Outlook Voice Access users can hear email messages and interact with the voice mail system, and Outlook Web App users and users who are using Outlook 2010 or a later version can view the transcript of a voice message using Voice Mail Preview in a specific language.

To support a specific language, a UM client language pack for that language must be installed on each Mailbox server.

In some cases, if a UM language pack for a specific language hasn't been installed and isn't

available, a client fallback language may be used. Fallback UM client languages are available to be used in place of some languages but, for other languages, no fallback language is available. If there isn't a UM language pack installed for a specific language, and no fallback language is available for that language, en-US (US English) will be used.

The following table includes a list of client languages and the fallback languages that are used when a specific UM language pack hasn't been installed on a Mailbox server.

Client fallback languages for UM

Language	Country/ Region	Culture ID	First language chosen, if installed	Second language chosen, if installed	Third language chosen, if installed
Catalan	Spain	ca-ES	ca-ES	en-US	
Chinese (Hong Kong)	China	zh-HK	zh-HK	zh-CN	zh-TW
Chinese (Simplified)	China	zh-CN	zh-CN	zh-HK	zh-TW
Chinese (Traditional)	Taiwan	zh-TW	zh-TW	zh-HK	zh-CN
Danish	Denmark	da-DK	da-DK	en-US	
Dutch	Netherlands	nl-NL	nl-NL	en-US	
English	Australia	en-AU	en-AU	en-US	
English	Canada	en-CA	en-CA	en-US	
English	India	en-IN	en-IN	en-US	
English	United Kingdom	en-GB	en-GB	en-US	
English	United States	en-US	en-US		
Finnish	Finland	fi-FL	fi-FL	en-US	
French	Canada	fr-CA	fr-CA	fr-FR	en-US

French	France	fr-FR	fr-FR	fr-CA	en-US
German	Germany	de-DE	de-DE	en-US	
Italian	Italy	it-IT	it-IT	en-US

Return to top

Voice mail greetings, announcements, menus, and prompts

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-04-30*

When you install Unified Messaging (UM), a common set of default audio files used for the voice mail system and for menu prompts, greetings, and informational announcements is installed. Although you can create a fully functional UM auto attendant or dial plan that uses only the default

audio prompts, these prompts are too generic to serve as an acceptable public interface for many companies. This topic discusses the system and menu prompts, greetings, and informational announcements that are used by UM dial plans and auto attendants and how they're used when callers access the voice mail system.

Contents

Overview of audio prompts and greetings

After Unified Messaging is installed, audio files for UM dial plans and auto attendants are copied to the Mailbox server. By default, the installation program copies the audio files to the Program Files \Microsoft\Exchange Server\V15\Unified Messaging\Prompts\<*language*> folder. If you've installed the U.S. English version, a folder named \en is created during installation to hold the U.S. English versions of the system prompts. The Mailbox server plays these system prompts to callers so they can hear greetings, menu prompts, and informational announcements and so they can navigate the UM menus.

These system audio files or prompts should never be replaced. However, UM enables you to customize UM dial plan and auto attendant welcome greetings, main menu prompts, and informational announcements.

The following table summarizes the prompts and greetings used with UM dial plans.

Audio prompts for UM dial plans

Prompts and greetings	Description
System prompts	Must not be modified.
Welcome greeting	The default welcome greeting is a system prompt that is played by default. However, you can use a customized greeting file that you create.
Informational announcement	By default, informational announcements are disabled. If you enable an informational announcement, you must specify a customized

	greeting file.

The following table summarizes the prompts and greetings used with UM auto attendants.

Audio prompts for UM auto attendants

Prompts and greetings	Description
System prompts	Must not be modified.
Business hours menu prompts	By default, business hours menu prompts are enabled and a system prompt is played. However, you can use a customized greeting file that you create.
Non-business hours menu prompts	By default, non-business hours menu prompts are enabled and a system prompt is played. However, you can use a customized greeting file that you create.
Business hours greeting	By default, a business hours greeting is enabled and a system prompt is played. However, you can use a customized greeting file that you create. This is also known as a welcome greeting.
Non-business hours greeting	By default, a non-business hours greeting is enabled and a system prompt is played. However, you can use a customized greeting file that you create. This is also known as a welcome greeting.
Informational announcement	By default, informational announcements are disabled. If you enable an informational announcement, you must specify a customized greeting file.

Caution:
Modifying the installed system prompts isn't supported.

Return to top

System prompts

Unified Messaging is installed with a set of default audio prompts for use with Outlook Voice Access, dial plans, and auto attendants. Hundreds of system prompts for each language are installed on a Mailbox server. The Mailbox server plays the audio files for these system prompts to callers when they access the voice mail system. The following are some examples of these system prompts:

- "Please enter your PIN."
- "To access your mailbox, enter your extension."
- "To contact someone, press the # key."
- "Spell the name of the person you are calling, last name first."
- "To reach a specific person, just tell me the name."

Caution:

Modifying the installed system prompts isn't supported.

Note:

When the Unified Messaging service starts on the Mailbox server, it will verify that all the system prompts are available. If a system prompt can't be found, Unified Messaging will return an error. To fix the error that is returned, locate the event using Event Viewer and copy the file listed in the **Event Properties** window from the installation DVD into the appropriate folder on the Mailbox server.

UM dial plan greetings and announcements

After you install the Mailbox server and create a UM dial plan, you have the option to use the audio files for the default system prompts that are created during installation or to create customized audio files that can be used with UM dial plans.

UM dial plans have a welcome greeting and an optional informational announcement you can modify. The welcome greeting is used when an Outlook Voice Access user or another caller calls the subscriber access number. The callers hear a default welcome greeting that says, "Welcome, you are connected to Microsoft Exchange." You might want to change this default greeting and provide an alternative welcome greeting specific to your company, for example, "Welcome to Outlook Voice Access for Woodgrove Bank." If you customize this greeting, you can record the customized greeting and save it as a .wav file, and then you can configure the dial plan to use this customized greeting.

Unified Messaging allows for an informational announcement to follow the welcome greeting. By default, there is no informational announcement configured. However, you may want to provide one for callers. You can use the informational announcement for general announcements that change more often than the welcome greeting or for announcements required by corporate

compliance policies. When it's important that the whole informational announcement is heard, you can configure it to be uninterruptible. This prevents a caller from pressing a key or speaking a command to interrupt and stop the informational announcement.

The following table describes the UM dial plan greetings and informational announcements.

UM dial plan greetings and informational announcements

Greeting	Default example	Customized example
Welcome greeting	"Welcome, you are connected to Microsoft Exchange."	"Welcome to Outlook Voice Access for Woodgrove Bank."
Informational announcement	By default, an informational announcement isn't configured.	"By using this system you agree to adhere to all corporate policies when you are accessing this system."

When you are customizing and configuring greetings and announcements, make sure the language setting configured on the UM dial plan is the same as the language of the custom prompts you create. If not, a caller may hear a message or greeting in one language and another message or greeting in a different language.

Return to top

UM auto attendant greetings, announcements, and menu prompts

As with UM dial plans, UM auto attendants have a welcome greeting, an optional informational announcement, and an optional custom menu prompt. You can configure different versions of the welcome greeting and menu prompt for business hours and non-business hours. You can modify all of them.

The welcome greeting is the first thing a caller hears when a UM auto attendant answers the call. By default, this says, "Welcome to the Microsoft Exchange auto attendant." The audio file that is played for the call is the default system prompt for the UM auto attendant. However, you may want to provide an alternative greeting specific to your company, for example, "Thank you for calling Woodgrove Bank." To customize this welcome greeting, record the customized greeting and save it as a .wav file, and then configure the auto attendant to use this customized greeting. As with the welcome greetings, you can also customize the menu prompts.

Unified Messaging also allows for an informational announcement to follow a business hours greeting or a non-business hour greeting. By default, no informational announcement is configured, but you may want to provide one to callers. The informational announcement can announce your

company's business hours, for example, "Our business hours are 8:00 A.M. to 5:00 P.M., Monday through Friday, and 8:30 A.M. to 1:00 P.M. on Saturday." The informational announcement can also provide information required for compliance with corporate policies, for example, "Calls may be monitored for training purposes." When it's important that the whole informational announcement is heard, you can configure it to be uninterruptible. This prevents the caller from pressing a key or speaking a command to interrupt and stop the informational announcement.

The following table describes the UM auto attendant greetings and informational announcements.

UM auto attendant greetings, informational announcement, and menu prompts

Greeting	Default example	Customized example
Business hours greeting	"Welcome to the Microsoft Exchange auto attendant."	"Thank you for calling Woodgrove Bank."
Non-business hours greeting	No default non-business hours greeting is played until you configure the business hours for the auto attendant. However, the business hours greeting is played for callers during all times of the day.	"You have reached Woodgrove Bank after business hours. Our business hours are from 8:00 A.M. until 5:00 P.M., Monday through Friday."
Informational announcement	By default, informational announcements aren't configured.	"Calls may be monitored for training purposes."
Business hours main menu prompt	No default business hours main menu prompt will be played until you configure key mappings on the auto attendant.	"For technical support, press or say 1. For corporate offices and administration, press or say 2. For sales, press or say 3."
Non-business hours main menu prompt	No default non-business hours main menu prompt will be played until you configure key mappings and the business hours schedule on the auto attendant.	"Your call is very important to us. However, you have reached Woodgrove Bank after business hours. If you want to leave a message, please press or say 1, and we will return

		your call as soon as possible."

As with UM dial plans, make sure the language setting configured on the UM auto attendant is the same as the language of the custom greetings you create and is set to the same language as the UM dial plan. If not, a caller may hear a message or greeting in one language and another message or greeting in a different language.

Return to top

Customizing greetings, announcements, and menu prompts, and navigation menus

Although the system prompts mustn't be replaced or changed, you'll probably want to customize the greetings, informational announcements, menu prompts and navigation menus used with UM dial plans and auto attendants. After installation, you can configure the UM dial plans and auto attendants to use custom audio files (.wav or .wma). You must follow these steps before you can enable custom voice prompts for callers:

1. Record the custom greetings, announcements, and prompts and save then as .wav files. The Linear PCM (16 bit/sample), 8 kilohertz (kHz) audio codec must be used to encode the .wav files. If you don't use this specific format for the .wav files, an error will be generated stating that the source file is in an unsupported format. Although an error is generated, the error won't appear in Event Viewer.
2. Configure the UM dial plan or auto attendant to use the customized greetings, announcements, and prompts.

By default, when you create a UM auto attendant, the business and non-business hours greetings or prompts aren't configured and no key mappings are defined for business or non-business hours main menu prompts. To correctly configure customized greetings and prompts for an auto attendant, you must:

- Configure business and non-business hours on the **Business hours** page.
- Create the greeting audio (.wav or .wma) files that will be used for the business and non-business hours welcome greetings.
- Configure the business and non-business hours welcome greetings on the **Greetings** page.
- Create the greeting files that will be used for the business and non-business hours main menu prompt greetings.
- Configure the business and non-business hours main menu prompt greetings on the **Greetings** page.
- Enable and configure the business and non-business hours menu navigation on the **Menu navigation** page.

Install a UM language pack

Set the default language on a dial plan

Select the language for an auto attendant

Remove a UM language pack

Import and export custom greetings, announcements, menus, and prompts

Import custom prompts from Exchange 2007 to Exchange 2013

Enable custom prompt recording using the telephone user interface

Install a UM language pack

Unified Messaging > UM languages, prompts, and greetings > UM languages, prompts, and greetings procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-11-16*

To make a language available in the list of available Unified Messaging languages on a UM dial plan or UM auto attendant, you must first install the appropriate UM language pack. You install the language pack on a Mailbox server running the Microsoft Exchange Unified Messaging service by using the language-specific self-extracting executable file or the **setup.exe /AddUmLanguagePack** command. Before you can install a UM language pack, you must first download it to a local folder on the Mailbox server. You can download UM language packs from Exchange Server 2013 UM Language Packs. There's a separate executable file for each language.

After you install the appropriate UM language pack, you can view the list of installed UM language packs by viewing the drop-down list on the **Settings** page of a UM dial plan or the **Language for automated voice interface** drop-down list on the **General** page of a UM auto attendant. You can also configure the default language to be a language other than English (en-US) on UM dial plans and auto attendants.

Caution:

The UM language packs for Microsoft Exchange Server 2007 or Exchange 2007 Service Pack 1 (SP1), SP2, or SP3 or Exchange 2010 Service Pack 1 SP1, SP2, or SP3 can't be used on an Exchange 2013 Mailbox server.

For additional tasks related to UM languages, see UM languages, prompts, and greetings procedures.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mailbox server (UM service)" entry in Unified Messaging permissions.
- Verify that the Mailbox server is installed on a different computer than the Client Access server or that the Client Access and Mailbox servers are on the same hardware.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the UM Language Pack Installation (.exe) file to install a UM language pack

1. From the Microsoft Download Center, download the language-specific UM language pack (.exe) file into a local folder on the Mailbox server.
2. Double-click the UMLanguagePack.<*CultureCode*>.*exe* file. For example, for the German UM language pack, you would download the file named UMLanguagePack.de-DE.exe.
3. In the Exchange 2013 Setup wizard, on the **License Agreement** page, read the terms of the agreement, select **I accept the terms in the license agreement**, and then click **Next**.
4. On the **Unified Messaging Language Pack** page, verify that the correct language is listed in the **The following Unified Messaging Language Pack(s) will be installed** window, and then click **Install**.
5. Click **Finish** to complete the installation of the UM language pack.

Use setup.exe to install a UM language pack

This example installs the Japanese (ja-JP) UM language pack that's been downloaded to the D:\Exchange\UMLanguagePacks folder on a Mailbox server.

```
setup.exe /AddUmLanguagePack:ja-JP /s:d:\Exchange
\UMLanguagePacks /IAcceptExchangeServerLicenseTerms
```

This example installs the Mexican Spanish (es-MX) and German (de-DE) UM language packs that have been downloaded to the D:\Exchange\UMLanguagePacks folder on a Mailbox server.

```
setup.exe /AddUmLanguagePack:es-MX,de-DE /s:d:\Exchange
\UMLanguagePacks /IAcceptExchangeServerLicenseTerms
```

⚠Warning:

If you don't use the /IAcceptExchangeServerLicenseTerms parameter, you'll see the following error: Welcome to Microsoft Exchange Server 2013 Unattended Setup. You need to accept the license terms to install Microsoft Exchange Server 2013. To read the license agreement, visit http://go.microsoft.com/fwlink/p/?LinkId=150127. To accept the license agreement, add the /IAcceptExchangeServerLicenseTerms parameter to the command you're running. For more information, run setup /?.

For more information about available UM languages and the culture codes, see UM languages, prompts, and greetings.

Set the default language on a dial plan

Unified Messaging > UM languages, prompts, and greetings > UM languages, prompts, and greetings procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-22*

You can set the default language for a Unified Messaging (UM) dial plan. Each dial plan you create will initially use English (en-US) as the default language. The English (en-US) language pack is installed on all versions of Microsoft Exchange Server 2013 and can't be removed.

If you want to select another language as the default language, for example, German (de-DE), you must first download the German UM language pack .exe file from Exchange Server 2013 UM Language Packs and install that language pack on the Mailbox server by using the UMLanguagePack.de-de.exe installation file. After you've installed the language pack, you can set the default language to a language other than English (en-US) on your UM dial plans.

For additional tasks related to UM languages, see UM languages, prompts, and greetings procedures.

What do you need to know before you begin?

- Estimated time to complete: Less than 1 minute.

- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to set the default language on a UM dial plan

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**.
2. In the list view, select the UM dial plan that you want to modify, and then, on the toolbar, click **Edit** .
3. On the **UM dial plan** page, click **Configure**.
4. On the **Settings** page, under **Audio language**, select the language you want to set from the drop-down list.
5. Click **Save** to accept your changes.

Use the Shell to set the default language on a UM dial plan

This example sets the default language on a UM dial plan named `MyUMDialPlan` to German.

```
Set-UMDialPlan -Identity MyUMDialPlan -DefaultLanguage de-DE
```

This example sets the default language on a UM dial plan named `MyUMDialPlan` to Japanese.

```
Set-UMDialPlan -Identity MyUMDialPlan -DefaultLanguage ja-JP
```

This example sets the default language on a UM dial plan named `MyUMDialPlan` to Australian English.

```
Set-UMDialPlan -Identity MyUMDialPlan -DefaultLanguage en-AU
```

Select the language for an auto attendant

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-22*

You can configure the default prompt language setting on a Unified Messaging (UM) auto attendant. The language setting available on a UM auto attendant enables you to configure the default prompt language on the auto attendant. When you're using the default system prompts for the auto attendant, this is the language that the caller hears when the auto attendant answers the incoming call. This language setting affects only the default system prompts that are provided after you have installed the Mailbox server that is running the Microsoft Exchange Unified Messaging service. This setting doesn't affect custom prompts that are configured on an auto attendant. The languages that are available are based on the Unified Messaging language packs that are installed on the Mailbox server.

Each auto attendant you create will initially use English (en-US) as the default language. The English (en-US) language pack is installed by default on all versions of Microsoft Exchange 2013 and can't be removed. If you want to select another language, for example, German (de-DE), you must first download the German UM language pack .exe file from Exchange Server 2013 UM Language Packs and install the UM language pack on the Mailbox server by using the UMLanguagePack.de-de.exe installation file. After you've installed the UM language pack, you can set the default language to a language other than English (en-US) on UM auto attendants.

For additional tasks related to UM languages, see UM languages, prompts, and greetings procedures.

What do you need to know before you begin?

- Estimated time to complete: Less than 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- Before you perform these procedures, confirm that a UM auto attendant has been created. For detailed steps, see Create a UM auto attendant.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to configure the default language setting

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**.
2. In the list view, select the UM dial plan you want to modify, and then on the toolbar, click **Edit** .
3. On the **UM dial plan** page, under **UM Auto Attendants**, select the UM auto attendant you want to change, and then click **Edit** .
4. On the **General** page, under **Language for automated voice interface**, select the required language from the drop-down list.
5. Click **Save** to accept your changes.

Use the Shell to configure the default language setting

This example sets the default language on the UM auto attendant `MyUMAutoAttendant` to English (Great Britain).

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -Language
en-GB
```

This example sets the default language on the UM auto attendant `MyUMAutoAttendant` to German.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -Language
de-DE
```

Remove a UM language pack

Unified Messaging > UM languages, prompts, and greetings > UM languages, prompts, and greetings procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-14*

You can use the EAC or the Shell to manage Unified Messaging (UM) languages on Mailbox servers running the Microsoft Exchange Unified Messaging service. However, to remove a language from the list on a UM dial plan, you must remove the appropriate UM language pack from the Mailbox server by using the **Setup.exe /RemoveUmLanguagePack** command. After you remove the UM

language pack from the Mailbox server, the language won't be available when you configure a UM dial plan or a UM auto attendant. You can view the UM language packs that are installed by viewing the properties of the Mailbox server or by using the **Get-UMService** cmdlet.

For additional tasks related to UM languages, see UM languages, prompts, and greetings procedures.

What do you need to know before you begin?

- Estimated time to complete: Less than 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mailbox server (UM service)" entry in the Unified Messaging permissions topic.
- Verify that a UM language pack other than en-US is installed.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

Use Setup.exe to remove a UM language pack

At a command prompt, run the following command.

```
Setup.exe /RemoveUmLanguagePack:<UmLanguagePackName>
```

In the previous command, *<UmLanguagePackName>* is the name of the UM language pack, for example, fr-FR.

Caution:

You can't use the Setup.exe file that's located in the \Bin folder to remove a UM language pack after you've installed any updates. You must use the Setup.exe file from the Exchange 2013 DVD or the downloaded source files. If you don't, you'll see the following error: There is a version mismatch between the running application and the installed application.

Import and export custom greetings, announcements, menus, and prompts

Applies to: *Exchange Server 2010 Service Pack 2 (SP2)*

Topic Last Modified: *2013-04-16*

You can import and export the audio files that you've recorded to use on Unified Messaging (UM) dial plans and auto attendants. For example, you might want to export and save a copy of an audio file if you're upgrading from a previous version of Exchange. Or, you might need to import a copy of a recorded audio prompt before configuring a dial plan or auto attendant.

The audio files are used for the following purposes:

- On UM dial plans, audio files are used for customized welcome greetings and informational announcements. They're played when Outlook Voice Access users call in to an Outlook Voice Access number.
- On UM auto attendants, audio files are used for customized non-business and business hours greetings, informational announcements, menu prompts, and navigation menus. They're played when callers call in to a UM auto attendant.

The following audio file formats are supported for custom greetings, announcements, menus, and prompts:

- .wma files encoded with Windows Media Audio 9.2 - 96 kbps/44 kHz/stereo 1-pass CBR (Windows Sound Recorder)
- Windows Media Audio Voice 9 - 8 kbps/8 kHz/Mono, and .wav files encoded with the Linear PCM (16 bit/sample), 8 kilohertz (kHz) audio codec

You import the audio files that are used by UM dial plans and auto attendants into the system mailbox named {e0dc1c29-89c3-4034-b678-e6c29d823ed9} and export the audio files from this system mailbox. The audio files can be imported and exported by using the **Import-UMPrompt** and **Export-UMPrompt** cmdlets.

For additional management tasks related to UM dial plans, see UM dial plan procedures.

For additional management tasks related to UM auto attendants, see UM auto attendant procedures.

What do you need to know before you begin?

- Estimated time to complete: 3 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM dial plans" and "UM auto attendants" entries in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- Before you perform these procedures, confirm that a UM auto attendant has been created. For detailed steps, see Create a UM auto attendant.
- You can only use the Shell to perform this procedure.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the Shell to import custom greetings, announcements, menus, and prompts for UM dial plans and auto attendants

This example imports the welcome greeting file named welcomegreeting.wav from d:\UMPrompts into the UM dial plan `MyUMDialPlan`.

```
[byte[]]$c = Get-content -Path "d:\UMPrompts
\welcomegreeting.wav" -Encoding Byte -ReadCount 0
Import-UMPrompt -UMDialPlan MyUMDialPlan -PromptFileName
"welcomegreeting.wav" -PromptFileData $c
```

This example imports the welcome greeting file named welcomegreeting.wav from d:\UMPrompts into the UM auto attendant `MyUMAutoAttendant`.

```
[byte[]]$c = Get-content -Path "d:\UMPrompts
\welcomegreeting.wav" -Encoding Byte -ReadCount 0
Import-UMPrompt -UMAutoAttendant MyUMAutoAttendant -
PromptFileName "welcomegreeting.wav" -PromptFileData $c
```

Use the Shell to export custom greetings, announcements, menus, and prompts from UM dial plans and auto attendants

This example exports the welcome greeting for the UM dial plan `MyUMDialPlan` and saves it as the file named welcomegreeting.wav.

```
$prompt = Export-UMPrompt -PromptFileName
"customgreeting.wav" -UMDialPlan MyUMDialPlan
set-content -Path "d:\DialPlanPrompts\welcomegreeting.wav"
-Value $prompt.AudioData -Encoding Byte
```

This example exports the business hours welcome greeting for the UM auto attendant

MYUMAutoAttendant and saves it as the file named BusinessHoursWelcomeGreeting.wav.

```
$prompt = Export-UMPrompt -BusinessHoursWelcomeGreeting -
UMAutoAttendant MyUMAutoAttendant
set-content -Path "d:\UMPrompts
\BusinessHoursWelcomeGreeting.wav" -Value $prompt.AudioData
-Encoding Byte
```

Import custom prompts from Exchange 2007 to Exchange 2013

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-04-16*

You can import the audio files that contain custom greetings, announcements, menus, and prompts from Exchange 2007 Unified Messaging (UM) to Exchange 2013 Unified Messaging. Using a Shell script, the prompts are imported into an Exchange system mailbox named {e0dc1c29-89c3-4034-b678-e6c29d823ed9}, which is created when you install Microsoft Exchange 2013. This system mailbox is used in Unified Messaging to store dial plan and auto attendant custom greetings, announcements, menus, prompts, and UM reports.

The audio files, in .wav or .wma format, are used as follows:

- On UM dial plans, audio files are used for customized welcome greetings and informational announcements. They're played when Outlook Voice Access users call in to an Outlook Voice Access number.
- On UM auto attendants, audio files are used for customized non-business and business hours greetings, informational announcements, menu prompts, and navigation menus. They're played when callers call in to a UM auto attendant.

You use the MigrateUMCustomPrompts.ps1 script to migrate a copy of all Exchange Server 2007 UM custom greetings, announcements, menus, and prompts to Exchange 2013 UM for all Exchange 2007 UM dial plans and UM auto attendants.

By default, the MigrateUMCustomPrompts.ps1 script is located in the <Program Files>\Microsoft \Exchange Server\V15\Scripts folder on an Exchange 2013 server.

Note:

The MigrateUMCustomPrompts.ps1 script is included with Exchange 2013. It must be run on an Exchange 2013 Mailbox server in the same organization with your Exchange 2007 UM

servers.

For additional management tasks related to UM dial plans, see UM dial plan procedures.

For additional management tasks related to UM auto attendants, see UM auto attendant procedures.

What do you need to know before you begin?

- Estimated time to complete: 3 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM dial plans" and “UM auto attendants” entries in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- Before you perform these procedures, confirm that a UM auto attendant has been created. For detailed steps, see Create a UM auto attendant.
- You can only use the Shell to perform this procedure. To learn how to open the Shell in your on-premises Exchange organization, see Open the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

Use the MigrateUMCustomPrompts.ps1 script to migrate a copy of all custom prompts for UM dial plans and auto attendants

1. Click **Start** > **All Programs** > **Microsoft Exchange Server 2013** > **Exchange Management Shell**.
2. In the Shell, at the prompt, type the path to the script. For example, type **cd "D:\Program Files \Microsoft\Exchange Server\V15\Scripts"**, and then press Enter.
3. At the Shell prompt, type **".\MigrateUMCustomPrompt",** and then press Enter.

Enable custom prompt recording using the telephone user interface

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-04-16*

You can use the Shell to enable the recording of custom prompts and greetings for Unified Messaging (UM) dial plans and auto attendants using the telephone user interface (TUI). This can be useful when you want to change a custom greeting or announcement by using the EAC or the Shell, or when there's an emergency such as an organization closure because of severe weather. When you're changing a custom greeting or announcement on a UM auto attendant, you must enable TUI prompt recording on the dial plan that the UM auto attendant is linked to.

For additional management tasks related to UM dial plans, see **UM Dial Plan Procedures**.

For additional management tasks related to UM auto attendants, see UM auto attendant procedures.

What do you need to know before you begin?

- Estimated time to complete: 3 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM dial plans" and "UM auto attendants" entries in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- Before you perform these procedures, confirm that a UM auto attendant has been created. For detailed steps, see Create a UM auto attendant.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the Shell to enable a custom prompt or greeting recording using the TUI

To record custom prompts and greetings by using the telephone user interface (TUI), follow these steps:

1. Create a domain user account that cannot log on interactively.
2. Delegate the Exchange Organization Administrator role to the domain user account.

3. Create a mailbox for the domain user.
4. Enable the domain user's mailbox for Unified Messaging.

Important:
Allow only those administrators who are managing prompts and greetings access to the extension number and PIN for the user account. Use this user account only for managing prompts over the telephone.

5. Create and save a .wav or .wma file to use for a custom greeting for the UM dial plan or auto attendant.

Note:
MP3 files can't be used for custom prompts.

6. Use the EAC or the Shell to configure the dial plan to use the custom welcome greeting or configure the auto attendant to use the business or non-business hours greeting. For details about configuring a dial plan, see Enable a customized greeting for Outlook Voice Access users. For details about configuring an auto attendant, see Enable a customized business hours greeting or Enable a customized non-business hours greeting.
7. Run the following cmdlet:

```
Set-UMDialPlan -identity MyUMDialPlan -
TUIPromptEditingEnabled $true
```

Note:
Before you can enable the recording of a custom prompt or greeting, you must sign in to the mailbox that's set up for recording prompts. After you record the new prompt or greeting, you must sign out and then sign back in before you can hear the new prompt or greeting when you use the TUI.

Perform TUI prompt recording on a UM auto attendant

1. Verify that the auto attendant is linked to the dial plan that you've enabled for TUI prompt recording.
2. Call a phone number that's been configured on the UM auto attendant.
3. While the non-business or business hours greeting for the auto attendant is being played, press the pound key (#), and then press the star key (*).
4. You'll be prompted to enter the extension number for the user. Enter the extension number of the UM-enabled user who has permission to perform TUI prompt recording.
5. You'll be prompted for a PIN. Enter the user's PIN.
6. Follow the system prompts to edit or update the greeting or informational announcement for the auto attendant.

Perform TUI prompt recording on a UM dial plan

1. Call an Outlook Voice Access number you use to sign in to Outlook Voice Access.
2. While the welcome greeting for the dial plan is being played, press the pound key (#), and then

press the star key (*).
3. If you're calling from a phone that's used by a UM-enabled user, you'll be prompted for a PIN. Instead of entering the PIN, press the star key (*). You'll be prompted for an extension number. Enter the extension number of the UM-enabled user who has permission to perform TUI prompt recording.
4. If you're calling from a phone that's not used by a UM-enabled user, you'll automatically be prompted for an extension number. Enter the extension number of the UM-enabled user who has permission to perform TUI prompt recording.
5. You'll be prompted for a PIN. Enter the user's PIN.
6. Follow the system prompts to edit or update the welcome greeting for the dial plan or the informational announcement.

Telephone system integration with UM

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-20*

To successfully deploy Unified Messaging (UM), you must have a good understanding of basic telephony concepts and telephony components. After you understand telephony basics, you can integrate UM into an Exchange organization. Basic concepts and components include the following:

- Circuit-switched and packet-switched networks
- Private Branch eXchange (PBX)
- IP PBX
- Voice over Internet Protocol (VoIP)
- VoIP gateways

In an on-premises, hybrid, or Office 365 environment, connecting and configuring the required telephony components is the most complex and important step in successfully deploying UM, with or without Lync Server Enterprise Voice. You'll need to connect and configure VoIP gateways, advanced VoIP gateways, PBXs, IP PBXs, and session border controllers (SBCs) for a traditional telephony network and connect to a telephony network if you'll be using Microsoft Lync Server and UM.

Planning and deploying a new deployment of UM or upgrading a legacy voice mail system can pose challenges for organizations. It requires significant knowledge about VoIP gateways, PBXs, IP PBXs, Microsoft Lync Server, and Unified Messaging. Depending on your technical experience with Exchange and voice mail systems, you might want to obtain the assistance of a Unified Messaging specialist. An Exchange Unified Messaging specialist will help make sure that there's a smooth transition from a legacy or third-party voice mail system to Exchange Unified Messaging. For more information about how to contact a Unified Messaging specialist, see Microsoft Exchange Server

2013 Unified Messaging (UM) Specialists.

Integrating your telephony network

Unified Messaging requires that you integrate your Exchange Server deployment with your existing telephony network or integrate UM with Microsoft Lync Server for your organization. To successfully deploy and manage UM voice mail you need to make a careful analysis of your existing telephony infrastructure or your Microsoft Lync Server Enterprise Voice deployment and complete the necessary planning steps.

VoIP gateways

When you're deploying UM in an Exchange organization, you must either install, deploy, and configure a single or multiple VoIP gateways to connect to the PBXs in your telephony network, or install, deploy, and configure Session Initiation Protocol (SIP)-enabled PBXs or IP PBXs.

A VoIP gateway is a third-party hardware device that connects a legacy PBX to your LAN. The VoIP gateway lets the PBX system communicate with the Exchange servers in your organization.

UM relies on the VoIP gateway's ability to translate or convert Time Division Multiplexing (TDM) or circuit-switched based protocols like ISDN and QSIG from a PBX to IP-based or VoIP-based protocols like SIP, Realtime Transport Protocol (RTP), or T.38 for Realtime Fax Transport. The VoIP gateway is integral to the functionality and operation of UM. The VoIP gateway can also connect to PBX systems that use VoIP instead of public switched telephone network (PSTN) circuit-switched protocols.

Choosing the correct VoIP gateway, IP PBX, SIP-enabled PBX, or SBC is only the first part of integrating your telephony network with UM. You must configure those devices to work with UM. In both on-premises and hybrid deployments, you would need to deploy the required Client Access and Mailbox servers, and create and configure all necessary UM components. For Office 365 with hosted voice mail, you're not required to install and configure any server. The components allow you to make the connection from your telephony, circuit-switched network to your IP data network and to enable voice mail for the users in your organization. For details and supported telephony devices, see the following resources:

- Telephony advisor for Exchange 2013
- Configuration notes for supported VoIP gateways, IP PBXs, and PBXs
- Configuration notes for supported session border controllers

Microsoft Lync Server

Unified Messaging can use Microsoft Lync Server to combine voice messaging, instant messaging, enhanced presence, audio/video conferencing, and email into a familiar, integrated communications experience. Providing Enterprise Voice features to the users in your organization by integrating UM and Microsoft Lync Server has the following benefits:

- Enhanced presence notifications across a variety of applications that keep users informed of the availability of contacts.
- Integration of instant messaging, voice messaging, conferencing, email, and other communication modes, which enables users to select the most appropriate mode for the task. Users can also switch from one mode to another as needed.
- Availability of communications alternatives from any location where an Internet connection is available.
- A smart client (Microsoft Lync) for telephony, instant messaging, and conferencing.
- Continuity of the user experience across multiple devices.

The Exchange UM routing component handles voice mail routing between Lync Server and Exchange servers to integrate Lync Server with Unified Messaging features. The Exchange UM routing component found in Lync Server also handles rerouting of voice mail over the PSTN if Exchange servers aren't available. If you have Enterprise Voice deployed at branch office sites, and those sites don't have a resilient WAN link to a central site, a Survivable Branch Appliance that you deploy at the branch site provides voice mail for branch users if a WAN link goes down. When the WAN link is unavailable, the Survivable Branch Appliance does the following:

- Reroutes unanswered calls over the PSTN to an Exchange server in the central site.
- Provides the ability for a user to retrieve voice messages over the PSTN.
- Queues missed call notifications, and then uploads them to the Exchange server when the WAN link is restored.

For more information about Microsoft Lync Server, see Microsoft Lync Server.

⚠**Warning:**
When you're integrating Unified Messaging and Lync Server in an on-premises or hybrid deployment, missed call notifications aren't available to users who have a mailbox located on Exchange 2007 or Exchange 2010 Mailbox servers. A missed call notification is generated when a user disconnects before the call is sent to a Mailbox server.

Telephony concepts and components

Exchange Server 2013 > Unified Messaging > Telephone system integration with UM >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-04-25*

If you're planning and deploying Microsoft Exchange 2013 Unified Messaging (UM) on your network, you must understand Unified Messaging and telephony networks. This topic provides an overview of telephony infrastructure concepts and components that will help you plan and deploy servers running Exchange 2013 Unified Messaging.

Contents

Overview

In versions of Microsoft Exchange before Exchange Server 2007, the Exchange administrator's main responsibility was managing email messages and, sometimes, managing a network infrastructure. Earlier versions of Exchange didn't have Unified Messaging capabilities. Exchange Server version 5.5, Exchange 2000 Server, and Exchange Server 2003 administrators focused on the Exchange environment and the network infrastructure, and relied heavily on telephony consultants to manage their telephony environment and infrastructure.

Concepts and components

To successfully deploy Unified Messaging in Exchange 2013, you must have a good understanding of basic telephony concepts and telephony components. After you gain a good understanding of telephony basics, you can successfully integrate Exchange 2013 Unified Messaging into an Exchange 2013 organization. Basic concepts and components include the following:

- Circuit-switched and packet-switched networks
- Private Branch eXchange (PBX)
- IP PBX
- Voice over Internet Protocol (VoIP)
- VoIP gateways

Circuit-switched networks

In circuit-switched networks, such as the Public Switched Telephone Network (PSTN), multiple calls are transmitted across the same transmission medium. Frequently, the medium used in the PSTN is copper. However, fiber optic cable might also be used.

A circuit-switched network is a network in which there exists a dedicated connection. A dedicated connection is a circuit or channel set up between two nodes so that they can communicate. After a call is established between two nodes, the connection may be used only by these two nodes. When the call is ended by one of the nodes, the connection is canceled.

Note:

PSTN is a grouping of the world's public circuit-switched telephone networks. This grouping resembles the way that the Internet is a grouping of the world's public IP-based packet-switched networks.

There are two basic types of circuit-switched networks: analog and digital. Analog was designed for voice transmission. For many years, the PSTN was only analog, but today, circuit-based networks such as the PSTN have transitioned from analog to digital. To support an analog voice transmission signal over a digital network, the analog transmission signal must be encoded or converted into a digital format before it enters the telephony WAN. On the receiving end of the connection, the digital signal must be decoded or converted back into an analog signal format.

There are advantages and disadvantages to circuit-switched networks. Circuit-switched networks have several disadvantages. Circuit-switched networks can be relatively inefficient, because bandwidth can be wasted. This isn't the case when VoIP is used on a packet-switched network. VoIP shares the available bandwidth with all other network applications and makes more efficient use of the available bandwidth. Another disadvantage to circuit-switched networks is that you have to provision for the maximum number of telephone calls that will be required for peak usage times and then pay for the use of the circuit or circuits to support the maximum number of calls.

Circuit switching has one big advantage over packet-switched networks. In a circuit-switched network, when you use a circuit, you have the full circuit for the time that you're using the circuit without competition from other users. This isn't the case with packet-switched networks.

Note:

Synchronous Digital Hierarchy (SDH) has become the primary transmission protocol for most PSTN networks. SDH is carried over fiber optic networks.

Return to top

Packet-switched networks

Packet switching is a technique that divides a data message into smaller units called packets. Packets are sent to their destination by the best route available, and then they are reassembled at the receiving end.

In packet-switched networks such as the Internet, packets are routed to their destination through the most expedient route, but not all packets traveling between two hosts travel the same route, even those from a single message. This almost guarantees that the packets will arrive at different times and out of order. In a packet-switched network, packets (messages or fragments of messages) are individually routed between nodes over data links that may be shared by other nodes. With packet switching, unlike circuit switching, multiple connections to nodes on the network share the available bandwidth.

Note:

With circuit switching, all packets go to the receiver in order and along a single path.

Packet-switched networks exist to enable data communication on the Internet throughout the world. A public data network or packet-switched network is the data counterpart to the PSTN.

Packet-switched networks are also found in such network environments as LAN and WAN networks. A WAN packet-switched environment relies on telephone circuits, but the circuits are arranged so that they retain a permanent connection with their endpoint. In a LAN packet-switched environment, such as with an Ethernet network, the transmission of the data packets relies on packet switches, routers, and LAN cables. In a LAN, the switch establishes a connection between two segments only long enough to send the current packet. Incoming packets are saved to a temporary memory area or buffer in memory. In an Ethernet-based LAN, an Ethernet frame contains the payload or data portion of the packet and a special header that includes the media access control (MAC) address information for the source and destination of the packet. When the packets arrive at their destination, they are put back in order by a packet assembler. A packet assembler is needed because of the different routes that the packets may take.

Packet-switched networking has made it possible for the Internet to exist and, at the same time, has made data networks—especially LAN-based IP networks—more available and widespread.

Return to top

PBX

A legacy PBX is a telephony device that acts as a switch for switching calls in a telephony or circuit-switched network.

Note:

A legacy PBX is a PBX that cannot pass IP packets. In many businesses, legacy PBXs have been replaced by IP PBXs.

A PBX is a telephony device used by most medium-size and larger-size companies. A PBX enables users or subscribers of the PBX to share a certain number of outside lines for making telephone calls considered external to the PBX. A PBX is a much less expensive solution than giving each user in a business a dedicated external telephone line. Telephone sets, in addition to fax machines, modems, and many other communication devices, can be connected to a PBX.

The PBX equipment is typically installed at a business's premises and connects calls between the telephones located and installed in the business site. A limited number of outside lines, also known as trunk lines, are typically available for making and receiving calls external to the business from an external source such as the PSTN.

Internal business calls made to external telephone numbers using a PBX are made by dialing 9 or 0 in some systems followed by the external number. An outgoing trunk line is automatically selected to complete the call. Conversely, the calls placed between users within the business don't ordinarily require special dialing digits or use of an external trunk line. This is because the internal calls are routed or switched by the PBX between telephones physically connected to the PBX.

In medium-size and larger-size businesses, the following PBX configurations are possible:

- A single PBX that supports the whole business.
- A grouping of two or more PBXs not networked or connected to each other.
- A grouping of two or more PBXs connected together or networked.

Note:
An Exchange 2013 UM dial plan can span more than one PBX or IP PBX.

Return to top

IP PBX

An IP PBX is a PBX that supports the IP protocol to connect phones using an Ethernet or packet-switched LAN and sends its voice conversations in IP packets. A hybrid IP PBX supports the IP protocol for sending voice conversations in packets, but also connects traditional analog and digital circuit-switched Time Division Multiplex (TDM) telephones. An IP PBX is telephone switching equipment that resides in a private business instead of the telephone company.

IP PBXs are frequently easier to administer than legacy PBXs, because administrators can easily configure their IP PBX services using an Internet browser or another IP-based utility. Plus, no additional wiring, cabling, or patch panels must be installed. With an IP PBX, moving an IP-based telephone is as simple as unplugging a telephone and plugging it in at a new location, instead of the costly service calls to move a telephone from legacy PBX vendors. Additionally, businesses that own an IP PBX don't have the additional infrastructure costs required to maintain and manage two separate circuit-switched and packet-switched networks.

SIP-enabled PBXs

A SIP-enabled PBX is a telephony device that acts as a networking switch for switching calls in a telephony or circuit-switched network. However, the difference between a SIP-enabled PBX and a traditional PBX is that the SIP-enabled PBX can connect to the Internet and use the SIP protocol to make calls over the Internet.

SIP-enabled PBXs use a format for calls that includes a SIP URI containing a global E.164 number and the "user=phone" parameter. For example: sip:+14255551234@contoso.com;user=phone

The E164 number begins with a leading "+", and doesn’t contain a phone-context parameter or any separators. SIP-enabled PBXs support both TCP and UDP. UDP is still widely used with legacy systems. SIP-enabled PBXs also support Mutual Transport Layer Security (mutual TLS) and DNS lookups.

VoIP

Voice over Internet Protocol (VoIP) is a technology that contains hardware and software that enables people to use an IP-based network as the transmission medium for telephone calls. In VoIP,

voice data is sent in packets using IP instead of traditional circuit transmissions or the circuit-switched telephone lines of the PSTN. A VoIP gateway that you connect to your IP network uses VoIP protocols to send voice data packets between Exchange 2013 Client Access and Mailbox servers and a PBX system.

VoIP gateways

A VoIP gateway is a third-party hardware device or product that connects a legacy PBX to your LAN. The VoIP gateway lets the PBX system communicate with your Exchange 2013 Mailbox and Client Access servers running the Microsoft Exchange Unified Messaging and Unified Messaging Call Router services.

Note:
The VoIP gateway can also connect to PBX systems that use VoIP instead of PSTN circuit-switched protocols.

Exchange 2013 Unified Messaging relies on the VoIP gateway's abilities to translate or convert TDM or telephony circuit-switched based protocols like ISDN and QSIG from a PBX to IP-based or VoIP-based protocols like Session Initiated Protocol (SIP), Realtime Transport Protocol (RTP), or T.38 for Realtime Facsimile Transport. The VoIP gateway is integral to the functionality and operation of Unified Messaging.

Important:
After you install the VoIP gateway, IP PBX, or SIP-enabled PBX, you must create a UM IP gateway to represent the physical device. After you create a UM IP gateway, the Client Access and Mailbox servers linked with the UM IP gateway will send a SIP OPTIONS request to the VoIP gateway, IP PBX, or SIP-enabled PBX to ensure that the device is responsive. If the VoIP gateway doesn't respond to the SIP OPTIONS request from the Mailbox server, the Mailbox server will log an event with ID 1088 stating that the request failed. To resolve this issue, ensure that the VoIP gateway, IP PBX, or is available and online and that the Unified Messaging configuration on both the Client Access and Mailbox server is correct.

For more information about IP PBX and PBX configurations, see PBX and IP PBX configurations.

PBX and IP PBX configurations

Applies to: *Exchange Server 2010 Service Pack 2 (SP2)*

Topic Last Modified: *2013-04-29*

Increasingly, organizations are purchasing, installing, and maintaining the hardware components, for example, Private Branch eXchanges (PBXs) or IP PBXs, that are required to support their own telephony systems. Many organizations are buying their own telephony equipment and training their staff to reduce expenses associated with maintaining their telephony systems and because they want more control over the telephony features they offer.

For an organization to own and maintain their telephony network, they must buy the required telephony hardware components. They must also consider the day-to-day maintenance of the telephony equipment and the training required for their staff to support their telephony system. This topic discusses the different types of telephony business or organizational systems and the telephony hardware components they require. The topic also gives examples of the different types of telephony configurations.

Important:

We recommend that all customers who plan to deploy Microsoft Exchange 2013 Unified Messaging obtain the help of a UM specialist. This will help ensure a smooth upgrade from a legacy voice mail system. Rolling out a new UM deployment or performing an upgrade of an existing voice mail system requires significant knowledge about PBXs, IP PBXs, and Unified Messaging. For more information about who to contact, see the Microsoft PinPointwebsite.

Contents

Overview of telephony systems

In circuit-switched networks, such as the Public Switched Telephone Network (PSTN), multiple calls are transmitted across the same transmission medium. Frequently, the medium that's used in the PSTN is copper. However, fiber optic cable might also be used.

A circuit-switched network is a network in which there exists a dedicated connection. A dedicated connection is a circuit or channel that's set up between two nodes so they can communicate. After a call is established between two nodes, the connection may be used only by these two nodes. When the call is ended by one of the nodes, the connection is canceled.

Different types or categories of telephone systems found in businesses and organizations include a circuit-based network, an IP-based network, or both. Each type of telephone system has distinct

advantages and disadvantages you need to consider when planning and implementing a telephony system.

- **Centrex:** Centrex is a type of telephone service that telephone companies lease to businesses and organizations. A traditional Centrex telephone system eliminates the need for a business or organization to purchase the telephony hardware used onsite to support the organization's telephone system. Typically, Centrex systems are used by small offices that rent Centrex services from a telephone company on a line-by-line and month-by-month basis. Centrex telephony systems are sometimes used by larger organizations, but are most frequently found in government, public, and private organizations. Centrex frequently uses analog telephone lines for the connections to a business or organization. But it can also use T1-circuits with a demultiplexer onsite to support analog and digital telephones or ISDN lines.

In a Centrex-based telephony system, the telephone company's central office acts as the telephone exchange. It's designed specifically to support the needs of a given organization. The central telephone office routes the calls that originate from inside the company to the appropriate internal or external telephone number. Centrex uses the telephone company’s central office exchange to route internal calls back to an extension. For example, with Centrex, the telephone exchange or telephone company's central office knows which extensions are internal. So an employee who's located within the organization's telephony network can dial another employee in the same telephony network or dial plan by using a four-digit extension number. When a call is dialed to the internal telephone extension number, it's forwarded to the telephone company’s central office and then routed back to the extension number that initiated the call.

A variation of a traditional Centrex telephony system is called *IP Centrex*. In an IP Centrex telephone system, the call is sent through a Voice over IP (VoIP) gateway located at a telephone company’s central office or located onsite at a service provider. In this kind of telephone system, the VoIP gateway translates the call into IP-based data packets that can be sent over the Internet or over a VoIP–based network. However, if the call is sent over the Internet, there's typically another VoIP gateway that receives the call and then translates the call back to a traditional circuit-switched call.

Organizations that currently have a traditional Centrex telephone system in place have to install, deploy, and maintain one or more VoIP gateways for Unified Messaging to work correctly. Unified Messaging may require that you install, deploy, and maintain VoIP gateways to work with IP Centrex. Several variables will determine whether you need a VoIP gateway. These variables include the type of telephones used in your organization (analog, digital, or IP) and the protocols supported by the IP Centrex system.

- **Key telephone:** In a Key telephone system, the telephone company’s central office is connected to the organization using standard analog or digital telephone lines. A single telephone extension number is connected to multiple telephones so when a call is placed into the organization using this telephone number, all the telephones associated with that line or extension number will ring at the same time.

With Key telephone systems, individual users share lines across telephones. Therefore, callers won't experience frequent busy signals when they try to call into an organization. Key telephone systems are typically used by small offices where internal call volume is high but external call volume is low.

Key telephone systems have become more sophisticated over time and can work with Unified Messaging if a VoIP gateway is added. However, some less sophisticated systems may not work even if a supported VoIP gateway is used.

- **PBX:** A legacy PBX is a telephony device that switches calls in a telephony or circuit-switched network. A legacy PBX is a PBX that doesn't have a network adapter and can't pass IP packets. Because they can't pass IP packets, some businesses and organizations have replaced legacy PBXs with IP PBXs. For a list of PBXs supported by Unified Messaging, see Telephony advisor for Exchange 2013.

PBXs are used by most medium- and larger-sized companies. A PBX enables users or subscribers of the PBX to share a certain number of outside lines for making telephone calls considered external to the PBX. A PBX is a much less expensive solution than giving each user in a business a dedicated external telephone line. Telephones, in addition to fax machines, modems, and many other communication devices, can be connected to a PBX.

The PBX equipment is typically installed on an organization's premises and connects calls between the telephones located onsite and the telephone company. A limited number of outside lines, also known as trunk lines, are typically available for making and receiving calls external to the business from an external source such as the PSTN.

To enable a legacy PBX to be used with Unified Messaging, you need to deploy a supported VoIP gateway. For a list of supported VoIP gateways, see Telephony advisor for Exchange 2013.

- **IP PBX:** An IP PBX is a PBX that has a network adapter that supports the IP protocol. It's a piece of telephone switching equipment that generally resides in an organization or business instead of being located at a telephone company office. There are two types of IP PBXs: traditional IP PBXs and hybrid IP PBXs. Both traditional IP PBXs and hybrid IP PBXs support the IP protocol for sending voice conversations in packets to VoIP-based telephones. However, hybrid IP PBXs also connect traditional analog and digital telephones.

IP PBXs are frequently easier to administer than legacy PBXs, because administrators can more easily configure IP PBX services using an Internet browser or another IP-based tool. Also, no additional wiring, cabling, or patch panels have to be installed. With an IP PBX, you can move an IP-based telephone by merely unplugging the telephone and plugging it in at a new location. This lets you avoid the costly service calls required to move a telephone from legacy PBX vendors. Additionally, organizations that own an IP PBX don't have to incur the additional infrastructure costs required to maintain and manage separate circuit-switched and packet-switched networks. For a list of IP PBXs supported for Unified Messaging, see Telephony advisor for Exchange 2013.

Return to top

Legacy and traditional PBX configurations

On telephony networks that have legacy or traditional PBXs, a PBX does the following:

- Creates connections or circuits between the telephone sets of two users.
- Maintains the connection as long as the users need the connection.
- Provides information for accounting purposes (for example, meters calls).

In addition to the three functions included in the previous list, PBXs may offer other calling features such as:

- Auto attendants
- Call accounting
- Call pick-up
- Call transfer
- Call waiting
- Conference calling
- Direct Inward Dialing (DID)
- Do Not Disturb (DND)

Although there are several manufacturers of PBXs, they all fit into two basic categories: analog and digital. These types of PBXs are frequently known as *legacy* or *traditional* PBXs.

Typically, PBX systems are connected to the telephone company's central office by using special telephone lines, known as T1- and E1-lines. T1- and E1-lines have multiple channels. These telephone lines are also known as *trunk lines*. They let the central office or the PBX send multiple calls over the same line for better efficiency using a simplified wiring layout. A PBX can also work with analog or ISDN lines.

By correctly configuring your PBX, you can control how many channels or lines you want to configure to receive calls that come from external callers and how many channels or lines to devote to calls that come from callers inside your organization. Configuring the number of channels or lines helps prevent busy signals and lets you configure the number of channels or lines devoted to applications such as call centers. Correctly configuring your PBX is a cost-effective method for managing the channels or lines in your organization because it reduces the number of leased lines required.

A PBX can route a specific dialed telephone number to a specific telephone so users can have their own individual telephone number or extension number. This is known as a Direct Inward Dialing number. When the telephone number is dialed for a user, the telephone company sends the DID number to the PBX by using Dialed Number Identification Service (DNIS). Because the telephone company uses DNIS to send the number, there's no need for operator intervention to route the call. The PBX has the information about the call to correctly route it to the number that was dialed by the caller. For a list of PBXs supported by Unified Messaging, see Telephony advisor for Exchange 2013.

Return to top

Analog and digital PBXs

Analog PBXs send voice and call signaling information, such as the touch tones of a dialed telephone number, as an analog sound. Therefore, the sound is never digitized. To correctly direct the call, the PBX and the telephone company's central office have to listen for the signaling information.

Note:

Touchtone is more technically known as dual tone multi-frequency. When a caller presses a key on a telephone keypad, the telephone produces two separate tones: a high-frequency tone and a low-frequency tone. When a person speaks into the telephone, only a single tone or frequency is emitted. Sending two tones with different frequencies at the same time reduces the possibility that the signaling tones will be interpreted as a human voice or that a human voice will be interpreted as the signaling tones.

Digital PBXs encode or digitize the analog sound into a digital format. Digital PBXs typically encode the voice sounds using a standard industry audio codec like G.711 or G.729. After the digitized voice is encoded, it's sent over a channel by using circuit switching. Circuit switching sets up an end-to-end open connection. It leaves the channel open for the length of the call and for the caller's exclusive use. However, the signaling method that's used by the PBX depends on the manufacturer. PBX manufacturers may have their own proprietary signaling method for call setup.

Note:

Digital PBXs can support both digital and analog trunk lines.

In larger organizations, PBXs make it possible for employees in separate physical locations to contact one another by dialing an extension number for a user. This can be done by using a single PBX or may involve multiple PBXs networked together. PBXs at different office locations can be connected to a single transparent circuit-switched network by using T1- or E1-lines. When these lines connect PBXs together, they are frequently known as *tie lines*. The PBXs communicate with one another across the tie lines using a PBX-to-PBX protocol, such as QSIG. QSIG lets a set of PBXs act as if they are a single PBX.

This kind of PBX environment can also include advanced features, such as call transferring and telephone conferencing. In addition to allowing for advanced features, having two connected PBXs can also save the organization money because long distance charges between employees in the different locations will be reduced. This is because a call made between two employees remains on a tie line between the PBXs and requires that the user dial only an extension number for the other user instead of placing a long distance call.

In a telephony environment that includes a single or multiple analog or digital PBXs, a VoIP gateway is required between the PBX and the Exchange 2013 Client Access and Mailbox servers to convert the circuit-based protocols found on a telephony network into the IP-based protocols found on a data network. For more information about VoIP gateways, see the following topics:

- UM IP gateways
- Connect a VoIP gateway to communicate with a PBX

For a list of VoIP gateways supported for Unified Messaging, see Telephony advisor for Exchange 2013.

Return to top

IP PBX configurations

An IP PBX is a PBX that supports the IP protocol to connect telephones by using an Ethernet or packet-switched LAN. It sends voice conversations in IP or data packets. An IP PBX may have multiple interfaces. These include interfaces for a data network and other interfaces that allow for a connection to a telephony or circuit-switched network.

The development of real-time Internet protocols has made it possible to successfully send voice and fax messages over a data network. Such real-time Internet protocols include the VoIP protocols used with Unified Messaging: Session Initiation Protocol (SIP) over Transmission Control Protocol (TCP) for voice messaging. These protocols have made it possible to successfully send voice and fax messages over a data network. Real-time VoIP protocols are required to send voice messages over a packet-switched or data network so the delivery order and timing of data packets can be maintained and controlled. If these protocols weren't used to maintain and control the delivery and timing of the data packets, a person's voice would be broken up and sound incoherent or the images might appear garbled. For a list of IP PBXs supported for Unified Messaging, see Telephony advisor for Exchange 2013.

Note:
Unified Messaging supports only SIP over TCP.

Traditional IP PBX configurations

A standard or traditional IP PBX contains at least a single network interface that connects to a data network using VoIP protocols. It may also contain additional network interfaces or other telephony interfaces that enable it to connect to an existing telephony network such as the PSTN. The connection to the data network allows for communication with other VoIP hosts located on the data network by using IP data packets. These VoIP hosts include other IP PBXs, VoIP-based telephones, VoIP gateways, and Client Access and Mailbox servers that are running UM services. A traditional IP PBX doesn't support analog or digital telephones. It supports only VoIP telephones.

Because the IP PBX can already connect to a data network and can convert the circuit-based protocols from the PSTN to packet-switched VoIP protocols, a VoIP gateway may not be required to enable communication with Client Access and Mailbox servers on the data network.

IP PBX hybrid configurations

Hybrid IP PBXs can provide analog, digital, and VoIP-based capabilities. If the correct interfaces are installed on an IP PBX and the software that supports multiple types of interfaces is installed correctly, the IP PBX is considered a hybrid IP PBX. An IP PBX hybrid makes it possible to use a mixture of analog, digital, and IP-based telephones.

Most modern IP PBXs can support and provide all three types of voice communication or a traditional IP PBX can be upgraded to a hybrid IP PBX by installing the necessary interfaces and software or firmware updates.

The mixture of analog, digital, and IP-based telephones makes it possible for users in your

organization to use many new features and also provides great flexibility in your telephony environment. Using an IP PBX hybrid also allows for a more gradual migration to a completely VoIP-based telephony environment and voice messaging system for your organization.

Several factors determine whether a VoIP gateway will be required when you connect with Client Access and Mailbox servers. One of these factors is the compatibility of the VoIP protocols used by the IP PBX or hybrid IP PBX and Unified Messaging. If a VoIP gateway isn't required, it will reduce the complexity of the telephony infrastructure, and the support that you must have for Unified Messaging will be simpler.

Return to top

Calling or called party identification

Calling or called party identification is a telephone company service that can tell the person who is receiving the call the telephone number and sometimes the name of the person who is calling and other information about the call. This information is sent over a serial cable by using call signaling. When a call is received by a PBX or IP PBX from a telephone company, the call includes calling identification information such as the following:

- The calling party's number
- The called party's number
- Status codes such as a ring-no-answer, the state or condition of the line, line busy, and call forward always
- The line or port number that's being used for the call
- In telephony, the signaling information is used to exchange information between endpoints on a network to set up, control, and end calls. Several signaling methods used by VoIP gateways and IP PBXs are supported by Unified Messaging. The signaling method that's used depends on the type of device that's being used and the type of signaling method that's used by the telephone company. The most important factor is that the device that's connecting to the telephone company and to the VoIP gateway or IP PBX must support at least one of the signaling methods that enable calling or called party information to be sent and received by callers. For more information about signaling configuration information for a supported VoIP gateway, see Telephony advisor for Exchange 2013.

Although other signaling methods can be used, the two most popular signaling methods are as follows:

- **Simplified Message Desk Interface (SMDI):** SMDI is a protocol that's used to provide signaling, call control, and calling identification information from an interface between a telephone system and a voice mail system. It's used to provide the voice mail system with the information it needs to process an incoming call. Every time an incoming call is sent by using SMDI over a serial interface or RS-232 interface, the information that's sent will identify the line or port, the type of call, and the calling or called party numbers. The SMDI cable connects from a device such as a PBX to a serial connection on the VoIP gateway. However, SMDI is also used with IP PBXs. The SMDI protocol allows for a maximum of only 10 digits for each calling and called number. This is

a limitation of the protocol and can't be changed.

- **In-band:** In-band signaling allows for the exchange of signaling, call control, and calling identification information from a telephone company. This information is sent over the same channel and in the same band (300 Hz to 3.4 kHz) as the voice and other sounds that are being made during the call. For example, when a user places a call by using DTMF or touchtone dialing and talks to the called party, both the touchtone and the voice conversation use the same channel and band. In-band signaling is less secure because the control signals are exposed to the user and is a less popular signaling method than SMDI. In-band signaling applies only to Channel Associated Signaling (CAS).

Connect UM to your telephone system

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-30*

Unified Messaging (UM) combines voice messaging and email messaging into one mailbox that can be accessed from many different devices. Users can listen to their voice mail messages from their email Inbox or by using Outlook Voice Access from any telephone.

When you're deploying UM in a Microsoft Exchange organization, you must install, deploy, and configure a single or multiple Voice over IP (VoIP) gateways to connect to the Private Branch eXchanges (PBXs) in your telephony network or install, deploy, and configure Session Initiation Protocol (SIP)-enabled PBXs or IP PBXs. If you're upgrading your current voice mail system, you'll need to deploy the devices that connect to your telephony network, install your Exchange Client Access and Mailbox servers, and then create the required UM components that allow your telephony network to connect to your data network. This enables incoming calls from the telephony network to connect to your VoIP gateways, IP PBXs, or SIP-enabled PBXs, and those devices to connect to your Exchange organization.

If you're installing, deploying, and configuring either Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server, you won't use VoIP gateways, IP PBXs, or SIP-enabled PBXs to directly connect to Exchange Unified Messaging. Instead, a Lync Mediation Server and VoIP gateway or an advanced VoIP gateway that has the functionality of a Mediation Server and a VoIP gateway will allow you to connect to Exchange UM. UM users that are enabled for Enterprise Voice can retrieve, listen to, and respond to voice messages and make outbound calls. They also have access to other Lync-related features including presence and Instant Messaging (IM) by using Office Communicator or a Lync client.

The following information will help you set up and deploy UM and enable voice mail features for

users in your organization:

- Connect a VoIP gateway, IP PBX, or session border controller to UM Learn how to connect VoIP gateways or IP PBXs to UM.
- Telephony advisor for Exchange 2013 Learn about supported VoIP gateways, IP PBXs, and PBXs.
- Configuration notes for supported VoIP gateways, IP PBXs, and PBXs Learn how to set up your VoIP gateways, IP PBXs, and PBXs.

Telephony advisor for Exchange 2013

Unified Messaging > Telephone system integration with UM > Connect UM to your telephone system >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-21*

Unified Messaging (UM) requires that you integrate Microsoft Exchange with the existing telephony system for your organization. A successful deployment requires you to make a careful analysis of your existing telephony infrastructure and to perform the correct planning steps to deploy Unified Messaging.

The planning phase can be a significant challenge to Exchange administrators who have little or no experience with a telephony network. To help address this challenge, see Resources to Help with Your UM Deployment later in this topic.

To see the supported VoIP gateways for Unified Messaging, determine whether your PBX is supported using a specific VoIP gateway model or manufacturer, whether your IP PBX is supported using a direct SIP connection, or to see supported session border controllers (SBCs) for Exchange Online UM, click one of the following links:

- Supported VoIP gateways
- Supported PBXs when using an AudioCodes VoIP gateway
- Supported PBXs when using a dialogic VoIP gateway
  - PBXs supported when using a DMG1000 series Media Gateway
  - PBXs supported when using a DMG 2000 series Media Gateway
  - PBXs supported when using a DMG3000 series Media Gateway
- Supported IP PBXs
- Supported IP PBXs when using SIP media gateways
- Exchange Unified Messaging, Office Communications Server 2007 R2, and Microsoft Lync Server

Resources to help with your UM deployment

It's challenging to create guidelines for deploying telephony networks. They can be very different from one another because they can include VoIP gateways, IP PBXs, and PBXs with different

configuration settings, firmware, and requirements. However, several resources are available to help you successfully deploy Unified Messaging:

- **Unified Messaging specialists** UM specialists are systems integrators who have received technical training about Exchange Unified Messaging conducted by the Exchange engineering team. To help ensure a smooth transition to Unified Messaging from legacy voice mail systems, Microsoft recommends that all customers engage a UM specialist. For contact information, visit Microsoft Exchange Server 2013 Unified Messaging (UM) Specialists or Microsoft Pinpoint for Unified Messaging.
- **Configuration Notes for Supported VoIP Gateways, IP PBXs and PBXs** These configuration notes contain settings and other information that's very useful when you're configuring VoIP gateways, IP PBXs, and PBXs to communicate with the Unified Messaging servers that are on your network. For more information, see Configuration notes for supported VoIP gateways, IP PBXs, and PBXs.
- **Configuration Notes for Supported Session Border Controllers** These configuration notes contain settings and other information that's very useful when you're configuring session border controllers (SBCs) to communicate with the Unified Messaging servers in hybrid and Exchange Online UM deployments. For more information, see Configuration notes for supported session border controllers.

Before you engage a Unified Messaging specialist, you should be able to answer key questions that they'll ask. Having the answers to the following questions will help make the conversation between you and the UM specialist productive:

- How many existing telephone or voice mail users, or both, are in your organization?
- How many users do you intend to provide with Unified Messaging?
- Which PBX or PBXs do you intend to use for integration with Unified Messaging?
- How many PBXs does your organization have? Specify the vendors, types (circuit- or IP-based), models, and firmware versions.
- Are the PBXs networked, and are they centralized or located in multiple locations?
- What voice mail system or systems does your organization currently use? Specify the vendors, types, models, and firmware versions.
- How are the voice mail systems integrated into your PBXs (Analog, T1/E1, PRI, Digital set emulation, VoIP, other)?
- Are you currently using voice networking?
- What type of fax system or systems does your organization use, and does the fax system or systems support inbound fax routing to Exchange?
- Does your organization use automated attendants?
- Do you need support for phone-only users, that is, users who won't have email access?

Supported VoIP gateways

Integrating Unified Messaging with PBXs requires you to use one or more VoIP gateways to translate the circuit-switched protocols that are used by TDM-based PBXs to IP-based, packet-switched protocols that are used by Unified Messaging. VoIP gateway vendors with several models

of VoIP and media gateways have been tested and are supported for Unified Messaging.

Interoperability testing of Unified Messaging with VoIP gateways, IP PBXs, and SBCs is now integrated with the Microsoft Unified Communications Open Interoperability Program. For more information, see Microsoft Unified Communications Open Interoperability Program.

The Microsoft Unified Communications Open Interoperability Program qualification program for VoIP gateways, IP PBXs, and advanced VoIP gateways ensures that customers have a seamless setup and support experience when they're using qualified telephony VoIP gateways and IP PBXs with Microsoft Unified Communications software. Only products that meet rigorous and extensive testing requirements and conform to the specifications and test plans receive qualification.

For details about configuring supported VoIP gateways, IP PBXs, PBXs, and SBCs, see one of the following resources:

- Configuration notes for supported VoIP gateways, IP PBXs, and PBXs
- Configuration notes for supported session border controllers

Interoperability was verified for the following VoIP gateway vendors:

- AudioCodes
- Dialogic
- The following table shows the VoIP gateway vendor, the VoIP gateway model, and the protocols that are supported by each model.

Supported VoIP gateways for Unified Messaging

Vendor	Model	Supported protocols
AudioCodes	MediaPack 114/8 FXO	• Analog with In-Band DTMF • Analog with SMDI
AudioCodes	Mediant 1000	• Analog with In-Band DTMF • Analog with SMDI • BRI Q.SIG • T1/E1 Q.SIG • IP-to-IP
AudioCodes	Mediant 2000	• T1/E1 CAS • T1/E1 Q.SIG • IP-to-IP
Dialogic	DMG1000PBXDNIW	Digital Set Emulation
Dialogic	DMG1000LSW	• Analog with In-Band DTMF • Analog with SMDI
Dialogic	DMG2000	• T1 CAS • T1/E1 Q.SIG

Dialogic	DMG3000	• BRI Q.SIG
NET	VX1200	• T1 Q.SIG
Quintum	Tenor DX Series	• T1 Q.SIG

Supported PBXs when using an AudioCodes VoIP gateway

The following table shows the PBXs that are supported using AudioCodes VoIP gateways, including MediaPack-114 FXO, MediaPack-118 FXO, and Mediant 2000.

PBXs supported with an AudioCodes VoIP gateway

PBX manufacturer	PBX model/type	AudioCodes model "x" - replace with 4 or 8 per need "y" - replace with 1, 2, 4, 8 or 16 per need
Alcatel	OmniPCX 4400	• MediaPack 11x/FXO/AC/SIP-0 • Mediant2000/ySpans/SIP
Aastra	M1000, M2000	• Mediant2000/ySpans/SIP
Avaya	Definity G3	• MediaPack 11x/FXO/AC/SIP-0 • Mediant1000/ySpans/SIP • Mediant2000/ySpans/SIP
Avaya	Magix/Merlin	• MediaPack 11x/FXO/AC/SIP-0
Avaya	S8300	• MediaPack 11x/FXO/AC/SIP-0 • Mediant1000/ySpans/SIP • Mediant2000/ySpans/SIP
Avaya	S8700	• MediaPack 11x/FXO/AC/SIP-0 • Mediant1000/ySpans/SIP • Mediant2000/ySpans/SIP
Avaya	IP Office	• MediaPack 11x/FXO/AC/SIP-0 • Mediant2000/ySpans/SIP
Cisco	CallManager 4.x	• Mediant1000/IP-to-IP • Mediant2000/IP-to-IP
NEC	Electra Elite	• MediaPack 11x/FXO/AC/SIP-0

NEC	NEAX2400	• MediaPack 11x/FXO/AC/SIP-0 • Mediant2000/ySpans/SIP/ RS232
NeXspan	S	• MediaPack 11x/FXO/AC/SIP-0
Nortel	Communication Server-1000M, 1000S, 1000E	• Mediant1000/ySpans/SIP • Mediant2000/ySpans/SIP
Nortel	Meridian 11c, 51c, 61c, 81c	• Mediant1000/ySpans/SIP • Mediant2000/ySpans/SIP
Panasonic	KX-TES824, KX-TEA308	• MediaPack 11x/FXO/AC/SIP-0
Panasonic	KX-TDA30, KX-TDA100, KX-TDA200, KX-TDA600	• MediaPack 11x/FXO/AC/SIP-0
Shortel	IP Telephony System	• MediaPack 11x/FXO/AC/SIP-0
Siemens	HiCom 150E	• MediaPack 11x/FXO/AC/SIP-0
Siemens	HiPath 3550	• MediaPack 11x/FXO/AC/SIP-0
Siemens	HiPath 4000	• MediaPack 11x/FXO/AC/SIP-0 • Mediant1000/ySpans/SIP • Mediant2000/ySpans/SIP
Tadiran Telecom	Coral Flexicom, Coral IPX	• MediaPack 11x/FXO/AC/SIP-0 • Mediant1000/ySpans/SIP • Mediant2000/ySpans/SIP

Supported PBXs when using a Dialogic VoIP gateway

Each Dialogic VoIP gateway model supports different PBXs. The following tables show the PBX manufacturer and model and which Dialogic VoIP gateway can be used. Each VoIP gateway uses different signaling methods, densities, and protocols.

PBXs supported when using a DMG1000 series Media Gateway

The following table shows the PBXs that are supported with the low-density Dialogic Media

Gateway (DMG1000). However, when an analog DMG1000 is used, supplemental signaling (RS232 SMDI, MD110, MCI protocols, or Inband DTMF signaling) is required.

PBXs supported when using a low-density Dialogic DMG1000 series VoIP gateway

PBX manufacturer	PBX model/type	DMG model and additional signaling
Aastra	Aastra MD110 (formerly Ericsson MD110)	DMG1008LSW Analog connectivity using the MD110 RS232 protocol
Alcatel	Omni PCX 4400	DMG1008LSW
Avaya	Definity G3 S8100, S8300, S8700, and S8710 (Communications Mgr SW V2.0 or later versions)	DMG1008DNIW
Intercom		DMG1008LSW Analog connectivity using SMDI serial protocol
Mitel	SX-200D, SX-200 Light, SX-2000 Light, SX-2000 S, SX-2000 VS, SX-200 ICP	DMG1008MTLDNIW
NEC	2000, 2400, 2400 IPX	DMG1008DNIW
Nortel	Meridian 1 - Option 11, 21, 21A, 51, 61, 71, and 81 Meridian SL1 - Generic X11, Release 15 or later versions Nortel Communication Server - 1000M, 1000S, 1000E with V3.0 or later versions	DMG1008DNIW
Nortel	SL 100	DMG1008LSW

		Analog connectivity using SMDI serial protocol
Siemens	HiCom 300E CS	DMG1008DNIW
Siemens	HiCom 300E (European)	DMG1008LSW Analog connectivity using Inband DTMF signaling
Siemens/ROLM	8000 (SW release 80003 or later versions) 9000 (All versions) 9751 (All versions of SW release 9005) 9751 (SW release 9006.4 or later versions)	DMG1008RLMDNIW
Siemens	HiPath 4000	DMG1008LSW
Toshiba	CTX (SW version AR1ME021.00)	DMG1008LSW
Others	Various	DMG1008LSW Analog connectivity using either Inband DTMF or SMDI

PBXs supported when using a DMG 2000 series Media Gateway

The following table shows the PBXs that are supported with the T1/E1 Dialogic Media Gateway (DMG2000). The DMG2000 gateway, which comes in single span (DMG2030DTIQ), dual span (DMG2060DTIQ), or quad span (DMG2120DTIQ) densities, supports the following protocols:

- T1 CAS
- T1 Q.SIG
- E1 Q.SIG
- T1 NI-2

- T1 5ESS
- T1 DMS100

If Channel Associated Signaling (CAS) signaling is used, supplemental signaling (RS232 SMDI, MD110, MCI protocols, or Inband DTMF signaling) is required. If Q.SIG signaling is used, the PBX must support the supplemental services that are associated with calling and called party information and the call transfer capabilities required by Unified Messaging.

PBXs supported with the DMG2000 Media Gateway

PBX manufacturer	PBX model/type	Required software version	Protocol and additional signaling
Alcatel	Omni PCX 4400	Version 3.2.712.5	T1 Q.SIG E1 Q.SIG
Avaya	Definity G3	Version 3 or later	T1 CAS
Avaya	S8500	Manager SW V2.0 or later versions	T1 CAS T1 Q.SIG E1 Q.SIG
Ericsson	MD110	Release MX1 TSW R2A (BC13)	E1 Q.SIG
Intercom			CAS (w/ SMDI serial protocol)
NEC	2400 IMX	Release 5200 Dec. 92 1b or later versions	CAS (w/ MCI serial protocol)
NEC	2400 IPX	R17 Release 03.46.001	T1 Q.SIG
Nortel	Meridian 1 - Option 11	Release 15 or later versions, and options 19 and 46 are required	T1 Q.SIG E1 Q.SIG
Nortel	Communication Server 1000	Version 2121, Release 4	T1 Q.SIG E1 Q.SIG
Siemens	HiCom 300E CS	Release 9006.4 or later	T1 CAS

		(Note: North American software load only)	
Siemens	HiPath 4000	V2 SMR 9 SMPO	T1 Q.SIG E1 Q.SIG
Mitel	SX-2000 S, SX-2000 VS	LW 34	T1 Q.SIG E1 Q.SIG
Mitel	3300	Version 5.1.4.8	T1 Q.SIG E1 Q.SIG

PBXs supported when using a DMG4008BRI series Media Gateway

The DMG4000 series Media Gateway comes with several TDM interface options. The DMG4008BRI supports 4-port/8-channel densities and supports the following protocols:

- ISDN BRI Q.SIG
- ETSI-DSS1 (Euro ISDN)
- NET 3 (Belgium)
- VN3 (France)
- 1TR6 (Germany)
- INS-64 (Japan)
- 5ESS Custom (North America - AT&T)
- National ISDN (NI1 - North America)

The following table shows the PBXs that are supported using a Dialogic 4000 Media Gateway Series (DMG4008).

PBXs supported using a DMG4008BRI Media Gateway

PBX manufacturer	PBX model/type	Required software version	Protocol and additional signaling
Siemens	HiCom 300	SA300-V3.05	BRI-Q.SIG (ECMAV2)
Siemens	HiPath 4000	S.0 B4400	BRI-Q.SIG (ECMAV2)

Supported IP PBXs

IP PBXs are also supported by Unified Messaging. The following table shows the IP PBXs that are

supported using a direct SIP connection to Unified Messaging.

IP PBXs supported when using a direct SIP connection

PBX manufacturer	PBX model/type	Required software version
Aastra	MX-ONE	4.0
Avaya	Aura	5.2.1 with Service Pack 5 (SP5)
Avaya	Communication Server 2100	CS2100 SE13
Cisco	Call Manager, Unified Communications Manager	5.1, 6.x, 7.0 and8.0

IP PBXs supported when using SIP media gateways

IP PBXs using SIP media gateways are also supported by Unified Messaging. The following table shows the IP PBXs that are supported using IP to IP capabilities of SIP media gateways to connect to Unified Messaging.

IP PBXs supported when using a SIP media gateway

PBX manufacturer	PBX model/type	SIP gateway model
Cisco	Call Manager 4.x	AudioCodes Mediant 1000/2000 (IP-to-IP enabled)

Exchange Unified Messaging, Office Communications Server 2007 R2, and Microsoft Lync Server

For on-premises and hybrid deployments, Exchange Unified Messaging can be deployed together with Microsoft Office Communications Server 2007 R2, Microsoft Lync Server 2010 or Lync Server 2013 to provide voice messaging, Instant Messaging (IM), enhanced user presence, audio-video conferencing, and an integrated email and messaging experience for users in your organization. For more information, see:

- Deploying Exchange 2013 UM and Lync Server overview
- Microsoft Lync Server 2013

To find out more about the Microsoft Unified Communications Open Interoperability Program for enterprise telephony infrastructure, including finding qualified SIP PSTN gateways and IP PBXs and the process for telephony infrastructure vendors to join and participate in the program, see Microsoft Unified Communications Open Interoperability Program.

Configuration notes for supported VoIP gateways, IP PBXs, and PBXs

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-23*

This page provides links to configuration notes that have been created and tested by Microsoft or a VoIP gateway partner. When Microsoft or a partner deploys Unified Messaging with a new VoIP gateway and PBX or IP PBX configuration, the prerequisites and configuration settings are documented. This information is used to create a configuration note.

Each PBX configuration note contains information about how to deploy Unified Messaging with a specific telephony configuration, and includes the manufacturer, model, and firmware version for the VoIP gateways, IP PBXs, or PBXs. In addition, each PBX configuration note includes other information, such as:

- Contributors in authoring the configuration note.
- Detailed prerequisites, including the following:
  - Features that have to be enabled or disabled on the PBX.
  - Specialized hardware that has to be installed.
  - Whether a VoIP gateway is required.
  - Features that must be present on the VoIP gateway, if one is needed.
  - Specific cabling requirements between an IP gateway and a PBX.
  - A list of Unified Messaging features that may not be available with a given telephony configuration.

To find out more about the Microsoft Unified Communications Open Interoperability Program for enterprise telephony infrastructure, including finding qualified SIP PSTN gateways and IP PBXs and the process telephony infrastructure vendors can use to join and participate in the program, see Microsoft Unified Communications Open Interoperability Program.

VoIP gateway, IP PBX, and PBX configuration notes

Microsoft is working with VoIP gateway partners, AudioCodes and Dialogic, to add to the list of PBXs that are tested. Because we are currently testing many combinations of telephony components, this topic is updated frequently. Please check back if you can't locate the appropriate configuration note for your deployment.

The following configuration notes are available:

• Aastra • Alcatel • Avaya • Cisco • Inter-Tel • Intecom • Mitel • NEC	• NeXspan • Nortel • Panasonic • Rolm • ShoreTel • Siemens • Tadiran • Toshiba

Aastra

Connect a VoIP gateway, IP PBX, or session border controller to UM

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-16*

You must configure the Voice over IP (VoIP) gateways and IP Private Branch eXchanges (PBXs) correctly when you deploy Unified Messaging (UM) for your organization. If you're deploying UM in a hybrid environment, you'll also need to correctly configure your session border controllers (SBCs). To do this, you need to configure the interface or interfaces of the VoIP gateways, IP PBXs, and SBCs to communicate with Client Access servers running the Microsoft Exchange Unified Messaging Call Router service and Mailbox servers running the Microsoft Exchange Unified Messaging service.

Important:

When you perform administrative tasks for a VoIP gateway, IP PBX, or SBC using a web browser, the HTTP requests sent over the network aren't encrypted. To increase the level of security for the VoIP gateways, IP PBXs, or SBCs on your network, use Internet Protocol security (IPsec) or Secure Sockets Layer (SSL) to help protect the administrative credentials and data transmitted over the network. We also recommend that you use a strong authentication mechanism and complex administrative passwords to protect the administrative credentials for the device.

Telephony IP device interfaces

There are several types of ports or interfaces that you must configure to enable communication between a PBX, VoIP gateway, IP PBX, or SBC and the Client Access and Mailbox servers on your network. When you configure a VoIP gateway, IP PBX, or SBC, you must consider whether the device is analog, digital, or analog and digital.

If the VoIP gateway interface that connects to a PBX is analog, you must correctly configure the appropriate settings to enable the VoIP gateway to communicate with your Client Access and Mailbox servers. For both IP PBXs and SBCs, you must also correctly configure the IP interfaces to enable these devices to communicate with Client Access and Mailbox servers. All of these devices have different types of connections or ports that are available depending on the device model and vendor.

To enable communication with the Client Access and Mailbox servers on your network:

- For VoIP gateways, you must configure the telephony interfaces to communicate with your PBXs, and you must configure the IP interface for the device.
- For IP PBXs, you must configure the circuit-based and network or IP-based connections.
- For SBCs, you must configure both IP interfaces, one for your network and the other interface that connects over the Internet or a dedicated WAN connection.

The following is a list of resources found on the Exchange TechCenter that provide information that can help you correctly configure your VoIP gateways, IP PBXs, and SBCs:

- **Supported IP gateway, IP PBX, and PBX documentation** Telephony advisor for Exchange 2013 includes configuration files and setup information that you can use when you configure VoIP gateways, IP PBXs, PBXs, and SBCs.
- **Configuration and technical notes** Configuration notes for supported VoIP gateways, IP PBXs, and PBXs includes configuration files and setup information that you can use when you configure VoIP gateways, IP PBXs, and PBXs.
- **Configuration notes for Exchange UM online** Configuration notes for supported session border controllers includes configuration files and setup information that you can use when you configure SBCs.

Unified Messaging specialists are available to assist you in configuring your telephony and IP-based network devices. A Unified Messaging specialist can help make sure that there's a smooth transition to Unified Messaging from a legacy or third-party voice mail system or help you plan and deploy a new voice mail system with Exchange Unified Messaging. Deploying a new voice mail system or upgrading a legacy one requires significant knowledge about VoIP gateways, IP PBXs, PBXs, and Unified Messaging. For more information about how to contact a Unified Messaging specialist, see Microsoft Exchange Server 2013 Unified Messaging (UM) Specialists or certified UM partners at Microsoft Pinpoint.

After you configure a VoIP gateway, IP PBX, or SBC IP interface, you must create and configure a UM IP gateway to represent each device that you've deployed. For more information about how to create a UM IP gateway, see Create a UM IP gateway.

After you create a UM IP gateway, the Client Access and Mailbox servers associated with the UM IP gateway send a SIP OPTIONS request to the VoIP gateway, IP PBX, or SBC to ensure that it's responsive. If the VoIP gateway, IP PBX, or SBC doesn't respond, the Mailbox server will log an event with ID 1088 stating that the request failed. To resolve this issue, make sure that the VoIP gateway, IP PBX, or SBC is available and online and the Unified Messaging configuration is correct.

A Client Access server and a Mailbox server will communicate only with a VoIP gateway, IP PBX, or SBC that's listed as a trusted Session Initiation Protocol (SIP) peer. An event with ID 1175 will be logged when multiple DNS hosts share the same IP address. This event may occur if you've configured your DNS zones with FQDNs for the VoIP gateways on your network. Unified Messaging protects against unauthorized requests by retrieving the internal URL of the Unified Messaging Web Services virtual directory that's located on the Mailbox server and then using the URL to build the list of FQDNs for the trusted SIP peers. After two FQDNs are resolved to the same IP address, this event will be logged.

Note:

You must restart the Microsoft Exchange Unified Messaging service if a VoIP gateway, IP PBX, or SBC is configured to have an FQDN and the DNS record of the VoIP gateway, IP PBX, or SBC is changed after the service has been started. If you don't restart the service, the Mailbox server won't be able to locate the VoIP gateway, IP PBX, or SBC. This occurs because a Mailbox server maintains a cache for all VoIP gateways, IP PBXs, or SBCs in memory, and DNS resolution is performed only when the service is restarted or when the configuration of a VoIP gateway, IP PBX, or SBC has changed.

Connect UM to a supported VoIP gateway

Unified Messaging > Telephone system integration with UM > Connect UM to your telephone system >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-04-19*

When you're setting up Unified Messaging (UM), you must configure the Voice over IP (VoIP) gateways, IP PBXs, SIP-enabled PBXs, or session border controllers (SBCs) on your network to communicate with the Client Access servers running the Microsoft Exchange Unified Messaging Call Router service and the Mailbox servers running the Microsoft Exchange Unified Messaging service in your Exchange organization. You must also configure the Client Access and Mailbox servers to communicate with the VoIP gateways, IP PBXs, SIP-enabled PBXs, or SBCs.

Note:

After you've connected your Client Access and Mailbox servers to the VoIP gateways, IP PBXs,

SIP-enabled PBXs, or SBCs on your data network you must create the required UM components and also enable users for Unified Messaging so they can use the voice mail system.

Steps

Here are the basic steps for connecting VoIP gateways, IP PBXs, SIP-enabled PBXs, or SBCs to Client Access and Mailbox servers:

Step 1: Install the Client Access and Mailbox servers in your organization.

Step 2: Create and configure a Telephone Extension, SIP URI, or E.164 UM dial plan.

Step 3: Create and configure a UM IP gateway. You must create and configure a UM IP gateway for each VoIP gateway, IP PBX, SIP-enabled PBX, or SBC that will be accepting incoming calls and sending outgoing calls.

Step 4: Create a new UM hunt group if needed. If you create a UM IP gateway and don't specify a UM dial plan, a UM hunt group will be automatically created.

See the following sections for information about each step.

Step 1: Install your Client Access and Mailbox servers

When you're deploying Exchange servers in your organization, you can install the Client Access and Mailbox servers on the same computer or install the Client Access server on a separate computer from the Mailbox server. To install the Client Access server, run Setup.exe from the installation media. You use the same command when you're installing the Client Access server on a separate computer from the Mailbox server or installing it on the same computer. For details, see Install Exchange 2013 using the Setup wizard. If you want to add features and functionality to your existing Exchange server, you can use **Programs and Features** or Setup.exe.

Step 2: Create and configure a UM dial plan

After you've installed the required servers, you must first create a UM dial plan. A UM dial plan contains the configuration settings that enable you to connect to your telephony network by linking to a single or multiple UM IP gateways. A UM IP gateway and UM hunt group are directly linked to a UM dial plan and are also required. For details, see Create a UM dial plan.

A UM dial plan establishes a link from the telephone extension number of a user to their UM-enabled mailbox. When you create a UM dial plan, you can configure the number of digits in the extension numbers, the Uniform Resource Identifier (URI) type, and the VoIP security setting for the dial plan.

There are three types of dial plans: Telephone Extension, Session Initiation Protocol (SIP) URI, and E.164. When you create and configure a UM dial plan, you must determine the type of information

that's sent from your IP PBX, SIP-enabled PBX, or PBX and whether the calls are being sent to a Client Access or Mailbox server in a telephone extension or E.164 format. If you're deploying Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server, you must create and configure a SIP URI dial plan.

Step 3: Create and configure a UM IP gateway

After you create a UM dial plan, you must create a UM IP gateway to represent each VoIP gateway, IP PBX, or SBC on your network. When you create a UM IP gateway, you can configure it to use an IP address or a fully qualified domain name (FQDN). If you use an FQDN, you must make sure you've correctly configured a DNS host record for the IP gateway so the host name will be correctly resolved to an IP address.

After you install a VoIP gateway, IP PBX, or SBC, you must create a UM IP gateway to represent the physical hardware device. After you've created a UM IP gateway, the Client Access server that use the UM IP gateway will send a SIP OPTIONS request to the VoIP gateway, IP PBX, or SBC to ensure that it's responsive. If the VoIP gateway, IP PBX, SIP-enabled PBX, or SBC doesn't respond, the Client Access server will log an event with ID 1088 stating that the request failed. To resolve this issue, make sure that the VoIP gateway, IP PBX, or SBC is available and online and that the Unified Messaging configuration is correct.

Client Access and Mailbox servers will communicate only with a VoIP gateway, IP PBX, or SBC that's listed as a trusted SIP peer. In some cases, if two VoIP gateways, IP PBXs, or SBCs are configured to use the same IP address, an event with ID 1175 will be logged. This event may occur if you've configured your DNS zones with fully qualified domain names (FQDNs) for the VoIP gateways on your network. Unified Messaging protects against unauthorized requests by retrieving the internal URL of the Unified Messaging Web Services virtual directory that's located on the Mailbox server and then using the URL to build the list of FQDNs for the trusted SIP peers. After two FQDNs are resolved to the same IP address, this event will be logged.

You must restart the Microsoft Exchange Unified Messaging service if a UM IP gateway is configured to use an FQDN and the DNS record of the UM IP gateway is changed after the service has been started. If you don't restart the service, the Mailbox server won't be able to locate the UM IP gateway. This occurs because a Mailbox server maintains a cache for all UM IP gateways in memory and DNS resolution is performed only when the service is restarted or when the configuration of a VoIP gateway, IP PBX, or SBC has changed.

Exchange Unified Messaging supports various VoIP gateway vendors and other vendors of IP PBXs, SIP-enabled PBXs, and SBCs. Each of the supported VoIP gateways is designed to connect to a variety of third-party PBX systems.

For detailed information about VoIP gateways, see the following topics:

- Create a UM IP gateway
- Configuration notes for supported VoIP gateways, IP PBXs, and PBXs
- Connect a VoIP gateway, IP PBX, or session border controller to UM

For details, see Connect your voice mail system to your telephone network.

Step 4: Create a new UM hunt group (if needed)

Hunt group is a term used to describe a group of Private Branch eXchange (PBX) or IP PBX extension numbers that are shared by users. Hunt groups are used to efficiently distribute calls into or out of a specific business unit. Creating and defining a hunt group minimizes the chance that a caller who places an incoming call will receive a busy signal when the call is received.

UM hunt groups mirror the hunt groups that are used on PBXs and IP PBXs. When you configure your PBXs or IP PBXs, you must create and configure one or more UM hunt groups. UM hunt groups act as a link between the UM IP gateway and the UM dial plan.

Depending on how you create your UM IP gateway, you may have to create one or multiple new UM hunt groups. If you don't link a UM IP gateway with a dial plan when you create the UM IP gateway, a single UM hunt group is created by default. If you link a UM IP gateway to a UM dial plan when you create the UM IP gateway, all incoming calls will be sent through the UM IP gateway and those calls will be accepted by Client Access and Mailbox servers. If you don't link a UM IP gateway to a UM dial plan when you create the UM IP gateway, you'll need to create a UM hunt group with the correct pilot identifier for incoming calls to be forwarded from an UM IP gateway to a dial plan.

If you have multiple Outlook Voice Access and auto attendant numbers and have linked a UM IP gateway to a dial plan, you'll need to delete the UM hunt group that was created by default and create multiple UM hunt groups. For details about how to create a UM hunt group, see Create a UM hunt group.

Connect a VoIP gateway to communicate with a PBX

Unified Messaging > Telephone system integration with UM > Connect UM to your telephone system >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-11-30*

When you configure your telephony and data networks for Unified Messaging (UM) in Microsoft Exchange Server 2013, you must configure the VoIP gateways so they communicate with Client Access servers running the Microsoft Exchange Unified Messaging Call Router service and Mailbox servers running the Microsoft Exchange Unified Messaging service. You must also configure the VoIP gateways to communicate with the Private Branch eXchanges (PBXs) in your organization. You

can use the information and links in this topic to configure a VoIP gateway to communicate with a PBX.

Configuring a VoIP gateway

When you configure a VoIP gateway, you must consider whether the VoIP gateway device is analog, digital, or analog and digital. If the VoIP gateway interface that connects to a PBX is analog, you must correctly configure the appropriate settings to enable the VoIP gateway to communicate with a PBX. If the VoIP gateway interface that connects to a PBX is digital, it may require no additional configuration to enable the digital interface to communicate with a PBX.

The following suggested resources in the Exchange TechCenter provide information that can help you correctly configure your VoIP gateways and PBXs:

- **Supported VoIP gateway, IP PBX, and PBX documentation** Telephony advisor for Exchange 2013 includes configuration files and setup information that you can use when you configure VoIP gateways and PBXs.
- **Configuration and technical notes** Configuration notes for supported VoIP gateways, IP PBXs, and PBXs includes configuration files and setup information that you can use when you configure VoIP gateways and PBXs.
- **Configuring an AudioCodes-based VoIP gateway** The Microsoft Exchange Server Resource page provides the latest support and configuration information to help you configure AudioCodes-based VoIP gateways for use with Unified Messaging.
- **Configuring a Dialogic-based VoIP gateway** The Microsoft Exchange | Exchange Gateway | Dialogic Web site provides the latest support and configuration information for Dialogic-based VoIP gateways.

We recommend that all customers who plan to deploy Unified Messaging obtain the assistance of a Unified Messaging specialist. An Exchange Unified Messaging specialist will help make sure that there's a smooth upgrade to Unified Messaging from a legacy or third-party voice mail system and help you plan and deploy a new voice mail system with Exchange Unified Messaging. Deploying a new voice mail system or upgrading a legacy voice one requires significant knowledge about VoIP gateways, PBXs, and Unified Messaging. For more information about how to contact a Unified Messaging specialist, see Microsoft Exchange Server 2013 Unified Messaging (UM) Specialists or certified UM partners at Microsoft Pinpoint.

Configuration notes for supported VoIP gateways, IP PBXs, and PBXs

Connect UM to a supported VoIP gateway

Configuration notes for supported session border controllers

Applies to: *Exchange Online*

Topic Last Modified: *2014-01-20*

Session border controllers (SBCs) enable you to connect your on-premises telephony network to a Microsoft datacenter over a dedicated public WAN connection. An SBC sits on the edge of your on-premises IP network and connects to a second SBC in a Microsoft datacenter.

SBCs require the use of digital certificates to encrypt all traffic between your on-premises organization and the Microsoft datacenter. You must obtain a digital certificate for the network border element, such as a session border controller, that you're using to communicate with Exchange hybrid and online deployments. Digital certificates establish trust between your on-premises organization and the Microsoft datacenter and enable mutual Transport Layer Security (mutual TLS). After this trust is established, the network border elements at your on-premises organization and at the Microsoft datacenter exchange session keys, and use these keys to encrypt the subsequent data traffic.

In hybrid or online deployments, a UM IP gateway represents an SBC. The subject common name in the certificate must match the fully qualified domain name (FQDN) value in the Address box on the UM IP gateway that you create. For example, if you specify the FQDN address sbcexternal.contoso.com on your UM IP gateway, make sure that the subject name and subject alternative name in the certificate contain the same value: sbcexternal.contoso.com. The name that you use is case-sensitive, so make sure the case is the same on both the certificate and the UM IP gateway. If you're using an Acme Packet SBC and the common name doesn't match the UM IP gateway's FQDN, the call will be rejected with a 403 error.

Note:

Because SBCs are designed to sit on the network edge, they also function as a firewall. If you set up an SBC behind your organization's firewall, it can cause configuration problems.

Supported session border controllers

The following SBCs have been successfully tested for interoperability with Exchange hybrid and online deployments. Note that the capabilities and compatibilities of SBCs can vary, and the way you set them up can be different depending on other equipment on your network. Consult with the SBC manufacturer to see whether there are specific configuration notes for Unified Messaging in a hybrid or online deployment.

Vendor	Model	Configuration notes	Comments
Acme Packet	Net-Net 3820 or 4500	Acme Packet SBC in Microsoft Office 365 Unified Messaging	Dedicated SBC
AudioCodes	Mediant 1000B MSBG	MSBG Session Border Controller (SBC) with IP PBX	Dedicated SBC
AudioCodes	Mediant 1000B MSBG	MSBG Gateway and Session Border Controller (SBC) with Legacy PBX	SBC and IP gateway
Ingate	SIParator	Ingate SIParator Configuration Notes	Dedicated SBC

Connect your voice mail system to your telephone network

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-04-20*

After you've deployed all the required telephony equipment for your organization, including your VoIP gateways, IP PBXs, and SIP-enabled PBXs or Microsoft Lync Server, you need to create all the Unified Messaging (UM) components that will enable your telephony devices to communicate with servers in your organization.

UM components

The UM components enable the integration of Unified Messaging into your directory structure and your existing telephony infrastructure. Your directory stores all the components and settings for UM. Each UM component is necessary to support Unified Messaging. Some UM components are created to represent a telephony hardware device. Others are created to represent a telephony dial plan for an organization or to support a specific feature of Unified Messaging.

There's a tightly integrated and interconnected relationship between the UM components and the features available in Unified Messaging. To successfully plan and deploy Unified Messaging in your organization, you need to fully understand the relationship between each UM component and the others.

For more information about the UM components, see:

- UM dial plans
- UM IP gateways
- UM hunt groups
- Automatically answer and route incoming calls

For more information about setting up voice mail for users, see:

- UM mailbox policies
- Voice mail for users

UM dial plans

Exchange Server 2013 > Unified Messaging > Connect your voice mail system to your telephone network >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-21*

Unified Messaging (UM) dial plans are the main component of Unified Messaging and are required to successfully deploy Unified Messaging voice mail on your network. The following sections discuss UM dial plans and how they're used in a UM deployment.

Overview of UM dial plans

A UM dial plan represents a set of Private Branch eXchanges (PBXs) or IP PBXs that share common user extension numbers. All users' extensions hosted on PBXs or IP PBXs within a dial plan contain the same number of digits. Users can dial one another's telephone extensions without appending a special number to the extension or dialing a full telephone number.

A UM dial plan mirrors a telephony dial plan. A telephony dial plan is configured on PBXs or IP PBXs.

In Unified Messaging, the following UM dial plan topologies can exist:

- A single dial plan that represents a subset of extensions or all extensions for an organization with one PBX or IP PBX.
- A single dial plan that represents a subset of extensions or all extensions for an organization with multiple networked PBXs or IP PBXs.
- Multiple dial plans that represent a subset of extensions or all extensions for an organization with one PBX or IP PBX.
- Multiple dial plans that represent a subset of extensions or all extensions for an organization with multiple PBXs or IP PBXs.

Users who belong to the same dial plan have these characteristics:

- An extension number that uniquely identifies the user mailbox in the dial plan.
- The ability to call or send voice messages to other members in the dial plan using only the extension number.

For more information about how to enable a user for Unified Messaging, see Enable a user for voice mail.

UM dial plans are used in Unified Messaging to make sure that user telephone extensions are unique. In some telephony networks, multiple PBXs or IP PBXs exist. In these telephony networks, there could be two users who have the same telephone extension number. UM dial plans resolve this situation. Putting the two users into two separate UM dial plans makes their extensions unique.

How dial plans work

When you integrate a telephony network with Unified Messaging, there must be one or more hardware devices called Voice over IP (VoIP) gateways or IP PBXs that connect your telephony network to your IP-based packet switched network. VoIP gateways convert circuit-switched protocols from a PBX found in a telephony network to a data-switched protocol such as IP. IP PBXs also convert circuit-switched protocols to a data-switched protocol. Session Border Controllers (SBCs) enable you to connect two IP based networks together over a public or private WAN and are found in UM hybrid or online deployments. Each VoIP gateway, IP PBX, or Session Border Controller (SBC) in your organization is represented by a UM IP gateway. For more information about UM IP gateways, see UM IP gateways.

Unified Messaging requires that you create at least one UM dial plan. Whether you create one or more dial plans, all the Exchange servers in your organization will answer incoming calls. There must also be a single or multiple UM IP gateways associated with the dial plan. In on-premises and hybrid deployments, after you install your Exchange servers and associate a UM IP gateway, all the Exchange servers will answer incoming calls for all dial plans. However, for on-premises or hybrid deployments, when you're integrating Exchange and Lync Server, you must create SIP URI dial plans.

Important:
Each time you create a UM dial plan, a default UM mailbox policy is also created. The UM mailbox policy is named <*Dial Plan Name*> Default Policy. This UM mailbox policy can be deleted or configured differently.

When you create the first UM IP gateway and specify a UM dial plan at the time you create it, a default UM hunt group is also created. Creating these components enables the Exchange servers to receive calls from a VoIP gateway, IP PBX, or SBC and then process those incoming calls for users who are associated with the UM dial plan. In on-premises or hybrid deployments, when a call comes in to the VoIP gateway, IP PBX, or SBC, it forwards the call to a Client Access server. The Client Access server then forwards the call to a Mailbox server and the Mailbox server tries to match the extension number of the user to the associated UM dial plan.

Types of dial plans

A Uniform Resource Identifier (URI) is a string of characters (numbers or alphabetic) that's used to identify or name a resource. In Unified Messaging, the main purpose of a URI is to enable VoIP devices to communicate with other devices using specific protocols. A URI defines the naming and numbering format or scheme used for the calling and called party information contained within a Session Initiation Protocol (SIP) header for an incoming or outgoing call.

The types of UM dial plans you create in Unified Messaging will depend on the URI types supported by the VoIP gateways or IP PBXs in your organization. The URI type is the type of string that's sent from the PBX or IP PBX. When you create a dial plan, you should know the specific URI types that are supported by your PBXs or IP PBXs. There are three formats or URI types that can be configured on UM dial plans:

- Telephone Extension (TeleExtn)
- SIP URI
- E.164

By default, each time you create a dial plan in Unified Messaging, the dial plan will be created to use the telephone extension URI type. After you create a dial plan, you won't be able to change the URI type. You must delete the existing dial plan and create another one with the correct URI type.

Telephone Extension URI type

The Telephone Extension URI type is the most common type of UM dial plan and is used with IP

PBXs and PBXs. When you configure a telephone extension (TelExtn) dial plan, the VoIP gateways, PBXs, and IP PBXs you use must support the TelExtn URI type. Today, most PBXs and IP PBXs support this URI type.

When a call is received by a PBX and the UM-enabled user isn't available to answer the call, the PBX will forward the call to a VoIP gateway. The VoIP gateway—or the IP PBX, if one is used—will translate the call from a circuit-based protocol to an IP based protocol. In the header for the SIP packet received from the VoIP gateway or IP PBX, the calling and called party information will be listed in one of the following formats:

- Tel:512345
- 512345@<*IP address*>

The telephone extension (TelExtn) format used is based on the configuration of the VoIP gateway or IP PBX.

SIP URI type

Session Initiation Protocol (SIP) is a standard protocol for initiating interactive user sessions that involve multimedia elements such as video, voice, chat, and gaming. SIP is a request-to-response based protocol that answers requests from clients and responses from servers. Clients are identified by SIP URIs. Requests can be sent through any transport protocol, such as UDP or TCP. SIP determines the endpoint to be used for the session by selecting the communication media and media parameters.

When you create a new dial plan, you have the option of creating a SIP URI dial plan if your environment has Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server deployed. You can also create a SIP URI dial plan if your organization has IP PBXs or SIP-enabled PBXs. In the latter case, your organization must also support SIP URIs and SIP routing.

A SIP URI is a user's SIP phone number. The SIP URI resembles an email address and is written in the following format: sip:<*user name*>@<*domain or IP address*>:*Port*. When a SIP-enabled IP PBX or PBX is used to send a call to the Exchange servers, the device will send the SIP URI for the calling and called party in the SIP header and will not include extension numbers.

E.164 URI type

E.164 is a standard numbering format that defines the international public telecommunication numbering plan used in the Public Switched Telephone Network (PSTN) and some data networks. E.164 defines the format of telephone numbers. E.164 numbers can have a maximum of 15 digits and are usually written with a plus sign (+) before the digits of the telephone number. To dial an E.164-formatted telephone number from a telephone, the appropriate international call prefix must be included in the number dialed. In an E.164 numbering plan for public telephone systems, each assigned number contains a country code (CC), a national destination code (NDC), and a subscriber number (SN).

When you create a new dial plan, you have the option to create an E.164 dial plan. However, if you create and configure an E.164 dial plan, the PBXs and IP PBXs must support E.164 routing. The SIP header received from a VoIP gateway associated with an E.164 dial plan will include the E.164-formatted telephone number and information about the calling and called party and will be listed in the following format: Tel:+14255550123. For Exchange Online deployments with Exchange Unified Messaging and Lync Server, you must use correctly formatted E.164 numbers for Outlook Voice Access and auto attendant numbers.

VoIP security

Exchange servers communicate with VoIP gateways, IP PBXs, and other Exchange computers in either Unsecured, SIP secured, or Secured mode, depending on how the UM dial plan is configured. In on-premises and hybrid deployments, Client Access and Mailbox servers can operate in any mode configured on a dial plan because the servers listen on TCP port 5060 for Unsecured requests and TCP port 5061 for Secured requests at the same time if they're configured to start in dual mode. Client Access and Mailbox servers answer all incoming calls for all UM dial plans, but these dial plans can have different VoIP security settings.

In on-premises and hybrid deployments, by default, when you create a UM dial plan, it will communicate in Unsecured mode, and the Client Access and Mailbox servers will send and receive data from VoIP gateways, IP PBXs, and SBCs without using encryption. In Unsecured mode, neither the Realtime Transport Protocol (RTP) media channel nor the SIP signaling information is encrypted. You can use the **Get-UMDialPlan** cmdlet in the Shell to determine the security setting for a specific UM dial plan.

In on-premises and hybrid deployments, you can configure a Client Access and Mailbox server to use mutual Transport Layer Security (mutual TLS) to encrypt the SIP and RTP traffic sent and received from other devices and servers. When you configure the dial plan to use SIP secured mode, only the SIP signaling traffic will be encrypted, and the RTP media channels will still use TCP, which isn't encrypted. However, when you configure the dial plan to use Secured mode, both the SIP signaling traffic and the RTP media channels are encrypted. An encrypted signaling media channel that uses Secure Realtime Transport Protocol (SRTP) also uses mutual TLS to encrypt the VoIP data.

You can configure the VoIP security mode either when you're creating a new dial plan or after you've created a dial plan using the EAC or the **Set-UMDialPlan** cmdlet in the Shell. When you configure the UM dial plan to use SIP secured or Secured mode, Client Access and Mailbox servers will encrypt the SIP signaling traffic or the RTP media channels or both. However, to be able to send encrypted data to and from Exchange servers, you must correctly configure the UM dial plan, and VoIP devices such as VoIP gateways, IP PBXs, and SBCs must support mutual TLS.

Outlook Voice Access

There are two types of callers who access the voice mail system using the Outlook Voice Access

number configured on a UM dial plan: unauthenticated callers and authenticated callers. When callers dial the Outlook Voice Access number configured on a dial plan, they're considered anonymous or unauthenticated until they input information including their voice mail extension and a PIN. The only option available to anonymous or unauthenticated callers is the directory search feature. After callers input their voice mail extension and their PIN, they'll be authenticated and given access to their mailbox. After they gain access to the voice mail system, they're using the Outlook Voice Access feature.

Outlook Voice Access is a series of voice prompts that give the caller access to email, voice mail, calendar, and other information. Outlook Voice Access lets authenticated callers navigate their personal information in their mailbox, place calls, or locate users using dual tone multi-frequency (DTMF), also known as touchtone, inputs or voice inputs.

Outlook Voice Access numbers

After you've created a UM dial plan, you need to add at least one Outlook Voice Access number. Outlook Voice Access numbers are also called dial plan pilot numbers. This number is used by Outlook Voice Access users to access their mailboxes and lets them search the directory.

By default, when you create a UM dial plan, no Outlook Voice Access number is configured. To enable users to use the Outlook Voice Access feature, you must configure at least one telephone or extension number. The number of alphanumeric characters in the Outlook Voice Access number can't exceed 20. After you configure this number on the dial plan, the number will be displayed in the voice mail options in Microsoft Outlook, and in Outlook Web App.

You can use the **Outlook Voice Access numbers** box on the UM dial plan to add a telephone number or extension that a user will call to access the voice mail system using Outlook Voice Access. In most cases, you'll enter an extension number or an external telephone number. However, because this field accepts alphanumeric characters, a SIP URI can be used if you're using an IP PBX, a SIP-enabled PBX, Office Communications Server 2007 R2 or Microsoft Lync Server.

Depending on the needs of your organization, you may want to configure one or more Outlook Voice Access number. You can have a single Outlook Voice Access number configured on a single UM dial plan or you can have multiple Outlook Voice Access numbers in a single UM dial plan, but you can't have a single Outlook Voice Access number that spans multiple UM dial plans.

Audio codecs

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-11-20*

In Unified Messaging (UM), an audio codec is used to store voice mail messages. Another codec is used between a VoIP gateway or IP Private Branch eXchange (PBX) and the Mailbox server running the Microsoft Exchange Unified Messaging service or the Client Access server running the Microsoft Exchange Unified Messaging Call Router service. Unified Messaging can use any of the following four audio codecs to create and store voice messages:

- MP3 (default)
- Windows Media Audio (WMA)
- Group System Mobile (GSM) 06.10
- G.711 Pulse Code Modulation (PCM) Linear

Warning:
The G.711 (PCMA and PCMU) and the G.723.1 codecs are VoIP codecs used between a VoIP gateway and the Client Access and Mailbox servers.

Part of planning your UM system involves selecting the correct audio codec based on the needs and requirements of your organization. This topic discusses the audio codecs that UM can use, and you can use it to help plan your UM deployment.

Codecs

The term *codec* is a combination of the words "coding" and "decoding" and is used with digital audio data. A codec is a software program that transforms digital data into an audio file format or audio streaming format. Codecs are used to convert an analog voice signal to a digital version of the voice signal. Codecs can vary in their sound quality, the bandwidth required to use them, and the system requirements needed to do the encoding.

Two types of codecs are used in Unified Messaging:

- The codec used between a VoIP gateway, IP PBX, or SIP-enabled PBX and the Client Access and Mailbox servers or between a PBX and a VoIP gateway.
- The codec used to encode and store voice messages for users.

When you use an ordinary telephone over the Public Switched Telephone Network (PSTN), your voice is transported in an analog format over the telephone line. But with Voice over IP (VoIP), your voice must be converted into digital signals. This conversion process is known as encoding. Encoding is performed by a codec. After the digitized voice has reached its destination, it must then be decoded back to its original analog format so the person on the other end of the call can hear and understand the caller.

VoIP codec

In UM, three types of codecs can be used between VoIP gateways or IP PBXs and the Client Access and Mailbox servers:

- G.711 µ-law
- G.711 A-law

- G.723.1

G.711 is a standard that was developed for use with audio codecs. There are two main algorithms defined in the standard for G.711: the μ-law algorithm that is used in North America and Japan and the A-law algorithm that is used in Europe and other countries. The G.723.1 audio codec is mostly used in VoIP applications and requires a license to be used. G.723.1 is a high-quality, high-compression type of codec.

A Client Access or Mailbox server and a supported VoIP gateway or IP PBX can offer both the G.711 and G.723.1 codecs. By default, the first codec to be used is G.723.1. If you want to use a codec other than G.723.1 between Client Access and Mailbox servers and the VoIP gateway or IP PBX, we recommend that you change the configuration on the VoIP gateway or IP PBX. The following table summarizes some common VoIP codecs.

VoIP codecs

VoIP codec	Bandwidth (Kbps)	Description
G.711	64	This codec requires very low processing. It needs a minimum of 128 kilobits per second (Kbps) for two-way communication.
G.723.1	5.3/6.3	This codec offers high compression with high-quality audio. It requires more processing than the G.711 codec. The G.723.1 codec uses reduced bandwidth but offers poorer-quality audio.

UM voice message storage codec

Unified Messaging dial plans are integral to the operation of UM. By default, when you create a UM dial plan, the UM dial plan uses the MP3 audio codec to create and store voice messages. However, after you create the UM dial plan, you can configure it to use WMA, GSM 06.10, or G.711 PCM Linear audio codecs.

Each audio codec has advantages and disadvantages. The MP3 audio codec was selected as the default audio codec because of its sound quality and compression properties. GSM 06.10 and G.711 PCM Linear audio codecs were included as available options because of their ability to support other types of messaging systems.

When you plan for UM, you must balance the size and the relative quality of the audio file that will be created for voice messages. Generally, the higher the bit rate for an audio file, the higher the quality. You must also consider whether the audio file is compressed. The following table shows the sample bit rate (bit/sec) and compression properties for each audio codec used in UM.

Default UM voice message storage codecs

Voice message storage codec	Bits	Compressed file?
MP3	16 bit	Yes
WMA	16 bit	Yes
G.711 PCM	16 bit	No
GSM 06.10	8-bit	Yes

In UM, the file type created for a voice message depends on the audio codec that's used to create the voice message audio file. The MP3 audio codec creates .mp3 audio files, the WMA audio codec creates .wma audio files, and the GSM 06.10 and G.711 PCM Linear audio codecs create .wav audio files. All these audio files are sent together with an email message to the recipient of the voice message.

Frequently, but not always, coding and decoding the digital data also involves compression or decompression. Audio compression is a form of data compression that reduces the size of audio data files. The audio compression algorithm used by the audio codec compresses the .wma or .wav audio files. In UM, the type of audio compression algorithm that is used is based on the type of audio codec selected in the UM dial plan properties. After the audio file is created and compressed, it's attached to the voice message.

Sometimes information from the digital data is lost during compression and decompression. The higher the compression that is used to compress the audio file, the greater the loss of information during the conversion. However, less disk space is used because the size of the audio file is reduced. Conversely, the lower the compression, the lower the loss of the information. However, more disk space must be used because of the increased size of each audio file.

RTAudio wideband or high fidelity audio for recording voice messages is also available as an audio codec. However, high fidelity audio using RTAudio is available only after you have successfully integrated Unified Messaging with Microsoft Lync Server . To enable RTAudio as the wire codec, either narrow or wideband, the UM dial plan must be configured as a Session Initiation Protocol (SIP) URI-type dial plan and you must set the call answering codec on the dial plan to MP3 or WMA to enable wideband audio (16Khz).

Important:
RTAudio is not available in environments where Lync Server is not deployed. This is because, in environments that haven't integrated Lync Server, the dial plan will be set to Telephone

Extension or E.164 and not to SIP URI.

There are two media streams for each incoming call: inbound to a Client Access server and outbound from a Mailbox server. When the dial plan type is set to SIP URI and the call-answering codec on the dial plan is set to MP3 or WMA, a Client Access server tries to select the RTAudio VoIP codec for the inbound media stream. If negotiation is successful, the RTAudio codec for the inbound stream will be used for call-answering calls or calls that originate from a Lync client or server.

Note:
Calls placed by using the Play on Phone feature will not use the RTAudio codec. The inbound stream for calls placed by using Play on Phone will use the G.711 or G.723.1 codec.

When the RTAudio codec is used, the voice message that is recorded will be recorded in high fidelity and will be stored as an audio file that has an .mp3 or .wma extension depending on how the dial plan is configured. When the voice message is played back to the user in Outlook or Outlook Web App they will hear the voice message in high fidelity audio. If negotiation is unsuccessful, either the G.711 or G.723.1 codec will be used. Both the G.711 and the G.723.1 codecs are narrowband codecs. When they're used as the VoIP codec, the voice message is recorded and stored as a narrowband audio file that has an .mp3 or .wma extension.

The outbound media stream will always be negotiated by using either the G.711 or G.723.1 codec. This means that callers will always hear narrowband audio over the telephone. This also applies to situations when a call is placed by using Microsoft Lync Server 2010 or later.

The audio format and codec that Mailbox servers use to store the audio in voice messages depends not only on the audio codec that's configured on the dial plan but also on the bit rate of the audio that UM negotiates with a SIP peer. If your environment includes Lync Server or SIP endpoints, a Mailbox server will also negotiate the audio codec to use with a SIP peer. For example, when wideband RTAudio is negotiated as the wire codec, a Mailbox server will then use either the 32 Kbps MP3 or WMA 9.2 format when creating voice messages, depending on the dial plan setting. The following table shows the relationship between the voice message storage audio codec and the VoIP or wire audio codec that's used.

Relationship between the storage audio codec and the VoIP or wire audio codec

Audio codec configured on a UM dial plan	VoIP or wire codec (narrowband) - G.723, G.711, or RTAudio (8KHz)	VoIP or wire codec (wideband) - RTAudio (16KHz)
G.711	G.711	Not applicable. A Client Access or Mailbox server doesn't negotiate wideband audio if the dial plan is set to G.711.
WMA	WMA 9 Voice	WMA 9.2

GSM	GSM 6.10	Not applicable. A Client Access or Mailbox doesn't negotiate wideband audio if the dial plan is set to GSM.
MP3	MP3 (16 Kbps)	MP3 (32 Kbps)

Return to top

UM message sizing

You can configure Unified Messaging to use one of the following four audio codecs for creating voice messages: MP3, WMA, GSM 06.10, and G.711 PCM Linear. By default, the MP3 format is selected.

The WMA audio codec is always stored in the Windows Media format, and the attachment is a file that has a .wma file name extension. Audio files encoded using the GSM or G.711 PCM Linear audio codecs are always stored in RIFF/WAV format, and the attachment is a file that has a .wav file name extension.

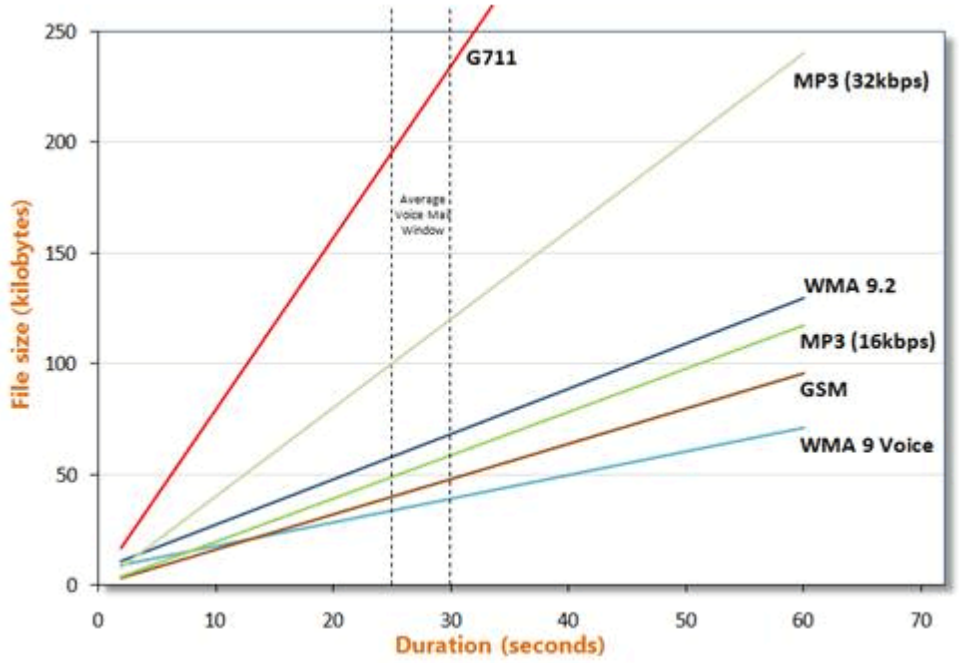
The size of UM voice messages depends on the size of the attachment that holds the voice data. In turn, the size of the attachment depends on the following factors:

- The duration of the voice mail recording
- The audio codec that's used
- The audio file storage format

The following figure shows how the size of the audio file depends on the duration of the voice mail recording for the three audio codecs that you can use in UM.

Note:
In this figure, the average length of a call-answered voice message is approximately 30 seconds.

Audio file size



MP3

By default, the MP3 format is selected and is the default audio file format for voice mail messages. The MP3 format is a common audio file format that's used to greatly reduce the size of the audio file and is most commonly used by personal audio devices or MP3 players. MP3 is a cross-platform type of audio codec and is used for compatibility with many mobile phones and devices and different computer operating systems.

WMA

WMA is the most highly compressed audio codec of the three kinds of codecs. The compression is approximately 11,000 bytes for each 10 seconds of audio. However, the .wma file format has a much larger header section than the .wav file format. The .wma file header section is approximately 7 kilobytes (KB), whereas the header section for the .wav file is less than 100 bytes. Although WMA audio recordings are recorded for longer than 15 seconds, they become smaller than GSM audio recordings. Therefore, for the smallest but highest-quality audio files, use the WMA audio codec.

Note:
If you using push notifications from your on-premises deployment for OWA for Devices, you can’t use the WMA format. OWA for Devices only supports the MP3 file format.

G.711 PCM Linear

The G.711 PCM Linear audio codec creates .wav audio files that are not compressed. Therefore, G.711 PCM Linear .wav audio files occupy the most space for any given duration when they're compared to the GSM and WMA audio codecs. G.711 PCM Linear .wav audio files occupy just over 160,000 bytes for each 10 seconds of audio. G.711 PCM Linear .wav audio files have the highest audio quality of the three audio codecs used by UM. However, the quality of comparable audio

files created using the WMA and GSM audio codecs is acceptable to most users who listen to voice messages.

GSM

The GSM audio codec creates .wav audio files that are compressed. GSM .wav audio files are just over 16,000 bytes for each 10 seconds of audio. However, GSM creates an audio file larger than the audio file created by the WMA audio codec. Therefore, when you are balancing the quality of the voice message and the size, this may not be the best choice.

Return to top

Secondary dial plans

Applies to: *Exchange Server 2010 Service Pack 2 (SP2)*

Topic Last Modified: *2013-06-11*

When you enable a user for Unified Messaging (UM), you're required to assign one extension number and a UM mailbox policy that will link the user to a UM dial plan. After the user is enabled for UM, you can assign additional extension numbers for that user within the same dial plan but the extension numbers within that dial plan must be unique. In some deployments, a user may need to be assigned the same extension number in two separate dial plans. If this is the case, you can link the user to a secondary UM dial plan. This can be useful, for example, if the user has two physical phones or travels between locations.

Contents

Overview

When you enable a user for Unified Messaging, you must define one extension number and one UM mailbox policy that links the user to a single UM dial plan. When you enable the user for UM and they're linked to a UM mailbox policy that's linked to a SIP URI or E.164 dial plan, you must also provide either a SIP address or E.164 number with the user's extension number. UM uses the dial plan and extension, along with the SIP address or E.164 number, to locate the user when a voice

mail message is submitted to the user's mailbox.

If you're using telephone extension dial plans and need to provide the same extension number for a user, you'll need to create a secondary dial plan, enable the user for UM and provide the same extension number for the user. This is because the extension number must be unique within a dial plan,

Note:

There's no limit to the number of secondary extension numbers that you can add for a UM-enabled user.

There may be times when a user travels between locations, has two or more phones, or wants to receive voice mail on one Direct Inward Dial (DID) extension number and receive faxes on a different DID extension number. To achieve this, you must add an additional DID extension to the user's mailbox and, in some cases, add a secondary dial plan.

In some configurations, after you add a second extension on a primary dial plan or add a single or multiple extension numbers to a secondary dial plan, the user can receive voice messages or faxes using one or more of the extension numbers. If you want UM to answer these fax calls and send them to the second DID extension number, you must configure the telephony equipment in your organization to forward the fax calls to the second DID extension number.

The mailbox of a UM-enabled user can be assigned the following:

- A single extension number, Session Initiation Protocol (SIP) address, or E.164 address on a single dial plan
- Multiple extension numbers on a single dial plan
- Multiple extension numbers on two separate dial plans

When a user is enabled for UM, you must specify an extension number and a UM mailbox policy. UM requires the extension number to identify the user when they sign in to Outlook Voice Access to retrieve messages. The UM mailbox policy contains a collection of configuration properties, with values that UM applies to any user who is UM-enabled under that policy. The UM mailbox policy is similar to the "class of service" found in other systems (for example, voice mail or PBX), in the sense that a change to a UM mailbox policy value can affect the behavior for a large number of associated users.

One property on a UM mailbox policy refers to a UM dial plan. This represents a set of telephony-capable extensions. This set has a numbering plan in which duplicate extension numbers aren't allowed.

Therefore, a user's extension number is unique within the UM dial plan in which they're UM-enabled. In fact, the UM dial plan and extension number pair must be unique within the organization. This is one way that UM uniquely identifies a UM-enabled user in an organization. Using a secondary dial plan makes it easier to keep the dial plan and extension number unique within an organization. For example, imagine an organization has two UM dial plans: Dial Plan A and Dial Plan B. A user's extension number in Dial Plan A is 55555 and, in Dial Plan B, it's 66666. When a secondary dial plan is used, the user's extension for Dial Plan A can be 55555 and their extension in Dial Plan B can also

be 55555. In both cases, the user's extension within the dial plan that's used is unique.

The following table defines terms that are used when discussing primary and secondary extensions, Outlook Voice Access numbers, and UM dial plans.

Term	Definition
primary extension	The extension number that's specified when the user is UM enabled.
primary dial plan	The UM dial plan that's specified when the user is UM enabled. The UM-enabled user is associated with the dial plan when the user is linked to the UM mailbox policy.
primary Outlook Voice Access number	The Outlook Voice Access number for the user's primary dial plan. The user's calls are forwarded to this number if there's no answer or their line is busy. It's also the number that the user calls when they want to sign in to Outlook Voice Access.
secondary extension	One or more extension numbers that may be added to a UM-enabled user's configuration.
secondary dial plan	A UM dial plan other than the primary dial plan in which one or more secondary extensions can be configured.
secondary Outlook Voice Access number	The Outlook Voice Access number of a user's secondary dial plan. A user can call this number from their secondary extension number when they want to sign in to Outlook Voice Access.

Return to top

Use of secondary extensions

In most deployments, only one extension is configured per UM-enabled user. However, there are some more advanced deployments that require you to add secondary extensions for your users.

When Microsoft Lync Server is used for Enterprise Voice, Unified Messaging can provide the voice mail system. However, the UM dial plan used for Enterprise Voice must be a SIP URI dial plan that's specific to UM configurations with Lync Server. In these deployments, the user's extension is provided by a Microsoft Unified Communications endpoint, such as Microsoft Office Communicator, running on the user's computer, or Office Communicator Phone Edition, running on a supported IP phone device. Thus, in most cases, the user's primary dial plan must be the same SIP URI dial plan used with Lync Server. But if the user requires more extension numbers, you shouldn't add another secondary extension to the primary dial plan. You must add a secondary dial plan and then add the secondary extension or EUM proxy address to the UM-enabled user.

For more information about adding, removing, or changing extensions, see one of the following:

- Change an extension number
- Add an extension number
- Remove an extension number

If you need to change SIP addresses or E.164 numbers for UM-enabled users, see:

- Add a SIP address
- Change a SIP address
- Remove a SIP address
- Add an E.164 number
- Change an E.164 number
- Remove an E.164 number

Call answering

Unified Messaging provides both of the following:

- **Call answering** Occurs when a user doesn't answer their phone and UM takes the call.
- **Outlook Voice Access** Used by users when they dial in to the voice mail system to access their mailbox.

Two configurations are used frequently:

- A UM-enabled user has two extension numbers (one primary, one secondary) in the primary dial plan. These extensions correspond to different phones on the user's desk and are connected to the same PBX. These different numbers are available to two separate audiences. In this configuration, the primary extension is the "general" work number and the secondary extension is the "task-specific" number, possibly a helpdesk line, or a dedicated fax number.
- A UM-enabled user spends a certain length of time, perhaps three weeks out of four, in their company's main office and the rest of the time in another office at one of the company's remote locations. The two offices have different PBXs, and the extension numbers are unique to each PBX. In this example, the user is configured to have a primary extension in their primary dial plan on the main office PBX and a secondary extension in a secondary dial plan on the PBX of the other office.

In either configuration, voice messages or missed call notification messages that are generated by

unanswered calls to either extension will be sent to the user's Inbox.

Outlook Voice Access

You may want UM-enabled users to be able to sign in to Outlook Voice Access from any extension, primary or secondary. While this is possible, there may be some architectural restrictions that keep this from working identically from all extensions. To sign in to Outlook Voice Access, UM-enabled users must perform the following steps:

1. Call an Outlook Voice Access number.
2. Key in their extension number if they're calling from another phone number.
3. Key in their PIN if they aren't enabled for Enterprise Voice and are calling from a Unified Communications phone, Office Communicator, or Lync Server.

Usage scenarios

- **Single extension with Outlook Voice Access** If the user has a single primary extension, they must always call the Outlook Voice Access number for their primary UM dial plan. If they call from their extension number, they won't be prompted to enter the extension number, and step 2 of the preceding steps will be skipped.
- **Two extensions in the primary dial plan with Outlook Voice Access** If the user has only two extensions, primary and secondary, and both the primary and secondary extension are in the same UM dial plan, they must always call the Outlook Voice Access number of the dial plan. If they call from either the primary or secondary extension, they won't be prompted to enter the extension number, and step 2 of the preceding steps will be skipped. Outlook Voice Access features will work the same way, whichever extension is used to sign in.
- **Extensions in the primary dial plan and in a secondary dial plan with Outlook Voice Access** If the user has only two extensions, primary and secondary, and the primary and secondary extensions are in different UM dial plans (primary and secondary); they should call the Outlook Voice Access number appropriate to their dial plan. From their primary extension, they should call the Outlook Voice Access number of the primary dial plan, and from their secondary extension, they should call the Outlook Voice Access number of the secondary dial plan. If they do this, they won't be prompted to enter the extension number, and step 2 of the preceding steps will be skipped.

Outlook Voice Access features that don't involve outbound dialing (for example "Call the sender" or "Call the office") will work the same way, whichever extension is used to sign in. However, Outlook Voice Access features that do require outbound dialing won't work as expected when the user signs in to the secondary dial plan unless the outbound dialing rules are exactly the same in both dial plans. For the behavior of outbound dialing to be exactly the same, you must ensure that the following properties are configured identically on the primary and secondary dial plans:

- Dialing codes (trunk access, national, and international)
- In-country or region dialing codes
- Dialing rules
- Dialing rule group names

A UM-enabled user is associated with a UM mailbox policy, and this UM mailbox policy is linked with the user's primary dial plan. The UM mailbox policy settings that are associated with the UM-enabled user's primary dial plan will be applied to the user. If a user is associated with a secondary dial plan with a second extension number in the secondary dial plan, the UM mailbox policy settings associated with the primary dial plan will still be applied. In Outlook Voice Access, the same UM mailbox policy settings associated with the primary dial plan are applied whether the user calls in to the primary dial plan or to a secondary dial plan.

The **AllowedInCountryOrRegionGroups** and **AllowedInternationalGroups** properties on the UM mailbox policy contain the names of groups of dialing rules that are configured on the **ConfiguredInCountryOrRegionGroups** and **ConfiguredInternationalGroups** properties of a UM dial plan. When a UM-enabled user calls in to Outlook Voice Access, the outbound calling rules from the UM mailbox policy associated with the primary or secondary dial plan will apply to calls the user makes, depending on whether the UM-enabled user has called in to the primary or secondary dial plan's Outlook Voice Access number.

For example, if a primary dial plan named “Contoso Dial Plan 1” has a dialing rule named “US and Canada” in its **ConfiguredInCountryOrRegionGroups** property, the UM mailbox policy “Contoso UM Policy 1” might also have “US and Canada” in its **AllowedInCountryOrRegionGroups** property. If you want to add a secondary extension in “Contoso Dial Plan 2” for a user in “Contoso UM Policy 2”, you would have to ensure that the **ConfiguredInCountryOrRegionGroups** property of “Contoso Dial Plan 2” also contains a rule named “US and Canada”. Otherwise, if the user signs in to Outlook Voice Access from their secondary extension, UM won't be able to find a rule on the secondary dial plan named “US and Canada”. If this happens, UM will only allow the user to call numbers allowed to any caller to the secondary dial plan, which could be more restrictive.

Return to top

UM features that operate differently for secondary dial plans

There's a set of UM features that can use secondary dial plans but may not work correctly in certain situations. It's important that you understand how each of these features is affected when you configure UM-enabled users to use a secondary dial plan.

Play on Phone

In Outlook Web App, Play on Phone uses the VoIP gateway that's associated with the user’s primary dial plan to make the outbound call. It applies dialing rules from the primary dial plan and the UM mailbox policy that's associated with the user's mailbox.

Directory search (Outlook Voice Access)

A search of the directory for a user who's been authenticated will follow these rules:

- The ability to search for a user and then leave a voice message or call a user will be available only if the user conducting the search is UM enabled and has a primary extension on the same dial plan as the user that's being called. If so, a search by name, alias, and primary extension will locate the user. However, searching by using the secondary extension won't locate the user.
- If the user being searched for is UM enabled and has a secondary extension on the called dial plan, then a search by name, alias, and secondary extension will find the user. However, although options to leave a voice message and call the contact will be offered, the call contact option won't succeed. In this case, a search by primary extension won't find the user.
- To find and be able to either call or leave a voice message for the user they're searching for, the UM-enabled user should use Outlook Voice Access through their primary dial plan's Outlook Voice Access number and search by name, alias, or primary extension. If the searched-for user is called using the secondary dial plan's Outlook Voice Access number, the user will only be found if the search is made by name, alias, or secondary extension. If the primary extension is used, the only option that will be available is for the user to leave a voice mail.

Directory search (Outlook Voice Access)

A search of the directory for a user who hasn't been authenticated will follow these rules:

- The user being searched for will be found and the option to leave a voice message or call the user will be offered only if the user is UM enabled and has a primary extension on the called dial plan. If so, a search by name, alias, and primary extension will find the user. However, a search by secondary extension won't find the user.
- If the user being searched for is UM enabled, has a secondary extension on the called dial plan, and the option **Transfer and search** > **Allow callers to** > **Leave voice messages without ringing a user's phone** is selected on the called dial plan, then a search by name, alias, and secondary extension will find them. However, the option to leave voice mail will be offered to the caller, and there will be no option to call them.
- To find and be able to either call or leave a voice message for a user, the caller must call the Outlook Voice Access number of the user's primary dial plan and search by name, alias, or the user's secondary extension. If the user's secondary Outlook Voice Access number is called, they will only be found if the **Allow callers to search by name of alias** option is set to **In the entire organization**. In this case, only the option to leave a voice message will be provided.

Call the Sender (Outlook Voice Access)

When a user calls in to Outlook Voice Access and chooses the option to Call the Sender, they can send either an email message or a voice mail message to a UM-enabled user. The options available depend on whether the caller is associated with the same dial plan as the sender they're calling. Calls to a UM-enabled user when the caller dials in to an Outlook Voice Access number and the caller is authenticated will follow these rules:

- **Email messages** If the sender of the email message is a UM-enabled user, choosing the option

to call the sender will result in a call to the sender's primary extension that's configured on the user's primary dial plan. In the case where the sender's primary extension is on a dial plan that's different from the caller's, the prompt to "Call the Sender" will only be provided if there's a business, home, or mobile phone configured for the sender and the dialing rules are configured to allow the call.

- **Voice mail messages** If the caller is a UM-enabled user, the option to call the sender will always result in a call to the extension that the sender uses to leave their voice message. If this extension has a number of digits different from the called dial plan, the prompt to call the sender won't be provided unless there are dialing rules in place that would permit the call. For example:
  - The "Call the sender" option will be offered if the sender uses an extension on the dial plan that was used to send the voice message.
  - The "Call the sender" option will be played if the sender uses an extension from a different dial plan than the dial plan that's used with Outlook Voice Access to send the voice message and both dial plans have the same number of digits. The success of the call will depend on whether the VoIP gateway and PBX infrastructure permit the call transfer.
  - The "Call the sender" option won't be played if the sender uses an extension from a different dial plan than the dial plan that's used with Outlook Voice Access to send the voice message, the dial plans have a different number of digits, and there are no outdialing rules that match the sender's extension.

Delete a UM dial plan

Create a UM dial plan

Connect your voice mail system to your telephone network > UM dial plans > UM dial plan procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-04-16*

A Unified Messaging (UM) dial plan contains configuration information related to your telephony network. A UM dial plan establishes a link from the telephone extension number of a user enabled for voice mail to their mailbox. When you create a UM dial plan, you can configure the number of digits in the extension numbers, the Uniform Resource Identifier (URI) type, and the Voice over IP (VoIP) security setting for the dial plan.

Each time you create a UM dial plan, a UM mailbox policy is also created. The UM mailbox policy is named <*DialPlanName*> Default Policy.

For additional management tasks related to UM dial plans, see UM dial plan procedures.

What do you need to know before you begin?

- Estimated time to complete: 3 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

What do you want to do?

Use the EAC to create a UM dial plan

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**, and then click **New +**.
2. On the **New UM dial plan** page, complete the following boxes:
   - **Name** Type the name of the dial plan. A UM dial plan name is required and must be unique.

However, it's used only for display in the EAC and the Shell. If you have to change the display name of the dial plan after it's been created, you must first delete the existing UM dial plan and then create another dial plan that has the appropriate name. If your organization uses multiple UM dial plans, we recommend that you use meaningful names for your UM dial plans. The maximum length of a UM dial plan name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.

Although you can include spaces in a UM dial plan name, if you integrate Unified Messaging with Office Communications Server 2007 R2 or Microsoft Lync Server, the dial plan name can't include spaces. Therefore, if you created a dial plan with spaces in the display name, and you're integrating with Office Communications Server 2007 R2 or Lync Server, you must first delete that dial plan and then create another dial plan that doesn't include spaces in the display name.

Important:

Although the box for the name of the dial plan can accept 64 characters, the name of the dial plan can't be longer than 49 characters. If you try to create a dial plan name that contains more than 49 characters, you'll receive an error message. The message will say that the UM mailbox policy couldn't be generated because the UM dial plan name is too long. This happens because, as mentioned earlier, when you create a dial plan a default UM mailbox policy named <*DialPlanName*> Default Policy is also created. When the 15 characters in Default Policy are added to the name of the dial plan, the total characters exceed the limit. The *name* parameter for both the UM dial plan and UM mailbox policy can be 64 characters. However, if the name of the dial plan is longer than 49 characters, the name of the default UM mailbox policy will be longer than 64 characters, and this isn't allowed by the system.

- **Extension length (digits)** Enter the number of digits for the dial plan. The number of digits for extension numbers is based on the telephony dial plan created on a Private Branch eXchange (PBX) or IP PBX. For example, if a user associated with a telephony dial plan dials a four-digit extension to call another user in the same telephony dial plan, you select 4 as the number of digits in the extension.

This is a required box that has a value range from 1 through 20. The typical extension length is from 3 through 7. If your existing telephony environment includes extension numbers, you must specify a number of digits that matches the number of digits in those extensions.

When you create a Session Initiation Protocol (SIP) or an E.164 dial plan and associate a UM-enabled user with the dial plan, you must still input an extension number to be used by the user. This number is used by Outlook Voice Access users when they access their mailbox.

- **Dial plan type** A Uniform Resource Identifier (URI) is a string of characters that identifies or names a resource. The main purpose of this identification is to enable VoIP devices to communicate with other devices over a network using specific protocols. URIs are defined in schemes that define a specific syntax and format and the protocols for the call. In simple terms, this format is passed from the IP PBX or PBX. After you create a UM dial plan, you won't be able to change the URI type without deleting the dial plan, and then re-creating the dial plan to include the correct URI type. You can select one of the following URI types for the dial plan:
  - **Telephone extension** This is the most common URI type. The calling and called party information from the VoIP gateway or IP Private Branch eXchange (PBX) is listed in one of

the following formats: Tel:512345 or 512345@<*IP address*>. This is the default URI type for dial plans.

- **SIP URI** Use this URI type if you must have a Session Initiation Protocol (SIP) URI dial plan such as an IP PBX that supports SIP routing or if you're integrating Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server and Unified Messaging. The calling and called party information from the VoIP gateway. IP PBX, or Communications Server 2007 R2 or Lync Server is listed as a SIP address in the following format: sip:<*username*>@<*domain* or *IP address*>:Port.
- **E.164** E.164 is an international numbering plan for public telephone systems in which each assigned number contains a country code, a national destination code, and a subscriber number. The calling and called party information sent from the VoIP gateway or IP PBX is listed in the following format: Tel:+14255550123.

Warning:

After you create a dial plan, you will be unable to change the URI type without deleting the dial plan, and then re-creating the dial plan to include the correct URI type.

- **VoIP security mode** Use this drop-down list to select the VoIP security setting for the UM dial plan. You can select one of the following security settings for the dial plan:
  - **Unsecured** By default, when you create a UM dial plan, it is set to not encrypt the SIP signaling or RTP traffic. In unsecured mode, the Client Access and Mailbox servers associated the UM dial plan send and receive data from VoIP gateways, IP PBXs, SBCs and other Client Access and Mailbox servers using no encryption. In unsecured mode, neither the Realtime Transport Protocol (RTP) media channel nor the SIP signaling information is encrypted.
  - **SIP secured** When you select **SIP secured**, only the SIP signaling traffic is encrypted, and the RTP media channels still use TCP, which isn't encrypted. With SIP secured, Mutual Transport Layer Security (TLS) is used to encrypt the SIP signaling traffic and VoIP data.
  - **Secured** When you select **Secured**, both the SIP signaling traffic and the RTP media channels are encrypted. Both the secure signaling media channel that uses Secure Realtime Transport Protocol (SRTP) and the SIP signaling traffic use mutual TLS to encrypt the VoIP data.
- **Audio language** Use this list to specify the default language to be used by Outlook Voice Access users. This setting doesn’t apply to the language setting on a UM auto attendant. You can set the language for Outlook Voice Access to be the same as or different from the language that’s used on a UM auto attendant. When a user places a call to a user who is linked with a dial plan, the audio language is the default language that the voice-recorded operator uses. The system prompts that callers hear are played in the same language. The language that is chosen on the UM dial plan is used to read email, voice mail, and calendar items; to say the user’s name if a personal greeting hasn’t been recorded; to transcribe a voice message using the Voice Mail Preview feature; and to enable Automatic Speech Recognition (ASR) to work correctly.
- **Country/Region code** Use this box to type the country/region code number to be used for outgoing calls. This number will precede the telephone number that’s dialed. This box accepts

from 1 through 4 digits. For example, in the United States, the country/region code is 1. In the United Kingdom, it's 44.

3. Click **Save**.

Use the Shell to create a UM dial plan

This example creates a new UM dial plan named `MyUMDialPlan` that uses four-digit extension numbers.

```
New-UMDialplan -Name MyUMDialPlan -NumberofDigits 4
```

This example creates a new UM dial plan named `MyUMDialPlan` that uses five-digit extension numbers and supports SIP URIs.

```
New-UMDialplan -Name MyUMDialPlan -UriType SIPName -
NumberofDigits 5
```

Manage a UM dial plan

Connect your voice mail system to your telephone network > UM dial plans > UM dial plan procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-04-16*

After you create a Unified Messaging (UM) dial plan, you can view and configure a variety of settings. For example, you can configure the level of Voice over IP (VoIP) security, the audio codec, and dialing restrictions. The settings that you configure on the UM dial plan affect all users who are linked with the dial plan through a UM mailbox policy.

For additional management tasks related to UM dial plans, see UM dial plan procedures.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

What do you want to do?

Use the EAC to view or configure UM dial plan settings

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**.
2. In the list view, select the UM dial plan you want to view or modify, and then click **Edit** .
3. On the **UM Dial Plan** page, click **Configure**. Use the configuration options to view specific dial plan settings and to enable or disable features as described in the following steps.
4. **General** Use this page to view specific dial plan settings or to enable or disable features for UM-enabled users:
   - **Name** This is the name of the dial plan that was created. The maximum length of a UM dial plan name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.
   - Although you can include spaces in a UM dial plan name, if you integrate Unified Messaging with Office Communications Server 2007 R2 or Microsoft Lync Server, the dial plan name can’t include spaces. Therefore, if you created a dial plan with spaces in the display name, and you’re integrating with Office Communications Server 2007 R2 or Lync Server, you must first delete that dial plan and then create another dial plan that doesn't include spaces in the display name.

Important:

Although the box for the name of the dial plan can accept 64 characters, the name of the dial plan can't be longer than 49 characters. If you try to create a dial plan name that contains more than 49 characters, you’ll receive an error message. The message will say that the UM mailbox policy couldn't be generated because the UM dial plan name is too long. This happens because, as mentioned earlier, when you create a dial plan a default UM mailbox policy named <*DialPlanName*> Default Policy is also created. When the 15 characters in Default Policy are added to the name of the dial plan, the total characters exceed the limit. The *name* parameter for both the UM dial plan and UM mailbox policy can be 64 characters. However, if the name of the dial plan is longer than 49 characters, the name of the default UM mailbox policy will be longer than 64 characters, and this isn't allowed.

   - **Extension length (digits)** This is the number of digits in the extension numbers for users who are associated with this dial plan. For example, if a user associated with a dial plan dials a 4-digit extension to call another user in the same dial plan, select 4 as the number of digits in the extension.

The number of digits for extension numbers is based on the telephony dial plan created on an IP PBX or PBX. This is a required field that has a value range from 1 through 20. The typical extension length is from 3 through 7 digits. If your existing telephony environment includes extension numbers, you must specify a number of digits that matches the number of digits in those extensions

when you create the UM dial plan.

- **Dial plan type** A Uniform Resource Identifier (URI) is a string of characters that identifies or names a resource. The main purpose of this identification is to enable VoIP devices and PBXs to communicate with other devices over a network using specific protocols. URIs are defined in schemes that define a specific syntax and format and the protocols for the call. In simple terms, this format is passed from the IP PBX or PBX and the type of dial plan you create must match that format. After you create a UM dial plan, you won't be able to change the dial plan type without deleting the dial plan, and then re-creating the correct type of dial plan. You can select one of the following dial plan types:
  - **Telephone extension** This is the most common dial plan type. The calling and called party information from the VoIP gateway or IP Private Branch eXchange (PBX) is listed in one of the following formats: Tel:512345 or 512345@<*IP address*>. This is the default type for dial plans.
  - **SIP URI** Use this dial plan type if you must have a Session Initiation Protocol (SIP) URI dial plan such as an IP PBX that supports SIP routing, a SIP-enabled PBX, or if you're integrating Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server and Unified Messaging. The calling and called party information from the VoIP gateway. IP PBX, SIP-enabled PBX, or Communications Server 2007 R2 or Lync Server is listed as a SIP address in the following format: sip:<*username*>@<*domain* or *IP address*>:Port.
  - **E.164** E.164 is an international numbering plan for public telephone systems in which each assigned number contains a country code, a national destination code, and a subscriber number. The calling and called party information sent from the VoIP gateway and PBX or IP PBX is listed in the following format: Tel:+14255550123.

Note:

After you create a dial plan, you won't be able to change the dial plan type without deleting the dial plan, and then re-creating the correct type of dial plan.

- **VoIP security mode** Use this drop-down list to select the VoIP security setting for the UM dial plan. You can select one of the following security settings for the dial plan:
  - **Unsecured** By default, when you create a UM dial plan, it's set to not encrypt the SIP signaling or RTP traffic. In Unsecured mode, the Exchange servers associated with the UM dial plan send and receive data from VoIP gateways, IP PBXs, SBCs, and other Exchange servers using no encryption. In Unsecured mode, neither the Realtime Transport Protocol (RTP) media channel nor the SIP signaling information is encrypted.
  - **SIP secured** When you select **SIP secured**, only the SIP signaling traffic is encrypted, and the RTP media channels still use TCP, which isn't encrypted. With SIP secured, mutual Transport Layer Security (TLS) is used to encrypt the SIP signaling traffic and VoIP data.
  - **Secured** When you select **Secured**, both the SIP signaling traffic and the RTP media channels are encrypted. Both the secure signaling media channel that uses Secure Realtime Transport Protocol (SRTP) and the SIP signaling traffic use mutual TLS to encrypt the VoIP data.

5. **Dial codes** Use this page to configure the dial codes for a UM dial plan. Several dial code settings can be configured on the dial plan. These include incoming and outgoing calling

options. You can configure the following:

- **Dial codes for outgoing calls** Use these settings to specify the dialing codes for outgoing calls that can be made by UM-enabled users. These outgoing calls are calls that are placed using Outlook Voice Access or from a voice mail message.
  - **Outside line access code** Use this field to type the number or numbers used to access an outside telephone number for outgoing external calls. This number will precede the telephone number dialed. This is also called a trunk access code. This field accepts from 1 through 16 digits. For many organizations, this number is 9. By default, this field isn't populated.

Frequently, this setting is used in telephony environments where a PBX or IP PBX is located onsite or maintained in an organization. It may not have to be configured if your organization's telephony environment is maintained by an external business or vendor.

  - **International access code** Use this field to type the number code used to access international telephone numbers for outgoing calls. This number will precede the telephone number dialed. By default, this field isn't populated. This field accepts from 1 through 4 digits. For example, the international access code for the United States is 011. For Europe, it's 00.
  - **National number prefix** Use this field to type the number code used to dial telephone numbers that are out of an area code but within the country/region. This number will precede the telephone number dialed. By default, this field isn't populated. This field accepts from 1 through 4 digits. For example, 0 is used in Europe, and 1 is used in North America.
  - **Country/Region code** Use this field to type the country/region code number used for outgoing calls. This number will precede the telephone number dialed. By default, this field isn't populated. This field accepts from 1 through 4 digits. For example, in the United States, the country/region code is 1. In the United Kingdom, it's 44.

- **Number formats for dialing between UM dial plans** Use these settings to configure calls between users in separate dial plans when they place calls between the dial plans.
  - **Country/Region number format** Use this field to specify how a user's telephone number should be dialed by the Exchange servers when users are in a different dial plan that has the same country code. This is used by auto attendants and when an Outlook Voice Access user searches and tries to call the user in the directory.

This entry consists of a number prefix and a variable number of characters (for example, 020*xxxxxxx*).To determine the telephone number, Unified Messaging will append the last *x* digits from the telephone number specified in the directory to the prefix specified.

  - **International number format** Use this field to specify how a user's telephone number should be dialed by Unified Messaging when the users are in different dial plans that have different country codes. This is used by an auto attendant and when an Outlook Voice Access user searches and tries to call the user in the directory.

This entry consists of a number prefix and a variable number of characters (for example, 4420*xxxxxxx*). To determine the telephone number, Unified Messaging will append the last *x* digits from the telephone number specified in the directory to the prefix specified.

- **Number formats for incoming calls within the same dial plan** Use this field to add or remove a number format for incoming calls that are placed between users in the same dial plan. This field accepts both numbers and the letter “x” as a wild card character. No other letters can be used in this field.

For incoming calls within the same dial plan add a number format. For example, to add a number format for 5-digit extensions, enter, 142570xxxxx and click **+**. To remove a number format, click **–**.

6. **Outlook Voice Access** Use this page to configure Outlook Voice Access settings for the UM dial plan. Outlook Voice Access enables users to access their individual mailboxes to retrieve email, voice messages, contacts, and calendaring information using a telephone. You can view or configure the following:
   - **Welcome greeting** This display-only field shows the name of the sound file that will be used for the welcome greeting.
     - **Default greeting** The welcome greeting is used when an Outlook Voice Access user or another caller calls the Outlook Voice Access number and does a directory search. This audio file is the default greeting for a UM dial plan. However, you may want to change this welcome greeting and provide another welcome greeting specific to your company, such as, "Welcome to Outlook Voice Access for Contoso, Ltd."

If you decide to customize this greeting, you must first record the customized greeting, save it as a .wav file, and then configure the dial plan to use this customized greeting. The file name and path must not exceed 255 characters.

You can add a customized greeting by clicking **Change**, and then clicking **Browse** to select a previously recorded custom greeting and specify the audio file (.wav) to use for the welcome greeting. If you don't specify an audio file, Outlook Voice Access users will hear a default welcome greeting that says, "Welcome, you are connected to Microsoft Exchange."

   - **Informational announcement** When enabled, this optional recording plays immediately after the business or non-business hours welcome greeting. An informational announcement may state the organization's security polices for accessing the system, for example, "When you gain access to our system using Outlook Voice Access, you have agreed to the terms of our business agreement and all security policies for our organization apply. Access to our system is monitored and gaining illegal access will be prosecuted.” An informational announcement can also provide information that's required for compliance with company policy, for example, "Calls may be monitored for training purposes." If it's important that callers hear the whole informational announcement, it can be marked as uninterruptible.

By default, there's no informational announcement configured on UM dial plans. To enable an informational announcement and use a custom audio file specific to your organization, click **Change** and then click **Browse**.

   - **Allow announcement to be interrupted** Select this check box to enable the Outlook Voice Access user to interrupt the informational announcement. You should do this if you have long informational announcements. Outlook Voice Access users may become frustrated if the informational announcement is long and they can't interrupt it to access the options provided by the UM dial plan.
   - **Outlook Voice Access numbers** Use this field to add a telephone or extension number or a

SIP URI that an Outlook Voice Access user will call to access the voice mail system using Outlook Voice Access. In most cases, you enter an extension number or an external telephone number. However, because this field accepts all alphanumeric characters, a SIP URI can be used if you're using an IP PBX, Office Communications Server 2007 R2, or Microsoft Lync Server.

By default, when a dial plan is created, no Outlook Voice Access numbers are defined. To enable Outlook Voice Access users to call into Outlook Voice Access, you must configure at least one telephone number. The number of alphanumeric characters can't exceed 20.

When you configure this number on the dial plan, this number will be displayed in Microsoft Office Outlook 2007 or later versions and Outlook Web App for voice mail options.

To add a new Outlook Voice Access number, enter the number in the box and click **+**. To remove an Outlook Voice Access number, click **–**.

7. **Settings** Use this page to configure dial plan settings for Unified Messaging. When you configure settings on this page, you can control how Outlook Voice Access users and external callers calling into an auto attendant linked to the dial plan locate users in your organization, the audio codec that is used for voice mail messages, the number of sign-in failures, and time-out values. You can configure the following:
   - **Primary way to search for names** Use this list to select the primary way that callers can locate a user when they dial in to the system.

By default, **Last First** is selected. This means that when users are searching for a user in the directory, they will enter the user's last name first and then the first name.

When an Outlook Voice Access user calls in to an Outlook Voice Access number to access their mailbox, a caller calls in to an Outlook Voice Access number to perform a directory search, or a caller calls in to an auto attendant linked to a UM dial plan, they can search for a user in the directory by spelling their name or alias.

You must select one of the supported methods to be able to use the dial-by-name primary method. The following methods are supported:

- **Last First (default)**
- **First Last**
- **SMTP address**

   - **Secondary way to search for names** Use this list to select the secondary way that callers can locate a user when they dial in to the system.

By default, **SMTP address** is selected. This means that when users search for a user in the directory, they will enter the user's email alias or SMTP address.

When an Outlook Voice Access user calls in to an Outlook Voice Access number to access their mailbox, a caller calls in to an Outlook Voice Access number to perform a directory search, or a caller calls in to an auto attendant linked to a UM dial plan, they can search for a user in the directory by spelling their name or alias. When you select one of these options, callers can use the primary way to search for names or the secondary way to search for names to locate users in the directory.

You aren't required to select one of the four methods that are supported. However, if you don't select a secondary way to search for users, callers will be given only one way to search for a user.

The following options are available:

- **Last First**
- **First Last**
- **SMTP address** (default)
- **None**

- **Audio codec** Use this list to select the audio codec that will be used by the dial plan. When a caller places a call to a user who is associated with the dial plan and leaves a voice message, Unified Messaging uses the audio codec that you select from this list to record voice messages that will be sent to voice mail-enabled users. The following audio codecs are supported:
  - **MP3** (default)
  - **WMA** (Windows Media Audio)
  - **G711** (Pulse Code Modulation (PCM) Linear)
  - **GSM** (Group System Mobile 06.10)

By default, the MP3 format is selected. The MP3 format is a common audio file format that's used to greatly reduce the size of the audio file and is most commonly used by personal audio devices or MP3 players. MP3 is a cross-platform type of audio codec and is used for compatibility with many mobile phone and devices and various computer operating systems.

WMA is used because it's highly compressed and has high-quality format properties. G.711 PCM Linear is a telephone-quality audio codec format that's the least compressed and has the lowest-quality format. GSM 06.10 is an audio codec format that's used by mobile phone vendors and is the standard for digital mobile phone services.

If you're concerned about users' disk quotas, select WMA as the audio codec. Voice files saved in .wma format are approximately half the size of the same voice recording made using one of the other audio codecs.

- **Operator extension** Use this text box to enter the telephone number or an extension number for the dial plan's operator. This is different than an operator extension that is configured on a UM auto attendant. However, you can put in the same phone or extension number for both types of operators.

You can configure this setting to transfer calls to an auto attendant if one is configured, to a human operator, to external telephone numbers, or to extension numbers.

When a caller who is using the telephone keypad presses 0, or says "reception" or "operator," or the **Number of input failures before disconnecting** threshold is exceeded, the caller is transferred to the telephone or extension number that you specify in this text box.

This telephone number can be a number external to the organization or an internal telephone extension number. For example, if the extension number for the receptionist or operator is 81964 and your organization has only one dial plan, enter 81964.

By default, this setting is blank. If you don't enter a number in this text box, the ability to transfer calls to the operator is disabled and callers are politely disconnected because there's no one to answer the call.

We recommend that you populate this text box with a telephone number that transfers callers to an operator if they can't locate a specific user in the directory.

- **Number of sign-in failures before disconnecting** Use this text box to enter the number of sequential unsuccessful logon attempts allowed before a caller is disconnected.

The value of this setting can be from 1 through 20. Setting this value too low can frustrate users. For most organizations, this value should be set to the default of three attempts.

- **Timeouts and retries** These settings apply to Outlook Voice Access users and external callers that dial into a UM auto attendant.
  - **Maximum call duration (minutes)** Use this text box to enter the maximum number of minutes that an incoming call can be connected to the system without being transferred to a valid extension number before the call is ended. For most organizations, this value should be set to the default of 30 minutes.

This setting applies to all kinds of calls. This includes incoming Outlook Voice Access calls, voice calls internal to your organization, and voice and incoming fax calls external to your organization.

The value of this setting can be from 10 through 120. Setting this value too low can cause incoming calls to be disconnected before they are completed. For example, if your organization receives many large fax messages, you may want to consider increasing this value from the default so that all the pages for fax messages are received.

  - **Maximum recording duration (minutes)** Use this text box to enter the maximum number of minutes allowed for each voice recording when a caller leaves a voice mail message. For most organizations, this value should be set to the default of 20 minutes.

The value of this setting can be from 1 through 100. Setting this value too low can cause long voice messages to be disconnected before they are completed. Setting this value too high lets users save lengthy voice messages in their Inboxes.

This setting is important if you have implemented strict disk quotas for users. This value must be less than the value set for the **Maximum call duration (minutes)** setting.

  - **Recording idle time out (seconds)** Use this text box to enter the number of seconds of silence that the system allows when a voice message is being recorded before the call is ended. For most organizations, this value should be set to the default of 5 seconds.

The value of this setting can be from 2 through 10. Setting this value too low can cause the system to disconnect callers before they are finished leaving their voice messages. Setting this value too high allows lengthy silences in voice messages.

  - **Number of input failures before disconnecting** Use this text box to configure the number of times that callers can enter incorrect menu choices before they are disconnected. For most organizations, this value should be set to the default of three attempts. This is an important setting for speech-enabled UM dial plans.

Examples of incorrect data include when a caller requests an extension number that isn't found in the system, the system can't locate the user's extension number to transfer the call, or the caller presses a menu option that isn't valid.

The value of this setting can be from 1 through 20. Setting this value too low may prematurely disconnect the caller.

- **Audio language** Use this list to specify the default language to be used by Outlook Voice Access users. This setting doesn’t apply to the language setting on a UM auto attendant. You

can set the language for Outlook Voice Access to be the same as or different from the language that's used on a UM auto attendant. When a user places a call to a user who is linked with a dial plan, the audio language is the default language that the voice-recorded operator uses. The system prompts that callers hear are played in the same language. The language that is chosen on the UM dial plan is used to read email, voice mail, and calendar items; to say the user's name if a personal greeting hasn't been recorded; to transcribe a voice message using the Voice Mail Preview feature; and to enable Automatic Speech Recognition (ASR) to work correctly.

For on-premises deployments, adding other languages lets Outlook Voice Access use a language other than U.S. English. For example, if an Outlook Voice Access user calls in using an Outlook Voice Access number from a desk telephone, the user is greeted with a prerecorded operator's voice in English. Even if the same user selects a different language, such as French, in Outlook Web App, the menus are still read in U.S. English. For the user to be able to hear the prerecorded operator menus in French, you must install the appropriate language pack.

Note:
For Exchange Online, all languages are available.

8. **Dialing rules** Use this page to specify dialing rules for in-country/region and international calls placed by UM-enabled users. Each entry defined on the dialing rule determines the types of calls that users within a specific dialing rule group can make. After you use the **Dialing rules** page to configure dialing rules, you must configure the UM dial plan, a UM mailbox policy, or a UM auto attendant to use the appropriate dialing rule. After you configure the UM mailbox policy to use a dialing rule group, the dialing restrictions configured apply to all UM-enabled users who are associated with the UM mailbox policy. For example, you can configure a dialing rule group that doesn't require users who are associated with the dial plan to dial an outside line access code when they place a call to an in-country/region telephone number. You can configure the following:
   - **In-country/region dialing rules** Use this box to add, remove, or edit in-country/region dialing rule groups used by UM mailbox policies. To create a dialing rule, click **+**. To edit an existing dialing rule, click ✎. To remove a dialing rule, click **–**. When you create a dialing rule, add the following information on the **New dialing rule** page:
     - **Dialing rule name** Use this text box to enter the name for the dialing rule you are creating. You can use the same name to collect several rules in a group and then enable or disable them under **Dialing authorization**. The name can be up to 32 characters long.
     - **Number pattern to transform (number mask)** Use this text box to enter the number pattern to transform before dialing, for example 91425xxxxxxx. If a user enters a number that matches this pattern, UM will transform the number dialed into a dialed number before placing the call. You can only enter numbers and the wildcard character, "x".
     - **Dialed number** Use this text box to enter the number you want to dial that matches the number pattern you set in the **Number pattern to transform (number mask)**. The dialed number is used to determine the actual dial string sent to the VoIP gateway or IP PBX. This number can be different from the number obtained by Unified Messaging for the outgoing call. However, your PBX or IP PBX can also be configured to omit the area code for local

calls and can be configured for private voice numbering plans. Any wildcard characters (*x*) in the dial string are replaced with the digits from the original number that were matched by the number mask on the dialing rule. An example of a valid dialed number is 9*xxxxxxx*. This field can contain only numbers and the character *x*.

- **Comment** Use this text box to put in a comment or description for the dialing rule that you're adding or modifying. By default, this text box is blank.

Note:

If you are integrating with Office Communications Server 2007 R2 or Microsoft Lync Server, you'll probably find it unnecessary to configure dialing rules or dialing rule groups in Unified Messaging. Office Communications Server 2007 R2 and Lync Server are designed to perform call routing and number translation for users in your organization, and will also do this when the calls are made on behalf of users.

- **International rules** Use this text box to add, remove, or edit international dialing rule groups used by UM mailbox policies.
  - **Dialing rule name** Use this text box to enter the name for the dialing rule you are creating. You can use the same name to collect several rules in a group and then enable or disable them under **Dialing authorization**. The name can be up to 32 characters long.
  - **Number pattern to transform (number mask)** Use this text box to enter the number pattern to transform before dialing, for example 91425xxxxxxx. If a user enters a number that matches this pattern, UM will transform the number dialed into a dialed number before placing the call. You can only enter numbers and the wildcard character, "x".
  - **Dialed number** Use this text box to enter the number you want to dial that matches the number pattern you set in **Number pattern to transform (number mask)**. The dialed number is used to determine the actual dial string sent to the VoIP gateway or IP PBX. This number can be different from the number obtained by Unified Messaging for the outgoing call. However, your PBX or IP PBX can also be configured to omit the area code for local calls and can be configured for private voice numbering plans. Any wildcard characters (*x*) in the dial string are replaced with the digits from the original number that were matched by the number mask on the dialing rule. An example of a valid dialed number is 9*xxxxxxx*. This field can contain only numbers and the character *x*.
  - **Comment** Use this text box to put in a comment or description for the dialing rule that you're adding or modifying. By default, this text box is blank.

Note:

For on-premises deployments, if you are integrating with Office Communications Server 2007 R2 or Microsoft Lync Server, you'll probably find it unnecessary to configure dialing rules or dialing rule groups in Unified Messaging. Office Communications Server 2007 R2 or Lync Server are designed to perform call routing and number translation for users in your organization, and will also do this when the calls are made on behalf of users.

9. **Dialing authorization** Use this page to select dialing rules for callers who call in to an Outlook Voice Access number configured on a UM dial plan. You can restrict the type of calls placed by callers when an unauthenticated user or an Outlook Voice Access user calls in to an Outlook Voice Access number configured on a dial plan by configuring dialing rule groups and dialing

restrictions. You can configure the following:

- **Calls in the same UM dial plan** Select this check box to let users who call in to an Outlook Voice Access number configured on a dial plan place or transfer calls to an extension number associated with a UM-enabled user who is within the same dial plan. By default, this setting is enabled.

When you disable this setting, users who call in to the Outlook Voice Access number won't be able to place or transfer calls to any users who aren't UM-enabled, to other extension numbers, or to UM-enabled users who are associated with the same dial plan. This is because the **Allow calls to any extension** setting is disabled by default.

- **Allow calls to any extension** When this setting is disabled, users who call in to an Outlook Voice Access number on the dial plan can't place calls to users who aren't UM-enabled or to other extension numbers not associated with a UM-enabled user. However, they can place a call or transfer a call to extension numbers associated with UM-enabled users. This is because the **Calls in the same UM dial plan** setting is enabled by default. The **Allow calls to any extension** setting is disabled by default.

When this setting is enabled, users who call in to an Outlook Voice Access number configured on the dial plan can place calls to users who aren't UM-enabled, to other extension numbers not associated with a UM-enabled user, and to UM-enabled users. This is because the **Calls in the same UM dial plan** setting is enabled by default.

You can enable this setting in an environment where not all users have been UM-enabled. This setting is also useful when you want to allow users who call in to a Outlook Voice Access number configured on a dial plan to call extension numbers that aren't associated.

- **Authorized in-country/region dialing rule groups** Use this section to add or remove allowed in-country/region dialing rules. By default, there are no in-country/region dialing rules configured on UM dial plans.

In-country/region dialing rule groups are used to allow or restrict the telephone numbers within a country or region that any user who has dialed in to the subscriber access number can dial. This helps prevent unnecessary or unauthorized telephone calls and charges.

To add in-country/region dialing rules, you must first create the appropriate in-country/region dialing rule on the dial plan, and then add the appropriate dialing rule entries on the dialing rule. After you create the required dialing rules on the dial plan, you must then add the dialing rule to the list of dialing authorizations on the **Dialing authorization** page on the dial plan.

In-country/region dialing rule groups can be used to allow or restrict access to telephone numbers within a country or region. This is applied to all users who have called in to an Outlook Voice Access number.

- **Authorized international dialing rule groups** Use this section to add or remove allowed international dialing rules. By default, there are no international dialing rules configured on UM dial plans.

International dialing rules are used to allow or restrict the telephone numbers outside a country or region that any user who has dialed in to the Outlook Voice Access number can dial. This helps prevent unnecessary or unauthorized telephone calls and charges.

To add international dialing rule groups, you must first create the appropriate international dialing rules on the dial plan, and then add the appropriate dialing rule entries. After you create the required dialing rules on the dial plan, you must then add the dialing rule to the list of dialing authorizations on the **Dialing authorization** page on the dial plan.

International dialing rule groups can be used to allow or restrict access to telephone numbers outside a country or region. This is applied to all users who have called in to an Outlook Voice Access number.

10. **Transfer & search** Use this page to configure the UM dial plan features. Several features can be configured on the UM dial plan. These include transferring calls, sending voice messages, and searching for users. You can configure the following:
    - **Allow callers to** Use these settings to determine how users who call in to an Outlook Voice Access number can contact users. You can configure the following:
        - **Transfer to users** Select this check box to enable Outlook Voice Access users to transfer calls to users. By default, this option is enabled. This lets users associated with the dial plan transfer calls to users in the same UM dial plan. After you select this check box, you can set the group of users callers can search for by selecting the appropriate option under the **Allow callers to search for users by name or alias** section on this page.

If you disable this option, Outlook Voice Access won't allow callers to be transferred to any users in the dial plan.

        - **Leave voice messages without ringing a user's phone** Select this check box to enable callers to send voice messages to users. By default, this option is enabled. This lets Outlook Voice Access users who are associated with the dial plan send voice messages to users in the same UM dial plan. After you select this check box, you can set the group of users callers can search for by selecting the appropriate option under the **Allow callers to search for users by name or alias** section on this page.

If you disable this option, Outlook Voice Access won't invite callers to send a voice message during a system prompt.

    - **Allow callers to search for users by name or alias** Use these options to determine a grouping of users that can be searched. By default, the **In this dial plan only** option is selected. However, you can change the grouping of users. Choose from the following options:
        - **In this dial plan only** Use this option to allow callers who connect to Outlook Voice Access to locate and contact users who are within the dial plan that they are a member of.
        - **In the entire organization** Use this option to allow callers who connect to Outlook Voice Access to locate and contact anyone who is listed in the entire organization. This includes all users who are mailbox-enabled or UM-enabled users in all dial plans.
        - **Only on this auto attendant** Use this list to allow Outlook Voice Access users to connect to a UM auto attendant and then potentially connect to another auto attendant you have configured. You must create this auto attendant to allow callers to be transferred to another auto attendant that's specified.
        - **Only for this extension** Use this option to allow Outlook Voice Access users to connect to an extension number that you specify in the field for this option. This field accepts only numeric digits. The number of digits that you define in this field must match the number of

digits configured on the dial plan associated with the auto attendant.

- **Information to include for users with the same name** Use this field to select how the dial plan differentiates between users who have the same or similar names. When a caller is prompted to enter letters or say the person's name to find a particular user in the organization, sometimes more than one name matches the caller's input. If there are two users with the same name, UM will use one of the following ways to add additional information to the user's name. For example, if you select **Department**, when an Outlook Voice Access user calls in to Outlook Voice Access and searches for a user and there are duplicate or similar names in the directory, the caller will hear the user's name and department, for example:
  - System: "Welcome to Outlook Voice Access. Please enter your PIN and press the pound key."
  - Caller inputs their PIN followed by the # key.
  - System: "Please say voice mail, email, calendar, personal contacts, directory, or personal options."
  - Caller: "Directory"
  - System: "Directory search. Please note, for the following tasks the system requires you to use your telephone keypad rather than speaking. Use the keypad to spell the name of the person you're trying to find, last name first, or to spell the first part of their email address, press the pound key twice, if you know the extension, press the pound key."
  - Caller uses the key pad and inputs "smithtony" and presses the # key.
  - System: "For Tony Smith, research, press 1. For Tony Smith, administration, press 2. For Tony Smith, technical support, press 3."
  - Caller presses the appropriate key on the keypad and the call is transferred to the user.

By default, all UM auto attendants associated with this dial plan inherit this setting. However, you can change this setting on each UM auto attendant you create.

Select one of the following methods for providing callers with more information to help them locate the correct user in the organization:

- **None** No additional information is given when matches are listed. By default, this method is selected.
- **Title** The voice mail system includes each user's title when matches are listed.
- **Department** The voice mail system includes each user's department when matches are listed.
- **Location** The voice mail system includes each user's location when matches are listed.
- **Prompt for alias** The voice mail system prompts the caller for the user's alias.

11.After you configure the required settings, click **Save** to save your changes.

Use the Shell to configure UM dial plan settings

This example configures a UM dial plan named `MyDialPlan` to use 9 for the outside line access code.

```
Set-UMDialplan -Identity MyDialPlan -OutsideLineAccessCode
9
```

This example configures a UM dial plan named `MyDialPlan` to use a welcome greeting.

```
Set-UMDialplan -Identity MyDialPlan -WelcomeGreetingEnabled
$true -WelcomeGreetingFilename welcome.wav
```

This example configures a UM dial plan named `MyDialPlan` with dialing rules.

```
$csv=import-csv "C:\MyInCountryGroups.csv"
Set-UMDialPlan -Identity MyDialPlan -
ConfiguredInCountryGroups $csv
Set-UMDialPlan -Identity MyDialPlan -AllowedInCountryGroups
"local, long distance"
```

Use the Shell to view UM dial plan settings

This example displays a list of all the UM dial plans.

```
Get-UMDialplan
```

This example displays a formatted list of all of the settings on a UM dial plan named `MyUMDialPlan`.

```
Get-UMDialplan -Identity MyUMDialPlan | Format-List
```

Add Mailbox and Client Access servers to a SIP URI dial plan

Connect your voice mail system to your telephone network > UM dial plans > UM dial plan procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-04-16*

You can add Client Access and Mailbox servers to SIP URI dial plans. Client Access and Mailbox servers can't be associated with Telephone Extension or E.164 dial plans, but the servers will answer all incoming calls.

If you're deploying Microsoft Lync Server, to enable outbound calling to work correctly, you must manually add all Client Access and Mailbox servers to all SIP URI dial plans that you've created for Lync Server.

For additional management tasks related to UM dial plans, see UM dial plan procedures.

What do you need to know before you begin?

- Estimated time to complete: Less than 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a SIP URI dial plan has been created. For detailed steps, see Create a UM dial plan.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

What do you want to do?

Use the EAC to add a Mailbox server to a SIP URI dial plan

1. In the EAC, navigate to **Servers** > **Servers**.
2. In the list view, select the Mailbox server you want to modify, and then click **Edit** .
3. On the **Exchange Server** page, click **Unified Messaging**.
4. Under **UM Service settings** > **Associated dial plans**, click **Add +**.
5. In the **Select a UM Dial Plan** window, select the SIP URI dial plan, click **Add**, click **OK**, and then click **Save**.

Use the Shell to add a Mailbox server to a SIP URI dial plan

This example adds the Mailbox server named `MyMailboxServer` to a SIP URI dial plan named `MySIPDialPlan` and prevents it from accepting new calls. It also sets the startup mode to Dual mode, which enables the Mailbox server to accept TCP and TLS requests.

```
Set-UMService -Identity MyMailboxServer -DialPlans
MySIPDialPlan -Status Disabled -UMStartupMode Dual
```

This example adds the Mailbox server named `MyMailboxServer` to two SIP dial plans, named `MySIPDialPlan` and `MySIPDialPlan2`, and sets the following:

- Allows both IPv4 and IPv6 addresses.
- Sets the maximum number of incoming calls to 50.
- Configures the SIP access service for Lync Server.

```
Set-UMService -Identity MyMailboxServer -DialPlans
```

```
MySIPDialPlan, MySIPDialPlan2 -IPAddressFamily Any -
MaxCallsAllowed 50 -SipAccessService
northamerica.lyncpoolna.contoso.com
```

Use the EAC to add a Client Access server to a SIP URI dial plan

1. In the EAC, navigate to **Servers** > **Servers**.
2. In the list view, select the Client Access server you want to modify, and then click **Edit** .
3. On the **Exchange Server** page, click **Unified Messaging**.
4. Under **UM Call Router settings** > **Associated dial plans**, click **Add +**.
5. In the **Select a UM Dial Plan** window, select the SIP URI dial plan, click **Add**, click **OK**, and then click **Save**.

Use the Shell to add a Client Access server to a SIP URI dial plan

This example adds the Client Access server named `MyClientAccessServer` to a SIP URI dial plan named `MySIPDialPlan`. It also sets the startup mode to Dual mode, which enables the Client Access server to accept TCP and TLS requests.

```
Set-UMCallRouterSettings -DialPlans MySIPDialPlan -Server
MyClientAccessServer -UMStartupMode Dual
```

This example adds the Client Access server named `MyClientAccessServer` to two SIP dial plans, named `MySIPDialPlan` and `MySIPDialPlan2`, and allows the server to use both IPv4 and IPv6 addresses.

```
Set-UMCallRouterSettings -DialPlans MySIPDialPlan,
MySIPDialPlan2 -IPAddressFamily Any -Server
MyClientAccessServer
```

Remove Mailbox and Client Access servers from a SIP URI dial plan

Connect your voice mail system to your telephone network > UM dial plans > UM dial plan procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-04-16*

You can remove Client Access and Mailbox servers from SIP URI dial plans. When you're deploying Microsoft Lync Server, to enable outbound calling to work correctly, you must manually add all Client Access and Mailbox servers to the SIP URI dial plans that you've created for Lync Server. However, you may need to remove a Client Access or Mailbox server from your Lync deployment, for example, if you're performing maintenance or taking the server offline.

For additional management tasks related to UM dial plans, see UM dial plan procedures.

What do you need to know before you begin?

- Estimated time to complete: Less than 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a SIP URI dial plan has been created. For detailed steps, see Create a UM dial plan.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

What do you want to do?

Use the EAC to remove a Mailbox server from a SIP URI dial plan

1. In the EAC, navigate to **Servers** > **Servers**.
2. In the list view, select the Mailbox server you want to modify, and then click **Edit** .
3. On the **Exchange Server** page, click **Unified Messaging**.
4. Under **UM Service settings** > **Associated dial plans**, locate the SIP URI dial plan to remove, click **Remove** —, and then click **Save**. If you want to remove more than one SIP URI dial plan, press and hold the CTRL key, select the dial plans you want to remove, and then click **Save**.

Use the Shell to remove a Mailbox server from a SIP URI dial plan

This example removes the Mailbox server named `MyMailboxServer` from a SIP URI dial plan named

MySIPDialPlan.

```
$dp= Get-UMDialPlan "MySIPDialPlan"
$s=Get-UMService MyMailboxServer
$s.dialplans-=$dp.identity
Set-UMService -id MyMailboxServer -dialplans:$s.dialplans
```

In this example, there are three SIP URI dial plans: SipDP1, SipDP2 and SipDP3. This example removes the Mailbox server named `MyMailboxServer` from the SipDP3 dial plan.

```
Set-UMService -id MyMailboxServer -DialPlans SipDP1,SipDP2
```

In this example, there are two SIP URI dial plans: SipDP1 and SipDP2. This example removes the Mailbox server named `MyMailboxServer` from the SipDP2 dial plan.

```
Set-UMService -id MyMailboxServer -DialPlans SipDP1
```

This example removes the Mailbox server named `MyMailboxServer` from all SIP dial plans.

```
Set-UMService -id MyUMServer -DialPlans $null
```

Use the EAC to remove a Client Access server from a SIP URI dial plan

1. In the EAC, navigate to **Servers** > **Servers**.
2. In the list view, select the Client Access server you want to modify, and then click **Edit** .
3. On the **Exchange Server** page, click **Unified Messaging**.
4. Under **UM Call Router settings** > **Associated dial plans**, locate the SIP URI dial plan to remove, click **Remove** —, and then click **Save**. If you want to remove more than one SIP URI dial plan, press and hold the CTRL key, select the dial plans you want to remove, and then click **Save**.

Use the Shell to remove a Client Access server from a SIP URI dial plan

This example removes the Client Access server named `MyClientAccessServer` from a SIP URI dial plan named `MySIPDialPlan`.

```
$dp= Get-UMDialPlan "MySIPDialPlan"
$s=Get-UMCallRouterSettings MyClientAccessServer
$s.dialplans-=$dp.identity
Set-UMCallRouterSettings -id MyClientAccessServer -
```

```
dialplans:$s.dialplans
```

In this example, there are three SIP URI dial plans: SipDP1, SipDP2 and SipDP3. This example removes the Client Access server named `MyClientAccessServer` from the SipDP3 dial plan.

```
Set-UMCallRouterSettings -id MyClientAccessServer -
DialPlans SipDP1,SipDP2
```

In this example, there are two SIP URI dial plans: SipDP1 and SipDP2. This example removes the Client Access server named `MyClientAccessServer` from the SipDP2 dial plan.

```
Set-UMCallRouterSettings -id MyClientAccessServer -
DialPlans SipDP1
```

This example removes the Client Access server named `MyClientAccessServer` from all SIP dial plans.

```
Set-UMCallRouterSettings -id MyClientAccessServer -
DialPlans $null
```

Change the audio codec

Connect your voice mail system to your telephone network > UM dial plans > UM dial plan procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-22*

Unified Messaging can use one of four codecs for creating voice mail messages: MP3, Windows Media Audio (WMA), Group System Mobile (GSM) 06.10, and G.711 Pulse Code Modulation (PCM) Linear. By default, when you create a Unified Messaging (UM) dial plan, the UM dial plan uses the MP3 audio codec to record voice messages. The MP3 audio format is a popular audio format that is used across multiple operating systems, email clients, and MP3 players. After the UM dial plan is created, you can configure the UM dial plan to use one of the other audio formats including the WMA, GSM 06.10, or G.711 PCM Linear audio codecs. To listen to the voice message, a mobile phone or computer must have a compatible audio software application installed.

For additional tasks related to UM dial plans, see UM dial plan procedures.

What do you need to know before you begin?

- Estimated time to complete: Less than 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging

permissions topic.

- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to change the audio codec on a Unified Messaging dial plan

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**.
2. In the list view, select the UM dial plan you want to modify, and then click **Edit** .
3. On the **UM dial plan** page, click **Configure**.
4. In **Settings**, under **Audio codec**, use the drop-down list to select one the following:
   - MP3
   - WMA
   - GSM
   - G711
5. Click **Save**.

Use the Shell to change the audio codec on a Unified Messaging dial plan

This example sets the audio codec on a UM dial plan named `MyUMDialPlan` to G.711.

```
Set-UMDialPlan -Identity MyUMDialPlan -AudioCodec G711
```

This example sets the audio codec on a UM dial plan named `MyUMDialPlan` to WMA.

```
Set-UMDialPlan -Identity MyUMDialPlan -AudioCodec Wma
```

Configure the maximum call duration

Connect your voice mail system to your telephone network > UM dial plans > UM dial plan

procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-09*

You can specify the maximum number of minutes that an incoming call can be connected to the system without being transferred to a valid extension number before the call is ended. For most organizations, this value should be set to the default: 30 minutes. This setting applies to all calls, including incoming Outlook Voice Access calls, voice calls internal to your organization, voice calls into Unified Messaging (UM) auto attendants, and fax calls placed from outside your organization.

This value can be set to a number from 10 through 120. Setting this value too low can cause incoming calls to be disconnected before they're completed. For example, if your organization receives many large fax messages, you may want to consider increasing this value from the default so that all the pages of fax messages are received.

For additional tasks related to UM dial plans, see UM dial plan procedures.

What do you need to know before you begin?

- Estimated time to complete: Less than 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to configure the maximum call duration

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**.
2. In the list view, select the UM dial plan you want to modify, and then click **Edit** .
3. On the **UM dial plan** page, click **Configure**.
4. In **Settings**, under **Maximum call duration (minutes)**, enter the number in minutes.
5. Click **Save**.

Use the Shell to configure the maximum call duration

This example sets the maximum call duration to 10 minutes on a UM dial plan named `MyUMDialPlan`.

```
Set-UMDialPlan -identity MyUMDialPlan -MaxCallDuration 10
```

Configure the maximum recording duration

Connect your voice mail system to your telephone network > UM dial plans > UM dial plan procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-09*

You can specify the maximum number of minutes allowed for each voice recording when a caller leaves a voice mail message. This value can be set to a number from 1 through 100. For most organizations, this value should be set to the default of 20 minutes. Setting this value too low can cause long voice messages to be disconnected before they're completed. Setting this value too high lets users save lengthy voice messages in their Inboxes.

This setting is important if you've implemented strict disk quotas for users. It must be set to a lower value than the one set for **Maximum call duration (minutes)**.

For additional tasks related to UM dial plans, see UM dial plan procedures.

What do you need to know before you begin?

- Estimated time to complete: Less than 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to configure the maximum recording duration

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**.
2. In the list view, select the UM dial plan you want to modify, and then click **Edit** .
3. On the **UM dial plan** page, click **Configure**.
4. In **Settings**, under **Maximum recording duration (minutes)**, enter the number in minutes.
5. Click **Save**.

Use the Shell to configure the maximum recording duration

This example sets the maximum recording duration to 10 minutes for a UM dial plan named `MyUMDialPlan`.

```
Set-UMDialPlan -identity MyUMDialPlan -MaxRecordingDuration
10
```

Configure the recording idle time-out value

Connect your voice mail system to your telephone network > UM dial plans > UM dial plan procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-11*

You can specify the number of seconds of silence that the system allows when a voice message is being recorded before the call is ended. For most organizations, this value should be set to the default of 5 seconds.

This value can be set from 2 through 10. Setting this value too low can cause the system to disconnect callers before they've finished leaving their voice messages. Setting this value too high allows lengthy silences in voice messages.

For additional management tasks related to UM dial plans, see UM dial plan procedures.

What do you need to know before you begin?

- Estimated time to complete: Less than 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to configure the recording idle time-out value

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**.
2. In the list view, select the UM dial plan you want to modify, and then click **Edit** .
3. On the **UM dial plan** page, click **Configure**.
4. In **Settings**, under **Recording idle time out (seconds)**, enter the number in seconds.
5. Click **Save**.

Use the Shell to configure the recording idle time-out value

This example sets the recording idle time-out value to 10 for a UM dial plan named `MyUMDialPlan`.

```
Set-UMDialPlan -identity MyUMDialPlan -RecordingIdleTimeout
10
```

Configure the VoIP security setting

Connect your voice mail system to your telephone network > UM dial plans > UM dial plan procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-22*

You can enable Voice over IP (VoIP) security for a Unified Messaging (UM) dial plan. By default, when a UM dial plan is created, it will use Unsecured mode or no encryption. Exchange servers can answer calls for single or multiple UM dial plans and can answer calls for dial plans that have different VoIP security settings.

When you configure a UM dial plan to use Session Initiation Protocol (SIP) secured or Secured mode, the Exchange servers that answer calls for the UM dial plan will encrypt the SIP signaling traffic (for SIP secured mode) or both the Realtime Transport Protocol (RTP) media channels and the SIP signaling traffic (for Secured mode).

Important:

For on-premises and hybrid deployments, when you configure the SipTCPListeningPort, SipTLSListeningPort, or the UMStartUpMode on a Client Access server running the Microsoft Exchange Unified Messaging Call Router service or a Mailbox server running the Microsoft Exchange Unified Messaging service, you will need to configure the Windows Firewall rules correctly to allow SIP and RTP network traffic.

For additional management tasks related to UM dial plans, see UM dial plan procedures.

What do you need to know before you begin?

- Estimated time to complete: Less than 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to configure VoIP security on a UM dial plan

1. In the EAC, navigate to **Unified Messaging** > **UM Dial Plans**, select the UM dial plan on which you want to change the VoIP security, and then click **Edit** ✎.
2. On the **UM Dial Plan** page, click **Configure**.
3. In **General**, under **VoIP security mode**, select one of the following options:
   - **SIP secured**
   - **Unsecured** (default)
   - **Secured**

4. Click **Save**.

Use the Shell to configure VoIP security on a UM dial plan

This example configures a UM dial plan named `MySecureDialPlan` to encrypt both SIP and RTP traffic.

```
Set-UMDialPlan -identity MySecureDialPlan -VoIPSecurity
Secured
```

This example configures a UM dial plan named `MySecureDialPlan` to encrypt SIP but not encrypt RTP traffic.

```
Set-UMDialPlan -identity MySecureDialPlan -VoIPSecurity
SIPsecured
```

This example configures a UM dial plan named `MySecureDialPlan` to not encrypt SIP and RTP traffic.

```
Set-UMDialPlan -identity MySecureDialPlan -VoIPSecurity
Unsecured
```

Configure a dial plan for users who have similar names

Connect your voice mail system to your telephone network > UM dial plans > UM dial plan procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-21*

You can configure a Unified Messaging (UM) dial plan to specify the information that is provided for callers when users have the same or similar names. UM uses this setting to differentiate between users who have the same or similar names and provide this information to callers. When a caller or an Outlook Voice Access user is prompted to enter letters to find a particular user, sometimes more than one name matches the caller's input. You can use one of the available options for providing the caller with more information to help them locate the user they're trying to reach.

You can set this setting on both UM dial plans and UM auto attendants. When a UM auto attendant is created, it inherits this setting from the dial plan associated with the auto attendant. By default, this setting isn't configured for dial plans, so no additional information will be given to callers to help them locate the correct user.

Note:
For the information that will be included for users with similar names to work correctly, you must provide the title, department, and location information for the recipients in your Microsoft Exchange organization.

For additional management tasks related to UM dial plans, see UM dial plan procedures.

What do you need to know before you begin?

- Estimated time to complete: Less than 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to configure a UM dial plan for users with similar names

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**. In the list view, select the UM dial plan you want to change, and then click **Edit** .
2. On the **UM dial plan** page, click **Configure** > **Transfer & search**, and under **Information to include for users with the same name**, select one of the following options:
   - **Title** The dial plan includes each user's title when it finds two or more users with similar names.
   - **Department** The dial plan includes each user's department when it finds two or more users with similar names.
   - **Location** The dial plan includes each user's location when it finds two or more users with similar names.
   - **None** The dial plan won't include any additional information when users have similar names. Although this is the default setting, we recommend that you include one of the available options for callers. If you don't, callers won't be able to tell the difference between two or more users with similar names.
   - **Prompt For alias** The dial plan prompts the caller for the user's alias. An alias is the part of

the user's email or SMTP address that is before the at (@) symbol.

3. Click **Save**.

Use the Shell to configure a UM dial plan for users with similar names

This example sets the information to include with users with similar names to prompt for the user's alias on a UM dial plan named `MyDialPlan`.

```
Set-UMDialplan -Identity MyDialPlan -
MatchedNameSelectionMethod PromptForAlias
```

This example sets the information to include with users with similar names to department on a UM dial plan named `MyDialPlan`.

```
Set-UMDialplan -Identity MyDialPlan -
MatchedNameSelectionMethod Department
```

This example sets the information to include with users with similar names to location on a UM dial plan named `MyDialPlan`.

```
Set-UMDialplan -Identity MyDialPlan -
MatchedNameSelectionMethod Location
```

Delete a UM dial plan

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-11*

You can delete an existing Unified Messaging (UM) dial plan. When you delete the UM dial plan, it will no longer be available for UM IP gateways, UM mailbox policies, and UM hunt groups. You can't delete a UM dial plan if it's referenced by or associated with UM mailbox policies, UM auto attendants, UM IP gateways, or UM hunt groups.

For additional management tasks related to UM dial plans, see UM dial plan procedures.

What do you need to know before you begin?

- Estimated time to complete: Less than 1 minute.

- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to delete an existing dial plan

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**.
2. In the list view, select the UM dial plan you want to delete, and then click **Delete** .
3. On the warning page, click **Yes**.

Use the Shell to delete an existing dial plan

This example deletes a UM dial plan named `MyUMDialPlan`.

```
RemoveUMDialplan -identity MyUMDialPlan
```

UM IP gateways

Exchange Server 2013 > Unified Messaging > Connect your voice mail system to your telephone network >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-06-24*

A Unified Messaging (UM) IP gateway represents a physical Voice over IP (VoIP) gateway, IP Private Branch eXchange (PBX), or session border controller (SBC) hardware device. Before a VoIP gateway, IP PBX, or SBC can be used to answer incoming calls and send outgoing calls for voice mail users, a UM IP gateway must be created in the directory service.

Contents

IPv6 support for UM IP gateways

Enabling and disabling a UM IP gateway

Overview of UM IP gateways

Traditionally, *gateway* is a term that describes a physical device that connects two incompatible networks. With Exchange Unified Messaging and other unified messaging solutions, the VoIP gateway is used to translate between the Public Switched Telephone Network (PSTN)/Time Division Multiplex (TDM) or circuit-switched based telephony network and an IP or packet-switched data network. An IP PBX also translates between the PSTN network and a packet-switched network, so when an IP PBX is used, a VoIP gateway isn't required. A VoIP gateway is only required if you are connecting a legacy PBX hardware device to your UM deployment.

Note:

A packet-switched network is a network in which packets (messages or fragments of messages) are individually routed between devices such as routers, switches, VoIP gateway, IP PBXs and SBCs. This contrasts with a circuit-switched network that sets up a dedicated connection between the two nodes for their exclusive use for the duration of the communication.

Exchange Unified Messaging relies on the ability of the VoIP gateway to translate TDM or telephony circuit-switched based protocols, such as Integrated Services Digital Network (ISDN) or QSIG, from a PBX to protocols based on VoIP or IP, such as Session Initiation Protocol (SIP), Realtime Transport Protocol (RTP), or T.38 for real-time facsimile transport.

IP PBXs are also used when connecting a circuit-switched telephony network to a data or packet-switched network. They are also used to translate circuit-switched protocols to protocols based on VoIP or IP, such as SIP, RTP, and Secure RTPC (SRTP).

Session Border Controllers (SBCs) are somewhat different than VoIP gateways and IP PBXs. Instead of connecting a circuit-switched network to a packet-switched network, they're used to connect two data networks over a public network like the Internet or over a private WAN connection. In Unified Messaging, SBCs are used in a hybrid deployment of UM in which UM uses some components that are located on-premises and others, such as mailboxes, that are located in the cloud.

VoIP device configurations

Although there are many types and manufacturers of PBXs, VoIP gateways, IP PBXs, and SBCs, there are basically three types of VoIP device configurations:

- **IP PBX** A single device that translates between the PSTN/TDM or circuit-switched based telephony network and an IP or packet-switched data network
- **PBX (legacy) and a VoIP gateway** Two separate components that together translate between the PSTN/TDM or circuit-switched telephony network and an IP or packet-switched data network
- **SBC** Single or multiple devices that connect two types of IP-based networks such as a LAN and a

datacenter.

To support Unified Messaging, one or both types of IP/VoIP device configurations are used when connecting a telephony network infrastructure to a data network infrastructure or connecting an on-premises deployment with a UM deployment in the cloud.

UM IP gateways

The UM IP gateway contains one or more UM hunt groups and configuration settings. UM hunt groups are used to link a UM IP gateway to a UM dial plan. The combination of the UM IP gateway and a UM hunt group establishes a link between a VoIP gateway, IP PBX, or SBC and a UM dial plan. By creating multiple UM hunt groups, you can associate a single UM IP gateway with multiple UM dial plans.

After you create a UM IP gateway, the Exchange servers linked to the UM IP gateway will send a SIP OPTIONS request to the VoIP gateway, IP PBX, or SBC to ensure that the device is responsive. If the VoIP gateway, IP PBX, or SBC doesn't respond to the request, an Exchange server will log an event with ID 1400 stating that the request failed. If this happens, make sure that the VoIP gateway, IP PBX, or SBC is available and online and that the Unified Messaging configuration is correct.

A Mailbox server communicates only with VoIP gateways, IP PBXs, or SBCs listed as trusted SIP peers. In some cases, if two VoIP gateways, IP PBXs, or SBCs are configured to use the same IP address, an event with ID 1175 will be logged. Unified Messaging protects against unauthorized requests by retrieving the internal URL of the Unified Messaging Web services virtual directory and then uses the URL to build the list of FQDNs for the trusted SIP peers. When two FQDNs are resolved to the same IP address, this event is logged.

IPv6 support for UM IP gateways

Internet Protocol version 6 (IPv6) is the most recent version of the Internet Protocol (IP). IPv6 is intended to correct many of the shortcomings of IPv4, which was the previous version of the IP. In Microsoft Exchange Server 2010 on-premises and hybrid deployments, IPv6 was supported only when IPv4 was also used.

In Exchange 2013 on-premises and hybrid deployments, UM-related components and speech services run only on Client Access and Mailbox servers. Because the UM architecture has changed and now requires Unified Communications Managed API (UCMA) v4.0 to support both IPv4 and IPv6 as well as other Exchange features, the Client Access and Mailbox servers that have Unified Messaging components and services fully support IPv6 networks and doesn’t require IPv4.

In on-premises, hybrid, and Exchange Online deployments, both enterprise and Exchange Online UM administrators can use IPv6 when they connect UM to IPv6-capable devices, including devices such as routers, IP gateways, IP PBXs, and Microsoft Office Communications Server 2007 R2 and Microsoft Lync servers. However, for interoperability and backward compatibility, IPv4 can be used instead without additional configuration changes if the *IPAddressFamily* parameter is set to Any on

UM IP gateways.

Exchange UM must still communicate directly with SIP peers (VoIP gateways, IP PBXs, and SBCs) that may not support IPv6 in their software or firmware. If they don't support IPv6, UM must be able to communicate directly with SIP peers that use IPv4. For hosted voice mail, UM communicates with customer equipment through SBCs, Lync Server 2010, or Lync Server 2013. In hosted environments, IPv6 SIP-aware clients such as SBCs and Lync servers can be deployed to handle the IPv6-to-IPv4 conversion process.

For on-premises and hybrid deployments after you install your Client Access and Mailbox servers, and for Exchange Online UM deployments, you need to create UM IP gateways. If you need your UM IP gateways to support IPv6, you must also:

1. Create a new UM IP gateway or configure an existing UM IP gateway with an IPv6 address for each of the IP gateways, IP PBXs, or SBCs on your network. When you're creating and configuring the required UM IP gateways, you must add the IPv6 address or the Fully Qualified Domain Name (FQDN) for the UM IP gateway. If you're adding the FQDN to the UM IP gateway, you must have created the correct DNS records to resolve the UM IP gateway FQDN to the IPv6 address. If you have an existing UM IP gateway, you can use the **Set-UMIPgateway** cmdlet to configure the IPv6 address or FQDN.
2. Configure the *IPAddressFamily* parameter on each UM IP gateway. To enable the VoIP gateway to accept IPv6 packets, you must set the UM IP gateway to either accept both IPv4 and IPv6 connections, or accept only IPv6 connections, by using the **Set-UMIPgateway** cmdlet.
3. After you've configured your UM IP gateways, you must also configure the VoIP gateways, IP PBXs, and SBCs on your network to support IPv6. For details, see your hardware vendor for a list of devices that support IPv6 and how to correctly configure them.

Note:

The maximum number of UM IP gateways per dial plan is 200. If you create more than 200 the UM service won't start.

Enabling and disabling a UM IP gateway

By default, a UM IP gateway is left in an enabled state after it's created. However, the UM IP gateway can be enabled or disabled. If you disable a UM IP gateway, you can set it to force all Exchange servers to drop existing calls. Alternatively, you can set it to force the Exchange servers associated with the UM IP gateway to stop handling any new calls presented by the VoIP gateway, IP PBX, or SBC.

If you're integrating Unified Messaging with Office Communications Server R2 or Microsoft Lync Server, you must allow only one UM IP gateway to make outgoing calls for users, and disable outbound calling on all other UM IP gateways associated with your SIP URI dial plans. Use either the Shell or the EAC to disable outbound calling.

When selecting the UM IP gateway through which to allow outgoing calls for on-premises and hybrid deployments, choose the one that's likely to handle the most traffic. Don't allow outgoing

traffic through a UM IP gateway that connects to a pool of Lync Server Directors. This is necessary to ensure that outbound calls to external users placed by a Mailbox server running the Microsoft Exchange Unified Messaging service (for example, in Play-on-Phone scenarios) reliably traverse the corporate firewall.

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-04-16*

When you create a Unified Messaging (UM) IP gateway, you enable Exchange servers to connect to a new Voice over IP (VoIP) gateway, a Private Branch eXchange (PBX) enabled for Session Initiation Protocol (SIP), an IP PBX, or a session border controller (SBC). Immediately after you create a UM IP gateway, you should create a new UM hunt group and then associate the UM hunt group with the UM IP gateway. You can associate the UM IP gateway with one or more UM dial plans by creating one or more UM hunt groups.

For additional management tasks related to UM IP gateways, see UM IP gateway procedures.

What do you need to know before you begin?

- Estimated time to complete: 3 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to create a UM IP gateway

1. In the EAC, navigate to **Unified Messaging** > **UM IP gateways**, and then click **New +**.
2. On the **New UM IP gateway** page, enter the following information:
   - **Name** Use this box to specify a unique name for the UM IP gateway. This is a display name that appears in the EAC. If you have to change the display name of the UM IP gateway after it's been created, you must first delete the existing UM IP gateway, and then create another UM IP gateway that has the name that you want. The UM IP gateway name is required, but it's used for display purposes only. Because your organization may use multiple UM IP gateways, we recommend that you use meaningful names for your UM IP gateways. The maximum length of a UM IP gateway name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.
   - **Address** You can configure a UM IP gateway with either an IP address or a fully qualified domain name (FQDN). Use this box to specify the IP address configured on the VoIP gateway, SIP-enabled PBX, IP PBX, or SBC, or an FQDN. This box accepts only FQDNs that are valid and formatted correctly.

You can enter alphabetical and numeric characters in this box. IPv4 addresses, IPv6 addresses, and FQDNs are supported. If you want to use mutual Transport Layer Security (mutual TLS) between a UM IP gateway and a dial plan operating in either SIP secured or Secured mode, you must configure the UM IP gateway with an FQDN. You must also configure it to listen on port 5061 and verify that any VoIP gateways or IP PBXs have also been configured to listen for mutual TLS requests on port 5061. To configure a UM IP gateway, run the following command: `Set-UMIPGateway -identity MyUMIPGateway -Port 5061`.

If you use an FQDN, you must also make sure that you've correctly configured a DNS host record for the VoIP gateway so that the host name will be correctly resolved to an IP address. Also, if you use

an FQDN instead of an IP address, and the DNS configuration for the UM IP gateway is changed, you must disable and then enable the UM IP gateway to make sure that configuration information for the UM IP gateway is updated correctly.

- **UM dial plan** Click **Browse** to select the UM dial plan that you want to associate with the UM IP gateway. When you select a UM dial plan to associate with a UM IP gateway, a default UM hunt group is also created and associated with the UM dial plan that you selected. If you don't select a UM dial plan, you must manually create a UM hunt group and then associate that UM hunt group with the UM IP gateway that you create.

3. Click **Save**.

Use the Shell to create a UM IP gateway

This example creates a UM IP gateway named `MyUMIPGateway` that enables Exchange servers to start accepting calls from a VoIP gateway, a PBX enabled for SIP, an IP PBX, or an SBC that has an IP address of 10.10.10.1.

```
New-UMIPGateway -Name MyUMIPGateway -Address 10.10.10.1
```

This example creates a UM IP gateway named `MyUMIPGateway` that enables Exchange servers to start accepting calls from a VoIP gateway, a PBX enabled for SIP, an IP PBX, or an SBC that has an FQDN of MyUMIPGateway.contoso.com and listens on port 5061.

```
New-UMIPGateway -Name MyUMIPGateway -Address
"MyUMIPGateway.contoso.com" -Port 5061
```

This example creates a UM IP gateway named `MyUMIPGateway` and prevents the UM IP gateway from accepting incoming calls or sending outgoing calls, sets an IPv6 address, and allows the UM IP gateway to use IPv4 and IPV6 addresses.

```
New-UMIPGateway -Identity MyUMIPGateway -Address
fe80::39bd:88f7:6969:d223%11 -IPAddressFamily Any -Status
Disabled -OutcallsAllowed $false
```

Manage a UM IP gateway

Connect your voice mail system to your telephone network > UM IP gateways > UM IP gateway procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-21*

After you create a Unified Messaging (UM) IP gateway, you can view or configure a variety of

settings. For example, you can configure the IP address or a fully qualified domain name (FQDN), configure outgoing call settings, and enable or disable Message Waiting Indicator.

For additional management tasks related to UM IP gateways, see UM IP gateway procedures.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- Before you perform these procedures, confirm that a UM IP gateway has been created. For detailed steps, see Create a UM IP gateway.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to view or configure UM IP gateway properties

1. In the EAC, navigate to **Unified Messaging** > **UM IP Gateways**. In the list view, select the UM IP gateway that you want to manage, and then click **Edit** .
2. Use the **UM IP Gateway** page to view and configure settings for the UM IP gateway. You can view or configure the following settings:
   - **Status** This display-only field shows the status of the UM IP gateway.
   - **Name** Use this box to specify a unique name for the UM IP gateway. This is a display name that appears in the EAC. If you have to change the display name of the UM IP gateway after it's been created, you must first delete the existing UM IP gateway, and then create another UM IP gateway that has the appropriate name. The UM IP gateway name is required, but it's used for display purposes only. Because your organization may use multiple UM IP gateways, we recommend that you use meaningful names for your UM IP gateways. The maximum length of a UM IP gateway name is 64 characters, and it can include spaces.
   - **Address** You can configure a UM IP gateway with either an IP address or a fully qualified domain name (FQDN). Use this box to specify the IP address or FQDN configured on the VoIP gateway, SIP-enabled PBX, IP PBX, or SBC.

You can enter alphabetical and numeric characters in this box. IPv4 addresses, IPv6 addresses, and FQDNs are supported. If you use an FQDN, you must also make sure that you have correctly configured a DNS host record for the VoIP gateway so that the host name will be correctly resolved to an IP address. Also, if you use an FQDN instead of an IP address, and the DNS configuration for the UM IP gateway is changed, you must disable and then enable the UM IP gateway to make sure that configuration information for the UM IP gateway is updated correctly.

If you want to use mutual Transport Layer Security (mutual TLS) between a UM IP gateway and a dial plan operating in either SIP secured or Secured mode, you must configure the UM IP gateway with an FQDN. You must also configure it to listen on port 5061 and verify that any IP gateways or IP PBXs have also been configured to listen for mutual TLS requests on port 5061. To configure a UM IP gateway, run the following command: `Set-UMIPGateway -identity MyUMIPGateway -Port 5061`.

- **Allow outgoing calls through this UM IP gateway** Select this check box to allow the UM IP gateway to accept and process outgoing calls. This setting doesn't affect call transfers or incoming calls from a VoIP gateway.

By default, when the UM IP gateway is created, this setting is enabled. If you disable this setting, users associated with the dial plan won't be able to make outgoing calls through the VoIP gateway, IP PBX, or SBC defined in the **Address** field.

- **Allow message waiting indicator** Select this check box to allow voice mail notifications to be sent to users for calls taken by the UM IP gateway. This setting allows the UM IP gateway to receive and send SIP NOTIFY messages for users. This setting is enabled by default and allows message waiting notifications to be sent to users.

Message Waiting Indicator can refer to any mechanism that indicates the existence of a new or unheard message. The indication that a new voice message has arrived can be found in the Inbox in clients such as Outlook and Outlook Web App. It can take the form of a Short Messaging Service (SMS) or text message sent to a registered mobile phone, an outbound call made from an Exchange server to a preconfigured number, or a lighted desktop phone lamp for a user.

Use the Shell to configure UM IP gateway properties

This example modifies the IP address of a UM IP gateway named `MyUMIPGateway`.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address 10.10.10.1
```

This example prevents the UM IP gateway named `MyUMIPGateway` from accepting incoming calls and prevents outgoing calls.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address
voipgateway.contoso.com -Status 2 -OutcallsAllowed $false
```

This example enables the UM IP gateway to function as a VoIP gateway simulator and can be used with the **Test-UMConnectivity** cmdlet.

```
Set-UMIPGateway -Identity MyUMIPGateway -Simulator $true
```

Important:
There is a period of latency before all changes that you make to the configuration of a UM IP gateway replicate to all Exchange servers in the same UM dial plan as the UM IP gateway.

This example prevents the UM IP gateway named `MyUMIPGateway` from accepting incoming calls and prevents outgoing calls, sets an IPv6 address, and allows the UM IP gateway to use IPv4 and IPV6 addresses.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address
fe80::39bd:88f7:6969:d223%11 -IPAddressFamily Any -Status
Disabled -OutcallsAllowed $false
```

Use the Shell to view UM IP gateway properties

This example displays a formatted list of all the UM IP gateways in the Active Directory forest.

```
Get-UMIPGateway |Format-List
```

This example displays the properties for a UM IP gateway named `MyUMIPGateway`.

```
Get-UMIPGateway -Identity MyUMIPGateway
```

This example displays all the UM IP gateways including VoIP gateway simulators in the Active Directory forest.

```
Get-UMIPGateway -IncludeSimulator $true
```

Enable a UM IP gateway

Connect your voice mail system to your telephone network > UM IP gateways > UM IP gateway procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-05*

By default, when a Unified Messaging (UM) IP gateway is created, its status is set to enabled. However, you might need to disable the UM IP gateway to take it offline and not allow it to take incoming or outgoing calls. After you create a UM IP gateway, you can control its operation and functionality by setting its status variable to enabled or disabled.

For additional management tasks related to UM IP gateways, see UM IP gateway procedures.

What do you need to know before you begin?

- Estimated time to complete: Less than 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- Before you perform these procedures, confirm that a UM IP gateway has been created and has been disabled. For detailed steps, see Create a UM IP gateway.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-13*

By default, when you create a Unified Messaging (UM) IP gateway, the status of the UM IP gateway is enabled. After the UM IP gateway is created, you can disable the operation of the gateway by

setting its status to disabled. After you disable the UM IP gateway, the Voice over IP (VoIP) gateway, IP Private Branch eXchange (PBX), or session border controller (SBC) that it's configured to use can no longer process incoming Unified Messaging calls.

For additional management tasks related to UM IP gateways, see UM IP gateway procedures.

What do you need to know before you begin?

- Estimated time to complete: Less than 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- Before you perform these procedures, confirm that a UM IP gateway has been created and is enabled. For detailed steps, see Create a UM IP gateway and Enable a UM IP gateway.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to disable a UM IP gateway

1. In the EAC, navigate to **Unified Messaging** > **UM IP Gateways**, select the UM IP gateway you want to disable, and then click the **Down arrow** ↓.
2. On the **Warning** page, click **Yes**.

Use the Shell to disable a UM IP gateway

This example disables a UM IP gateway named `MyUMIPGateway` and stops it from accepting incoming calls from a VoIP gateway, IP PBX, or SBC.

```
Disable-UMIPGateway -Identity MyUMIPGateway
```

This example disables a UM IP gateway named `MyUMIPGateway` and disconnects all current calls immediately.

```
Disable-UMIPGateway -Identity MyUMIPGateway -Immediate
$true
```

Configure a fully qualified domain name

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-09*

You can configure a Unified Messaging (UM) IP gateway with either an IP address or a fully qualified domain name (FQDN). When you create a UM IP gateway, you must define the IP address or the FQDN configured on the VoIP gateway, IP PBX, or session border controller (SBC) that you're using. You can change the IP address or FQDN after the UM IP gateway is created.

If you create a UM IP gateway using an FQDN, you must create the appropriate HOST (A) records in your DNS forward lookup zone. If you create a UM IP gateway using an FQDN, and the DNS configuration for the UM IP gateway is changed, you must disable and then enable the UM IP gateway to make sure that its configuration information is updated correctly.

If you want to use mutual Transport Layer Security (mutual TLS) between a UM IP gateway and a dial plan operating in either SIP secured or Secured mode, you must configure the UM IP gateway with an FQDN. You must also configure it to listen on port 5061 and verify that the VoIP gateway, IP PBX, or SBC has also been configured to listen for mutual TLS requests on port 5061. To configure a UM IP gateway, run the following command: `Set-UMIPGateway -identity MyUMIPGateway -Port 5061`.

For additional management tasks related to UM IP gateways, see UM IP gateway procedures.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- Before you perform these procedures, confirm that a UM IP gateway has been created. For detailed steps, see Create a UM IP gateway.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to configure an FQDN

1. In the EAC, navigate to **Unified Messaging** > **UM IP Gateways**, select the UM IP gateway that you want to modify, and then click **Edit** .
2. On the **UM IP gateway** page, in **Address**, enter the FQDN for the VoIP gateway, PBX enabled for SIP, IP PBX, or SBC.
3. Click **Save**.

Important:
When you use an FQDN instead of an IP address on the UM IP gateway, verify that the correct DNS records have been created.

Use the Shell to configure an FQDN

This example configures a UM IP gateway named `MyUMIPGateway` with an FQDN named voipgateway.contoso.com.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address
voipgateway.contoso.com
```

This example configures a UM IP gateway named `MySBC` with an FQDN of sbc.contoso.com and listens for SIP requests on TCP port 5061.

```
Set-UMIPGateway -Identity MySBC -Address sbc.contoso.com -
Port 5061
```

Configure the IP address

Connect your voice mail system to your telephone network > UM IP gateways > UM IP gateway procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-11*

Before you create a Unified Messaging (UM) IP gateway, you must first set the IP address or the fully qualified domain name (FQDN) on the VoIP gateway, IP PBX, or session border controller (SBC) that you're using. Then, when you create the UM IP gateway, you set the IP address or FQDN. You can change the IP address or FQDN later.

You can configure the IP address or FQDN using either the EAC or the Shell. In the EAC, the **Address**

box on the **UM IP gateway** page can accept an IPv4 IP address, an IPv6 address, or an FQDN. You can also use the *Address* parameter on the **Set-UMIPGateway** cmdlet in the Shell to set an IPv4 IP address, an IPv6 address, or an FQDN. If you create a UM IP gateway using an FQDN, you must create the appropriate HOST A records in your DNS forward lookup zone. If the DNS configuration for the UM IP gateway is changed, you must disable and then enable the UM IP gateway to make sure that its configuration information is updated correctly.

For additional management tasks related to UM IP gateways, see UM IP gateway procedures.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- Before you perform these procedures, confirm that a UM IP gateway has been created. For detailed steps, see Create a UM IP gateway.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to configure the IP address on a UM IP gateway

1. In the EAC, navigate to **Unified Messaging** > **UM IP Gateways**, select the UM IP gateway that you want to modify, and then click **Edit** .
2. On the **UM IP gateway** page, in the **Address** box, enter the IP address for the VoIP gateway, IP PBX, or session border controller (SBC).
3. Click **Save** to save your changes.

Important:

If you use an FQDN instead of an IP address on the UM IP gateway, verify that the correct DNS records have been created.

Use the Shell to configure the IP address on a UM IP

gateway

This example configures a UM IP gateway named `MyUMIPGateway` with an IP address of 10.10.10.1.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address 10.10.10.1
```

This example configures a UM IP gateway named `MyUMIPGateway` with an IP address of 10.10.10.10 and listens for SIP requests on TCP port 5061.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address
10.10.10.10 -Port 5061
```

This example prevents the UM IP gateway named `MyUMIPGateway` from accepting incoming and outgoing calls, sets an IPv6 address, and allows the UM IP gateway to use IPv4 and IPV6 addresses.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address
fe80::39bd:88f7:6969:d223%11 -IPAddressFamily Any -Status
Disabled -OutcallsAllowed $false
```

Configure the listening port

Connect your voice mail system to your telephone network > UM IP gateways > UM IP gateway procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-22*

You can configure the TCP port that's used to listen for Session Initiation Protocol (SIP) requests on a Unified Messaging (UM) IP gateway. By default, when you create a UM IP gateway, the TCP SIP listening port number is set to 5060. The TCP SIP listening port can't be configured or changed by using the EAC. You must configure the TCP SIP listening port number by using the **Set-UMIPGateway** cmdlet.

You may have to configure the TCP listening port number to 5061 if you want to:

- Set the VoIP security setting on a UM dial plan to SIP Secured.
- Set the VoIP security setting on a UM dial plan to Secured.
- Integrate with Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server.
- Use mutual Transport Layer Security (mutual TLS) to encrypt network data between Exchange servers and a VoIP gateway, Private Branch eXchange (PBX) enabled for SIP, IP PBX, or session border controller (SBC).

If you want to use mutual TLS between a UM IP gateway and a dial plan operating in either SIP

Secured or Secured mode, when you create the UM IP gateway you must configure it with a fully qualified domain name (FQDN) and then use the Shell to configure the UM IP gateway to listen on TCP port 5061. You must also verify that any VoIP gateways, PBXs enabled for SIP, IP PBXs, and SBCs have also been configured to listen for mutual TLS requests on port 5061.

Important:

When you create a UM IP gateway using an FQDN, you must create the appropriate HOST (A) records in your DNS forward lookup zone. If you create a UM IP gateway using an FQDN, and the DNS configuration for the UM IP gateway is changed, you must disable and then enable the UM IP gateway to make sure that the UM IP gateway's configuration information is updated correctly.

For additional management tasks related to UM IP gateways, see UM IP gateway procedures.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging permissions topic.
- Before you perform this procedure, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- Before you perform this procedure, confirm that a UM IP gateway has been created. For detailed steps, see Create a UM IP gateway.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

Use the Shell to configure the TCP listening port

This example configures a UM IP gateway named `MyUMIPGateway` that has an FQDN of mTLS.MyUMIPGateway.contoso.com and listens for SIP requests on TCP port 5061.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address
mTLS.MYUMIPGateway.contoso.com -Port 5061
```

This example configures a UM IP gateway named `MyUMIPGateway` that has an FQDN of SIPSecured.MyUMIPGateway.contoso.com and listens for SIP requests on TCP port 5061.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address
SIPSecured.MyUMIPGateway.contoso.com -Port 5061
```

This example configures a UM IP gateway named `MyUMIPGateway` that has an FQDN of MyOCSUMIPGateway.contoso.com and listens for SIP requests on TCP port 5061.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address
MyOCSUMIPGateway.contoso.com -Port 5061
```

Delete a UM IP gateway

Connect your voice mail system to your telephone network > UM IP gateways > UM IP gateway procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-21*

When you delete a Unified Messaging (UM) IP gateway, Exchange servers can no longer accept incoming calls from the Voice over IP (VoIP) gateway, Session Initiation Protocol (SIP)–enabled Private Branch eXchange (PBX), IP PBX, or session border controller (SBC) associated with the UM IP gateway.

Important:
You should delete a UM IP gateway only when you fully understand the implications of disabling communication with a VoIP gateway, IP PBX, or SBC.

For additional tasks related to UM IP gateways, see UM IP gateway procedures.

What do you need to know before you begin?

- Estimated time to complete: Less than 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- Before you perform these procedures, confirm that a UM IP gateway has been created. For detailed steps, see Create a UM IP gateway.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to delete a UM IP gateway

1. In the EAC, navigate to **Unified Messaging** > **UM IP Gateways**, select the UM IP gateway you want to delete, and then click **Delete** 🗑.
2. On the **Warning** page, click **Yes**.

Use the Shell to delete a UM IP gateway

This example deletes the UM IP gateway named `MyUMIPGateway`.

```
Remove-UMIPGateway -Identity MyUMIPGateway
```

UM hunt groups

Exchange Server 2013 > Unified Messaging > Connect your voice mail system to your telephone network >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-18*

A telephony hunt group provides a way to distribute telephone calls from a single number to multiple extensions or telephone numbers. In Unified Messaging (UM), a UM hunt group is a logical representation of a telephony hunt group, and it links a UM IP gateway to a UM dial plan.

Looking for management tasks related to Unified Messaging hunt groups? See UM hunt group procedures.

Contents

What is a hunt group?

Hunt group is a term used to describe a group of Private Branch eXchange (PBX) or IP PBX extension numbers that are shared by users. Hunt groups are used to efficiently distribute calls into or out of a specific business unit. Creating and defining a hunt group minimizes the chance that a caller who places an incoming call will receive a busy signal when the call is received.

Hunt groups are used to locate an open line, extension, or channel when an incoming call is received. Calls are "rolled over" to the next available line when a primary phone line is busy or isn't answered. The calling party gets a busy signal or is sent to voice mail only if no extensions in the group are open. For example, a PBX or IP PBX might be configured to have 10 extension numbers for the sales department. The 10 sales extension numbers would be configured as one hunt group.

The settings for a simple hunt group include a name, an extension number, a list of available group members, and a hunt group selection method. The hunt group selection method determines the order in which incoming calls are presented to the members of the hunt group.

There are multiple algorithms or methods that a PBX or IP PBX can use to locate an open line, extension, or channel. These include:

- **Group hunt or ring all extensions** When an incoming call is received on the hunt group extension number, the PBX or IP PBX rings all extension numbers in the group.
- **Start with lowest number or linear hunting** This is the default setting on most PBXs and IP PBXs. With this method, calls are routed to the first idle line in sequential order, starting with the first line in the group. This configuration is most often found on multiline phones at small businesses.
- **Round-robin or circular hunting** With this method, calls are routed to the first idle line, starting with the line after the one that last handled a call. When calls are distributed using the "round-robin" method, if a call is delivered to line 1, the next call goes to line 2, the next to line 3, and so on. This process continues even if one of the previous lines becomes free. When the end of the hunt group is reached, the hunting starts over at the first line. Lines are skipped only if they are still busy on a previous call. Circular or round-robin hunting spreads call disruption evenly throughout all the calls, minimizing the possibility for a major disruption in service.
- **Most-idle or uniform-distribution hunting** With this method, the call is routed to the first available line in the group that has been idle the longest. This method uses the length of time that the person taking the call has been busy instead of whether the line is available. This method is typically used in large call centers where the incoming calls are being answered by people and the load is distributed evenly across the group of extension numbers.

You can configure one or more hunt groups. Each hunt group must include a minimum of two lines. If a number is already being used in one hunt group, it won't be available in another.

Following are examples of simple telephony hunt groups and how they work.

Example 1

Extension 300 (pilot number) is programmed so that when a call comes in, it rings extension 301, then 302, then 303, then 304.

1. Extension 301 is busy.
2. Extension 302 rings and isn't answered.
3. Extension 303 answers the call.
4. Extension 304 is free and waiting for an incoming call.

Example 2

Extension 1000 (pilot number) is programmed so that when a call comes in, it rings all the extensions 2000 through 2003 at the same time:

1. Extension 2000 is free.
2. Extension 2001 is free.
3. Extension 2002 is free.
4. Extension 2003 answers the incoming call.

Return to top

What is a pilot number?

In a telephony network, a PBX or an IP PBX can be configured to have a single hunt group or multiple hunt groups. Each hunt group created on a PBX or IP PBX must have an associated *pilot number*. Using a pilot number helps to eliminate busy signals and to route incoming calls to the extension numbers that are available. The PBX or IP PBX uses the pilot number to locate the hunt group and in turn to locate the telephone extension number on which the incoming call was received and the extensions that are assigned to the hunt group. Without a defined pilot number, the PBX or IP PBX can't locate where the incoming call was received.

A pilot number is the address, extension, or location of the hunt group inside the PBX or IP PBX. It's generally a blank extension number or one extension number from a hunt group of extension numbers that doesn't have a person or telephone associated with it. For example, you might configure a hunt group on a PBX or IP PBX to contain extension numbers 4100, 4101, 4102, 4103, 4104, and 4105. The pilot number for the hunt group is configured as extension 4100. When a call is received on extension number 4100, the PBX or IP PBX looks for the next available extension number to determine where to deliver the call. In this example, the PBX or IP PBX will use its programmed search algorithm to look at extension numbers 4101, 4102, 4103, 4104, and 4105.

Using a pilot number helps eliminate busy signals and helps route incoming calls to the extension numbers that are available. In Unified Messaging, the PBX or IP PBX pilot number is used as the target. If none of the extension numbers in the hunt group answer an incoming call, the call is routed to a Mailbox server running the Microsoft Exchange Unified Messaging service.

Return to top

What is a UM hunt group?

Unified Messaging hunt groups are critical to the operation of the UM system. A UM hunt group is a logical representation of an existing PBX or IP PBX hunt group. It's used to link a UM IP gateway with a UM dial plan. A single UM hunt group can also link multiple UM IP gateways with a UM dial plan. By default, when you create a UM IP gateway and associate it with a UM dial plan, a UM hunt group is created, and you can also create other hunt groups. You must create at least one UM hunt group.

UM hunt groups are used to locate the PBX or IP PBX hunt group from which an incoming call is

received. A pilot number defined for a hunt group on the PBX or IP PBX must also be defined for the UM hunt group. The pilot number is used to match the information presented for incoming calls using the Session Initiation Protocol (SIP) signaling information on the voice message. The pilot number enables Exchange servers to interpret the call together with the correct dial plan so that the call can be routed correctly. The absence of a hunt group prevents Exchange servers from knowing the location of the incoming call. Knowing the location of incoming calls enables the Exchange servers to accept the call header information that's passed from the VoIP gateway, IP PBX, or SIP-enabled PBX. It's very important that you configure your UM hunt groups correctly, because incoming calls that don't match the pilot number defined on the UM hunt group won't be answered, and routing of incoming calls will fail.

In on-premises and hybrid deployments when you create a UM hunt group, you're enabling all Client Access and Mailbox servers, regardless of whether they've been added to a UM dial plan, to communicate with a VoIP gateway, IP PBX, or SIP-enabled PBX. This is because all Client Access and Mailbox servers answer incoming calls for all dial plans, instead of for a specific UM dial plan like the UM server did in previous versions of Exchange. If you delete the UM hunt group, the associated UM IP gateway won't be able to answer incoming calls from a VoIP gateway, IP PBX, or SIP-enabled PBX or place outgoing calls through the VoIP gateway, IP PBX or SIP-enabled PBX using the specified pilot number.

However, for on-premises and hybrid deployments if you're integrating UM with Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server, you must add all Client Access and Mailbox servers to all SIP URI dial plans that have been created to work with Communications Server 2007 R2 or Lync Server. This enables call routing and outdialing to work correctly.

For more information about UM IP gateways, see UM IP gateways.

A Unified Messaging (UM) hunt group is a logical representation of a Private Branch eXchange (PBX) or IP PBX hunt group. A UM hunt group acts as a connection or link between a UM IP gateway and a UM dial plan.

Note:
If you associate a UM dial plan with the UM IP gateway when you create a UM IP gateway, a UM hunt group will also be created.

Note:
If you want to change the settings for a UM hunt group, you must delete the hunt group and then create another hunt group that has the appropriate settings.

For additional management tasks related to UM hunt groups, see UM hunt group procedures.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM hunt groups" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- Before you perform these procedures, confirm that a UM IP gateway has been created. For detailed steps, see Create a UM IP gateway.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to create a UM hunt group

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**. In the list view, select the UM dial

plan you want to modify, and then click **Edit** ✎.

2. On the **UM Dial Plan** page, under **UM Hunt Groups**, click **New +**.
3. On the **New UM hunt group** page, enter the following information:
   - **Name** Use this box to create the display name for the UM hunt group. A UM hunt group name is required and must be unique, but it's used only for display purposes in the EAC and the Shell. If you have to change the display name of the hunt group after it's been created, you must first delete the existing hunt group and then create another hunt group that has the appropriate name.

If your organization uses multiple hunt groups, we recommend that you use meaningful names for your hunt groups. The maximum length of a UM hunt group name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.

   - **UM IP gateway** Use this box to specify the UM IP gateway to be used. Click **Browse** to select the UM IP gateway, and then click **OK**.
   - **Pilot identifier** Use this box to specify a string that uniquely identifies the pilot identifier configured on the PBX or IP PBX.

An extension number or a Session Initiation Protocol (SIP) Uniform Resource Identifier (URI) can be used in this box. Alphanumeric characters are accepted in this box. For legacy PBXs, a numeric value is used as a pilot identifier. However, some IP PBXs can use SIP URIs.

4. Click **Save**.

Use the Shell to create a UM hunt group

This example creates a UM hunt group named `MyUMHuntGroup` that has a pilot identifier of 12345.

```
New-UMHuntGroup -Name MyUMHuntGroup -PilotIdentifier 12345
-UMDialplan MyUMDialPlan -UMIPGateway MyUMIPGateway
```

This example creates a UM hunt group named `MyUMHuntGroup` that has multiple pilot identifiers.

```
New-UMHuntGroup -Name MyUMHuntGroup -PilotIdentifier
5551234,55555 -UMDialplan MyUMDialPlan -UMIPGateway
MyUMIPGateway
```

View a UM hunt group

Connect your voice mail system to your telephone network > UM hunt groups > UM hunt group procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-05*

When you view the properties for a Unified Messaging (UM) hunt group, you can view the properties associated with a single UM hunt group or with all UM hunt groups associated with a single UM IP gateway. If neither parameter is specified, all UM hunt groups will be returned. You can't use the EAC to view UM hunt group properties; you must use the Shell.

After a UM hunt group has been created, the configured settings can't be changed. If you want to change a configuration setting such as the pilot identifier on a UM hunt group, you must delete the existing UM hunt group and create a new UM hunt group that has the correct settings.

For additional tasks related to UM hunt groups, see UM hunt group procedures.

What do you need to know before you begin?

- Estimated time to complete: Less than 1 minute
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM hunt groups" entry in the Unified Messaging permissions topic.
- Before you perform this procedure, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- Before you perform this procedure, confirm that a UM gateway has been created. For detailed steps, see Create a UM IP gateway.
- Before you perform this procedure, confirm that a UM hunt group has been created. For detailed steps, see Create a UM hunt group.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to view the properties of a UM hunt group

This example displays all the UM hunt groups in the Active Directory forest.

```
Get-UMHuntGroup
```

This example displays the details of a UM hunt group named `MyUMHuntGroup` in a formatted list.

```
Get-UMHuntGroup -identity MyUMIPGateway\MyUMHuntGroup |
Format-List
```

Note:

When you're using the **Get-UMHuntGroup** cmdlet, you can't enter only the name of the UM hunt group. You must also include the name of the UM IP gateway that's associated with the UM hunt group.

Delete a UM hunt group

Connect your voice mail system to your telephone network > UM hunt groups > UM hunt group procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-11-05*

After you delete a Unified Messaging (UM) hunt group, the UM IP gateway associated with the UM hunt group will no longer service or answer incoming calls. If deleting the UM hunt group leaves the UM IP gateway without any remaining configured hunt groups, the UM IP gateway can't handle or process UM calls.

For additional tasks related to UM hunt groups, see UM hunt group procedures.

Warning:

If you want to change the UM hunt group settings, you must delete the hunt group and then create another hunt group that has the appropriate settings.

What do you need to know before you begin?

- Estimated time to complete: Less than 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "UM hunt groups" entry in the Unified Messaging permissions topic.
- Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM dial plan.
- Before you perform these procedures, confirm that a UM IP gateway has been created. For detailed steps, see Create a UM IP gateway.
- Before you perform these procedures, confirm that a UM hunt group has been created. For detailed steps, see Create a UM hunt group.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to delete a UM hunt group

1. In the EAC, navigate to **Unified Messaging** > **UM dial plans**. In the list view, click the UM dial

plan you want to change, and on the toolbar, click **Edit** .

2. On the **UM Dial Plan** page, under **UM Hunt Groups**, select the hunt group you want to delete, and on the toolbar, click **Delete** .
3. On the **Warning** page, click **Yes**.

Use the Shell to delete a UM hunt group

This example deletes a UM hunt group named `MyUMHuntGroup`.

```
Remove-UMHuntGroup -identity MyUMHuntGroup
```

UM services

Client Access servers running the Microsoft Exchange Unified Messaging Call Router service and Mailbox servers running the Microsoft Exchange Unified Messaging service enable you to deploy Unified Messaging (UM) and voice mail functionality for users in your organization.

Looking for management tasks related to UM services? See UM services procedures.

Client Access and Mailbox servers

In Exchange 2013, the server roles found in Exchange 2007 and Exchange 2010 are combined into two types of servers, and all components or services from those server roles are run on the same physical server or on two separate servers called Client Access and Mailbox.

In this new model, the Client Access server is responsible for Autodiscover, Secure Sockets Layer (SSL), authentication, redirection, and proxying. The Client Access server is the entry point for any inbound calls or Session Initiation Protocol (SIP) requests for Unified Messaging. The routing logic and SIP REDIRECT is implemented as a service that's automatically included on a Client Access server. This service is known as the Microsoft Exchange Unified Messaging Call Router service. It runs on each Client Access server in your organization.

When a Client Access server receives a SIP INVITE for an incoming call, the Microsoft Exchange Unified Messaging Call Router service redirects the incoming call to the Mailbox server. Then a media channel (RTP or SRTP) is created between the VoIP gateway, IP PBX, or session border controller (SBC) and the Mailbox server that hosts the user's mailbox. Although the Client Access server acts as a SIP redirector, it only handles SIP requests from VoIP gateways, IP PBXs, or SBCs. It doesn't receive any media traffic. Media traffic that uses RTP or SRTP is only passed between the Mailbox server and SIP peers such as VoIP gateways, IP PBXs, or SBCs. When you deploy Exchange 2013 and UM, you have to configure your VoIP gateways, IP PBXs, or SBCs to point to the Client Access servers that you've installed so that incoming calls will be routed correctly for UM.

In Exchange 2013, the Mailbox server handles the same processes as the Unified Messaging server role handled in Exchange 2007 and Exchange 2010. The Mailbox server runs both the Microsoft Exchange Unified Messaging service and UM worker processes.
