To add parameters to a role entry, you need to specify the parameters you want to add using the *Parameters* parameter. You then need to specify the *AddParameter* parameter to indicate that you want to perform an add operation.

To add parameters to a role entry, use the following syntax.

```
Set-ManagementRoleEntry <role name>\<cmdlet> -Parameters
<parameter 1>, <parameter 2>, <parameter...> -AddParameter
```

This example adds the *EmailAddresses* and *Type* parameters to the **Set-Mailbox** cmdlet on the

Recipient Administrators role.

```
Set-ManagementRoleEntry "Recipient Administrators\Set-
Mailbox" -Parameters EmailAddresses, Type -AddParameter
```

For detailed syntax and parameter information, see Set-ManagementRoleEntry.

Use the Shell to remove one or more parameters from a role entry

To remove parameters from a role entry, you need to specify the parameters you want to remove using the *Parameters* parameter. You then need to specify the *RemoveParameter* parameter to indicate that you want to perform a remove operation.

To remove parameters from a role entry, use the following syntax.

```
Set-ManagementRoleEntry <role name>\<cmdlet> -Parameters
<parameter 1>, <parameter 2>, <parameter...> -
RemoveParameter
```

This example removes the *Port*, *ProtocolLoggingLevel*, and *SmartHostAuthMechanism* parameters from the **Set-SendConnector** cmdlet on the Tier 1 Server Administrators role.

```
Set-ManagementRoleEntry "Tier 1 Server Administrators\Set-
SendConnector" -Parameters Port, ProtocolLoggingLevel,
SmartHostAuthMechanism -RemoveParameter
```

For detailed syntax and parameter information, see Set-ManagementRoleEntry.

Use the Shell to remove all parameters from a role entry

To remove all the parameters from a role entry, you need to specify the value `$Null` on the *Parameters* parameter. You don't need to include the *RemoveParameters* parameter.

Removing all the parameters from a role entry is most useful when you want to make only a few parameters available on a cmdlet and exclude all of the other parameters. If you don't want the role to have access to a cmdlet, remove the associated role entry from the role completely instead of just removing the parameters. For more information about how to remove a role entry from a role, see Remove a role entry from a role.

Caution:
You can't undo remove operations. If you mistakenly remove all the parameters from a role entry, you must add them again manually.

To remove all the parameters from a role entry, use the following syntax.

```
Set-ManagementRoleEntry <role name>\<cmdlet> -Parameters
$Null
```

This example removes all the parameters from the **Set-CASMailbox** cmdlet on the Recipient Administrators role.

```
Set-ManagementRoleEntry "Recipient Administrators\Set-
CASMailbox" -Parameters $Null
```

For detailed syntax and parameter information, see Set-ManagementRoleEntry.

Use the Shell to apply a specific set of parameters

If you want only a specific set of parameters to be included on a role entry, specify the *Parameters* parameter only. Don't include the *AddParameter* or *RemoveParameter* parameters. When you specify only the *Parameters* parameter, only the parameters you specify in the command are included on the role entry. All other parameters are removed.

To specify a specific set of parameters, use the following syntax.

```
Set-ManagementRoleEntry <role name>\<cmdlet> -Parameters
<parameter 1>, <parameter 2>, <parameter...>
```

This example includes only the *Identity*, *DisplayName*, *MissedCallNotificationEnabled*, and *PersonalAuthAttendantEnabled* parameters on the **Set-UMMailbox** cmdlet on the Seattle Mail Recipients role.

```
Set-ManagementRoleEntry "Seattle Mail Recipients\Set-
UMMailbox" -Parameters Identity, DisplayName,
MissedCallNotificationEnabled, PersonalAutoAttendantEnabled
```

For detailed syntax and parameter information, see Set-ManagementRoleEntry.

View role entries

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

Each management role entry represents a single cmdlet or script. The parameters included on a

role entry determine what parameters on the cmdlet or script a user can access.

The identity of role entries consists of the management role name that the role entry is associated with, and the cmdlet or script that the role entry refers to. For more information about role entries in Microsoft Exchange Server 2013, see Understanding management roles.

Looking for other management tasks related to role entries? Check out Advanced permissions.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Management roles" entry in the Role management permissions topic.
- You must use the Shell to perform these procedures.
- This topic makes use of pipelining, the **Format-List** cmdlet, objects, and properties. For more information about these concepts, see the following topics:
  - Pipelining
  - Working with command output
  - Structured data
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

View a list of role entries

You can use the **Get-ManagementRoleEntry** cmdlet to retrieve a list of role entries. When you use the **Get-ManagementRoleEntry** cmdlet, you must specify a value that contains both the role name that contains the role entries you want to list and also the cmdlet name of the role entry you want to list. By combining the role name and cmdlet name with the wildcard character (*), you can return specific or broad lists of role entries.

For detailed syntax and parameter information, see Get-ManagementRoleEntry.

View a list of all role entries on a role

To view a list of role entries on a specific role, use the following syntax.

```
Get-ManagementRoleEntry <role name>\*
```

This examples retrieves all the role entries on the `Recipient Administrators` role.

```
Get-ManagementRole "Recipient Administrators\*"
```

For detailed syntax and parameter information, see Get-ManagementRoleEntry.

View a list of roles that contain a specific role entry

To view a list of all the roles that contain a specific role entry, use the following syntax.

```
Get-ManagementRoleEntry *\<cmdlet name>
```

This example retrieves all the roles that contain the **Set-Mailbox** role entry.

```
Get-ManagementRoleEntry *\Set-Mailbox
```

For detailed syntax and parameter information, see Get-ManagementRoleEntry.

View a targeted list of roles that contain similar role entries

To view a list of targeted roles that contain cmdlets with similar names, use the following syntax.

```
Get-ManagementRoleEntry *<partial role name>*\*<partial cmdlet name>*
```

This example returns a list of role entries that contain the string `Mailbox` that are on roles that contain the string `Tier 1` in their names.

```
Get-ManagementRoleEntry "*Tier 1*\*Mailbox*"
```

For detailed syntax and parameter information, see Get-ManagementRoleEntry.

View a single role entry

To view the details of a single role entry, use the following syntax.

```
Get-ManagementRoleEntry <role name>\<cmdlet name> | Format-List
```

This example retrieves the details of the **Set-Mailbox** role entry on the `Recipient Administrators` role.

```
Get-ManagementRoleEntry "Recipient Administrators\Set-Mailbox" | Format-List
```

If the role entry you view has too many parameters to list using the **Format-List** cmdlet, see "View the parameters on a single role entry" later in this topic.

For detailed syntax and parameter information, see Get-ManagementRoleEntry.

View the parameters on a single role entry

Some role entries have more parameters than can be viewed by piping the results of the **Get-ManagementRoleEntry** cmdlet to the **Format-List** cmdlet. If you need to view all the parameters on a role entry, you need to directly access the **Parameters** property of the role entry object.

To view parameters stored in the **Parameters** property of a role entry object, use the following syntax.

```
(Get-ManagementRoleEntry <role name>\<cmdlet name>).Parameters
```

This example retrieves the parameters on the **Set-Mailbox** role entry on the Mail Recipients role.

```
(Get-ManagementRoleEntry "Mail Recipients\Set-Mailbox").Parameters
```

For detailed syntax and parameter information, see Get-ManagementRoleEntry.

Remove a role entry from a role

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

Management role entries on a management role determine what cmdlets and parameters are available on a management role. By removing role entries or parameters on a role entry, you can restrict what users assigned the management role can perform. For more information about management role entries in Microsoft Exchange Server 2013, see Understanding management roles.

Looking for other management tasks related to roles? Check out Advanced permissions.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Management roles" entry in the Role management permissions topic.
- You must use the Shell to perform these procedures.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see

Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Remove a single entire role entry from a role

When you remove a role entry from a role, you remove the ability for users assigned that role to access the associated cmdlet or script.

Use the following syntax to remove an entire management role entry from a role.

```
Remove-ManagementRoleEntry <management role>\<management role entry>
```

This example removes the **Enable-MailUser** cmdlet from the Seattle Server Administrators role.

```
Remove-ManagementRoleEntry "Seattle Server Administrators\Enable-MailUser"
```

For detailed syntax and parameter information, see Remove-ManagementRoleEntry.

Remove multiple entire role entries from a role

When you remove multiple role entries from a role, you remove the ability for users assigned that role to access the associated cmdlets or scripts.

To remove multiple role entries from a role, you need to retrieve the list of role entries to remove using the **Get-ManagementRoleEntry** cmdlet. Then you need to pipe the output to the **Remove-ManagementRoleEntry** cmdlet. You can use wildcard characters with the **Get-ManagementRoleEntry** cmdlet to match multiple role entries. It's a good idea to use the *WhatIf* switch to verify that you're removing the correct role entries. Use the following syntax.

```
Get-ManagementRoleEntry <management role>\<role entry with wildcard character> | Remove-ManagementRoleEntry -WhatIf
```

This example removes all the role entries that contain the word journal from the Seattle Server Administrators role.

```
Get-ManagementRoleEntry "Seattle Server Administrators\*Journal*" | Remove-ManagementRoleEntry -WhatIf
```

When you run the command with the *WhatIf* switch, the cmdlet returns a list of all the role entries that would be removed. If the list looks correct, run the command again without the *WhatIf* switch to remove the role entries.

```
Get-ManagementRoleEntry "Seattle Server Administrators
\*Journal*" | Remove-ManagementRoleEntry
```

For detailed syntax and parameter information, see Get-ManagementRoleEntry and Remove-ManagementRoleEntry.

Remove parameters from a role entry on a role

When you remove parameters from a role entry on a role, those parameters are no longer available to users assigned the role.

Use the following syntax to remove parameters from a role entry.

```
Set-ManagementRoleEntry <management role>\<role entry> -
Parameters <parameter 1>,<parameter 2...> -RemoveParameter
```

This example removes the *MaxSafeSenders*, *MaxSendSize*, *SecondaryAddress*, and *UseDatabaseQuotaDefaults* parameters from the **Set-Mailbox** role entry on the Seattle Server Administrators role.

```
Set-ManagementRoleEntry "Seattle Server Administrators\Set-
Mailbox" -Parameters
MaxSafeSenders,MaxSendSize,SecondaryAddress,UseDatabaseQuot
aDefaults -RemoveParameter
```

For detailed syntax and parameter information, see Set-ManagementRoleEntry.

Create an unscoped role

Permissions > Advanced permissions > Management roles and role entries >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-06-09*

An unscoped management role can be used to provide administrators and specialist users access to Windows PowerShell scripts and non-Exchange cmdlets. You can either create an unscoped top-level role and add scripts or non-Exchange cmdlets to that role, or create a role that's based on an existing, unscoped top-level role. After an unscoped role has been created and customized, the role

can be assigned to management role groups, users, and universal security groups (USGs). Unscoped roles can't be assigned to management role assignment policies. For more information about unscoped roles, see Understanding management roles.

Caution:
Unscoped roles can be powerful because, as their name implies, no management scopes are applied to them. This means that the scripts and non-Exchange cmdlets that they contain can be run against any object in your Exchange organization. Consider this when adding scripts or non-Exchange cmdlets to an unscoped role and when assigning the unscoped role.

Note:
If you want to create a role that contains Exchange cmdlets, you must create a role that's based on an existing management role. For more information about creating roles with Exchange cmdlets, see Create a role.

Looking for other management tasks related to roles? Check out Advanced permissions.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Management roles" entry in the Role management permissions topic.
- You must use the Shell to perform these procedures.
- The ability to create unscoped roles isn't included in any management role group by default. You must first assign the Unscoped Role Management role to a user, or to a USG or role group of which the user is a member, before the user is able to create a role group. For more information about adding a role to a user, USG, or role group, see the following topics:
  - Manage role groups
  - Add a role to a user or USG
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Create an unscoped top-level management role

If you want to make scripts or non-Exchange cmdlets available to administrators or specialists in your organization, you need to create an unscoped top-level role. Scripts and non-Exchange cmdlets can only be added to an unscoped role that's created as a top-level role, because the initial unscoped role doesn't inherit from other roles. The new, unscoped top-level role can then be

a parent to other unscoped roles that can also use the added scripts and non-Exchange cmdlets.

Here are the steps to create an unscoped top-level role:

Step 1: Create the unscoped top-level role

Unscoped top-level roles don't have a parent role. You need to specify the *UnscopedTopLevel* switch to create a role without a parent. Use the following syntax to create the new role.

```
New-ManagementRole <name of new role> -UnscopedTopLevel
```

This example creates the IT Scripts unscoped top-level role.

```
New-ManagementRole "IT Scripts" -UnscopedTopLevel
```

After it's created, the role is empty until you add scripts or non-Exchange cmdlets to it.

For detailed syntax and parameter information, see New-ManagementRole.

Step 2a: Add script management role entries

If you want to add a script to the new unscoped role, use this step. If you want to add a non-Exchange cmdlet to the new unscoped role, use Step 2b.

To add a Windows PowerShell script to an unscoped top-level role, you must add a management role entry to the role. The role entry contains the script's name and the parameters on the script that you want to make available to the role.

The script must reside in the `RemoteScripts` directory in the Microsoft Exchange Server 2013 installation path on every server running Exchange 2013 where users might connect to run the script. If a user has access to run a script, but the script isn't located on the Exchange 2013 server the user is connected to, an error occurs. By default, the path to the `RemoteScripts` directory is C:\Program Files\Microsoft\Exchange Server\V15\RemoteScripts.

After you copy the script to the appropriate Exchange 2013 servers and you decide what script parameters should be used, create the role entry using the following syntax.

```
Add-ManagementRoleEntry <unscoped top-level role name>
\<script filename> -Parameters <parameter 1, parameter 2,
parameter...> -Type Script -UnscopedTopLevel
```

This example adds the BulkProvisionUsers.ps1 script to the IT Scripts role with the *Name* and *Location* parameters.

```
Add-ManagementRoleEntry "IT Scripts\BulkProvisionUsers.ps1"
-Parameters Name, Location -Type Script -UnscopedTopLevel
```

Note:

The **Add-ManagementRoleEntry** cmdlet performs basic validation to make sure that you add only the parameters that exist in the script. However, no further validation is done after the role entry is added. If parameters are later added or removed, you must manually update the role entries that contain the script.

Step 2b: Add non-Exchange cmdlet role entries

If you want to add a non-Exchange cmdlet to the new unscoped role, use this step. If you want to add a script to the new unscoped role, use Step 2a.

To add a non-Exchange cmdlet to an unscoped top-level role, you must add a management role entry to the role. The role entry contains the cmdlet snap-in, cmdlet name, and the parameters on the cmdlet that you want to make available to the role.

If you add non-Exchange cmdlets to the new role, the cmdlets must be installed on every Exchange 2013 server where users might connect to run the cmdlets. To learn how to properly install and register the Windows PowerShell snap-ins that contain the cmdlets you want to use, refer to the documentation for your product.

After you install the Windows PowerShell snap-in that contains the cmdlets on the appropriate Exchange 2013 servers and you decide what cmdlet parameters should be used, create the role entry using the following syntax.

```
Add-ManagementRoleEntry <unscoped top-level role name>
\<cmdlet name> -PSSnapinName <snap-in name> -Parameters
<parameter 1, parameter 2, parameter...> -Type Cmdlet -
UnscopedTopLevel
```

This example adds the **Set-WidgetConfiguration** cmdlet in the Contoso.Admin.Cmdlets snap-in to the Widget Cmdlets role with the *Database* and *Size* parameters.

```
Add-ManagementRoleEntry "Widget Cmdlets\Set-
WidgetConfiguration" -PSSnapinName Contoso.Admin.Cmdlets -
Parameters Database, Size -Type Cmdlet -UnscopedTopLevel
```

Note:

The **Add-ManagementRoleEntry** cmdlet performs basic validation to make sure that you add only the parameters that exist in the cmdlet. However, no further validation is done after the role entry is added. If the cmdlet is later changed, and parameters are added or removed, you must manually update the role entries that contain the cmdlet.

Step 3: Assign the management role

The final step when you create and configure a role is to assign it to a role assignee.

Important:

Management scopes can't be configured on role assignments that assign an unscoped role.

Whether you choose to create a role assignment for a role group, user, or USG, you must choose the option to create a role assignment without a management scope.

You can assign the new role to a role group, user, or USG. For more information, see the following topics:

- Manage role groups
- Add a role to a user or USG

Create an unscoped role based on another unscoped role

If you have an existing, unscoped top-level role or other unscoped roles that you want to base new unscoped roles on, you can create child unscoped roles. The child unscoped roles can contain a subset of the scripts and cmdlets that exist on the parent unscoped roles. This is useful, for example, if you want to give only a subset of the scripts or cmdlets available on a parent unscoped role to a less experienced administrator.

Here are the steps to create an unscoped child role:

Step 1: Create the unscoped child role

New, unscoped child roles can be based on existing unscoped roles. When you create a role, an existing role and its management role entries are copied to the new role. The existing role becomes the parent to the new child role. If you create an unscoped role that's based on another unscoped role, you must choose a role that contains all the cmdlets and parameters you need to use, and then remove the ones you don't want. Child unscoped roles can't have management role entries that don’t exist in the parent role.

Note:

If you need to create an unscoped role that contains scripts or non-Exchange cmdlets that don't exist in any other unscoped role, create an unscoped top-level role. For more information, see Create an unscoped top-level management role earlier in this topic.

Use the following syntax to create the new role.

```
New-ManagementRole -Parent <existing unscoped role to copy>
-Name <name of new unscoped role>
```

This example copies the IT Global Scripts role and its management role entries to the Diagnostic IT Scripts role.

```
New-ManagementRole -Parent "IT Global Scripts" -Name
"Diagnostic IT Scripts"
```

For detailed syntax and parameter information, see New-ManagementRole.

Step 2: Change the role's management role entries

After you create your role, you need to change the role's entries. You can remove an entire role entry, which removes access to the associated script or non-Exchange cmdlet completely. Or, you can remove parameters from a role entry to remove access to those specific parameters on the associated script or non-Exchange cmdlet.

You can't add role entries or parameters on role entries unless they exist in the parent role. Because you just created a role from a parent role in Step 1, you can't add any additional role entries or parameters on role entries because they don't exist in the parent role.

When you change a role entry on a role, you can do one of the following:

- Remove a single, entire role entry.
- Remove multiple, entire role entries.
- Remove parameters from a role entry.

To remove role entries from your new role, see Remove a role entry from a role.

Step 3: Assign the management role

The final step when you create and configure a role is to assign it to a role assignee.

Important:
Management scopes can't be configured on role assignments that assign an unscoped role. Whether you choose to create a role assignment for a role group, user, or USG, you must choose the option to create a role assignment without a management scope.

You can assign the new role to a role group, user, or USG. For more information, see the following topics:

- Manage role groups
- Add a role to a user or USG

Change a role entry on an unscoped top-level role

Permissions > Advanced permissions > Management roles and role entries >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

Management role entries on unscoped top-level management roles refer to the scripts and non-Exchange cmdlets, and their parameters, that you want to make available to those assigned the role. By changing the parameters available on a role entry, you control what those assigned the role can do with the script or non-Exchange cmdlet. For more information about unscoped role entries, see Understanding management roles.

Note:

If you want to change a role entry on a management role that contains Exchange cmdlets, see Change a role entry.

Looking for other management tasks related to roles? Check out Advanced permissions.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Management roles" entry in the Role management permissions topic.
- You must use the Shell to perform these procedures.
- The ability to change a role entry on an unscoped top-level role isn't included in any management role group by default. You must first assign the Unscoped Role Management role to a user, or to a universal security group (USG) or role group of which the user is a member, before the user is able to add or change an unscoped top-level role entry. For more information about adding a role to a user, USG, or role group, see the following topics:
  - Manage role groups
  - Add a role to a user or USG
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to add one or more parameters to a role entry

To add parameters to an unscoped top-level role entry, you need to do the following:

- Specify the parameters you want to add using the *Parameters* parameter.
- Specify the *AddParameter* parameter to indicate that you want to perform an add operation.
- Specify the *UnscopedTopLevel* parameter to indicate that you're changing a role entry on an unscoped top-level role. If you don't specify this parameter when you change a role entry on an unscoped role, an error occurs.

To add parameters to a role entry, use the following syntax.

```
Set-ManagementRoleEntry <role name>\<script or non-
```

```
Exchange cmdlet> -Parameters <parameter 1>, <parameter 2>,
<parameter...> -AddParameter -UnscopedTopLevel
```

This example adds the *EmailAddress* and *City* parameters to the **CreateUsers.ps1** script on the Recipient Administrators unscoped role.

```
Set-ManagementRoleEntry "Recipient Administrators
\CreateUsers.ps1" -Parameters EmailAddress, City -
AddParameter -UnscopedTopLevel
```

For detailed syntax and parameter information, see Set-ManagementRoleEntry.

Use the Shell to remove one or more parameters from a role entry

To remove parameters from a role entry, you need to do the following:

- Specify the parameters you want to remove using the *Parameters* parameter.
- Specify the *RemoveParameter* parameter to indicate that you want to perform a remove operation.
- Specify the *UnscopedTopLevel* parameter to indicate that you're changing a role entry on an unscoped top-level role. If you don't specify this parameter when you change a role entry on an unscoped role, an error occurs.

Caution:
You can't undo remove operations. If you mistakenly remove a parameter from a role entry, you must add it again manually.

To remove parameters from a role entry, use the following syntax.

```
Set-ManagementRoleEntry <role name>\<script or non-Exchange
cmdlet> -Parameters <parameter 1>, <parameter 2>,
<parameter...> -RemoveParameter -UnscopedTopLevel
```

This example removes the *Delay*, *Force*, and *Credential* parameters from the **Start-Widget** non-Exchange cmdlet on the Tier 1 Server Administrators role.

```
Set-ManagementRoleEntry "Tier 1 Server Administrators
\Start-Widget" -Parameters Delay, Force, Credential -
RemoveParameter -UnscopedTopLevel
```

For detailed syntax and parameter information, see Set-ManagementRoleEntry.

Use the Shell to remove all parameters from a role entry

To remove all of the parameters from a role entry, you need to do the following:

- Specify the value `$Null` on the *Parameters* parameter. You don't need to include the *RemoveParameter* parameter.
- Specify the *UnscopedTopLevel* parameter to indicate that you're changing a role entry on an unscoped top-level role. If you don't specify this parameter when you change a role entry on an unscoped role, an error occurs.

Removing all the parameters from a role entry is most useful when you want to make only a few parameters available on a script or non-Exchange cmdlet and exclude all of the other parameters.

If you don't want the role to have access to a script or non-Exchange cmdlet, remove the associated role entry from the role completely instead of just removing the parameters. For more information about how to remove a role entry from a role, see Remove a role entry from a role.

Caution:

You can't undo remove operations. If you mistakenly remove all the parameters from a role entry, you must add them again manually.

To remove all the parameters from a role entry, use the following syntax.

```
Set-ManagementRoleEntry <role name>\<script or non-Exchange cmdlet> -Parameters $Null -UnscopedTopLevel
```

This example removes all the parameters from the FindMailboxesOverQuota.ps1 script on the Recipient Administrators role.

```
Set-ManagementRoleEntry "Recipient Administrators\FindMailboxesOverQuota.ps1" -Parameters $Null -UnscopedTopLevel
```

For detailed syntax and parameter information, see Set-ManagementRoleEntry.

Use the Shell to apply a specific set of parameters

If you want only a specific set of parameters to be included on a role entry, you need to do the following:

- Specify the *Parameters* parameter only. Don't include the *AddParameter* or *RemoveParameter* parameters.
- Specify the *UnscopedTopLevel* parameter to indicate that you're changing a role entry on an unscoped role. If you don't specify this parameter when you change a role entry on an unscoped top-level role, an error occurs.

Caution:

When you specify only the *Parameters* parameter, only the parameters you specify in the command are included on the role entry. All other parameters are removed.

To specify a specific set of parameters, use the following syntax.

```
Set-ManagementRoleEntry <role name>\<script or non-Exchange cmdlet> -Parameters <parameter 1>, <parameter 2>, <parameter...> -UnscopedTopLevel
```

This example includes only the *Alias*, *DisplayName*, *WidgetConfig*, and *Enabled* parameters on the **Set-Widget** cmdlet on the Seattle Mail Recipient Admins role.

```
Set-ManagementRoleEntry "Seattle Mail Recipient Admins\Set-UMMailbox" -Parameters Alias, DisplayName, WidgetConfig, Enabled -UnscopedTopLevel
```

For detailed syntax and parameter information, see Set-ManagementRoleEntry.

Other tasks

After you change a role entry on an unscoped top-level role, you may also want to:

Add a role entry to a role

Manage role groups

Manage role group members

Add a role to a user or USG

Remove a role from a user or USG

Add a role entry to an unscoped top-level role

Permissions > Advanced permissions > Management roles and role entries >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

You can add scripts and non-Exchange cmdlets to unscoped top-level management roles if you want to make new scripts or non-Exchange cmdlets available to existing unscoped roles. These scripts and non-Exchange cmdlets are added as management role entries to unscoped top-level management roles. They can then be used by those unscoped top-level role entries or any unscoped roles derived from the top-level roles. For more information about unscoped role entries, see Understanding management roles.

Note:

If you want to change a role entry on a management role that contains Exchange cmdlets, see Change a role entry.

Looking for other management tasks related to roles? Check out Advanced permissions.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Management roles" entry in the Role management permissions topic.
- You must use the Shell to perform these procedures.
- The ability to add a role entry on an unscoped top-level role isn't included in any management role group by default. You must first assign the Unscoped Role Management role to a user, or to a universal security group (USG) or role group of which the user is a member, before the user is able to add an unscoped top-level role entry. For more information about adding a role to a role group, user, or USG, see the following topics:
  - Manage role groups
  - Add a role to a user or USG
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Add a script role entry to an unscoped top-level role

If you want to add a script to an existing unscoped role, use this procedure. If you want to add a non-Exchange cmdlet to an existing unscoped role, see "Add a non-Exchange cmdlet role entry to an unscoped top-level role" later in this topic.

To add a Windows PowerShell script to an unscoped top-level role, you must add a management role entry to the role. The role entry contains the script's name and the parameters on the script that you want to make available to the role.

The script must reside in the Scripts directory in the Microsoft Exchange Server 2013 installation path on every server running Exchange 2013 where users might connect to run the script. If a user has access to run a script, but the script isn't located on the Exchange 2013 server the user is connected to, an error occurs. By default, the path to the Scripts directory is C:\Program Files \Microsoft\Exchange Server\V15\Scripts.

After you copy the script to the appropriate Exchange 2013 servers and you decide what script parameters should be used, create the role entry using the following syntax.

```
Add-ManagementRoleEntry <unscoped top-level role name>
\<script filename> -Parameters <parameter 1, parameter 2,
parameter...> -Type Script -UnscopedTopLevel
```

This example adds the BulkProvisionUsers.ps1 script to the IT Scripts role with the *Name* and *Location* parameters.

```
Add-ManagementRoleEntry "IT Scripts\BulkProvisionUsers.ps1"
-Parameters Name, Location -Type Script -UnscopedTopLevel
```

Note:

The **Add-ManagementRoleEntry** cmdlet performs basic validation to make sure that you add only the parameters that exist in the script. However, no further validation is done after the role entry is added. If parameters are later added or removed, you must manually update the role entries that contain the script.

Add a non-Exchange cmdlet role entry to an unscoped top-level role

If you want to add a non-Exchange cmdlet to an existing unscoped role, use this procedure. If you want to add a script to an existing unscoped role, see "Add a script role entry to an unscoped top-level role" earlier in this topic.

To add a non-Exchange cmdlet to an unscoped top-level role, you must add a management role entry to the role. The role entry contains the cmdlet snap-in, cmdlet name, and the parameters on the cmdlet that you want to make available to the role.

If you add non-Exchange cmdlets to the new role, the cmdlets must be installed on every Exchange 2013 server where users might connect to run the cmdlets. To learn how to properly install and register the Windows PowerShell snap-ins that contain the cmdlets you want to use, refer to the documentation for your product.

After you install the Windows PowerShell snap-in that contains the cmdlets on the appropriate the Exchange 2013 servers and you decide what cmdlet parameters should be used, create the role entry using the following syntax.

```
Add-ManagementRoleEntry <unscoped top-level role name>
\<cmdlet name> -PSSnapinName <snap-in name> -Parameters
<parameter 1, parameter 2, parameter...> -Type Cmdlet -
UnscopedTopLevel
```

This example adds the **Set-WidgetConfiguration** cmdlet in the Contoso.Admin.Cmdlets snap-in to the Widget Cmdlets role with the *Database* and *Size* parameters.

```
Add-ManagementRoleEntry "Widget Cmdlets\Set-
WidgetConfiguration" -PSSnapinName Contoso.Admin.Cmdlets -
Parameters Database, Size -Type Cmdlet -UnscopedTopLevel
```

Note:

The **Add-ManagementRoleEntry** cmdlet performs basic validation to make sure that you add only the parameters that exist in the cmdlet. However, no further validation is done after the role entry is added. If the cmdlet is later changed, and parameters are added or removed, you must manually update the role entries that contain the cmdlet.

Other tasks

After you add a role entry or an unscoped top-level role, you may also want to:

Add a role entry to a role

Manage role groups

Manage role group members

Add a role to a user or USG

Remove a role from a user or USG

Management role scopes

Exchange Server 2013 > Permissions > Advanced permissions >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-13*

The following procedures enable you to perform advanced permissions management. You should only use these procedures if management role groups and management role assignment policies don't meet the needs of your organization.

Create a regular or exclusive scope

Change a role scope

View role scopes

Remove a role scope

Control automatic mailbox distribution using database scopes

For more information about managing role groups and role assignment policies, see the following topics:

Manage role groups

Manage linked role groups

Manage role assignment policies

Create a regular or exclusive scope

Permissions > Advanced permissions > Management role scopes >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-17*

Management role scopes determine what objects are made available to a user so that the objects can be changed using the cmdlets and parameters assigned to them. By adding a management scope, you can configure management role assignments so users can administer specific servers, databases, recipients, and other objects in your organization while being restricted from changing other objects.

Important:
When you create a regular or exclusive scope, you override the write scope that's defined on the management role you're assigning. You can't override the read scope that's configured on the management role.

You can create a custom management scope and add or change a management role assignment. If you want to create a management role assignment with a prebuilt or organizational unit (OU) management scope, see Add a role to a user or USG.

For more information about management role scopes and assignments in Microsoft Exchange Server 2013, see the following topics:

- Understanding management role scopes
- Understanding management role assignments

Looking for other management tasks related to scopes? Check out Advanced permissions.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Management scopes" entry in the Role management permissions topic.
- You must use the Shell to perform these procedures.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

How do you do this?

Step 1: Create a custom scope

To create a custom scope, choose one of the following types of scopes.

Recipient filter scope

Recipient filter-based scopes are created by using the *RecipientRestrictionFilter* parameter on the **New-ManagementScope** cmdlet. When you create a recipient filter, in addition to the recipient properties to filter, you can specify the OU in which the filter query runs. When you specify a base OU, you further restrict the write scope of the role.

For more information about management scope filters, see Understanding management role scope filters.

Use the following syntax to create a domain restriction filter scope with a base OU.

```
New-ManagementScope -Name <scope name> -
RecipientRestrictionFilter <filter query> [-RecipientRoot
<OU>]
```

This example creates a scope that includes all mailboxes within the contoso.com/Sales OU.

```
New-ManagementScope -Name "Mailboxes in Sales OU" -
RecipientRestrictionFilter { RecipientType -eq
'UserMailbox' } -RecipientRoot "contoso.com/Sales OU"
```

Note:
You can omit the *RecipientRoot* parameter if you want the filter to apply to the entire implicit read scope of the management role and not just within a specific OU.

For detailed syntax and parameter information, see New-ManagementScope.

Server filter configuration scope

Server filter-based configuration scopes are created by using the *ServerRestrictionFilter* parameter on the **New-ManagementScope** cmdlet. A server filter enables you to create a scope that applies only to the servers that match the filter you specify.

For more information about management scope filters and for a list of filterable server properties, see Understanding management role scope filters.

Use the following syntax to create a server filter scope.

```
New-ManagementScope -Name <scope name> -
ServerRestrictionFilter <filter query>
```

This example creates a scope that includes all the servers within the 'CN=Redmond,CN=Sites,CN=Configuration,DC=contoso,DC=com' AD (Active Directory) site.

```
New-ManagementScope -Name "Servers in Seattle AD site" -
ServerRestrictionFilter { ServerSite -eq
'CN=Redmond,CN=Sites,CN=Configuration,DC=contoso,DC=com' }
```

For detailed syntax and parameter information, see New-ManagementScope.

Server list configuration scope

Server list-based configuration scopes are created by using the *ServerList* parameter on the **New-ManagementScope** cmdlet. A server list scope enables you to create a scope that applies only to the servers you specify in a list.

Use the following syntax to create a server list scope.

```
New-ManagementScope -Name <scope name> -ServerList <server
1>, <server 2...>
```

This example creates a scope that applies only to MBX1, MBX3, and MBX5.

```
New-ManagementScope -Name "Mailbox servers" -ServerList
MBX1,MBX3,MBX5
```

For detailed syntax and parameter information, see New-ManagementScope.

Database filter configuration scope

Database filter-based configuration scopes are created by using the *DatabaseRestrictionFilter* parameter on the **New-ManagementScope** cmdlet. A database filter enables you to create a scope that applies only to the databases that match the filter you specify.

Important:
Role assignments associated with database scopes are applied only to users who connect to servers running Microsoft Exchange Server 2010 Service Pack 1 (SP1) or later or Exchange 2013. If a user assigned a role assignment associated with a database scope connects to a pre-Exchange 2010 SP1 server, the role assignment isn't applied to the user, and the user won't be granted any permissions provided by the role assignment.

For more information about management scope filters and for a list of filterable database properties, see Understanding management role scope filters.

Use the following syntax to create a database restriction filter.

```
New-ManagementScope -Name <scope name> -
DatabaseRestrictionFilter <filter query>
```

This example creates a scope that includes all the databases that contain the string "Executive" in the **Name** property of the database.

```
New-ManagementScope -Name "Executive Databases" -
DatabaseRestrictionFilter { Name -Like '*Executive*' }
```

For detailed syntax and parameter information, see New-ManagementScope.

Database list configuration scope

Database list-based configuration scopes are created by using the *DatabaseList* parameter on the **New-ManagementScope** cmdlet. A database list scope enables you to create a scope that applies only to the databases you specify in a list.

Important:
Role assignments associated with database scopes are applied only to users who connect to servers running Microsoft Exchange Server 2010 Service Pack 1 (SP1) or later or Exchange 2013. If a user assigned a role assignment associated with a database scope connects to a pre-Exchange 2010 SP1 server, the role assignment isn't applied to the user, and the user won't be granted any permissions provided by the role assignment.

Use the following syntax to create a database list scope.

```
New-ManagementScope -Name <scope name> -DatabaseList
<database 1>, <database 2...>
```

This example creates a scope that applies only to the databases Database 1, Database 2, and Database 3.

```
New-ManagementScope -Name "Primary databases" -DatabaseList
"Database 1", "Database 2", "Database 3"
```

For detailed syntax and parameter information, see New-ManagementScope.

Exclusive scope

Any scope that you create with the **New-ManagementScope** cmdlet can be designated as an exclusive scope. To create an exclusive scope, you use the same commands in one of the preceding sections to create a recipient filter-based scope, server filter-based scope, server list-based scope,

database filter-based scope, or database list-based scope, and then add the *Exclusive* switch to the command.

Caution:
When you create exclusive management scopes, only the role assignees assigned exclusive scopes that contain objects to be modified can access those objects. Only those administrators assigned a role with the exclusive scope can access these exclusive, or protected, objects.

This example creates an exclusive recipient filter-based scope that matches any user in the Executives department.

```
New-ManagementScope "Executive Users Exclusive Scope" -
RecipientRestrictionFilter { Department -Eq "Executives" }
-Exclusive
```

By default, when an exclusive scope is created, you're required to acknowledge that you created an exclusive scope and that you're aware of the impact that an exclusive scope has on existing role assignments that aren't exclusive. If you want to suppress the warning, you can use the *Force* switch. This example creates the same scope as the previous example, but without a warning.

```
New-ManagementScope "Executive Users Exclusive Scope" -
RecipientRestrictionFilter { Department -Eq "Executives" }
-Exclusive -Force
```

For detailed syntax and parameter information, see New-ManagementScope.

Step 2: Add or change a management role assignment

After you create the scope, you must add it to a new or existing management role assignment.

If you create a management scope and want to add it to a new management role assignment that you're going to create, see the following topics:

- Manage role groups
- Add a role to a user or USG

If you create a management role scope and want to add it to an existing management role assignment, see the following topics:

- Manage role assignment policies
- Change a role assignment

Change a role scope

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

Management role scopes determine what objects are made available to a user so that the objects can be changed using the cmdlets and parameters assigned to them. By changing a scope, you can change what objects are made available to users to create, change, or remove.

You can change a custom management scope. You can change either exclusive or regular scopes. If you change an exclusive scope, the new scope takes effect immediately. If you want to change a management role assignment with a predefined or organizational unit (OU) management scope, see Change a role assignment.

For more information about management role scopes and assignments in Microsoft Exchange Server 2013, see the following topics:

- Understanding management role scopes
- Understanding management role assignments

Looking for other management tasks related to role scopes? Check out Advanced permissions.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Management scopes" entry in the Role management permissions topic.
- You must use the Shell to perform these procedures.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Change the name of a scope

To change the name of a scope, use the following syntax.

```
Set-ManagementScope <current scope name> -Name <new scope name>
```

This example changes the Seattle Servers scope to Seattle Exchange Servers.

```
Set-ManagementScope "Seattle Servers" -Name "Seattle
```

```
Exchange Servers"
```

For detailed syntax and parameter information, see Set-ManagementScope.

Change a recipient filter on a scope

To change the recipient filter on a scope, use the following syntax.

```
Set-ManagementScope <scope name> -
RecipientRestrictionFilter { <new recipient filter> }
```

This example changes the recipient filter to match all the recipient objects where the **Company** property is set to contoso.

```
Set-ManagementScope "Company Scope" -
RecipientRestrictionFilter { Company -eq 'contoso' }
```

For detailed syntax and parameter information, see Set-ManagementScope.

For more information about recipient filters and to see a list of filterable recipient properties, see Understanding management role scope filters.

Change the organizational unit root on a scope

To change the OU root on a scope, use the following syntax.

```
Set-ManagementScope <scope name> -RecipientRoot <OU>
```

This example changes the OU root to the North America/Sales Sales Users OU under the contoso.com domain.

```
Set-ManagementScope "Sales Users" -RecipientRoot
"contoso.com/North America/Sales"
```

For detailed syntax and parameter information, see Set-ManagementScope.

Change a server filter on a scope

To change the server filter on a scope, use the following syntax.

```
Set-ManagementScope <scope name> -ServerRestrictionFilter
{ <new server filter> }
```

This example changes the server filter to match all the server objects where the **ServerSite** property is set to 'CN=Redmond,CN=Sites,CN=Configuration,DC=contoso,DC=com'.

```
Set-ManagementScope "Company Scope" -
ServerRestrictionFilter { ServerSite -eq
'CN=Redmond,CN=Sites,CN=Configuration,DC=contoso,DC=com' }
```

For detailed syntax and parameter information, see Set-ManagementScope.

For more information about server filters and to see a list of filterable server properties, see Understanding management role scope filters.

Change the server list on a scope

You can't change the list of servers on a scope. If you need to change the server list, you need to do the following:

1. If needed, retrieve the current server list in the scope to be replaced by using the "View a specific scope" procedure in the View role scopes topic.
2. Create a scope with the new server list by using the "Step 1: Create a custom scope" procedure in the Create a regular or exclusive scope topic.
3. Change all the management role assignments that use the old scope to use the new scope by using the "Use the Shell to change the server filter or list-based scope on a role assignment" procedure in the Change a role assignment topic.
4. Remove the old scope by using the procedure in the Remove a role scope topic.

Change a database filter on a scope

To change the database filter on a scope, use the following syntax.

```
Set-ManagementScope <scope name> -DatabaseRestrictionFilter
{ <new database filter> }
```

This example changes the database filter to match all the database objects where the **Name** property contains the string "Executive".

```
Set-ManagementScope "Database Executive Scope" -
DatabaseRestrictionFilter { Name -Like "*Executive*" }
```

For detailed syntax and parameter information, see Set-ManagementScope.

For more information about database filters and to see a list of filterable database properties, see Understanding management role scope filters.

Change the database list on a scope

You can't change the list of databases on a scope. If you need to change the database list, you need to do the following:

1. If needed, retrieve the current database list in the scope to be replaced by using the "View a specific scope" procedure in the View role scopes topic.
2. Create a scope with the new database list by using the "Step 1: Create a custom scope" procedure in the Create a regular or exclusive scope topic.
3. Change all the management role assignments that use the old scope to use the new scope by using the "Use the Shell to change the database filter or list-based scope on a role assignment" procedure in the Change a role assignment topic.
4. Remove the old scope by using the procedure in the Remove a role scope topic.

View role scopes

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

Management role scopes determine what objects are made available to a user so that the objects can be changed using the cmdlets and parameters assigned to them. You can view scopes to determine what scopes have been added to your organization, the configuration of a specific scope, or what scopes are orphans.

For more information about management role scopes in Microsoft Exchange Server 2013, see Understanding management role scopes.

Looking for other management tasks related to role scopes? Check out Advanced permissions.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Management scopes" entry in the Role management permissions topic.
- You must use the Shell to perform these procedures.
- This topic makes use of pipelining and the **Format-List** cmdlet. For more information about these concepts, see the following topics:
  - Pipelining
  - Working with command output
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

View a specific scope

You can view the details of a scope by piping the output of the **Get-ManagementScope** cmdlet to the **Format-List** cmdlet.

To view the details of a specific scope, use the following syntax.

```
Get-ManagementScope <scope name> | Format-List
```

This example retrieves the details of the Seattle Servers scope.

```
Get-ManagementScope "Seattle Servers" | Format-List
```

For detailed syntax and parameter information, see Get-ManagementScope.

List all scopes

This example retrieves a list of scopes in your organization.

```
Get-ManagementScope
```

This cmdlet retrieves both exclusive and regular scopes. If you only want to return exclusive scopes or regular scopes, see "List all exclusive or regular scopes only" later in this topic.

For detailed syntax and parameter information, see Get-ManagementScope.

List all orphaned scopes

Orphaned scopes are scopes that haven't been associated with any management role assignments.

This examples retrieves a list of orphaned scopes.

```
Get-ManagementScope -Orphan
```

For detailed syntax and parameter information, see Get-ManagementScope.

List all exclusive or regular scopes only

By default, the **Get-ManagementScope** cmdlet returns a list of scopes that contains both exclusive and regular scopes. If you want to return only exclusive scopes or only regular scopes use the following syntax.

```
Get-ManagementScope -Exclusive < $true | $false >
```

This example returns only exclusive scopes.

```
Get-ManagementScope -Exclusive $true
```

This example returns a list of regular scopes only.

```
Get-ManagementScope -Exclusive $false
```

For detailed syntax and parameter information, see Get-ManagementScope.

Remove a role scope

Permissions > Advanced permissions > Management role scopes >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-02*

Management role scopes determine what objects are made available to a user who can then change the objects using the cmdlets and parameters assigned to the user. If you're no longer using a scope, it can be removed. For more information about management role scopes in Microsoft Exchange Server 2013, see Understanding management role scopes.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Management scopes" entry in the Role management permissions topic.
- You must use the Shell to perform these procedures.
- Before you can remove a scope, you must remove the scope from any management role assignments that might be using it. For more information about how to remove a scope from a role assignment, see Change a role assignment.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to remove a scope

To remove a scope, use the following syntax.

```
Remove-ManagementScope <scope name>
```

For example, to remove the "Dublin Servers" scope, use the following command.

```
Remove-ManagementScope "Dublin Servers"
```

Control automatic mailbox distribution using database scopes

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-08-19*

Automatic mailbox distribution is a feature in Microsoft Exchange Server 2013 that randomly selects a mailbox database to store a new or moved mailbox when you don't specify a database explicitly. This feature can be helpful when you want to allow junior administrators or help desk staff to create mailboxes without needing to know which mailbox databases mailboxes should be created on.

You can use database management scopes to control which mailbox databases can be selected by automatic mailbox distribution. When you apply database scopes to an administrator, only the databases that match the defined database scope are available to the administrator. Because automatic mailbox distribution uses the context of the current user, it's also constrained by the database scopes applied to the administrator.

For more information about automatic mailbox distribution, database scopes, and role assignments, see the following topics:

- Automatic mailbox distribution
- Understanding management role scopes
- Understanding management role assignments

Looking for other management tasks related to scopes? Check out Advanced permissions.

What do you need to know before you begin?

- Estimated time to complete this procedure: 10 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Management scopes" entry in the Role management permissions topic.

- You must use the Shell to perform these procedures.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

How do you do this?

Step 1: Create a database scope

In this step, decide which databases you want to include in the database scope. Also, decide whether you want to specify a static list of databases, or whether you want to create a database filter that includes only the databases that match the criteria you specify.

Important:
Role assignments associated with database scopes are applied only to users who connect to servers running Microsoft Exchange Server 2010 Service Pack 1 (SP1) or later or Exchange 2013. If a user assigned a role assignment associated with a database scope connects to a pre-Exchange 2010 SP1 server, the role assignment isn't applied to the user, and the user won't be granted any permissions provided by the role assignment.

Use a database list scope

Use a database list if you want to define a static list of mailbox databases that should be included in this scope. Use the following syntax to create a database list scope.

```
New-ManagementScope -Name <scope name> -DatabaseList
<database 1>, <database 2...>
```

This example creates a scope that applies only to the databases Database 1, Database 2, and Database 3.

```
New-ManagementScope -Name "Accounting databases" -
DatabaseList "Database 1", "Database 2", "Database 3"
```

For detailed syntax and parameter information, see New-ManagementScope.

Use a database filter scope

Use a database filter if you want to create a dynamic database scope that includes only the databases that match the criteria you specify. This can be useful if you don't want to manage the database scope after it's created and you've defined standard values for your organization that can identify specific sets of mailbox databases.

For a list of filterable database properties, see Understanding management role scope filters.

Use the following syntax to create a database filter scope.

```
New-ManagementScope -Name <scope name> -
DatabaseRestrictionFilter <filter query>
```

This example creates a scope that includes all the databases that contain the string "ACCT" in the **Name** property of the database.

```
New-ManagementScope -Name "Accounting Databases" -
DatabaseRestrictionFilter { Name -Like '*ACCT*' }
```

For detailed syntax and parameter information, see New-ManagementScope.

Step 2: Add the database scope to a management role assignment

After you create the scope, you must add it to a new or existing management role assignment. We recommend that you use management role groups to control administrative permissions, so the examples in this step use an example role group called Accounting Administrators. For more information about how to create a role group, see Manage role groups.

After you assign the role to a role group with the database scope, the members of the role group will only be able to create mailboxes on, and move mailboxes to, the databases included in the scope.

For a list of built-in roles that you can assign to role groups, see Built-in management roles.

Add a new role assignment

Use this procedure if you've just created a role group and you need to add roles to it.

Use the following syntax to create a role assignment between the management role you want to assign and the new role group, with the new database scope.

```
New-ManagementRoleAssignment -SecurityGroup <role group
name> -Role <role name> -CustomConfigWriteScope <database
scope name>
```

This example creates a role assignment between the Mail Recipients and Mail Recipient Creation roles and the Accounting Administrators role group, using the Accounting Databases database scope.

```
New-ManagementRoleAssignment -SecurityGroup "Accounting
```

```
Administrators" -Role "Mail Recipients" -
CustomConfigWriteScope "Accounting Databases"
New-ManagementRoleAssignment -SecurityGroup "Accounting
Administrators" -Role "Mail Recipient Creation" -
CustomConfigWriteScope "Accounting Databases"
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Modify an existing role assignment

Use this procedure if you have an existing role group that already has role assignments between it and the roles you want to apply the new database scope to.

This procedure uses pipelining. For more information, see Pipelining.

Use the following syntax to modify a role assignment between the management role that you want to apply the database scope to, and an existing role group.

```
Get-ManagementRoleAssignment -RoleAssignee <role group
name> -Role <role name> | Set-ManagementRoleAssignment -
CustomConfigWriteScope <database scope name>
```

This example adds the Accounting Databases database scope to the Mail Recipients and Mail Recipient Creation roles assigned to the Accounting Administrators role group.

```
Get-ManagementRoleAssignment -RoleAssignee "Accounting
Administrators" -Role "Mail Recipients" | Set-
ManagementRoleAssignment -CustomConfigWriteScope
"Accounting Databases"
Get-ManagementRoleAssignment -RoleAssignee "Accounting
Administrators" -Role "Mail Recipient Creation" | Set-
ManagementRoleAssignment -CustomConfigWriteScope
"Accounting Databases"
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment or Set-ManagementRoleAssignment.

Step 3: Add members to a role group (if applicable)

If you want to add members to a role group, see Manage role group members.

Important:
If you add members to this role group to restrict what databases they can create users on, or move mailboxes to, make sure they aren't members of other role groups that could grant extra permissions.

Step 4: Remove members from a role group (if applicable)

If you've added members to a new role group that restricts what databases they can create mailbox on, or move mailboxes to, and they're members of another role group that has additional permissions, remove them from the old role group. For more information, see Manage role group members.

Management role assignments

Exchange Server 2013 > Permissions > Advanced permissions >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-13*

The following procedures enable you to perform advanced permissions management. You should only use these procedures if management role groups and management role assignment policies don't meet the needs of your organization.

Add a role to a user or USG

Change a role assignment

View role assignments

Remove a role from a user or USG

Delegate role assignments

For more information about managing role groups and role assignment policies, see the following topics:

Manage role groups

Manage linked role groups

Manage role assignment policies

Add a role to a user or USG

Permissions > Advanced permissions > Management role assignments >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

Management role assignments can assign a management role to a user or universal security group (USG). By assigning a role to a user or USG, you enable those users to perform tasks dependent on cmdlets or scripts and their parameters defined on the management role.

If you want to assign roles to a management role group or a management role assignment policy, see the following topics:

- Manage role groups
- Manage role assignment policies

If you want to add members to a role group or assign a role assignment policy to an end user, see the following topics:

- Manage role group members
- Change the assignment policy on a mailbox

For more information, see Understanding Role Based Access Control.

Looking for other management tasks related to roles? Check out Advanced permissions.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Role assignments" entry in the Role management permissions topic.
- You must use the Shell to perform these procedures.
- Although you can assign roles directly to users and USGs, the recommended method of granting permissions to administrators and end users is to use management role groups and management role assignment policies. When you use role groups and assignment policies, you simplify your permissions model.
- Role assignments are additive. This means that all the roles are added together when they're evaluated. If two roles are assigned to a user and one role contains a cmdlet but the other doesn't, the cmdlet will still be available to the user.

By default, role assignments don't grant the ability to assign roles to other users. To enable a user to assign roles to other users or USGs, see Delegate role assignments.

- If you create an assignment with a scope, the scope overrides the role's implicit write scope. However, the role's implicit read scope still applies. The new scope can't return objects outside of the role's implicit read scope. For more information, see Understanding management role scopes.
- All the procedures in this topic use the *SecurityGroup* parameter to assign roles to a USG. If you want to assign the role to a specific user, use the *User* parameter instead of the *SecurityGroup* parameter. All other syntax for each command is the same.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server,

Exchange Online, or Exchange Online Protection.

What do you want to do?

Create a role assignment with no scope

You can create a role assignment with no scope. When you do this, the implicit read and implicit write scopes of the role apply.

Use the following syntax to assign a role to a USG without any scope.

```
New-ManagementRoleAssignment -Name <assignment name> -
SecurityGroup <USG> -Role <role name>
```

This example assigns the Exchange Servers role to the SeattleAdmins USG.

```
New-ManagementRoleAssignment -Name "Exchange
Servers_SeattleAdmins" -SecurityGroup SeattleAdmins -Role
"Exchange Servers"
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Create a role assignment with a predefined relative scope

If a predefined relative scope meets your business requirements, you can apply that scope to the role assignment rather than create a custom scope. For a list of predefined scopes and their descriptions, see Understanding management role scopes.

Use the following syntax to assign a role to a USG with a predefined scope.

```
New-ManagementRoleAssignment -Name <assignment name> -
SecurityGroup < USG> -Role <role name> -
RecipientRelativeWriteScope < MyDistributionGroups |
Organization | Self >
```

This example assigns the Exchange Servers role to the SeattleAdmins USG and applies the Organization predefined scope.

```
New-ManagementRoleAssignment -Name "Exchange
Servers_SeattleAdmins" -SecurityGroup SeattleAdmins -Role
"Exchange Servers" -RecipientRelativeWriteScope
Organization
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Create a role assignment with a recipient filter-based scope

If you created a recipient filter-based scope and want to use it with a role assignment, you need to include the scope in the command used to assign the role to a USG by using the *CustomRecipientWriteScope* parameter. If you use the *CustomRecipientWriteScope* parameter, you can't use the *RecipientOrganizationalUnitScope* parameter.

Before you can add a scope to a role assignment, you need to create one. For more information, see Create a regular or exclusive scope.

Use the following syntax to assign a role to a USG with a recipient filter-based scope.

```
New-ManagementRoleAssignment -Name <assignment name> -
SecurityGroup < USG> -Role <role name> -
CustomRecipientWriteScope <role scope name>
```

This example assigns the Mail Recipients role to the Seattle Recipient Admins USG and applies the Seattle Recipients scope.

```
New-ManagementRoleAssignment -Name "Mail Recipients_Seattle
Recipient Admins" -SecurityGroup "Seattle Recipient Admins"
-Role "Mail Recipients" -CustomRecipientWriteScope "Seattle
Recipients"
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Create a role assignment with a server or database filter or list-based configuration scope

If you created a server or database filter or list-based configuration scope and want to use it with a role assignment, you need to include the scope in the command used to assign the role to a USG by using the *CustomConfigWriteScope* parameter.

Before you can add a scope to a role assignment, you need to create one. For more information, see Create a regular or exclusive scope.

Use the following syntax to assign a role to a USG with a configuration scope.

```
New-ManagementRoleAssignment -Name <assignment name> -
```

```
SecurityGroup <USG> -Role <role name> -
CustomConfigWriteScope <role scope name>
```

This example assigns the Exchange Servers role to the MailboxAdmins USG and applies the Mailbox Servers scope.

```
New-ManagementRoleAssignment -Name "Exchange
Servers_MailboxAdmins" -SecurityGroup MailboxAdmins -Role
"Exchange Servers" -CustomConfigWriteScope "Mailbox
Servers"
```

The preceding example shows how to add a role assignment with a server configuration scope. The syntax to add a database configuration scope is the same. You specify the name of a database scope instead of a server scope.

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Create a role assignment with an OU scope

If you want to scope a role's write scope to an organizational unit (OU), you can specify the OU in the *RecipientOrganizationalUnitScope* parameter directly. If you use the *RecipientOrganizationalUnitScope* parameter, you can't use the *CustomRecipientWriteScope* parameter.

Use the following syntax to assign a role to a USG and restrict the write scope of a role to a specific OU.

```
New-ManagementRoleAssignment -Name <assignment name> -
SecurityGroup <USG> -Role <role name> -
RecipientOrganizationalUnitScope <OU>
```

This example assigns the Mail Recipients role to the SalesRecipientAdmins USG and scopes the assignment to the sales/users OU in the contoso.com domain.

```
New-ManagementRoleAssignment -Name "Mail
Recipients_SalesRecipientAdmins" -SecurityGroup
SalesRecipientAdmins -Role "Mail Recipients" -
RecipientOrganizationalUnitScope contoso.com/sales/users
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Create a role assignment with an exclusive recipient or

configuration scope

To create an exclusive role assignment with an exclusive recipient or configuration scope, the same procedures provided in the Create a role assignment with a recipient filter-based scope and Create a role assignment with a server or database filter or list-based configuration scope sections can be used. The only difference is that when you create a role assignment with an exclusive scope, you must specify the following exclusive parameters depending on whether you're using an exclusive recipient scope or an exclusive configuration scope:

- **Exclusive recipient scopes** Use the *ExclusiveRecipientWriteScope* parameter instead of the *CustomRecipientWriteScope* parameter.
- **Exclusive configuration scopes** Use the *ExclusiveConfigWriteScope* parameter instead of the *CustomConfigWriteScope* parameter.

When you perform this procedure, the role assignees assigned the role can perform actions against the objects included in the exclusive scope. For more information about exclusive scopes, see Understanding exclusive scopes.

You can't create a role assignment with both exclusive and regular scopes.

This example assigns the Mail Recipients role to the Protected User Admins USG and applies the Protected Users exclusive scope.

```
New-ManagementRoleAssignment -Name "Mail
Recipients_Protected User Admins" -SecurityGroup "Protected
User Admins" -Role "Mail Recipients" -
ExclusiveRecipientWriteScope "Protected Users"
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Change a role assignment

Permissions > Advanced permissions > Management role assignments >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

Management role assignments assign a management role to a role assignee. By changing the role assignment, you can control what objects role assignees assigned a role can change. Management role scopes applied to role assignments override the role's implicit write scope. However, the role's implicit read scope still applies. Scopes that you apply can't return objects outside of the role's implicit read scope.

For more information about management role scopes and assignments in Microsoft Exchange

Server 2013, see the following topics:

- Understanding management role assignments
- Understanding management role scopes

Looking for other management tasks related to role assignments? Check out Advanced permissions.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Role assignments" entry in the Role management permissions topic.
- You must use the Shell to perform these procedures.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to enable or disable a role assignment

Role assignments are enabled by default, meaning that the associated role is applied to the role assignee to which the role is assigned. If a role assignment is disabled, the associated role isn't applied to the role assignee.

To enable a role assignment, use the following syntax.

```
Set-ManagementRoleAssignment <role assignment> -Enabled
$true
```

To disable a role assignment, use the following syntax.

```
Set-ManagementRoleAssignment <role assignment> -Enabled
$false
```

This example disables the Help Desk Assignment role assignment.

```
Set-ManagementRoleAssignment "Help Desk Assignment" -
Enabled $false
```

For detailed syntax and parameter information, see Set-ManagementRoleAssignment.

Use the Shell to change a management role or role assignee on a role assignment

You can't change the management role or role assignee specified on a role assignment. If you want a role assignment to be associated with another role or role assignee, you must create a new role assignment, and then delete the old role assignment. For more information about how to add and remove role assignments, see the following topics:

- Add a role to a user or USG
- Remove a role from a user or USG

If you've created assignments directly to a user or universal security group (USG), we recommend that you consider using management role groups and management role assignment policies. Role groups and assignment policies enable you to simplify your permissions model and reduce the number of role assignments you need to manage. For more information, see Understanding Role Based Access Control.

Use the Shell to change a predefined relative scope on a role assignment

You can change or add a predefined relative scope on a role assignment. If you add or change a predefined scope, any previously specified recipient scopes are removed from the role assignment. For a list of predefined scopes and their descriptions, see Understanding management role scopes.

To change or add a predefined scope on a role assignment, use the following syntax.

```
Set-ManagementRoleAssignment <assignment name> -
RecipientRelativeWriteScope < MyDistributionGroups |
Organization | Self >
```

This example changes the predefined scope on the John's Assignment role assignment to MyDistributionGroups.

```
Set-ManagementRoleAssignment "John's Assignment" -
RecipientRelativeWriteScope MyDistributionGroups
```

For detailed syntax and parameter information, see Set-ManagementRoleAssignment.

Use the Shell to change a recipient filter scope on a role assignment

You can either specify a new recipient filter-based scope or change the recipient filter-based scope that's already applied to the role assignment. If you add a recipient filter scope, any previously defined recipient scopes are removed from the role assignment.

To specify a new recipient filter-based scope or replace an existing one, use the following syntax.

```
Set-ManagementRoleAssignment <assignment name> -
CustomRecipientWriteScope <role scope name>
```

This example adds or changes the recipient filter-based scope to Redmond Recipients.

```
Set-ManagementRoleAssignment "Redmond Recipient
Administrators Assignment" -CustomRecipientWriteScope
"Redmond Recipients"
```

If you want to keep the same recipient filter-based scope that's applied to the role assignment but change the recipient filter used to match recipient objects, you need to change the recipient filter on the scope itself. For more information about how to change scopes, see Change a role scope.

For detailed syntax and parameter information, see Set-ManagementRoleAssignment.

Use the Shell to change the server filter or list-based configuration scope on a role assignment

You can either specify a new server filter or list-based configuration scope, or change the scope that's already applied to the role assignment. If you add or change the configuration scope, any previously specified configuration scopes are removed from the role assignment.

To specify a new configuration scope or replace an existing one, use the following syntax.

```
Set-ManagementRoleAssignment <assignment name> -
CustomConfigWriteScope <role scope name>
```

This example adds or changes the configuration scope to Redmond Servers.

```
Set-ManagementRoleAssignment "Redmond Administrators
Assignment" -CustomConfigWriteScope "Redmond Servers"
```

If you want to keep the same configuration scope that's applied to the role assignment but change the server filter or server list on the scope, you need to change the configuration scope itself. For more information about how to change scopes, see Change a role scope.

For detailed syntax and parameter information, see Set-ManagementRoleAssignment.

Use the Shell to change the database filter or list-based configuration scope on a role assignment

You can either specify a new database filter or list-based configuration scope, or change the scope that's already applied to the role assignment. If you add or change the configuration scope, any previously specified configuration scopes are removed from the role assignment.

To specify a new configuration scope or replace an existing one, use the following syntax.

```
Set-ManagementRoleAssignment <assignment name> -
CustomConfigWriteScope <role scope name>
```

This example adds or changes the configuration scope to Redmond Databases.

```
Set-ManagementRoleAssignment "Redmond Database Admins" -
CustomConfigWriteScope "Redmond Databases"
```

If you want to keep the same configuration scope that's applied to the role assignment but change the database filter or database list on the scope, you need to change the configuration scope itself. For more information about how to change scopes, see Change a role scope.

For detailed syntax and parameter information, see Set-ManagementRoleAssignment.

Use the Shell to change the organizational unit on a role assignment

You can either add a new OU or change an OU that's already applied to the role assignment. If you specify a new OU, any previously specified recipient scopes are removed from the role assignment.

To change or add a new OU on a role assignment, use the following syntax.

```
Set-ManagementRoleAssignment <assignment name> -
RecipientOrganizationalUnitScope <OU>
```

This example adds the Engineering\Users OU in the contoso.com domain to the Engineering Help Desk role assignment.

```
Set-ManagementRoleAssignment "Engineering Help Desk" -
RecipientOrganizationalUnitScope contoso.com/Engineering/
Users
```

For detailed syntax and parameter information, see Set-ManagementRoleAssignment.

Use the Shell to change an exclusive recipient or configuration scope

To change exclusive recipient or exclusive configuration scopes, you can use the procedures provided in the "Use the Shell to change a recipient filter scope on a role assignment," "Use the Shell to change the server filter or list-based configuration scope on a role assignment," and "Use the Shell to change the database filter or list-based configuration scope on a role assignment" sections earlier in this topic. The only difference is that when you change an exclusive scope, you must specify the following exclusive parameters depending on whether you're changing an exclusive recipient scope or an exclusive configuration scope:

- **Exclusive recipient scopes** Use the *ExclusiveRecipientWriteScope* parameter instead of the *CustomRecipientWriteScope* parameter.
- **Exclusive server and database configuration scopes** Use the *ExclusiveConfigWriteScope* parameter instead of the *CustomConfigWriteScope* parameter.

As with regular recipient and configuration scopes, if you add or change an exclusive scope, any previously defined recipient or configuration scopes are replaced.

This example changes an exclusive recipient write scope.

```
Set-ManagementRoleAssignment "Exclusive Executive Users" -
ExclusiveRecipientWriteScope "Exclusive Executives"
```

For detailed syntax and parameter information, see Set-ManagementRoleAssignment.

View role assignments

Permissions > Advanced permissions > Management role assignments >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

Management role assignments assign a management role to a role assignee. For more information about management role assignments in Microsoft Exchange Server 2013, see Understanding management role assignments.

Looking for other management tasks related to roles? Check out Advanced permissions.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To

see what permissions you need, see the "Role assignments" entry in the Role management permissions topic.

- You must use the Shell to perform these procedures.
- This topic makes use of pipelining and the **Format-List** cmdlet. For more information about these concepts, see the following topics:
  - Pipelining
  - Working with command output
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

View a list of all role assignments

You can view a list of all role assignments configured in your organization by running the **Get-ManagementRoleAssignment** cmdlet. If you want to retrieve a list of role assignments that match a partial string that you specify, use wildcard characters (*). This example retrieves a list of all the role assignments that start with the string "Tier 1".

```
Get-ManagementRoleAssignment "Tier 1*"
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View the details of a specific role assignment

You can view the details of a role assignment by piping the results of the **Get-ManagementRoleAssignment** cmdlet to the **Format-List** cmdlet. Use the following syntax.

```
Get-ManagementRoleAssignment <assignment name> | Format-List
```

This example retrieves the details of the Help Desk Assignment role assignment.

```
Get-ManagementRoleAssignment "Help Desk Assignment" | Format-List
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View the list of role assignments assigned to a specific role

assignee

To view a list of role assignments associated with a management role group, role, or role assignment policy, or associated with a user or universal security group (USG), use the following syntax.

```
Get-ManagementRoleAssignment -RoleAssignee <role assignee name>
```

This example retrieves all of the role assignments associated with the Server Management role group.

```
Get-ManagementRoleAssignment -RoleAssignee "Server Management"
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View the role assignments associated with a specific role

Each role can have multiple role assignments. You can use the **Get-ManagementRoleAssigment** cmdlet to view a list of role assignments associated with a specified role.

To view a list of role assignments associated with a specified role, use the following syntax.

```
Get-ManagementRoleAssignment -Role <role name>
```

This example retrieves all of the role assignments associated with the Mail Recipients role.

```
Get-ManagementRoleAssignment -Role "Mail Recipients"
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View a list of role assignments that use a specific predefined scope

To view a list of role assignments that use a specific predefined scope, use the following syntax.

```
Get-ManagementRoleAssignment -RecipientWriteScope < MyGAL | MyDistributionGroups | Organization | Self | CustomRecipientScope | ExecutiveRecipientScope >
```

This example retrieves all of the role assignments that use the Organization predefined scope.

```
Get-ManagementRoleAssignment -RecipientWriteScope
Organization
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View a list of role assignments that have been scoped to a specific OU

To view a list of role assignments that have been scoped to a specific organizational unit (OU), use the following syntax.

```
Get-ManagementRoleAssignment -
RecipientOrganizationalUnitScope <OU>
```

This example retrieves all of the role assignments that have been scoped to the North America \Engineering\Users OU in the contoso.com domain.

```
Get-ManagementRoleAssignment -
RecipientOrganizationalUnitScope "contoso.com/North
America/Engineering/Users"
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View a list of assignments that use a specific custom scope

To view a list of role assignments that use a specific custom scope, you need to first determine whether the scope is a recipient scope, configuration scope, exclusive recipient scope, or exclusive configuration scope. Each type of scope uses a different parameter on the **Get-ManagementRoleAssignment** cmdlet. The following lists each scope and its associated parameter:

- **Recipient scopes** *CustomRecipientWriteScope*
- **Configuration scopes** *CustomConfigWriteScope*
- **Exclusive recipient scopes** *ExclusiveRecipientWriteScope*
- **Exclusive configuration scopes** *ExclusiveConfigWriteScope*

The syntax for each parameter is the same. Specify the name of the scope with the parameter that matches the type of scope it is.

This example retrieves all of the role assignments that use the Vancouver Recipients recipient scope.

```
Get-ManagementRoleAssignment -CustomRecipientWriteScope
"Vancouver Recipients"
```

This example retrieves all of the role assignments that use the Seattle AD Site exclusive configuration scope.

```
Get-ManagementRoleAssignment -ExclusiveConfigWriteScope
"Seattle AD Site"
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View a list of exclusive or regular scopes

To view a list of exclusive or regular role assignments, use the following syntax.

```
Get-ManagementRoleAssignment -Exclusive < $True | $False >
```

For example, to view a list of exclusive scopes, run the following command:

```
Get-ManagementRoleAssignment -Exclusive $True
```

This example retrieves a list of regular scopes without any exclusive scopes.

```
Get-ManagementRoleAssignment -Exclusive $False
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View who can modify a specific recipient or server

To view a list of role assignments that can modify a specific recipient or server, use the *WritableRecipient* and *WritableServer* parameters. Specify the name of the recipient with the *WritableRecipient* parameter, and the name of the server with the *WritableServer* parameter.

This example retrieves a list of role assignments that can modify the recipient Brian.

```
Get-ManagementRoleAssignment -WritableRecipient "Brian"
```

You can combine the *WritableRecipient* and *WritableServer* parameters with other parameters, such as the *RoleAssignee* parameter and the *GetEffectiveUsers* switch to refine your query and expand any role groups or USGs. This example retrieves all of the users who can modify the server EX02 and who are assigned the Server Management role group.

```
Get-ManagementRoleAssignment -WritableServer EX02 -
RoleAssignee "Server Management" -GetEffectiveUsers
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View the users who receive permissions from an assignment via a role group or USG

To view a list of users that receive permissions from a role assignment, use the following syntax.

```
Get-ManagementRoleAssignment <assignment name> -
GetEffectiveUsers
```

This example retrieves a list of users in the Help Desk Assignment role assignment.

```
Get-ManagementRoleAssignment "Help Desk Assignment" -
GetEffectiveUsers
```

You can also combine the *GetEffectiveUsers* switch with several other parameters on the **Get-ManagementRoleAssignment** cmdlet to expand the role groups and USGs that the role assignments are assigned to. For an example of how the *GetEffectiveUsers* switch is used with other parameters, see "View who can modify a specific recipient or server" earlier in this topic.

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View a list of role assignments that are enabled or disabled

To view a list of role assignments that are enabled or disabled, use the following syntax.

```
Get-ManagementRoleAssignment -Enabled < $True | $False >
```

This example retrieves a list of role assignments that are disabled.

```
Get-ManagementRoleAssignment -Enabled $False
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

Remove a role from a user or USG

Permissions > Advanced permissions > Management role assignments >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-02*

Management role assignments assign a management role to a user or universal security group (USG). If you remove a role assignment, the users assigned the role will no longer have access to the

cmdlets available on that role. For more information about management role assignments in Microsoft Exchange Server 2013, see Understanding management role assignments.

Looking for other management tasks related to roles? Check out Advanced permissions.

What do you need to know before you begin?

- Estimated time to complete this procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Role assignments" entry in the Role management permissions topic.
- You must use the Shell to perform these procedures.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Remove a management role assignment

If you know the name of the role assignment you want to remove, use the following syntax.

```
Remove-ManagementRoleAssignment <assignment name>
```

For example, to remove the "Tier 2 Help Desk Assignment" role assignment, use the following command.

```
Remove-ManagementRoleAssignment "Tier 2 Help Desk Assignment"
```

If you don't know the name of the role assignment, you can use the following syntax.

```
Get-ManagementRoleAssignment -RoleAssignee <user or USG> -Role <role name> -Delegating <$true | $false> | Remove-ManagementRoleAssignment
```

For example, if you want to remove the Mail Recipients regular role assignment from the user davids, use the following command.

```
Get-ManagementRoleAssignment -RoleAssignee davids -Role "Mail Recipients" -Delegating $false | Remove-ManagementRoleAssignment
```

Delegate role assignments

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-02*

Management role delegation enables role assignees to assign a specified management role to other management role groups, management role assignment policies, users, or universal security groups (USG). By default, only members of the Organization Management management role group can delegate role assignments. When a new installation of Microsoft Exchange Server 2013 is deployed, only the user account that installed Exchange 2013 is a member of the Organization Management role group.

If you assign a delegating role assignment to a role group, any member of the role group can delegate the associated management role to other role assignees.

Important:

Delegating role assignments doesn't give the role assignee the permissions granted by the role, only the ability to assign the role to others. If you want to also give the permissions granted by the role to the role assignee, you must also create a regular role assignment. To create a regular role assignment, see the following topics:
Manage role groups
Manage role assignment policies
Add a role to a user or USG

Note:

This topic discusses management role assignment delegation. If you want to delegate who can add members to or remove members from role groups, which is the recommended method of delegation, see Manage role groups.

For more information about regular role assignments and delegating management role assignments, see Understanding management role assignments.

Looking for other management tasks related to managing permissions? Check out Advanced permissions.

What do you need to know before you begin?

- Estimated time to complete this procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Role assignments" entry in the Role management permissions topic.
- You must use the Shell to perform these procedures.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see

Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to delegate a management role

You can create delegating role assignments using the same predefined scopes, recipient filter or server-filter-based scopes, server list-based scopes, and organizational unit (OU) scopes that can be used to create regular or exclusive scopes. The only difference between creating a regular role assignment and a delegating role assignment is the addition of the *Delegating* switch to the command. For more information about how to create role assignments, see the following topics:

- Manage role groups
- Add a role to a user or USG

Note:
You can't create a delegating role assignment to a management role assignment policy.

This example creates a delegating role assignment to enable members of the Senior Admins role group to assign the Mail Recipients role to any role assignee in the Exchange organization.

```
New-ManagementRoleAssignment -Role "Mail Recipients" -
SecurityGroup "Senior Admins" -Name "Mail Recipients_Senior
Admin - Delegate" -Delegating
```

This example creates a delegating role assignment to enable members of the Senior Admins role group to assign the Mail Recipients role only to users in the Sales/Users OU in the contoso.com domain.

```
New-ManagementRoleAssignment -Role "Mail Recipients" -
SecurityGroup "Senior Admins" -Name "Mail Recipients_Senior
Admins - Delegate" -RecipientOrganizationalUnitScope
contoso.com/sales/users -Delegating
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Managing split permissions

Exchange Server 2013 > Permissions > Advanced permissions >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-13*

The following procedures enable you to perform advanced permissions management. You should only use these procedures if management role groups and management role assignment policies don't meet the needs of your organization.

Configure Exchange 2013 for split permissions

Configure Exchange 2013 for shared permissions

For more information about managing role groups and role assignment policies, see the following topics:

Manage role groups

Manage linked role groups

Manage role assignment policies

Configure Exchange 2013 for split permissions

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-17*

Split permissions enable two separate groups, such as Active Directory administrators and Microsoft Exchange Server 2013 administrators, to manage their respective services, objects, and attributes. Active Directory administrators manage security principals, such as users, that provide permissions to access an Active Directory forest. Exchange administrators manage the Exchange-related attributes on Active Directory objects and Exchange-specific object creation and management.

Microsoft Exchange Server 2013 offers the following types of split permissions models:

- **RBAC split permissions** Permissions to create security principals in the Active Directory domain partition are controlled by Role Based Access Control (RBAC). Only those who are members of the appropriate role groups can create security principals.
- **Active Directory split permissions** Permissions to create security principals in the Active Directory domain partition are completely removed from any Exchange user, service, or server. No option is provided in RBAC to create security principals. Creation of security principals in Active Directory must be performed using Active Directory management tools.

Note:
Active Directory split permissions are available in organizations running Microsoft Exchange

Server 2010 Service Pack 1 (SP1) or later, Exchange 2013, or both versions of Exchange.

The model that you choose depends on the structure and needs of your organization. Choose the procedure that follows that's applicable to the model you want to configure. We recommend that you use the RBAC split permissions model. The RBAC split permissions model provides significantly more flexibility while providing the same administration separation as Active Directory split permissions.

For more information about shared and split permissions, see Understanding split permissions.

For more information about management role groups, management roles, and regular and delegating management role assignments, see the following topics:

- Understanding Role Based Access Control
- Understanding management role groups
- Understanding management roles
- Understanding management role assignments

Looking for other management tasks related to permissions? Check out Advanced permissions.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Active Directory split permissions" entry in the Role management permissions topic.
- You must use Windows PowerShell, Windows Command Shell, or both, to perform these procedures. For more information, see each procedure.
- If you have Exchange 2010 servers in your organization, the permissions model you select will also be applied to those servers.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Switch to RBAC split permissions

You can configure your Exchange 2013 organization for RBAC split permissions. When you are done, only Active Directory administrators will be able to create Active Directory security principals. This means that Exchange administrators won't be able to use the following cmdlets:

- **New-Mailbox**
- **New-MailContact**

- **New-MailUser**
- **New-RemoteMailbox**
- **Remove-Mailbox**
- **Remove-MailContact**
- **Remove-MailUser**
- **Remove-RemoteMailbox**

Exchange administrators will only be able to manage the Exchange attributes on existing Active Directory security principals. However, They will be able to create and manage Exchange-specific objects, such as transport rules and distribution groups. For more information, see the "RBAC Split Permissions" section in Understanding split permissions.

To configure Exchange 2013 for split permissions, you must assign the Mail Recipient Creation role and the Security Group Creation and Membership role to a role group that contains members that are Active Directory administrators. You must then remove the assignments between those roles and any role group or universal security group (USG) that contains Exchange administrators.

To configure RBAC split permissions, do the following:

1. If your organization is currently configured for Active Directory split permissions, do the following from a Windows command shell prompt.
   a. Disable Active Directory split permissions by running the following command from the Exchange 2013 installation media.

```
setup.exe /PrepareAD /ActiveDirectorySplitPermissions:false
```

   b. Restart the Exchange 2013 servers in your organization or wait for the Active Directory access token to replicate to all of your Exchange 2013 servers.

Note:
If you have Exchange 2010 servers in your organization, you also need to restart those servers.

2. Do the following from the Exchange Management Shell:
   a. Create a role group for the Active Directory administrators. In addition to creating the role group, the command creates regular role assignments between the new role group and the Mail Recipient Creation role and the Security Group Creation and Membership role.

```
New-RoleGroup "Active Directory Administrators" -Roles
"Mail Recipient Creation", "Security Group Creation and
Membership"
```

Note:
If you want members of this role group to be able to create role assignments, include the Role Management role. You don't have to add this role now. However, if you ever want to assign either the Mail Recipient Creation role or Security Group Creation and Membership role to other role assignees, the Role Management role must be assigned to this new role group. The steps that follow configure the Active Directory Administrators role group as the only role group that can delegate these roles.

b. Create delegating role assignments between the new role group and the Mail Recipient Creation role and Security Group Creation and Membership role using the following commands.

```
New-ManagementRoleAssignment -Role "Mail Recipient
Creation" -SecurityGroup "Active Directory Administrators"
-Delegating
New-ManagementRoleAssignment -Role "Security Group Creation
and Membership" -SecurityGroup "Active Directory
Administrators" -Delegating
```

c. Add members to the new role group using the following command.

```
Add-RoleGroupMember "Active Directory Administrators" -
Member <user to add>
```

d. Replace the delegate list on the new role group so that only members of the role group can add or remove members.

```
Set-RoleGroup "Active Directory Administrators" -ManagedBy
"Active Directory Administrators"
```

Important:

Members of the Organization Management role group, or those who are assigned the Role Management role, either directly or through another role group or USG, can bypass this delegate security check. If you want to prevent any Exchange administrator from adding himself or herself to the new role group, you must remove the role assignment between the Role Management role and any Exchange administrator and assign it to another role group.

e. Find all of the regular and delegating role assignments to the Mail Recipient Creation role using the following command. The command displays only the **Name**, **Role**, and **RoleAssigneeName** properties.

```
Get-ManagementRoleAssignment -Role "Mail Recipient
Creation" | Format-Table Name, Role, RoleAssigneeName -Auto
```

f. Remove all of the regular and delegating role assignments to the Mail Recipient Creation role that aren't associated with the new role group or any other role groups, USGs, or direct assignments you want to keep using the following command.

```
Remove-ManagementRoleAssignment <Mail Recipient Creation
role assignment to remove>
```

Note:

If you want to remove all of the regular and delegating role assignments to the Mail Recipient Creation role on any role assignee other than the Active Directory Administrators role group,

use the following command. The *WhatIf* switch lets you see what role assignments will be removed. Remove the *WhatIf* switch and run the command again to remove the role assignments.

```
Get-ManagementRoleAssignment -Role "Mail Recipient
Creation" | Where { $_.RoleAssigneeName -NE "Active
Directory Administrators" } | Remove-
ManagementRoleAssignment -WhatIf
```

g. Find all of the regular and delegating role assignments to the Security Group Creation and Membership role using the following command. The command displays only the **Name**, **Role**, and **RoleAssigneeName** properties.

```
Get-ManagementRoleAssignment -Role "Security Group Creation
and Membership" | Format-Table Name, Role, RoleAssigneeName
-Auto
```

h. Remove all of the regular and delegating role assignments to the Security Group Creation and Membership role that aren't associated with the new role group or any other role groups, USGs, or direct assignments you want to keep using the following command.

```
Remove-ManagementRoleAssignment <Security Group Creation
and Membership role assignment to remove>
```

Note:

You can use the same command in the preceding Note to remove all of the regular and delegating role assignments to the Security Group Creation and Membership role on any role assignee other than the Active Directory Administrators role group, as shown in this example.

```
Get-ManagementRoleAssignment -Role "Security Group Creation
and Membership" | Where { $_.RoleAssigneeName -NE "Active
Directory Administrators" } | Remove-
ManagementRoleAssignment -WhatIf
```

For detailed syntax and parameter information, see the following topics:

- New-RoleGroup
- New-ManagementRoleAssignment
- Add-RoleGroupMember
- Set-RoleGroup
- Get-ManagementRoleAssignment
- Remove-ManagementRoleAssignment

Switch to Active Directory split permissions

You can configure your Exchange 2013 organization for Active Directory split permissions. Active Directory split permissions completely remove the permissions that allow Exchange administrators and servers from creating security principals in Active Directory or modifying non-Exchange attributes on those objects. When you are done, only Active Directory administrators will be able to create Active Directory security principals. This means that Exchange administrators won't be able to use the following cmdlets:

- **Add-DistributionGroupMember**
- **New-DistributionGroup**
- **New-Mailbox**
- **New-MailContact**
- **New-MailUser**
- **New-RemoteMailbox**
- **Remove-DistributionGroup**
- **Remove-DistributionGroupMember**
- **Remove-Mailbox**
- **Remove-MailContact**
- **Remove-MailUser**
- **Remove-RemoteMailbox**
- **Update-DistributionGroupMember**

Exchange administrators and servers will only be able to manage the Exchange attributes on existing Active Directory security principals. However, they will be able to create and manage Exchange-specific objects, such as transport rules and Unified Messaging dial plans.

Caution:

After you enable Active Directory split permissions, Exchange administrators and servers will no longer be able to create security principals in Active Directory, and they won't be able to manage distribution group membership. These tasks must be performed using Active Directory management tools with the required Active Directory permissions. Before you make this change, you should understand the impact it will have on your administration processes and third-party applications that integrate with Exchange 2013 and the RBAC permissions model.
For more information, see the "Active Directory split permissions" section in Understanding split permissions.

To switch from shared or RBAC split permissions to Active Directory split permissions, do the following:

1. From a Windows command shell, run the following command from the Exchange 2013 installation media to enable Active Directory split permissions.

```
setup.exe /PrepareAD /ActiveDirectorySplitPermissions:true
```

2. If you have multiple Active Directory domains in your organization, you must either run `setup.exe /PrepareDomain` in each child domain that contains Exchange servers or objects or run `setup.exe /PrepareAllDomains` from a site that has an Active Directory server from every domain.
3. Restart the Exchange 2013 servers in your organization or wait for the Active Directory access

token to replicate to all of you Exchange 2013 servers.

Note:
If you have Exchange 2010 servers in your organization, you also need to restart those servers.

Configure Exchange 2013 for shared permissions

Permissions > Advanced permissions > Managing split permissions >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

Shared permissions enable you, as an administrator of Microsoft Exchange Server 2013, to create Active Directory security principals, such as users, and then configure them as Exchange recipients. Unlike split permissions, which separate management tasks between groups of Exchange administrators and Active Directory administrators, there's no separation of tasks with shared permissions.

For more information about shared and split permissions, see Understanding split permissions.

You can configure your Exchange 2013 organization for shared permissions if you've previously set your organization for split permissions. The procedure to switch to shared permissions is different depending on whether you're currently using Role Based Access Control (RBAC) split permissions or Active Directory split permissions. Choose the procedure that follows that's applicable to your current configuration. If the following are true, your organization is using Active Directory split permissions:

- The Microsoft Exchange Protected Groups organizational unit (OU) exists.
- The Exchange Windows Permissions security group is located in the Microsoft Exchange Protected Groups OU.
- The Exchange Trusted Subsystem security group is a member of the Exchange Windows Permissions security group.
- There are no regular management role assignments to the Mail Recipient Creation role or Security Group Creation and Membership role.

If you've never configured your organization for split permissions, you don't need to perform this procedure. Exchange 2013 is configured for shared permissions by default.

For more information about management role groups, management roles, and regular and delegating management role assignments, see the following topics:

- Understanding Role Based Access Control
- Understanding management role groups
- Understanding management roles

- Understanding management role assignments

Looking for other management tasks related to permissions? Check out Advanced permissions.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- Procedures in this topic require specific permissions. See each procedure for its permissions information.
- You must use Windows PowerShell, the Windows Command Shell, or both, to perform these procedures. For more information, see each procedure.
- The Exchange 2013 organization must currently be configured for RBAC or Active Directory split permissions.
- If you have Microsoft Exchange Server 2010 servers in your organization, the permissions model you select will also be applied to those servers.
- You must have permissions to delegate the Mail Recipient Creation management role and the Security Group Creation and Membership management role to the Organization Management management role group or another role group that's assigned the Mail Recipients role.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Switch from RBAC split permissions to shared permissions

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Role groups" entry in the Role management permissions topic.

To switch from RBAC split permissions to Exchange 2013 shared permissions, you must assign the Mail Recipient Creation role and the Security Group Creation and Membership role to a role group that's also assigned the Mail Recipients role and has Exchange 2013 administrators as members. In the default shared permissions configuration, the Organization Management role group contains each of these roles. Because of this, the Organization Management role group is in this procedure.

Configure shared permissions

To configure shared permissions on the Organization Management role group, do the following using an account that has permissions to delegate role assignments for the Mail Recipient Creation role and the Security Group Creation and Membership role:

1. Add delegating role assignments for the Mail Recipient Creation role and Security Group Creation and Membership role to the Organization Management role group using the following

commands.

```
New-ManagementRoleAssignment -Role "Mail Recipient
Creation" -SecurityGroup "Organization Management" -
Delegating
New-ManagementRoleAssignment -Role "Security Group Creation
and Membership" -SecurityGroup "Organization Management" -
Delegating
```

Note:

The role group (in this procedure, the Active Directory Administrators role group) that has delegating role assignments for the Mail Recipient Creation role and Security Group Creation and Membership role must be assigned the Role Management role to run the **New-ManagementRoleAssignment** cmdlet. The role assignee that can delegate the Role Management role must assign that role to the Active Directory Administrators role group.

2. Add regular role assignments for the Mail Recipient Creation role to the Organization Management and Recipient Management role groups using the following commands.

```
New-ManagementRoleAssignment -Role "Mail Recipient
Creation" -SecurityGroup "Organization Management"
New-ManagementRoleAssignment -Role "Security Group Creation
and Membership" -SecurityGroup "Recipient Management"
```

3. Add a regular role assignment for the Security Group Creation and Membership role to the Organization Management role group using the following command.

```
New-ManagementRoleAssignment -Role "Security Group Creation
and Membership" -SecurityGroup "Organization Management"
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Remove permissions from Active Directory administrators (Optional)

You can optionally remove the permissions granted to Active Directory administrators if you no longer want them to be able to create or manage Active Directory objects using the Exchange management tools. If you want to remove permissions from Active Directory administrators, perform this procedure.

Note:

Although you can remove permissions for Active Directory administrators to manage Active Directory objects using the Exchange management tools, Active Directory administrators can continue to manage Active Directory objects using Active Directory management tools, if their Active Directory permissions allow it. They won't, however, be able to manage Exchange-specific attributes on Active Directory objects. For more information, see Understanding split permissions.

To remove Exchange-related split permissions from Active Directory administrators, do the following:

1. Remove the regular and delegating role assignments that assign the Mail Recipient Creation role to the role group or universal security group (USG) that contains the Active Directory administrators as members using the following command. This command uses the Active Directory Administrators role group as an example. The *WhatIf* switch lets you see what role assignments will be removed. Remove the *WhatIf* switch, and run the command again to remove the role assignments.

```
Get-ManagementRoleAssignment -Role "Mail Recipient
Creation" | Where { $_.RoleAssigneeName -EQ "Active
Directory Administrators" } | Remove-
ManagementRoleAssignment -WhatIf
```

2. Remove the regular and delegating role assignments that assign the Security Group Creation and Membership role to the role group or USG that contains the Active Directory administrators as members using the following command. This command uses the Active Directory Administrators role group as an example. The *WhatIf* switch lets you see what role assignments will be removed. Remove the *WhatIf* switch, and run the command again to remove the role assignments.

```
Get-ManagementRoleAssignment -Role "Security Group Creation
and Membership" | Where { $_.RoleAssigneeName -EQ "Active
Directory Administrators" } | Remove-
ManagementRoleAssignment -WhatIf
```

3. Optional. If you want to remove all Exchange permissions from the Active Directory administrators, you can remove the role group or USG in which they're members. For more information about how to remove a role group, see Manage role groups.

For detailed syntax and parameter information, see Get-ManagementRoleAssignment or Remove-ManagementRoleAssignment.

Switch from Active Directory split permissions to shared permissions

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Active Directory split permissions" entry in the Role management permissions topic.

To switch from Active Directory split permissions to Exchange 2013 shared permissions, you must rerun Exchange Setup to disable Active Directory split permissions in the Exchange organization, and then create role assignments between a role group and the Mail Recipient Creation role and Security Group Creation and Membership role. In the default shared permissions configuration, the

Organization Management role group contains each of these roles. Because of this, the Organization Management role group is in this procedure.

Important:

The setup.com command in this procedure makes changes to Active Directory. You must use an account that has the permissions required to make these changes. This account might not be the same account that has permissions to create role assignments using the **New-ManagementRoleAssignment** cmdlet. Use the account, or accounts, with the permissions necessary to successfully complete each step in this procedure.

To switch from Active Directory split permissions to shared permissions, do the following:

1. From a Windows command shell, run the following command from the Exchange 2013 installation media to disable Active Directory split permissions.

```
setup.exe /PrepareAD /ActiveDirectorySplitPermissions:false
```

2. From the Exchange Management Shell, run the following commands to add regular role assignments between the Mail Recipient Creation role and Security Group Creation and Management role and the Organization Management and Recipient Management role groups.

```
New-ManagementRoleAssignment "Mail Recipient
Creation_Organization Management" -Role "Mail Recipient
Creation" -SecurityGroup "Organization Management"
New-ManagementRoleAssignment "Security Group Creation and
Membership_Org Management" -Role "Security Group Creation
and Membership" -SecurityGroup "Organization Management"
New-ManagementRoleAssignment "Mail Recipient
Creation_Recipient Management" -Role "Mail Recipient
Creation" -SecurityGroup "Recipient Management"
```

3. Restart the Exchange 2013 servers in your organization.

Note:

If you have Exchange 2010 servers in your organization, you also need to restart those servers.

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Messaging policy and compliance

Exchange Server 2013 >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-22*

Email has become a reliable and ubiquitous communication medium for information workers in organizations of all sizes. Messaging stores and mailboxes have become repositories of valuable data. It's important for organizations to formulate messaging policies that dictate the fair use of their messaging systems, provide user guidelines for how to act on the policies, and where required, provide details about the types of communication that may not be allowed.

Organizations must also create policies to manage email lifecycle, retain messages for the length of time based on business, legal, and regulatory requirements, preserve email records for litigation and investigation purposes, and be prepared to search and provide the required email records to fulfill eDiscovery requests.

Leakage of sensitive information such as intellectual property, trade secrets, business plans, and personally identifiable information (PII) collected or handled by your organization must also be protected.

Messaging policy and compliance in Exchange 2013

The following table provides an overview of the messaging policy and compliance features in Microsoft Exchange Server 2013 and includes links to topics that will help you learn about and manage these features.

Feature	Description	Resources
Messaging records management (MRM)	To comply with applicable regulations or meet legal or business requirements, organizations include email lifecycle policies as part of their messaging policy. Common questions that should be addressed by these policies include: • How long should messages be retained? • Where should the messages be retained? • Should all messages be retained for the same period? Exchange 2013 includes MRM features that allow you to	Messaging records management

	implement your organization's email lifecycle policies. You can use MRM to apply uniform retention settings to all messages, use custom retention policies to apply a baseline retention setting for the mailbox, and optionally allow users to classify messages so that they can be retained for a specified duration.	
In-Place Archiving	*In-Place Archiving* helps you regain control of your organization's messaging data by eliminating the need for personal store (.pst) files and allowing users to store messages in an *archive mailbox* accessible in Outlook 2010 and later and Outlook Web App.	In-Place Archiving
In-Place Hold	When a reasonable expectation of litigation exists, organizations are required to preserve electronically stored information (ESI), including email that's relevant to the case. In-Place Hold allows you to search and preserve messages matching query parameters. Messages are protected from deletion, modification, and tampering and can be preserved indefinitely or for a specified period.	In-Place Hold

In-Place eDiscovery	In-Place eDiscovery allows you to search mailbox data across your Exchange organization, preview search results, and copy them to a Discovery mailbox.	In-Place eDiscovery
Journaling	Journaling can help your organization respond to legal, regulatory, and organizational compliance requirements by recording inbound and outbound email communications. When planning for messaging retention and compliance, it's important to understand journaling, how it fits in your organization's compliance policies, and how Exchange 2013 can help you secure journaled messages.	Journaling
Transport Rules	Using Transport rules, you can look for specific conditions for messages that pass through your organization and then take action on them. Transport rules let you apply messaging policies to email messages, secure messages, protect messaging systems, and prevent information leakage.	Transport rules
Data Loss Prevention (DLP)	DLP capabilities help you protect your sensitive data and inform users of your policies and regulations. DLP can also help	Data loss prevention

	you prevent users from mistakenly sending sensitive information to unauthorized people. When you configure DLP polices, you can identify and protect sensitive data by analyzing the content of your messaging system, which includes numerous associated file types. The DLP policy templates supplied in Exchange 2013 are based on regulatory standards such as PII and payment card industry data security standards (PCI-DSS). DLP is extensible, which allows you to include other policies that important to your organization. Additionally, the new Policy Tips capability allows you to inform users about policy violations before sensitive data is sent.	
Information Rights Management (IRM)	Information Rights Management (IRM) provides persistent online and offline protection for email messages and attachments using Active Directory Rights Management Services (AD RMS).	Information Rights Management
S/MIME	Secure/Multipurpose Internet Mail Extensions (S/MIME) allows people who have Office 365 mailboxes and Exchange 2013	S/MIME for message signing and encryption

	and Exchange Online to help protect sensitive information by sending signed and encrypted email within their organization. Administrators can enable S/MIME for Office 365 mailboxes by synchronizing user certificates between Office 365 and their on-premises server and then configuring Outlook Online to support S/MIME.	
Mailbox audit logging	Because mailboxes can potentially contain sensitive, high business impact (HBI) information and PII, it's important that you track who logs on to the mailboxes in your organization and what actions are taken. It's especially important to track access to mailboxes by users other than the mailbox owner (known as delegate users). Using mailbox audit logging, you can log mailbox access by mailbox owners, delegates (including administrators with full mailbox access permissions), and administrators.	Mailbox audit logging Exchange auditing reports
Administrator audit logging	Administrator audit logs enable you to keep a log of changes made by administrators to Exchange server and organization configuration and to Exchange	Administrator audit logging

	recipients. You might use administrator audit logging as part of your change control process or to track changes and access to configuration and recipients for compliance purposes.	

In-Place Archiving

Exchange Server 2013 > Messaging policy and compliance >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-03-25*

In-Place Archiving helps you regain control of your organization's messaging data by eliminating the need for personal store (.pst) files and allowing users to store messages in an *archive mailbox* accessible in Microsoft Outlook 2010 and later and Microsoft Office Outlook Web App.

In Microsoft Exchange Server 2013, In-Place Archiving provides users with an alternate storage location in which to store historical messaging data. An In-Place Archive is an additional mailbox (called an archive mailbox) enabled for a mailbox user. Outlook 2007 and later and Outlook Web App users have seamless access to their archive mailbox. Using either of these client applications, users can view an archive mailbox and move or copy messages between their primary mailbox and the archive. In-Place Archiving presents a consistent view of messaging data to users and eliminates the user overhead required to manage .pst files.

You can provision a user's archive on the same mailbox database as the user's primary mailbox, another mailbox database on the same Mailbox server, or a mailbox database on another Mailbox server in the same Active Directory site. This provides flexibility to use tiered storage architecture and to store archive mailboxes on a different storage subsystem, such as near-line storage. In cross-premises Exchange 2010 and later deployments, you can also provision a cloud-based archive for mailboxes located on your on-premises Mailbox servers.

In-Place Archives and other Exchange features

Managing archive mailboxes

Messaging data and .pst files

Outlook uses .pst files to store data locally on users' computers or network shares. Unlike offline store (.ost) files (which are used by Outlook in Cached Exchange Mode to store a copy of the mailbox for offline access), .pst files aren't synchronized with the user's Exchange mailbox. If a user moves messages to a .pst file, those messages are removed from the mailbox.

Using .pst files to manage messaging data can result in the following issues:

- **Unmanaged files** Generally, .pst files are created by users and reside on their computers or network shares. They aren't managed by your organization. As a result, users can create several .pst files containing the same or different messages and store them in different locations, with no organizational control.
- **Increased discovery costs** Lawsuits and some business or regulatory requirements sometimes result in discovery requests. Locating messaging data that resides in .pst files on users' computers can be a costly manual effort. Because tracking unmanaged .pst files can be difficult, .pst data may be undiscoverable in many cases. This could possibly expose your organization to legal and financial risks.
- **Inability to apply messaging retention policies** Messaging retention policies can't be applied to messages located in .pst files. As a result, depending on business or applicable regulations, your organization may not be in compliance.
- **Risk of data theft** Messaging data stored in .pst files is vulnerable to data theft. For example, .pst files are often stored in portable devices such as laptops, removable hard drives, and portable media such as USB drives, CDs, and DVDs.
- **Fragmented view of messaging data** Users who store information in .pst files don't get a uniform view of their data. Messages stored in .pst files are generally available only on the computer where the .pst file resides. As a result, if users access their mailboxes using Outlook Web App or Outlook on another computer, the messages stored in their .pst files are inaccessible.

Client access to archive mailboxes

The following table lists the client applications that can be used to access archive mailboxes.

Client	Access to archive mailbox
Outlook 2013, Outlook 2010, Outlook 2007, and Outlook Web App	Yes. Outlook 2013, Outlook 2010, Outlook 2007 and Outlook Web App users can copy or

	move items from their primary mailbox to their archive mailbox, and can also use retention policies to move items to the archive. **Note:** Outlook 2010 and later and Outlook 2007 users can also copy or move items from .pst files to their archive mailbox. Outlook 2007 users require the Office 2007 Cumulative Update for February 2011. Some differences in archive support exist between Outlook 2010 and later and Outlook 2007. For more information, see Exchange Team Blog article, see Yes Virginia, there is Exchange 2010 archive support in Outlook 2007.
Exchange ActiveSync	No

Note:
In-Place Archiving is a premium feature and requires an Exchange Enterprise client access license (CAL). For details about how to license Exchange, see Exchange Server Licensing. For details about the versions of Outlook required to access an archive mailbox, see License requirements for Personal Archive and retention policies.

Outlook doesn't create a local copy of the archive mailbox on a user's computer, even if it's configured to use Cached Exchange Mode. Users can access an archive mailbox in online mode only.

Delegate access

Delegate access is when a user or set of users is provided access to another user's mailbox. There are several scenarios for providing delegate access, including:

- Providing one or more users with access to the mailbox of a user who is no longer employed by the organization. In this case, users who may be given delegate access include the departed user's manager or supervisor or another user who will assume the departed user's responsibilities.
- Providing one or more users with access to a shared mailbox.
- Providing executive assistants with access to the mailboxes of the executives they're assisting.

In Exchange 2013, when you assign Full Access permissions to a mailbox, the delegate to which you assign the permissions can also access the user's archive. Delegates must use Outlook to access the mailbox, and they must connect to an Exchange 2010 SP1 or later Client Access server for Autodiscover purposes. Autodiscover is an Exchange service that provides configuration settings to automatically configure Outlook clients. When delegates use Outlook to access an Exchange 2013 mailbox, both the primary mailbox and the archive to which they have access are visible from

Outlook.

Moving messages to the archive mailbox

There are several ways to move messages to archive mailboxes:

- **Move or copy messages manually** Mailbox users can manually move or copy messages from their primary mailbox or a .pst file to their archive mailbox. The archive mailbox appears as another mailbox or .pst file in Outlook and Outlook Web App.
- **Move or copy messages using Inbox rules** Mailbox users can create Inbox rules in Outlook or Outlook Web App to automatically move messages to a folder in their archive mailbox. To learn more, see Learn About Inbox Rules.
- **Move messages using retention policies** You can use retention policies to automatically move messages to the archive. Users can also apply a personal tag to move messages to the archive. For details about archive and retention policies, see Archive and retention policies later in this topic.

Note:
Personal tags are available only in Outlook Web App and Outlook 2010 and later.

- **Import messages from .pst files** In Exchange 2013, you can use a mailbox import request to import messages from a .pst file to a user's archive or primary mailbox. For details, see Mailbox import and export requests. You can also use the PST Capture tool to search for .pst files on computers in your organization and import .pst file data to users' archives. Additionally, tools used to locate .pst files within an organization are also available from Microsoft partners. For a list of Microsoft partners for archiving, see "Archive and Compliance Partners" in Independent Software Vendors.

Archive and retention policies

In Exchange 2013, you can apply archive policies to a mailbox to automatically move messages from a user's primary mailbox to the archive mailbox after a specified period. Archive policies are implemented by creating retention tags that use the **Move to Archive** retention action.

Messages are moved to a folder in the archive mailbox that has the same name as the source folder in the primary mailbox. If a folder with the same name doesn't exist in the archive mailbox, it's created when the Managed Folder Assistant moves a message. Re-creating the same folder hierarchy in the archive mailbox allows users to find messages easily.

To learn more about retention policies, retention tags, and the **Move to Archive** retention action, see Retention tags and retention policies.

Default MRM policy

Exchange 2013 Setup creates a default archive and retention policy named **Default MRM Policy**.

This policy contains retention tags that have the **Move to Archive** action, as shown in the following table.

Note:
In Exchange 2010, the default archive and retention policy created by Exchange Setup is named **Default Archive and Retention Policy**.

Retention tag name	Tag type	Description
Default 2 year move to archive	Default (DPT)	Messages are automatically moved to the archive mailbox after two years. Applies to items in the entire mailbox that don't have a retention tag applied explicitly or inherited from the folder.
Personal 1 year move to archive	Personal	Messages are automatically moved to the archive mailbox after one year.
Personal 5 year move to archive	Personal	Messages are automatically moved to the archive mailbox after five years.
Personal never move to archive	Personal	Messages are never moved to the archive mailbox.
Recoverable Items 14 days move to archive	Recoverable Items Folder	Messages are moved from the Recoverable Items folder of the user's primary mailbox to the Recoverable Items folder of the archive mailbox. Users attempting to recover deleted items in the archive must use the Recover Deleted Items feature on the archive mailbox.

If you enable an In-Place Archive for a mailbox user and the mailbox doesn't already have a retention policy assigned, the default archive and retention policy is automatically assigned. After

the Managed Folder Assistant processes the mailbox, these tags become available to the user, who can then tag folders or messages to be moved to the archive mailbox. By default, email messages from the entire mailbox are moved after two years.

Before provisioning archive mailboxes for your users, we recommend that you inform them about the archive policies that will be applied to their mailbox and provide subsequent training or documentation to meet their needs. This should include details about the following:

- Functionality available within the archive, the default archive, and retention policies.
- Information about when messages may be moved automatically to the archive.
- Information about the folder hierarchy created in the archive mailbox.
- How to apply personal tags (displayed in the Archive policy menu in Outlook and Outlook Web App).

Note:

If you apply a retention policy to users who have an archive mailbox, the retention policy replaces the default MRM policy. You can create one or more retention tags with the **Move to Archive** action, and then link the tags to the retention policy. You can also add the default **Move to Archive** tags (which are created by Setup and linked to the Default MRM Policy) to any retention policies you create.

For information about compliance and archiving in Outlook 2010 and later, see Plan for compliance and archiving in Outlook 2010.

Archive quotas

Archive mailboxes are designed so that users can store historical messaging data outside their primary mailbox. Often, users use .pst files due to low mailbox storage quotas and the restrictions imposed when these quotas are exceeded. For example, users can be prevented from sending messages when their mailbox size exceeds the *Prohibit send quota*. Similarly, users can be prevented from sending and receiving messages when their mailbox size exceeds the *Prohibit send and receive quota*.

To eliminate the need for .pst files, you can provide an archive mailbox with storage limits that meet the user's requirements. However, you may still want to retain some control of the storage quotas and growth of archive mailboxes to help monitor costs and expansion.

To help with this control, you can configure archive mailboxes with an *archive warning quota* and an *archive quota*. When an archive mailbox exceeds the specified archive warning quota, a warning event is logged in the Application event log. When an archive mailbox exceeds the specified archive quota, messages are no longer moved to the archive, a warning event is logged in the Application event log, and a quota message is sent to the mailbox user. By default, in Exchange 2013, the archive warning quota is set to 45 gigabytes (GB) and the archive quota is set to 50 GB.

The following table lists the events logged and warning messages sent when the archive warning quota and archive quota are met.

Quota	Event ID	Type	Source	Category	Message

Archive warning quota	10022	Warning	MSExchangeMailboxAssistants	Managed Folder Assistant	The archive mailbox '<Display Name>:<GUID>:<Mailbox Database>:<Server FQDN>' exceeded the archive warning quota '<Archive warning quota>'. Archive mailbox size is '<Size>' bytes.
Archive quota	8537	Warning	MSExchangeIS	General	The archive mailbox for <Legacy DN> has exceeded the maximum archive mailbox size. You can't copy or move items into the archive mailbox. All message retention actions that move items to the archive

					mailbox will fail, and the primary mailbox may contain items with expired retention tags until the archive mailbox is within the maximum size limit. The mailbox owner should be notified about the condition of the archive mailbox.

In-Place Archives and other Exchange features

This section explains the functionality between In-Place Archives and various Exchange features:

- **Exchange Search** The ability to quickly search messages becomes even more critical with archive mailboxes. For Exchange Search, there's no difference between the primary and archive mailbox. Content in both mailboxes is indexed. Because the archive mailbox isn't cached on a user's computer (even when using Outlook in Cached Exchange Mode), search results for the archive are always provided by Exchange Search. When searching the entire mailbox in Outlook 2010 and later and Outlook Web App, search results include the users' primary and archive mailbox.
- **In-Place eDiscovery** When a discovery manager performs an In-Place eDiscovery search, users' archive mailboxes are also searched. There's no option to exclude archive mailboxes when creating a discovery search from the Exchange Administration Center (EAC). When using the Exchange Management Shell to create a discovery search, you can exclude the archive by using the *DoNotIncludeArchive* switch. For details, see New-MailboxSearch. To learn more, see In-Place eDiscovery.

Important:

You can't use In-Place eDiscovery to search a disconnected mailbox.

- **In-Place Hold and litigation hold** When you put a mailbox on In-Place Hold or litigation hold, the hold is placed on both the primary and the archive mailbox. To learn more about In-Place Hold and litigation hold, see In-Place Hold.
- **Recoverable Items folder** The archive mailbox contains its own Recoverable Items folder and is subject to the same Recoverable Items folder quotas as the primary mailbox. To learn more about recoverable items, see Recoverable Items folder.
- **Archiving Lync content in Exchange** You can archive instant messaging conversations and shared online meeting documents in the user's primary mailbox. The mailbox must reside on an Exchange 2013 Mailbox server and you must have Microsoft Lync 2013 deployed in your organization. For details, see Integration with SharePoint and Lync.

Managing archive mailboxes

In Exchange 2013, creating and managing archive mailboxes is integrated with common mailbox management tasks, including:

- **Creating an archive mailbox** You can create an archive mailbox when creating a mailbox, or you can enable an archive mailbox for an existing mailbox. For details, see Manage In-Place Archives.
- **Moving an archive mailbox** You can move a user's archive mailbox to another mailbox database on the same Mailbox server or to another server, independent of the primary mailbox. To move a user's archive mailbox, you must create a mailbox move request. For details, see Manage on-premises moves.

Important:

Locating a user's mailbox and archive on different versions of Exchange Server is not supported.

- **Disabling an archive mailbox** You may want to disable a user's archive mailbox for troubleshooting purposes or if you're moving the primary mailbox to a version of Exchange that doesn't support In-Place Archiving. Disabling an archive is similar to disabling a primary mailbox. For details, see Manage In-Place Archives. In on-premises deployments, a disabled archive mailbox is retained in the mailbox database until the deleted mailbox retention period for that database is reached. During this period, you can reconnect the archive to a mailbox user. When the deleted mailbox retention period is reached, the disconnected archive mailbox is purged from the mailbox database.
- **Retrieving mailbox statistics and folder statistics** You can retrieve mailbox statistics and mailbox folder statistics for a user's archive mailbox by using the *Archive* switch with the Get-MailboxStatistics and Get-MailboxFolderStatistics cmdlets.
- **Test archive connectivity** In Exchange 2013, you can use the Test-ArchiveConnectivity cmdlet to test connectivity to a specified user's on-premises or cloud-based archive.

Manage In-Place Archives

Exchange Server 2013 > Messaging policy and compliance > In-Place Archiving >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-08-25*

In-Place Archiving helps you regain control of your organization's messaging data by eliminating the need for personal store (.pst) files and allowing you to meet your organization's message retention and eDiscovery requirements. With archiving enabled, users can store messages in an archive mailbox, which is accessbile by using Microsoft Outlook and Outlook Web App.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "In-Place Archive" entry in the Messaging policy and compliance permissions topic.
- It's not supported to have a user's primary mailbox reside on an older Exchange version than the user's archive. If the user's primary mailbox is still on Exchange 2010, you must move it to Exchange 2013 before or at the same time when you move the archive to Exchange 2013.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Create a mailbox and enable an on-premises archive

Use the EAC

1. Navigate to **Recipients** > **Mailboxes**.
2. Click **New** > **User mailbox**.
3. On the **New user mailbox** page, in the **Alias** box, type an alias for the user.

Note:

If you leave this box blank, the value you type in the **User logon name** box is used for the alias.

4. Select one of the following options:
   - **Existing user** Click this button and then click **Browse** to open the **Select User – Entire Forest**

dialog box. This dialog box displays a list of Active Directory user accounts in the forest that aren't mail-enabled or don't have Exchange mailboxes. Select the user account you want to mail-enable, and then click **OK**. If you select this option, you don't have to provide user account information because this information already exists in Active Directory.

- **New user** Click this button to create a new user account in Active Directory and create a mailbox for the user. If you select this option, you'll have to provide the required user account information.

Note:

The Active Directory account that is associated with user mailboxes must reside in the same forest as the Exchange server. To create a mailbox for a user account that resides in a trusted forest, you have to create a linked mailbox. For details, see Manage linked mailboxes.

5. Click **More options** to configure the following settings.
   - **Mailbox database** Click **Browse** to select a mailbox database in which to store the mailbox. If you don't select a database, Exchange will automatically assign one.
   - **Archive** Select this check box to create an archive mailbox for the mailbox. If you create an archive mailbox, mailbox items will be moved automatically from the primary mailbox to the archive, based on the default retention policy settings or those you define.

Click **Browse** to select a database that resides in the local forest to store the archive mailbox.

To learn more, see In-Place Archiving.

   - **Address book policy** Use this list to select an address book policy (ABP) for the mailbox. ABPs contain a global address list (GAL), an offline address book (OAB), a room list, and a set of address lists. When assigned to mailbox users, an ABP provides them with access to a customized GAL in Outlook and Outlook Web App. To learn more, see Address book policies.

6. When you're finished, click **Save** to create the mailbox.

Use the Shell

This example creates the user Chris Ashton in Active Directory, creates the mailbox on mailbox database DB01, and enables an archive. The password must be reset at the next logon. To set the initial value of the password, this example creates a variable ($password), prompts you to enter a password, and assigns that password to the variable as a SecureString object.

```
$password = Read-Host "Enter password" -AsSecureString
New-Mailbox -UserPrincipalName chris@contoso.com -Alias
chris -Archive -Database "DB01" -Name ChrisAshton -
OrganizationalUnit Users -Password $password -FirstName
Chris -LastName Ashton -DisplayName "Chris Ashton"
```

For detailed syntax and parameter information, see New-Mailbox.

How do you know this worked?

To verify that you've successfully created a user mailbox with an on-premises archive, do one of the following:

- In the EAC, navigate to **Recipients** > **Mailboxes**, and then select the new user mailbox from the list. In the details pane, under **In-Place Archive**, confirm that it is set to **Enabled**. Click **View details** to view archive properties, including archive status and the mailbox database in which it is created.
- In the Shell, run the following command to display information about the new user mailbox and archive.

```
Get-Mailbox <Name> | FL
Name,RecipientTypeDetails,PrimarySmtpAddress,*Archive*
```

- In the Shell, use the **Test-ArchiveConnectivity** cmdlet to test connectivity to the archive. For an example of how to test archive connectivity, see the Examples section in Test-ArchiveConnectivity.

Enable an on-premises archive for existing mailbox

You can also create archives for existing users that have a mailbox but aren't archive-enabled. This is known as *enabling an archive* for an existing mailbox.

Use the EAC

1. Navigate to **Recipients** > **Mailboxes**.
2. Select a mailbox.
3. In the details pane, under **In-Place Archive**, click **Enable**

Tip:
You can also bulk-enable archives by selecting multiple mailboxes (use the Shift or Ctrl keys). After selecting multiple mailboxes, in the details pane, click **More options**. Then, under **Archive** click **Enable**.

4. On the **Create in-place archive** page, click **OK** to have Exchange automatically select a mailbox database for the archive or click **Browse** to specify one.

Use the Shell

This example enables the archive for Tony Smith's mailbox.

```
Enable-Mailbox "Tony Smith" -Archive
```

This example retrieves mailboxes in database DB01 that don't have an on-premises or cloud-based archive enabled and don't have a name starting with DiscoverySearchMailbox. It pipes the result to the **Enable-Mailbox** cmdlet to enable the archive for all mailboxes on mailbox database DB01.

```
Get-Mailbox -Database DB01 -Filter {ArchiveGuid -Eq $null -
AND ArchiveDomain -eq $null -AND Name -NotLike
"DiscoverySearchMailbox*"} | Enable-Mailbox -Archive
```

For detailed syntax and parameter information, see Enable-Mailbox and Get-Mailbox.

How do you know this worked?

To verify that you've successfully enabled an on-premises archive for an existing mailbox, do one of the following:

- In the EAC, navigate to **Recipients** > **Mailboxes**, and then select the mailbox from the list. In the details pane, under **In-Place Archive**, confirm that it is set to **Enabled**. Click **View details** to view archive properties, including archive status and the mailbox database in which it is created.
- In the Shell, run the following command to display information about the new archive.

```
Get-Mailbox <Name> | FL Name,*Archive*
```

- In the Shell, use the **Test-ArchiveConnectivity** cmdlet to test connectivity to the archive. For an example of how to test archive connectivity, see Examples in Test-ArchiveConnectivity.

Disable an on-premises archive

You may want to disable a user's archive for troubleshooting purposes or if you're moving the mailbox to a version of Exchange that doesn't support In-Place Archiving. If you disable an on-premises archive, all information in the archive will be kept in the mailbox database until the mailbox retention time passes and the archive is permanently deleted. (By default, Exchange keeps disconnected mailboxes, including archive mailboxes, for thirty days.)

Important:
Disabling the archive will remove the archive from the mailbox and mark it in the mailbox database for deletion.

If you want to reconnect the on-premises archive to that mailbox, you can use the Connect-Mailbox cmdlet with the *Archive* parameter.

Use the EAC

1. Navigate to **Recipients** > **Mailboxes**.
2. Select a mailbox.
3. In the details pane, under **In-Place Archive**, click **Disable**.

Tip:
You can also bulk-disable archives by selecting multiple mailboxes (use the Shift or Ctrl keys). After selecting multiple mailboxes, in the details pane, click **More options**. Then, under **Archive** click **Disable**.

Use the Shell

This example disables the archive for Chris Ashton's mailbox. It doesn't disable the mailbox.

```
Disable-Mailbox -Identity "Chris Ashton" -Archive
```

For detailed syntax and parameter information, see Disable-Mailbox.

How do you know this worked?

To verify that you have successfully disabled an archive, do the following:

- In the EAC, select the mailbox. Then, in the details pane check its archive status under **In-Place Archive**.
- In the Shell, run the following command to check the archive properties for the mailbox user.

```
Get-Mailbox -Identity "Chris Ashton" | Format-List
*Archive*
```

If the archive is disabled, the following values are returned for archive-related properties.

Property	Value
ArchiveDatabase (for on-premises archives)	<blank>
ArchiveState	None
DisabledArchiveDatabase (for on-premises archives)	<name of mailbox database>
DisabledArchiveGuid	<guid of disabled archive>

Connect an on-premises archive

When you disable an archive mailbox, it becomes disconnected. A disconnected archive mailbox is retained in the mailbox database for a specified amount of time. By default, Exchange retains disconnected archives for 30 days. During this time, you can recover the archive by associating it with an existing mailbox. You can modify the deleted mailbox retention period to retain a deleted mailbox or archive for a longer or shorter period.

Caution:

If you disable an archive for a user and then enable an archive for that same user, the user will get a new archive. The new archive won't contain the data that was in the user's disconnected archive. If you want to reconnect a user to his or her disconnected archive, you must perform this procedure.

Note:

You can't use the EAC to connect a disconnected archive to a mailbox user.

Use the Shell

1. If you don't know the name of the archive, you can view it in the Shell by running the following command. This example retrieves the mailbox database DB01, pipes it to the **Get-MailboxStatistics** cmdlet to retrieve mailbox statistics for all mailboxes on the database, and then uses the **Where-Object** cmdlet to filter the results and retrieve a list of disconnected archives. The command displays additional information about each archive such as the GUID and item count.

```
Get-MailboxDatabase "DB01" | Get-MailboxStatistics | Where {($_.DisconnectDate -ne $null) -and ($_.IsArchiveMailbox -eq $true)} | Format-List
```

2. Connect the archive to the primary mailbox. This example connects Chris Ashton's archive to Chris Ashton's primary mailbox and uses the GUID as the archive's identity.

```
Enable-Mailbox -ArchiveGuid "8734c04e-981e-4ccf-a547-1c1ac7ebf3e2" -ArchiveDatabase "DB01" -Identity "Chris Ashton"
```

For detailed syntax and parameter information, see the following topics:

- Get-MailboxDatabase
- Get-MailboxStatistics
- Enable-Mailbox

How do you know this worked?

To verify that you have successfully connected a disconnected archive to a mailbox user, run the following Shell command to retrieve the mailbox user's archive properties and verify the values returned for the *ArchiveGuid* and *ArchiveDatabase* properties.:

```
Get-Mailbox -Identity "Chris Ashton" | Format-List *Archive*
```

Modify archive policies

Exchange Server 2013 > Messaging policy and compliance > In-Place Archiving >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-14*

In Microsoft Exchange Server 2013, you can use archive policies to automatically move mailbox items to personal (on-premises) or cloud-based archives. Archive policies are retention tags that use the **Move to Archive** retention action.

Exchange Setup creates a retention policy called **Default MRM Policy**. This policy has a default policy tag (DPT) assigned that moves items to the archive mailbox after two years. The policy also includes a number of personal tags that users can apply to folders or mailbox items to automatically move or delete messages. If a mailbox doesn't have a retention policy assigned when it's archive-enabled, the **Default MRM Policy** is automatically applied to it by Exchange. You can also create your own archive and retention policies and apply them to mailbox users. To learn more, see Retention tags and retention policies.

You can modify retention tags included in the default policy to meet your business requirements. For example, you can modify the archive DPT to move items to the archive after three years instead of two. You can also create additional personal tags and either add them to a retention policy, including the **Default MRM Policy**, or allow users to add personal tags to their mailboxes from Outlook Web App Options.

For additional management tasks related to archives, see Manage In-Place Archives.

What do you need to know before you begin?

- Estimated time to completion: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Messaging records management" entry in the Messaging policy and compliance permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to modify the default archive policy

1. Navigate to **Compliance management** > **Retention tags** and then.
2. In the list view, select the tag **Default 2 year move to archive** and then click **Edit** ✎.

Tip:

You can click the **TYPE** column to sort retention tags by type. The default archive policy is displayed as type **Default** and has the **Archive** retention action. Alternatively, click **NAME** to sort retention tags by name.

3. In **Retention Tag**, view or modify the following settings, and then click **Save**:
   - **Name** Use this box at the top of the page to view or change the tag name.
   - **Retention tag type** This read-only field displays the tag type.
   - **Retention action** Don't modify this field for archive policies.
   - **Retention period** Select one of the following options:
     - **Never** Click this button to disable the tag. If the DPT is disabled, the tag is no longer applied to the mailbox.

Important:

Items that have a disabled retention tag applied aren't processed by the Mailbox Assistant. If you want to prevent a tag from being applied to items, we recommend disabling the tag rather than deleting it. When you delete a tag, the tag configuration is deleted from Active Directory, and the Mailbox Assistant processes all messages to remove the deleted tag.

Note:
If a user applies a tag to an item believing the item will never be moved, enabling the tag later may move items the user wanted to retain in the primary mailbox.

- **When the item reaches the following age (in days)** Click this button to specify that items be moved to archive after a certain period. By default, this setting is configured to move items to the archive after two years (730 days). To modify this setting, in the corresponding text box, type the number of days in the retention period. The range of values is from 1 through 24,855 days.

- **Comment** Use this box to type a comment that will be displayed to Outlook and Outlook Web App users.

Use the Shell to modify archive policies

This example modifies the `Default 2 year move to archive` tag to move items after 1,095 days (3 years).

```
Set-RetentionPolicyTag "Default 2 year move to archive" -
Name "Default 3 year move to archive" -AgeLimitForRetention
1095
```

This example disables the `Default 2 year move to archive` tag.

```
Set-RetentionPolicyTag "Default 2 year move to archive" -
RetentionEnabled $false
```

This example retrieves all archive DPTs and personal tags and disables them.

```
Get-RetentionPolicyTag | ? {$_.RetentionAction -eq
"MoveToArchive"} | Set-RetentionPolicyTag -RetentionEnabled
$false
```

For detailed syntax and parameter information, see Set-RetentionPolicyTag and Get-RetentionPolicyTag.

How do you know this worked?

Use the Get-RetentionPolicyTag cmdlet to retrieve settings of the retention tag.

This command retrieves properties of the `Default 2 year move to archive` retention tag and pipes the output to the **Format-List** cmdlet to display all properties in a list format.

```
Get-RetentionPolicyTag "Default 2 year move to archive" |
Format-List
```

Configure archive quotas for an In-Place Archive (on-premises)

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-12-04*

In on-premises deployments, In-Place Archives are created with unlimited storage quotas by default. As a result, you'll need to edit a mailbox's properties to set storage quotas for the archive. You can set the following quotas for an archive:

- **Archive warning quota** When an In-Place Archive exceeds the specified archive warning quota, an event is logged for the Exchange administrator and a warning message is sent to the mailbox user.
- **Archive quota** When an In-Place Archive exceeds the specified archive quota, messages are no longer moved to the archive and a warning message is sent to the mailbox user.

To learn more about In-Place Archives, see In-Place Archiving.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- In the Exchange Administration Center (EAC), you can use a drop-down list with fixed values to configure the archive quota and archive warning quota. If you want to set either quota to a value that's not listed in the EAC, use the Shell.
- Configure the archive warning quota to a lower value than the archive quota. Depending on the rate of archive growth for a user, the difference between the archive warning quota and the archive quota should allow for sufficient time for the user to take appropriate actions, such as deleting items from the archive or requesting that an administrator or IT helpdesk to raise the archive quota.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to configure the archive quota and archive warning quota for a mailbox

1. Navigate to **Recipients** > **Mailboxes**
2. In the list view, select a mailbox,
3. In the details pane, under **In-Place Archive**, click **View details**.
4. In **Archive Mailbox**, use the **Quota value (GB)** and **Issue warning at (GB)** lists to select the desired values.
5. Click **OK**.

Use the Shell to configure the archive quota and archive warning quota for a mailbox

This example sets Chris Ashton's mailbox archive quota to 10 gigabyte (GB), at which time the user will receive a warning message that the In-Place Archive is full and he will no longer be able to move items to the archive. This example also sets the archive warning quota to 9.5 GB, at which time the user will receive a warning message that the In-Place Archive is almost full.

```
Set-Mailbox -Identity "Chris Ashton" -ArchiveQuota 10GB -
ArchiveWarningQuota 9.5GB
```

For detailed syntax and parameter information, see Set-Mailbox.

How do you know this worked?

To verify that you've successfully enabled an on-premises archive for an existing mailbox, do one of the following:

- In the EAC, navigate to **Recipients** > **Mailboxes** and select the mailbox you want. In the details pane, under **In-Place Archive**, click **View Details** and verify the archive's quota settings.
- In the Shell, run the following command to display quota information about the archive.

```
Get-Mailbox <Name> | FL Name,Archive*Quota
```

Archive Lync conversations and meeting content to Exchange

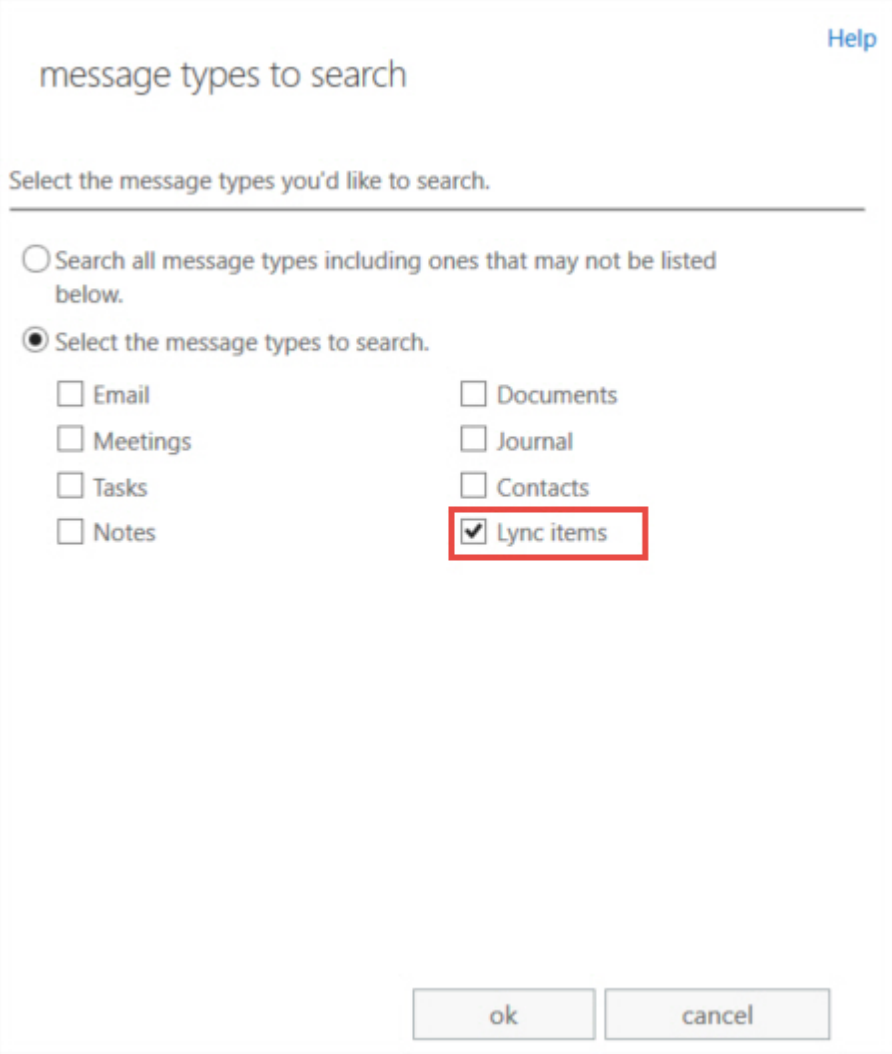
Exchange Server 2013 > Messaging policy and compliance > In-Place Archiving >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-05-23*

You can archive Lync Online content, such as IM conversations, to a user's mailbox in Exchange Online. In on-premises deployments, you can archive Lync 2013 content to Exchange 2013 mailboxes. This requires placing the user on In-Place Hold. Archived Lync content is preserved in the Recoverable Items folder in the user's mailbox. It's not visible to your users but it is included in eDiscovery searches.

When you create an In-Place Hold, all content types in the mailbox, including Lync items, are preserved by default. If you want to preserve only Lync items, use the **select message types** option from the **In-Place eDiscovery & Hold** wizard and select **Lync items**, as shown in the screenshot below.



You can also specify how long the content should be preserved. See In-Place Hold for details.

For step-by-step instructions for placing a user on In-Place Hold, see Create or remove an In-Place Hold.

For additional management tasks related to archiving, see **Manage In-Place Archives in Exchange Online**.

More information

- Archiving of Lync content occurs on the server, independent of whether the user has Lync client configured to save Lync IM conversations in the Conversation History folder.
- Archiving of Lync content begins after the user is placed on In-Place Hold. To ensure user's Lync communications are archived from the time their account is created, place the account on In-Place Hold immediately after it's created.

Additionally, in on-premises Exchange 2013 and Lync 2013 deployments:

- You must configure OAuth authentication between Lync 2013 and Exchange 2013. For details, see Integration with SharePoint and Lync.
- You can also archive Lync 2013 content to Exchange 2013 regardless of whether a user is placed on In-Place Hold. This is done by configuring the user's Exchange Archiving Policy. Use the `Set-CsUser` cmdlet on Lync 2013 server to set the Lync user's *ExchangeArchivingPolicy* property to `ArchivingToExchange`.
- For more details about archiving Lync content in on-premises deployments, see Planning for Archiving in Lync 2013 documentation.

Using OAuth authentication to support Archiving in an Exchange hybrid deployment

Exchange Server 2013 > Messaging policy and compliance > In-Place Archiving >

Topic Last Modified: *2014-05-22*

If you're in an Exchange 2013 hybrid deployment and use Exchange Online Archiving (EOA) for Exchange Server, you must configure OAuth authentication between your on-premises and Exchange Online organizations after upgrading to Exchange 2013 Cumulative Update 5 (CU5). EOA allows you to have a cloud-based archive for your users with on-premises mailboxes. In this scenario, the Messaging Records Management (MRM) assistant on your on-premises mailbox server applies archiving policies and moves messages automatically from a user's mailbox to their cloud-based archive. In Exchange 2013 CU5, it uses OAuth authentication.

For step-by-step instructions for configuring OAuth authentication, see Configure OAuth authentication between Exchange and Exchange Online organizations.

What is OAuth authentication?

OAuth authentication is a server-to-server authentication protocol that allows applications to

authenticate to each other. With OAuth authentication, user credentials and passwords are not passed from one computer to another. Instead, authentication and authorization is based on the exchange of security tokens, which grant access to a specific set of resources for a specific amount of time.

OAuth authentication typically involves three parties: a single authorization server and the two realms that need to communicate with one another. Security tokens are issued by the authorization server (also known as a security token server) to the two realms that need to communicate; these tokens verify that communications originating from one realm should be trusted by the other realm. When using OAuth authentication between an on-premises Exchange organization and Exchange Online, the function of the authorization server is provided by Microsoft Azure Active Directory Access Control Services (ACS) in your Office 365 organization. For example, during a cross-premises eDiscovery search, Windows Azure ACS issues tokens that verify that an administrator or compliance officer from the Exchange on-premises organization is able to access mailboxes in the Exchange Online organization, and vice-versa.

Configuring OAuth authentication to support Archiving

As previously stated, see Configure OAuth authentication between Exchange and Exchange Online organizations for instructions to configure OAuth authentication to support Archiving in an Exchange hybrid deployment.

If OAuth isn't configured for your Exchange hybrid deployment, you can't use archive policies to automatically move items from a user's primary mailbox in your on-premises organization to the user's cloud-based archive in Exchange Online.

More information

- You must also configure OAuth authentication to perform cross-premises eDiscovery searches of your on-premises and cloud-based mailboxes in a single eDiscovery search. See Using OAuth authentication to support eDiscovery in an Exchange hybrid deployment.
- You can also configure OAuth authentication to allow other applications, such as SharePoint 2013 and Lync Server 2013, to authenticate to Exchange 2013. For more information, see Configure OAuth authentication with SharePoint 2013 and Lync 2013.
- You can configure server-to-server authentication between Exchange 2013 and SharePoint 2013 so administrators and compliance officers can use the eDiscovery Center in SharePoint 2013 to search Exchange 2013 mailboxes. For more information, see Configure Exchange for SharePoint eDiscovery Center.
- You can configure an Exchange hybrid deployment using the Hybrid Configuration Wizard in Exchange 2013. For a customized, step-by-step hybrid deployment configuration checklist, see the Exchange Server Deployment Assistant.

In-Place Hold

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-08-11*

When a reasonable expectation of litigation exists, organizations are required to preserve electronically stored information (ESI), including email that's relevant to the case. This expectation often exists before the specifics of the case are known, and preservation is often broad. Organizations may need to preserve all email related to a specific topic or all email for certain individuals. Depending on the organization's electronic discovery (eDiscovery) practices, the following measures can be adopted to preserve email:

- End users may be asked to preserve email by not deleting any messages. However, users can still delete email knowingly or inadvertently.
- Automated deletion mechanisms such as messaging records management (MRM) may be suspended. This could result in large volumes of email cluttering the user mailbox, and thus impacting user productivity. Suspending automated deletion also doesn't prevent users from manually deleting email.
- Some organizations copy or move email to an archive to make sure it isn't deleted, altered, or tampered with. This increases costs due to the manual efforts required to copy or move messages to an archive, or third-party products used to collect and store email outside Exchange.

Failure to preserve email can expose an organization to legal and financial risks such as scrutiny of the organization's records retention and discovery processes, adverse legal judgments, sanctions, or fines.

In Exchange 2013, you can use In-Place Hold to accomplish the following goals:

- Place user mailboxes on hold and preserve mailbox items immutably
- Preserve mailbox items deleted by users or automatic deletion processes such as MRM
- Use query-based In-Place Hold to search for and retain items matching specified criteria
- Preserve items indefinitely or for a specific duration
- Place a user on multiple holds for different cases or investigations
- Keep In-Place Hold transparent from the user by not having to suspend MRM
- Enable In-Place eDiscovery searches of items placed on hold

In-Place Hold and litigation hold

Preserving archived Lync content

In-Place Hold scenarios

In Exchange Server 2010, the notion of legal hold is to hold all mailbox data for a user indefinitely or until when hold is removed. In Exchange 2013, In-Place Hold introduces a new model that allows you to specify the following parameters:

- **What to hold** You can specify which items to hold by using query parameters such as keywords, senders and recipients, start and end dates, and also specify the message types such as email messages, calendar items, etc. that you want to place on hold.
- **How long to hold** You can specify a duration for items on hold.

Using this new model, In-Place Hold allows you to create granular hold policies to preserve mailbox items in the following scenarios:

- **Indefinite hold** The indefinite hold scenario is similar to litigation hold in Exchange 2010. It's intended to preserve mailbox items so you can meet eDiscovery requirements. During the period of litigation or investigation, items are never deleted. The duration isn't known in advance, so no end date is configured. To hold all mail items indefinitely, you don't specify any query parameters or time duration when creating an In-Place Hold.
- **Query-based hold** If your organization preserves items based on specified query parameters, you can use a query-based In-Place Hold. You can specify query parameters such as keywords, start and end dates, sender and recipient addresses, and message types. After you create a query-based In-Place Hold, all existing and future mailbox items (including messages received at a later date) that match the query parameters are preserved.

Important:

Items that are marked as unsearchable, generally because of failure to index an attachment, are also preserved because it can't be determined whether they match query parameters. For more details about unsearchable item, see Unsearchable items in Exchange eDiscovery.

- **Time-based hold** Whereas litigation hold places all mailbox content on hold indefinitely or until you remove the hold, In-Place Hold allows you to specify a duration of time for which to hold items. The duration is calculated from the date a mailbox item is received or created.

If your organization requires that all mailbox items be preserved for a specific period, for example 7 years, you can create a time-based hold. In Exchange 2013, you can specify a retention period for items on hold. Items on hold are aged based on their date received. For example, consider a mailbox that's placed on a time-based In-Place Hold and has a retention period set to 365 days. If an item in that mailbox is deleted after 300 days from the date it was received, it's held for an additional 65 days before being permanently deleted. You can use a time-based In-Place Hold in conjunction with a retention policy to make sure items are preserved for the specified duration and permanently removed after that period.

You can use In-Place Hold to place a user on multiple holds. When a user is placed on multiple

holds, search parameters of all In-Place Holds are applied together (using an OR operator). If a mailbox is placed on more than five holds, all items are held until the holds are removed, replicating the litigation hold behavior until the number of holds on the mailbox is reduced to five or less.

If an administrator deletes a user account that has a mailbox, the Exchange Information store will eventually detect that the mailbox is no longer connected to a user account and mark that mailbox for deletion, even if the mailbox is on hold. If you want to retain the mailbox you must do the following:

1. Instead of deleting the user account, disable the user account.
2. Change the properties of the mailbox to restrict its use and access to the mailbox. For example, set send and receive quotas equal to 1, block who can send messages to the mailbox, and restrict who can access the mailbox.
3. Retain the mailbox until all data has been expunged, or until hold is no longer required.

Placing a mailbox on In-Place Hold

Authorized users that have been added to the Discovery Management role-based access control (RBAC) role group or assigned the Legal Hold and Mailbox Search management roles can place mailbox users on In-Place Hold. You can delegate the task to records managers, compliance officers, or attorneys in your organization's legal department, while assigning the least privileges. To learn more about assigning the Discovery Management role group, see Add a user to the Discovery Management role group.

Important:

In Exchange 2010, the Legal Hold role provided user with sufficient permissions to place mailboxes on litigation hold. In Exchange 2013, you can use the same permission to place mailboxes on an indefinite or time-based In-Place Hold. However, to create a query-based In-Place Hold, the user must be assigned the Mailbox Search role. The Discovery Management role group has both these roles assigned.

In Exchange 2013, In-Place Hold functionality is integrated with In-Place eDiscovery searches. You can use the **In-Place eDiscovery & Hold** wizard in the Exchange Administration Center (EAC) or the **New-MailboxSearch** and related cmdlets in Exchange Management Shell to place a mailbox on In-Place Hold. To learn more about placing a mailbox on In-Place Hold, see Create or remove an In-Place Hold.

Note:

If you use Exchange Online Archiving to provision a cloud-based archive for your on-premises mailboxes, you must manage In-Place Hold from your on-premises Exchange 2013 organization. Hold settings are automatically propagated to the cloud-based archive using DirSync.

Many organizations require that users be informed when they're placed on hold. Additionally, when a mailbox is on hold, any retention policies applicable to the mailbox user don't need to be

suspended. Because messages continue to be deleted as expected, users may not notice they're on hold. If your organization requires that users on hold be informed, you can add a notification message to the mailbox user's **Retention Comment** property and use the **RetentionUrl** property to link to a web page for more information. Outlook 2010 and later displays the notification and URL in the backstage area. You must use the Shell to add and manage these properties for a mailbox.

In-Place Hold and the Recoverable Items Folder

In-Place Hold uses the Recoverable Items folder to preserve items. The Recoverable Items folder replaces the feature informally known as the *dumpster* in previous versions of Exchange. The Recoverable Items folder is hidden from the default view of Outlook, Outlook Web App, and other email clients. To learn more about the Recoverable Items folder, see Recoverable Items folder.

By default, when a user deletes a message from a folder other than the Deleted Items folder, the message is moved to the Deleted Items folder. This is known as a *move*. When a user *soft deletes* an item (accomplished by pressing the SHIFT and DELETE keys) or deletes an item from the Deleted Items folder, the message is moved to the Recoverable Items folder, thereby disappearing from the user's view.

Items in the Recoverable Items folder are retained for the deleted item retention period configured on the user's mailbox database. By default, the deleted item retention period is set to 14 days for mailbox databases. You can also configure a storage quota for the Recoverable Items folder. This protects the organization from a potential denial of service (DoS) attack due to rapid growth of the Recoverable Items folder and therefore the mailbox database. If a mailbox isn't placed on In-Place Hold or litigation hold, items are purged permanently from the Recoverable Items folder on a first in, first out basis when the Recoverable Items warning quota is exceeded, or the item has resided in the folder for a longer duration than the deleted item retention period.

The Recoverable Items folder contains the following subfolders used to store deleted items in various sites and facilitate In-Place Hold and litigation hold:

1. **Deletions** Items removed from the Deleted Items folder or soft-deleted from other folders are moved to the Deletions subfolder and are visible to the user when using the Recover Deleted Items feature in Outlook and Outlook Web App. By default, items reside in this folder until the deleted item retention period configured for the mailbox database or the mailbox expires.
2. **Purges** When a user deletes an item from the Recoverable Items folder (by using the Recover Deleted Items tool in Outlook and Outlook Web App, the item is moved to the Purges folder. Items that exceed the deleted item retention period configured on the mailbox database or the mailbox are also moved to the Purges folder. Items in this folder aren't visible to users if they use the Recover Deleted Items tool. When the mailbox assistant processes the mailbox, items in the Purges folder are purged from the mailbox database. When you place the mailbox user on litigation hold, the mailbox assistant doesn't purge items in this folder.
3. **DiscoveryHold** If a user is placed on an In-Place Hold, deleted items are moved to this folder. When the mailbox assistant processes the mailbox, it evaluates messages in this folder. Items

matching the In-Place Hold query are retained until the hold period specified in the query. If no hold period is specified, items are held indefinitely or until the user is removed from the hold.

4. **Versions** When a user placed on In-Place Hold or litigation hold, mailbox items must be protected from tampering or modification by the user or a process. This is accomplished using a *copy-on-write* process. When a user or a process changes specific properties of a mailbox item, a copy of the original item is saved in the Versions folder before the change is committed. The process is repeated for subsequent changes. Items captured in the Versions folder are also indexed and returned in In-Place eDiscovery searches. After the hold is removed, copies in the Versions folder are removed by the Managed Folder Assistant.

Properties that trigger copy-on-write

Item type	Properties that trigger copy-on-write
Messages (IPM.Note*) Posts (IPM.Post*)	• Subject • Body • Attachments • Senders/Recipients • Sent/Received Dates
Items other than messages and posts	Any change to a visible property, except the following: • Item location (when an item is moved between folders) • Item status change (read or unread) • Changes to retention tag applied to an item
Items in the default folder Drafts	None (items in the Drafts folder are exempt from copy on write)

Important:
Copy-on-write is disabled for calendar items in the organizer's mailbox when meeting responses are received from attendees and the tracking information for the meeting is updated. For calendar items and items that have a reminder set, copy-on-write is disabled for the ReminderTime and ReminderSignalTime properties. Changes to these properties are not captured by copy-on-write. Changes to RSS feeds aren't captured by copy-on-write.

Although the DiscoveryHold, Purges, and Versions folders aren't visible to the user, all items in the Recoverable Items folder are indexed by Exchange Search and are discoverable using In-Place eDiscovery. After a mailbox user is removed from In-Place Hold or litigation hold, items in the DiscoveryHold, Purges, and Versions folders are purged by the Managed Folder Assistant.

In-Place Hold and mailbox quotas

Items in the Recoverable Items folder aren't calculated toward the user's mailbox quota. In Exchange 2013, the Recoverable Items folder has its own quota. When a user's Recoverable Items folder exceeds the warning quota for recoverable items (as specified by the *RecoverableItemsWarningQuota* parameter), an event is logged in the Application event log of the Mailbox server. When the folder exceeds the quota for recoverable items (as specified by the *RecoverableItemsQuota* parameter), users won't be able to empty the Deleted Items folder or permanently delete mailbox items. Also copy-on-write won't be able to create copies of modified items. Therefore, it's critical that you monitor Recoverable Items quotas for mailbox users placed on In-Place Hold.

For mailbox databases, the default *RecoverableItemsWarningQuota* and *RecoverableItemsQuota* values are set to 20 Gb and 30 Gb respectively. These settings are usually sufficient for storing several years of mailbox data when on In-Place Hold. To modify these values for a mailbox database, use the Set-MailboxDatabase cmdlet. To modify them for individual mailboxes, use the Set-Mailbox cmdlet.

Note:

In Exchange Online, it’s possible to reach or exceed the 30 GB quota for the Recoverable Items folder for a mailbox placed on In-Place Hold. If this happens, you can contact Office 365 support to request an increase of the Recoverable Items quota for a mailbox on In-Place Hold.

In-Place Hold and litigation hold

Litigation hold, the hold feature introduced in Exchange 2010 to preserve data for eDiscovery, is still available in Exchange 2013. Litigation hold uses the **LitigationHoldEnabled** property of a mailbox. Whereas In-Place Hold provides granular hold capability based on query parameters, hold period, and the ability to place multiple holds, litigation hold only allows you to place all items on hold indefinitely or until hold is removed.

In Exchange Online, you can also specify the litigation hold duration for a mailbox.

When an item is placed on one or more In-Place Holds and litigation hold at the same time, all items are held indefinitely or until the holds are removed. If you remove litigation hold and the user is still placed on one or more In-Place Holds, items matching the In-Place Hold criteria are held for the period specified in the hold settings. When you move a mailbox that’s on litigation hold in Exchange 2010 to an Exchange 2013 Mailbox server, the litigation hold setting continues to apply, ensuring that compliance requirements are met during and after the move.

Preserving archived Lync content

Exchange 2013, Microsoft Lync 2013 and Microsoft SharePoint 2013 provide an integrated preservation and eDiscovery experience that allows you to preserve and search for items across the

different data stores. Exchange 2013 allows you to archive Lync Server 2013 content in Exchange, removing the requirement of having a separate SQL Server database to store archived Lync content. The integrated hold and eDiscovery capability in SharePoint 2013 allows you to preserve and search data across all stores from a single console.

When you place an Exchange 2013 mailbox on In-Place Hold or litigation hold, Microsoft Lync 2013 content (such as instant messaging conversations and files shared in an online meeting) are archived in the mailbox. If you search the mailbox using the eDiscovery Center in Microsoft SharePoint 2013 or In-Place eDiscovery in Exchange 2013, any archived Lync content matching the search query is also returned in search results. You can also restrict the search to Lync content archived in the mailbox.

To enable archiving of Lync content in Exchange 2013 mailbox, you must configure Lync 2013 integration with Exchange 2013. For details, see the following topics:

- Planning for Archiving
- Deploying Archiving

Create or remove an In-Place Hold

Exchange Server 2013 > Messaging policy and compliance > In-Place Hold >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-03-26*

An In-Place Hold preserves all mailbox content, including deleted items and original versions of modified items. All such mailbox items are returned in an In-Place eDiscovery search.

Note:

Depending on your Active Directory topology and replication latency, it may take up to an hour for an In-Place Hold to take effect.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "In-Place Hold" entry in the Messaging policy and compliance permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Create an In-Place Hold

Use the EAC to create an In-Place Hold

1. Navigate to **Compliance management** > **In-place eDiscovery & hold**.
2. Click **New +**.
3. In **In-Place eDiscovery & Hold**, on the **Name and description** page, type a name for the search and an optional description, and then click **Next**.
4. On the **Mailboxes** page, click **Specify mailboxes to search**, click **Add +**, select the mailboxes you want to place on hold, and then click **Next**.

Important:

You can use the **Search all mailboxes** option for In-Place eDiscovery searches. You can't select this option to place all mailboxes on hold. To create an In-Place Hold, you must select the specific mailboxes you want to be placed on hold.

5. On the **Search query** page, complete the following fields, and then click **Next**:
   - **Include all user mailbox content** Click this button to place all content in selected mailboxes on hold.

Note:

To get the same results as litigation hold in Exchange 2010, you can use this option and select **Hold indefinitely** on the next page (**In-Place Hold settings**).

   - **Filter based on criteria** Click this button to specify search criteria, including keywords, start and end dates, sender and recipient addresses, and message types.

Important:

If a mailbox is placed on more than five query-based holds, the query parameters are ignored and all mailbox content is placed on hold.

6. On the **In-Place Hold settings** page, select the **Place content matching the search query in selected mailboxes on hold** check box and then select one of the following options:
   - **Hold indefinitely** Click this button to place items returned by the search on an indefinite hold. Items on hold will be preserved until you remove the mailbox from the search or remove the search.
   - **Specify number of days to hold items relative to their received date** Click this button to hold items for a specific period. For example, you can use this option if your organization requires that all messages be retained for at least seven years. You can use a *time-based* In-Place Hold along with a retention policy to make sure items are deleted in seven years. To learn more about retention polices, see Retention tags and retention policies.

Use the Shell to create an In-Place Hold

This example creates an In-Place Hold named Hold-CaseId012 and adds the mailbox joe@contoso.com to the hold.

Important:

If you don't specify additional search parameters for an In-Place Hold, all items in the specified source mailboxes are placed on hold. If you don't specify the *ItemHoldPeriod* parameter, items are placed on hold indefinitely or until the mailbox is either removed from hold or the hold is deleted.

```
New-MailboxSearch "Hold-CaseId012" -SourceMailboxes
"joe@contoso.com" -InPlaceHoldEnabled $true
```

For detailed syntax and parameter information, see New-MailboxSearch.

How do you know this worked?

To verify that you have successfully created the In-Place Hold, do one of the following:

- Use the EAC to verify that the In-Place Hold is listed in the list view of the **In-place eDiscovery & hold** tab.
- Use the **Get-MailboxSearch** cmdlet to retrieve the mailbox search and check the search parameters. For an example of how to retrieve a mailbox search, see the examples in Get-MailboxSearch.

Remove an In-Place Hold

Important:

In Exchange 2013, mailbox searches can be used for an In-Place Hold and In-Place eDiscovery. You can't remove a mailbox search that's used for In-Place Hold. You must first disable the In-Place Hold by clearing the **Place content matching the search query in selected mailboxes on hold** check box on the **In-Place Hold settings** page or by setting the *InPlaceHoldEnabled* parameter to `$false` in the Shell. You can also remove a mailbox by using the *SourceMailboxes* parameter specified in the search.

Use the EAC to remove an In-Place Hold

1. Navigate to **Compliance management** > **In-Place eDiscovery & hold**.
2. In the list view, select the In-Place Hold you want to remove and then click **Edit** .
3. In **In-Place eDiscovery & Hold** properties, on the **In-Place Hold** page, clear the **Place content matching the search query in selected mailboxes on hold**, and then click **Save**.
4. Select the In-Place Hold again from the list view, and then click **Delete** .
5. In warning, click **Yes** to remove the search.

Use the Shell to remove an In-Place Hold

This example first disables In-Place Hold named Hold-CaseId012 and then removes the mailbox search.

```
Set-MailboxSearch "Hold-CaseId012" -InPlaceHoldEnabled
$false
Remove-MailboxSearch "Hold-CaseId012"
```

For detailed syntax and parameter information, see Set-MailboxSearch.

How do you know this worked?

To verify that you have successfully removed an In-Place Hold, do one of the following:

- Use the EAC to verify that the In-Place Hold doesn't appear in the list view of the **In-place eDiscovery & hold** tab.
- Use the **Get-MailboxSearch** cmdlet to retrieve all mailbox searches and check that the search you removed is no longer listed. For an example of how to retrieve a mailbox search, see the examples in Get-MailboxSearch.

Place a mailbox on Litigation Hold

Exchange Server 2013 > Messaging policy and compliance > In-Place Hold >

Topic Last Modified: *2014-06-05*

Place a mailbox on Litigation Hold to preserve all mailbox content, including deleted items and original versions of modified items. Deleted and modified items are preserved for a specified period, or until you remove the mailbox from Litigation Hold. All such mailbox items are returned in an In-Place eDiscovery search.

Caution:
Litigation Hold preserves items in the Recoverable Items folder in the user's mailbox. Depending on number and size of items deleted or modified, the size of the Recoverable Items folder of the mailbox may increase quickly. The Recoverable Items folder is configured with a high quota by default. We recommend that you monitor mailboxes that are placed on Litigation Hold on a weekly basis to ensure they do not reach the Recoverable Items quotas.

Important:
Litigation Hold setting may take up to 60 minutes to take effect.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "In-Place Hold" entry in the Messaging policy and compliance permissions topic.
- Litigation Hold preserves deleted items and also preserves original versions of modified items until the hold is removed. You can optionally specify a hold duration, which preserves a mailbox item for the specified duration. To preserve items that meet your specified criteria, use an In-Place Hold to create a *query-based* hold.
- You can't use the Exchange admin center (EAC) to specify the litigation hold duration option.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see

Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the EAC to place a mailbox on Litigation Hold

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of user mailboxes, click the mailbox that you want to configure message delivery restrictions for, and then click **Edit**.
3. On the mailbox properties page, click **Mailbox Features.**
4. Under **Litigation Hold**, click **Enable** to place the mailbox on Litigation Hold.
5. On the Litigation Hold page, enter the following optional information:
   - **Note** Use this field to inform the user their mailbox is on Litigation Hold. The note will appear in the user's mailbox if they're using Outlook 2010 or later.
   - **URL** Use this field to direct the user to a website for more information about Liigation Hold. This URL appears in the user's mailbox if they are using Outlook 2010 or later.

Use the Shell to place a mailbox on Litigation Hold

This example places the mailbox bsuneja@contoso.com on Litigation Hold.

```
Set-Mailbox bsuneja@contoso.com -LitigationHoldEnabled
$true
```

Use the Shell to place a mailbox on Litigation Hold and preserve items for a specified duration

This examples places the mailbox bsuneja@contoso.com on Litigation Hold and preserves items for 2555 days (approximately 7 years).

```
Set-Mailbox bsuneja@contoso.com -LitigationHoldEnabled
$true -LitigationHoldDuration 2555
```

Use the Shell to place all mailboxes on Litigation Hold for a specified duration

Your organization may require that all mailbox data be preserved for a specified duration. Before you place all mailboxes in an organization on Litigation Hold, consider the following:

- When you use the command to place all mailboxes in an organization, or a subset of mailboxes

matching a specified filter on Litigation Hold, only mailboxes that exist at the time you run the command are placed on hold. If you create new mailboxes later, you must run the command again to place the new mailboxs on hold. If you frequently create new mailboxes, you can run the command as a scheduled task as frequently as required..

- Placing all mailboxes in an organization on hold can significantly impact mailbox sizes. In on-premises deployments, plan for adequate storage to meet your organization's preservation requirements.
- Preserving mailbox data for a long duration will result in growth of the Recoverable Items folder in a user's mailbox and archive. The Recoverable Items folder has its own storage limit, so items in the folder don't count towards the mailbox storage limit For most users, the default storage limit is sufficient for storing several years' worth of messages. We recommend monitoring the size of the folder periodically to ensure it doesn't reach the limit. See Recoverable Items folder for more details

This examples places all the mailboxes in an organization on Litigation Hold for 2555 days (approximately 7 years). The hold is not applied to the Discovery mailboxes.

```
Get-Mailbox -ResultSize Unlimited -Filter
{RecipientTypeDetails -ne "DiscoveryMailbox"} | Set-Mailbox
-LitigationHoldEnabled $true -LitigationHoldDuration 2555
```

The example uses the Get-Mailbox cmdlet to retrieve all mailboxes in the organization, specifies a recipient filter to exclude the Discovery mailboxes, and pipes the mailboxes to the Set-Mailbox cmdlet to enable Litigation Hold. You can use other user properties in a filter to exclude or include one or more mailboxes. For details, see Filterable properties for the -Filter parameter.

Use the Shell to remove a mailbox from Litigation Hold

This example removes the mailbox bsuneja@contoso.com from Litigation Hold.

```
Set-Mailbox bsuneja@contoso.com -LitigationHoldEnabled
$false
```

How do you know this worked?

To verify that you have successfully placed a mailbox on Litigation Hold, do the following:

1. In the EAC, navigate to **Recipients** > **Mailboxes**.
2. In the list of user mailboxes, click the mailbox that you want to verify Litigation Hold settings for, and then click **Edit**.
3. On the mailbox properties page, click **Mailbox Features.**
4. Under **Litigation Hold**, verify that hold is enabled.
5. Click View details to verify when the mailbox was placed on Litigation Hold and by whom. You can also verify or change the values in the optional **Note** and **URL** fields.

Place all mailboxes on hold

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-07-15*

Your organization may require all mailbox data to be preserved for a specific period. You can use Litigation Hold or In-Place Hold to meet this requirement. After you place a mailbox on Litigation Hold or In-Place Hold, mailbox items attempted to be permanently deleted or modified are preserved in the Recoverable Items folder. For more details, see In-Place Hold.

Before you place all mailboxes in an organization on Litigation Hold or In-Place Hold, consider the following:

- Placing all mailboxes in an organization on hold can significantly impact mailbox sizes. In on-premises deployments, plan for adequate storage to meet your organization's preservation requirements. In Exchange Online, mailbox storage limits for your users depend on the user's subscription license.
- Preserving mailbox data for a long duration will result in growth of the Recoverable Items folder in a user's mailbox and archive. The Recoverable Items folder has its own storage limit, so items in the folder don't count towards the mailbox storage limit. For most users, the default storage limit is sufficient for storing several years' worth of messages. We recommend monitoring the size of the folder periodically to ensure it doesn't reach the limit. See Recoverable Items folder for more details.

Choosing between Litigation Hold and In-Place Hold to place all mailboxes on hold

Here are some factors you should consider in deciding the hold feature you should use to place all mailboxes on hold.

You want to...	Use Litigation Hold	Use In-Place Hold
Use the EAC	Yes. For setting Litigation Hold, EAC is best suited for quick one-off actions on a few mailboxes. We recommend using the Shell for setting Litigation Hold for all users in an organization. You	Yes. However, you can't select more than 500 source mailboxes in the EAC.

	can't specify the litigation hold duration in the EAC.	
Use the Shell	Yes	Yes
Place more than 10,000 mailboxes on hold	Yes. Litigation Hold is a mailbox property. You can place all mailboxes in an organization on hold using a Shell command.	Yes, using multiple In-Place Holds. You can specify a maximum of 10,000 mailboxes in a single In-Place Hold. To place additional mailboxes on hold, you must create additional In-Place Holds. This will result in additional management overhead. Using Litigation Hold is simpler.
Place many different mailboxes on hold for different periods.	Yes Litigation Hold is a mailbox property. You can place each mailbox (or sets of mailboxes) on hold for a different duration.	Yes If you're placing individual holds on thousands of mailboxes, we recommend using Litigation Hold. If you're creating holds for specific events that involve multiple users, use a single in-Place hold for the group of users. It's not recommended to create separate in-place holds for each mailbox as this will create many in-place hold queries that will be more difficult to manage than litigation holds. A large number of In-Place Hold objects may also result in slow

		performance in the EAC when refreshing, creating or modifying hold objects.
Automatically place new mailboxes on hold	No You must place a new mailbox on litigation hold after it's created. You can also schedule the command or script to run as frequently as required to achieve the same effect.	No You must add a new mailbox to an In-Place Hold. You can also schedule the command or script to run as frequently as required to achieve the same effect. We recommend that the script check if an existing In-Place Hold has already reached the 10,000 mailbox limit and creating a new In-Place Hold if required.

Place all mailboxes on Litigation Hold

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "In-Place Hold" entry in the Messaging policy and compliance permissions topic.

You can easily and quickly place all mailboxes on hold indefinitely or for a specified duration using the Shelll. This command places all mailboxes on hold for 7 years. The hold is not applied to Discovery mailboxes.

```
Get-Mailbox -ResultSize Unlimited -Filter
{RecipientTypeDetails -ne "DiscoveryMailbox"} | Set-Mailbox
-LitigationHoldEnabled $true -LitigationHoldDuration 2555
```

The example uses the Get-Mailbox cmdlet to retrieve all mailboxes in your organization, specifies a recipient filter to exclude Discovery mailboxes and pipes the mailboxes to the Set-Mailbox cmdlet to enable Litigation Hold. You can use other user properties in a filter to exclude or include one or more mailboxes. For a list of properties you can use in a filter, see Filterable properties for the -Filter parameter.

Place all mailboxes on In-Place Hold

You can use the EAC to select up to 500 mailboxes and place them on hold. For details, see Create or remove an In-Place Hold.

To place more than 500 users on In-Place Hold, use the Shell.

More Info

- Only mailboxes that exist at the time you run the command are placed on hold. If you create new mailboxes later, run the command again to place them on hold. If you frequently create new mailboxes, you can run the command as a scheduled task as frequently as required.
- Placing mailboxes on hold preserves data by preventing deletion before the specified period and saving the original version of a message before it's modified. It does not automatically delete messages after the specified period. Combine Litigation Hold or In-Place Hold with a Retention Policy, which can automatically delete messages after the specified period, to meet your organization's email retention requirements. See Retention tags and retention policies for details.

In-Place eDiscovery

Exchange Server 2013 > Messaging policy and compliance >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-08-26*

If your organization adheres to legal discovery requirements (related to organizational policy, compliance, or lawsuits), In-Place eDiscovery in Microsoft Exchange Server 2013 and Exchange Online can help you perform discovery searches for relevant content within mailboxes. Exchange 2013 and Exchange Online also offer federated search capability and integration with Microsoft SharePoint 2013 and Microsoft SharePoint Online. Using the eDiscovery Center in SharePoint, you can search for and hold all content related to a case, including SharePoint 2013 and SharePoint Online websites, documents, file shares indexed by SharePoint (SharePoint 2013 only), mailbox content in Exchange, and archived Lync 2013 content. You can also use In-Place eDiscovery in an Exchange hybrid environment to search on-premises and cloud-based mailboxes in the same search.

Important:
In-Place eDiscovery is a powerful feature that allows a user with the correct permissions to potentially gain access to all messaging records stored throughout the Exchange 2013 or Exchange Online organization. It's important to control and monitor discovery activities, including addition of members to the Discovery Management role group, assignment of the Mailbox Search management role, and assignment of mailbox access permission to discovery mailboxes.

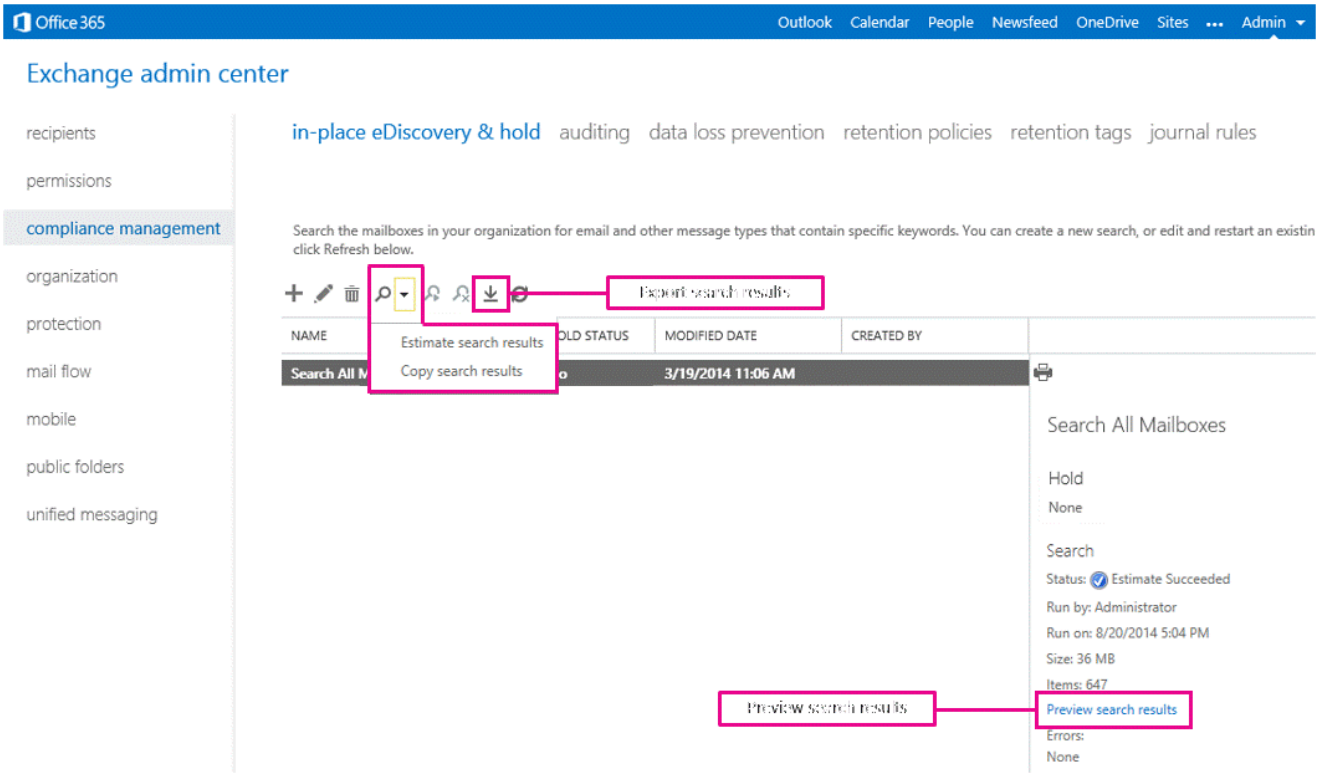
Contents

How In-Place eDiscovery works

In-Place eDiscovery uses the content indexes created by Exchange Search. Role Based Access Control (RBAC) provides the Discovery Management role group to delegate discovery tasks to non-technical personnel, without the need to provide elevated privileges that may allow a user to make any operational changes to Exchange configuration. The Exchange admin center (EAC) provides an easy-to-use search interface for non-technical personnel such as legal and compliance officers, records managers, and human resources (HR) professionals.

Authorized users can perform an In-Place eDiscovery search by selecting the mailboxes, and then specifying search criteria such as keywords, start and end dates, sender and recipient addresses, and message types. After the search is complete, authorized users can then select one of the following actions:

- **Estimate search results** This option returns an estimate of the total size and number of items that will be returned by the search based on the criteria you specified.
- **Preview search results** This option provides a preview of the results. Messages returned from each mailbox searched are displayed.
- **Copy search results** This option lets you copy messages to a discovery mailbox.
- **Export search results** After search results are copied to a discovery mailbox, you can export them to a PST file.



Exchange Search

In-Place eDiscovery uses the content indexes created by Exchange Search. Exchange Search has been retooled to use Microsoft Search Foundation, a rich search platform that comes with significantly improved indexing and querying performance and improved search functionality. Because the Microsoft Search Foundation is also used by other Office products, including SharePoint 2013, it offers greater interoperability and similar query syntax across these products.

With a single content indexing engine, no additional resources are used to crawl and index mailbox databases for In-Place eDiscovery when eDiscovery requests are received by IT departments.

In-Place eDiscovery uses Keyword Query Language (KQL), a querying syntax similar to the Advanced Query Syntax (AQS) used by Instant Search in Microsoft Outlook and Outlook Web App. Users familiar with KQL can easily construct powerful search queries to search content indexes.

For more information about the file formats indexed by Exchange search, see File formats indexed by Exchange Search.

Discovery Management role group and management roles

For authorized users to perform In-Place eDiscovery searches, you must add them to the Discovery Management role group. This role group consists of two management roles: the Mailbox Search role, which allows a user to perform an In-Place eDiscovery search, and the Legal Hold role, which allows a user to place a mailbox on In-Place Hold or litigation hold.

By default, permissions to perform In-Place eDiscovery-related tasks aren't assigned to any user or Exchange administrators. Exchange administrators who are members of the Organization Management role group can add users to the Discovery Management role group and create

custom role groups to narrow the scope of a discovery manager to a subset of users. To learn more about adding users to the Discovery Management role group, see Add a user to the Discovery Management role group.

Important:
If a user hasn't been added to the Discovery Management role group or isn't assigned the Mailbox Search role, the **In-Place eDiscovery & Hold** user interface isn't displayed in the EAC, and the In-Place eDiscovery cmdlets aren't available in the Exchange Management Shell.

Auditing of RBAC role changes, which is enabled by default, makes sure that adequate records are kept to track assignment of the Discovery Management role group. You can use the administrator role group report to search for changes made to administrator role groups. For more information, see Search the role group changes or administrator audit logs.

Return to top

Custom management scopes for In-Place eDiscovery

You can use a custom management scope to let specific people or groups use In-Place eDiscovery to search a subset of mailboxes in your Exchange 2013 or Exchange Online organization. For example, you might want to let a discovery manager search only the mailboxes of users in a specific location or department. You do this by creating a custom management scope that uses a custom recipient filter to control which mailboxes can be searched. Recipient filter scopes use filters to target specific recipients based on recipient type or other recipient properties.

For In-Place eDiscovery, the only property on a user mailbox that you can use to create a recipient filter for a custom scope is distribution group membership. If you use other properties, such as *CustomAttributeN*, *Department*, or *PostalCode*, the search fails when it's run by a member of the role group that's assigned the custom scope. For more information, see Create a custom management scope for In-Place eDiscovery searches.

Integration with SharePoint Server 2013 and SharePoint Online

Exchange 2013 and Exchange Online offer integration with SharePoint 2013 and SharePoint Online, allowing a discovery manager to use eDiscovery Center in SharePoint to perform the following tasks:

- **Search and preserve content from a single location** An authorized discovery manager can search and preserve content across SharePoint and Exchange, including Lync content such as instant messaging conversations and shared meeting documents archived in Exchange mailboxes.
- **Case management** eDiscovery Center uses a case management approach to eDiscovery, allowing you to create cases and search and preserve content across different content repositories for each case.

- **Export search results** A discovery manager can use eDiscovery Center to export search results. Mailbox content included in search results is exported to a PST file.

SharePoint also uses Microsoft Search Foundation for content indexing and querying. Regardless of whether a discovery manager uses the EAC or the eDiscovery Center to search Exchange content, the same mailbox content is returned.

In on-premises deployments, before you can use eDiscovery Center in SharePoint to search Exchange mailboxes, you must establish trust between the two applications. In Exchange 2013 and SharePoint 2013, this is done using OAuth authentication. For details, see Configure Exchange for SharePoint eDiscovery Center. eDiscovery searches performed from SharePoint are authorized by Exchange using RBAC. For a SharePoint user to be able to perform an eDiscovery search of Exchange mailboxes, they must be assigned delegated Discovery Management permission in Exchange. To be able to preview mailbox content returned in an eDiscovery search performed using SharePoint eDiscovery Center, the discovery manager must have a mailbox in the same Exchange organization.

For step-by step instructions for setting up an eDiscovery Center in an Office 365 organization, see Set up an eDiscovery Center in SharePoint Online.

eDiscovery in an Exchange hybrid deployment

To successfully perform cross-premises eDiscovery searches in an Exchange 2013 hybrid organization, you will have to configure OAuth (Open Authorization) authentication between your Exchange on-premises and Exchange Online organizations so that you can use In-Place eDiscovery to search on-premises and cloud-based mailboxes. OAuth authentication is a server-to-server authentication protocol that allows applications to authenticate to each other.

OAuth authentication supports the following eDiscovery scenarios in an Exchange hybrid deployment:

- Search on-premises mailboxes that use Exchange Online Archiving for cloud-based archive mailboxes.
- Search on-premises and cloud-based mailboxes in the same eDiscovery search.
- Search on-premises mailboxes by using the eDiscovery Center in SharePoint Online.

For more information about the eDiscovery scenarios that require OAuth authentication to be configured in an Exchange hybrid deployment, see Using OAuth authentication to support eDiscovery in an Exchange hybrid deployment. For step-by-step instructions for configuring OAuth authentication to support eDiscovery, see Configure OAuth authentication between Exchange and Exchange Online organizations.

Discovery mailboxes

After you create an In-Place eDiscovery search, you can copy the search results to a target mailbox. The EAC allows you to select a discovery mailbox as the target mailbox. A discovery mailbox is a

special type of mailbox that provides the following functionality:

- **Easier and secure target mailbox selection** When you use the EAC to copy In-Place eDiscovery search results, only discovery mailboxes are made available as a repository in which to store search results. You don't need to sort through a potentially long list of mailboxes available in the organization. This also eliminates the possibility of a discovery manager accidentally selecting another user's mailbox or an unsecured mailbox in which to store potentially sensitive messages.
- **Large mailbox storage quota** The target mailbox should be able to store a large amount of message data that may be returned by an In-Place eDiscovery search. By default, discovery mailboxes have a mailbox storage quota of 50 gigabytes (GB). This storage quota can’t be increased.
- **More secure by default** Like all mailbox types, a discovery mailbox has an associated Active Directory user account. However, this account is disabled by default. Only users explicitly authorized to access a discovery mailbox have access to it. Members of the Discovery Management role group are assigned Full Access permissions to the default discovery mailbox. Any additional discovery mailboxes you create don't have mailbox access permissions assigned to any user.
- **Email delivery disabled** Although visible in Exchange address lists, users can't send email to a discovery mailbox. Email delivery to discovery mailboxes is prohibited by using delivery restrictions. This preserves the integrity of search results copied to a discovery mailbox.

Exchange 2013 Setup creates one discovery mailbox with the display name **Discovery Search Mailbox**. You can use the Shell to create additional discovery mailboxes. By default, the discovery mailboxes you create won't have any mailbox access permissions assigned. You can assign Full Access permissions for a discovery manager to access messages copied to a discovery mailbox. For details, see Create a discovery mailbox.

In-Place eDiscovery also uses a system mailbox with the display name **SystemMailbox{e0dc1c29-89c3-4034-b678-e6c29d823ed9}** to hold In-Place eDiscovery metadata. System mailboxes aren't visible in the EAC or in Exchange address lists. In on-premises organizations, before removing a mailbox database where the In-Place eDiscovery system mailbox is located, you must move the mailbox to another mailbox database. If the mailbox is removed or corrupted, your discovery managers are unable to perform eDiscovery searches until you re-create the mailbox. For details, see Re-create the Discovery system mailbox.

Return to top

Using In-Place eDiscovery

Users who have been added to the Discovery Management role group can perform In-Place eDiscovery searches. You can perform a search using the web-based interface in the EAC. This makes it easier for non-technical users such as records managers, compliance officers, or legal and HR professionals to use In-Place eDiscovery. You can also use the Shell to perform a search. For more information, see Create an In-Place eDiscovery search

Note:

In on-premises organizations, you can use In-Place eDiscovery to search mailboxes located on Exchange 2013 Mailbox servers. To search mailboxes located on Exchange 2010 Mailbox servers, use Multi-Mailbox Search on an Exchange 2010 server.
In a hybrid deployment, which is an environment where some mailboxes exist on your on-premises Mailbox servers and some mailboxes exist in a cloud-based organization, you can perform In-Place eDiscovery searches of your cloud-based mailboxes using the EAC in your on-premises organization. If you intend to copy messages to a discovery mailbox, you must select an on-premises discovery mailbox. Messages from cloud-based mailboxes that are returned in search results are copied to the specified on-premises discovery mailbox. To learn more about hybrid deployments, see **Exchange Server 2013 Hybrid Deployments**.

The **In-Place eDiscovery & Hold** wizard in the EAC allows you to create an In-Place eDiscovery search and also use In-Place Hold to place search results on hold. When you create an In-Place eDiscovery search, a search object is created in the In-Place eDiscovery system mailbox. This object can be manipulated to start, stop, modify, and remove the search. After you create the search, you can choose to get an estimate of search results, which includes keyword statistics that help you determine query effectiveness. You can also do a live preview of items returned in the search, allowing you to view message content, the number of messages returned from each source mailbox and the total number of messages. You can use this information to further fine-tune your query if required.

When satisfied with the search results, you can copy them to a discovery mailbox. You can also use the EAC or Outlook to export a discovery mailbox or some of its content to a PST file.

When creating an In-Place eDiscovery search, you must specify the following parameters:

- **Name** The search name is used to identify the search. When you copy search results to a discovery mailbox, a folder is created in the discovery mailbox using the search name and the timestamp to uniquely identify search results in a discovery mailbox.
- **Mailboxes** You can choose to search all mailboxes in your Exchange 2013 organization or specify the mailboxes to search. If you also want to use the same search to place items on hold, you must specify the mailboxes. You can specify a distribution group to include mailbox users who are members of that group. Membership of the group is calculated once when creating the search and subsequent changes to group membership are not automatically reflected in the search. A user's primary and archive mailboxes are included in the search.
- **Search query** You can either include all mailbox content from the specified mailboxes or use a search query to return items that are more relevant to the case or investigation. You can specify the following parameters in a search query:
  - **Keywords** You can specify keywords and phrases to search message content. You can also use the logical operators **AND**, **OR**, and **NOT**. Additionally, Exchange 2013 also supports the **NEAR** operator, allowing you to search for a word or phrase that's in proximity to another word or phrase.

To search for an exact match of a multiple word phrase, you must enclose the phrase in quotation marks. For example, searching for the phrase “plan and competition” returns messages that contain an exact match of the phrase, whereas specifying **plan AND competition** returns messages that

contain the words **plan** and **competition** anywhere in the message.

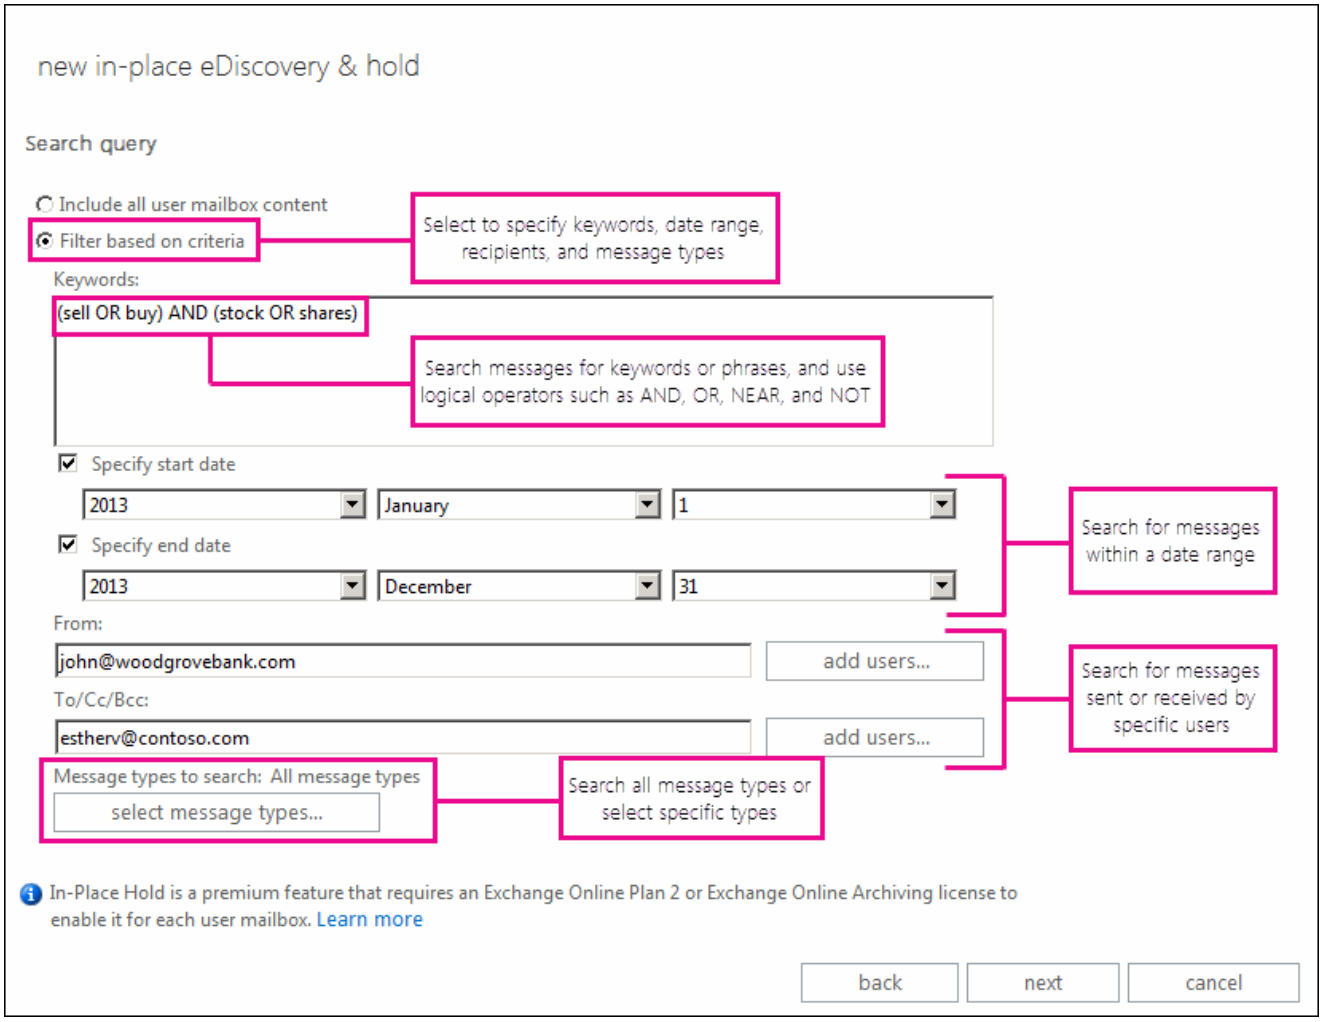
Exchange 2013 also supports the Keyword Query Language (KQL) syntax for In-Place eDiscovery searches.

Note:
In-Place eDiscovery does not support regular expressions.

You must capitalize logical operators such as **AND** and **OR** for them to be treated as operators instead of keywords. We recommend that you use explicit parenthesis for any query that mixes multiple logical operators to avoid mistakes or misinterpretations. For example, if you want to search for messages that contain either WordA or WordB AND either WordC or WordD, you must use **(WordA OR WordB) AND (WordC OR WordD)**.

- **Start and End dates** By default, In-Place eDiscovery doesn't limit searches by a date range. To search messages sent during a specific date range, you can narrow the search by specifying the start and end dates. If you don't specify an end date, the search will return the latest results every time you restart it.
- **Senders and recipients** To narrow down the search, you can specify the senders or recipients of messages. You can use email addresses, display names, or the name of a domain to search for items sent to or from everyone in the domain. For example, to find email sent by or sent to anyone at Contoso, Ltd, specify **@contoso.com** in the **From** or the **To/cc** field in the EAC. You can also specify **@contoso.com** in the *Senders* or *Recipients* parameters in the Shell.
- **Message types** By default, all message types are searched. You can restrict the search by selecting specific message types such as email, contacts, documents, journal, meetings, notes and Lync content.

The following screenshot shows an example of a search query in the EAC.



When using In-Place eDiscovery, also consider the following:

- **Attachments** In-Place eDiscovery searches attachments supported by Exchange Search. For details, see File formats indexed by Exchange Search. In on-premises deployments, you can add support for additional file types by installing search filters (also known as an iFilter) for the file type on Mailbox servers.
- **Unsearchable items** Unsearchable items are mailbox items that can't be indexed by Exchange Search. Reasons they can't be indexed include the lack of an installed search filter for an attached file, a filter error, and encrypted messages. For a successful eDiscovery search, your organization may be required to include such items for review. When copying search results to a discovery mailbox or exporting them to a PST file, you can include unsearchable items. For more information, see Unsearchable items in Exchange eDiscovery.
- **Encrypted items** Because messages encrypted using S/MIME aren't indexed by Exchange Search, In-Place eDiscovery doesn't search these messages. If you select the option to include unsearchable items in search results, these S/MIME encrypted messages are copied to the discovery mailbox.
- **IRM-protected items** Messages protected using Information Rights Management (IRM) are indexed by Exchange Search and therefore included in the search results if they match query parameters. Messages must be protected by using an Active Directory Rights Management Services (AD RMS) cluster in the same Active Directory forest as the Mailbox server. For more information, see Information Rights Management.

Important:

When Exchange Search fails to index an IRM-protected message, either due to a decryption failure or because IRM is disabled, the protected message isn't added to the list of failed items. If you select the option to include unsearchable items in search results, the results may not include IRM-protected messages that could not be decrypted.

To include IRM-protected messages in a search, you can create another search to include messages with .rpmsg attachments. You can use the query string `attachment:rpmsg` to search all IRM-protected messages in the specified mailboxes, whether successfully indexed or not. This may result in some duplication of search results in scenarios where one search returns messages that match the search criteria, including IRM-protected messages that have been indexed successfully. The search doesn't return IRM-protected messages that couldn't be indexed.

Performing a second search for all IRM-protected messages also includes the IRM-protected messages that were successfully indexed and returned in the first search. Additionally, the IRM-protected messages returned by the second search may not match the search criteria such as keywords used for the first search.

- **De-duplication** When copying search results to a discovery mailbox, you can enable *de-duplication* of search results to copy only one instance of a unique message to the discovery mailbox. De-duplication has the following benefits:
  - Lower storage requirement and smaller discovery mailbox size due to reduced number of messages copied.
  - Reduced workload for discovery managers, legal counsel, or others involved in reviewing search results.
  - Reduced cost of eDiscovery, depending on the number of duplicate items excluded from search results.

Return to top

Estimate, preview, and copy search results

After an In-Place eDiscovery search is completed, you can view search result estimates in the Details pane in the EAC. The estimate includes number of items returned and total size of those items. You can also view keyword statistics, which returns details about number of items returned for each keyword used in the search query. This information is helpful in determining query effectiveness. If the query is too broad, it may return a much bigger data set, which could require more resources to review and raise eDiscovery costs. If the query is too narrow, it may significantly reduce the number of records returned or return no records at all. You can use the estimates and keyword statistics to fine-tune the query to meet your requirements.

Note:

In Exchange 2013, keyword statistics also include statistics for non-keyword properties such as dates, message types, and senders/recipients specified in a search query.

You can also preview the search results to further ensure that messages returned contain the content you're searching for and further fine-tune the query if required. eDiscovery Search Preview

displays the number of messages returned from each mailbox searched and the total number of messages returned by the search. The preview is generated quickly without requiring you to copy messages to a discovery mailbox.

After you're satisfied with the quantity and quality of search results, you can copy them to a discovery mailbox. When copying messages, you have the following options:

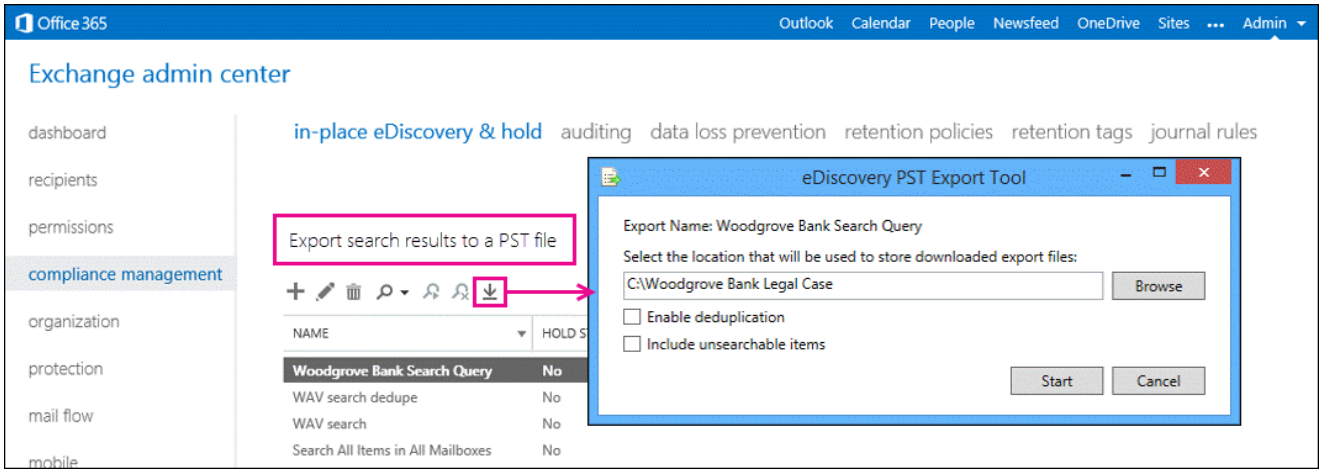
- **Include unsearchable items** For details about the types of items that are considered unsearchable, see the eDiscovery search considerations in the previous section.
- **Enable de-duplication** De-duplication reduces the dataset by only including a single instance of a unique record if multiple instances are found in one or more mailboxes searched.
- **Enable full logging** By default, only basic logging is enabled when copying items. You can select full logging to include information about all records returned by the search.
- **Send me mail when the copy is completed** An In-Place eDiscovery search can potentially return a large number of records. Copying the messages returned to a discovery mailbox can take a long time. Use this option to get an email notification when the copying process is completed. For easier access using Outlook Web App, the notification includes a link to the location in a discovery mailbox where the messages are copied.

For more information, see Copy eDiscovery search results to a discovery mailbox.

Return to top

Export search results to a PST file

After search results are copied to a discovery mailbox, you can export the search results to a PST file.



After search results are exported to a PST file, you or other users can open them in Outlook to review or print messages returned in the search results. For more information, see Export eDiscovery search results to a PST file.

Different search results

Because In-Place eDiscovery performs searches on live data, it's possible that two searches of the

same content sources and using the same search query can return different results. Estimated search results can also be different from the actual search results that are copied to a discovery mailbox. This can happen even when rerunning the same search within a short amount of time. There are several factors that can affect the consistency of search results:

- The continual indexing of incoming email because Exchange Search continuously crawls and indexes your organization's mailbox databases and transport pipeline.
- Deletion of email by users or automated processes.
- Bulk importing large amounts of email, which takes time to index.

If you do experience dissimilar results for the same search, consider placing mailboxes on hold to preserve content, running searches during off-peak hours, and allowing time for indexing after importing large amounts of email.

Logging for In-Place eDiscovery searches

There are two types of logging available for In-Place eDiscovery searches:

- **Basic logging** Basic logging is enabled by default for all In-Place eDiscovery searches. It includes information about the search and who performed it. Information captured about basic logging appears in the body of the email message sent to the mailbox where the search results are stored. The message is located in the folder created to store search results.
- **Full logging** Full logging includes information about all messages returned by the search. This information is provided in a comma-separated value (.csv) file attached to the email message that contains the basic logging information. The name of the search is used for the .csv file name. This information may be required for compliance or record-keeping purposes. To enable full logging, you must select the **Enable full logging** option when copying search results to a discovery mailbox in the EAC. If you're using the Shell, specify the full logging option using the *LogLevel* parameter.

Note:
When using the Shell to create or modify an In-Place eDiscovery search, you can also disable logging.

Besides the search log included when copying search results to a discovery mailbox, Exchange also logs cmdlets used by the EAC or the Shell to create, modify or remove In-Place eDiscovery searches. This information is logged in the admin audit log entries. For details, see Administrator audit logging.

Return to top

In-Place eDiscovery and In-Place Hold

As part of eDiscovery requests, you may be required to preserve mailbox content until a lawsuit or investigation is disposed. Messages deleted or altered by the mailbox user or any processes must also be preserved. In Exchange 2013, this is accomplished by using In-Place Hold. For details, see

In-Place Hold.

In Exchange 2013, you can use the new **In-Place eDiscovery & Hold** wizard to search items and preserve them for as long as they're required for eDiscovery or to meet other business requirements. When using the same search for both In-Place eDiscovery and In-Place Hold, be aware of the following:

- You can't use the option to search all mailboxes. You must select the mailboxes or distribution groups.
- You can't remove an In-Place eDiscovery search if the search is also used for In-Place Hold. You must first disable the In-Place Hold option in a search and then remove the search.

Preserving mailboxes for In-Place eDiscovery

When an employee leaves an organization, it's a common practice to disable or remove the mailbox. After you disable a mailbox, it is disconnected from the user account but remains in the mailbox for a certain period, 30 days by default. The Managed Folder Assistant does not process disconnected mailboxes and any retention policies are not applied during this period. You can't search content of a disconnected mailbox. Upon reaching the deleted mailbox retention period configured for the mailbox database, the mailbox is purged from the mailbox database.

Important:
In Exchange Online, In-Place eDiscovery can search content in inactive mailboxes. Inactive mailboxes are mailboxes that are placed on In-Place Hold or litigation hold and then removed. Inactive mailboxes are preserved as long as they’re placed on hold. When an inactive mailbox is removed from In-Place Hold or when litigation hold is disabled, it is permanently deleted. For details, see **Manage inactive mailboxes in Exchange Online**.

In on-premises deployments, if your organization requires that retention settings be applied to messages of employees who are no longer in the organization or if you may need to retain an ex-employee's mailbox for an ongoing or future eDiscovery search, do not disable or remove the mailbox. You can take the following steps to ensure the mailbox can't be accessed and no new messages are delivered to it.

1. Disable the Active Directory user account using **Active Directory Users & Computers** or other Active Directory or account provisioning tools or scripts. This prevents mailbox logon using the associated user account.

Important:
Users with Full Access mailbox permission will still be able to access the mailbox. To prevent access by others, you must remove their Full Access permission from the mailbox. For information about how to remove Full Access mailbox permissions on a mailbox, see Manage Permissions for Recipients.

2. Set the message size limit for messages that can be sent from or received by the mailbox user to a very low value, 1 KB for example. This prevents delivery of new mail to and from the mailbox. For details, see Configure message size limits for a mailbox.
3. Configure delivery restrictions for the mailbox so nobody can send messages to it. For details,

see Configure message delivery restrictions for a mailbox.

Important:
You must take the above steps along with any other account management processes required by your organization, but without disabling or removing the mailbox or removing the associated user account.

When planning to implement mailbox retention for messaging retention management (MRM) or In-Place eDiscovery, you must take employee turnover into consideration. Long-term retention of ex-employee mailboxes will require additional storage on Mailbox servers and also result in an increase in Active Directory database because it requires that the associated user account be retained for the same duration. Additionally, it may also require changes to your organization's account provisioning and management processes.

Return to top

In-Place eDiscovery limits and throttling policies

In Exchange 2013 and Exchange Online, the resources In-Place eDiscovery can consume are controlled using throttling policies.

The default throttling policy contains the following throttling parameters.

Parameter	Description	Default value
DiscoveryMaxConcurrency	The maximum number of In-Place eDiscovery searches a user can perform concurrently.	2
DiscoveryMaxMailboxes	The maximum number of mailboxes that can be searched in a single In-Place eDiscovery search.	Exchange Online: 10,000[1] Exchange 2013: 5,000
DiscoveryMaxStatsSearchMailboxes	The maximum number of mailboxes that can be searched in a single In-Place eDiscovery search that still allows you to view keyword statistics.	100 **Note:** After you run an eDiscovery search estimate, you can view keyword statistics. These statistics show details about the number of items returned for each keyword used in the search query. If more than 100 source mailboxes are included in the search, an error will be

		returned if you try to view keyword statistics.
DiscoveryMaxKeywords	The maximum number of keywords that can be specified in a single In-Place eDiscovery search.	500
DiscoveryMaxSearchResultsPageSize	The maximum number of items displayed on a single page when previewing In-Place eDiscovery search results.	200
DiscoverySearchTimeoutPeriod	The number of minutes that an In-Place eDiscovery search will run before it times out.	10 minutes

Note:

[1] If you initiate an eDiscovery search from the eDiscovery Center in SharePoint Online in an Office 365 organization, you can search a maximum of 1,500 mailboxes in a single search.

In Exchange Server 2013, you can change the default values for these parameters to suit your requirements or create additional throttling policies and assign them to users with delegated Discovery Management permission. In Exchange Online, the default values for these throttling parameters can't be changed.

In-Place eDiscovery documentation

The following table contains links to topics that will help you learn about and manage In-Place eDiscovery.

Topic	Description
Add a user to the Discovery Management role group	Learn how to give a user access to use In-Place eDiscovery in the EAC to search Exchange mailboxes. Adding a user to the Discovery Management role group also allows the person to use the eDiscovery Center in SharePoint 2013 and SharePoint Online to search Exchange mailboxes.

Create a discovery mailbox	Learn how to use the Shell to create a discovery mailbox and assign access permissions.
Create an In-Place eDiscovery search	Learn how to create an In-Place eDiscovery search, and how to estimate and preview eDiscovery search results.
Message properties and search operators for In-Place eDiscovery	Learn which email message properties can be searched using In-Place eDiscovery. The topic provides syntax examples for each property, information about search operators such as **AND** and **OR**, and information about other search query techniques such as using double quotation marks (" ") and prefix wildcards.
Search limits for In-Place eDiscovery in Exchange Online	Learn In-Place eDiscovery limits in Exchange Online that help maintain the health and quality of eDiscovery services for Office 365 organizations.
Start or stop an In-Place eDiscovery search	Learn how to start, stop, and restart eDiscovery searches.
Modify an In-Place eDiscovery search	Learn how to modify an existing eDiscovery search.
Copy eDiscovery search results to a discovery mailbox	Learn how to copy the results of an eDiscovery search to a discovery mailbox.
Export eDiscovery search results to a PST file	Learn how to export the results of an eDiscovery search to a PST file.
Create a custom management scope for In-Place eDiscovery searches	Learn how to use custom management scopes to limit the mailboxes that a discovery manager can search.

Remove an In-Place eDiscovery search	Learn how to delete an eDiscovery search.
Search and delete messages	Learn how to use the **Search-Mailbox** cmdlet to search for and then delete email messages.
Reduce the size of a discovery mailbox in Exchange	Use this process to reduce the size of a discovery mailbox that's larger than 50 GB.
Delete and re-create the default discovery mailbox in Exchange	Learn how to delete the default discovery mailbox, re-create it, and then reassign permissions to it. Use this procedure if this mailbox has exceeded the 50 GB limit and you don't need the search results.
Re-create the Discovery system mailbox	Learn how to recreate the discovery system mailbox. This task is applicable only to Exchange 2013 organizations.
Using OAuth authentication to support eDiscovery in an Exchange hybrid deployment	Learn about the eDiscovery scenarios in an Exchange hybrid deployment that require you to configure OAuth authentication.
Configure Exchange for SharePoint eDiscovery Center	Learn how to configure Exchange 2013 so that you can use the eDiscovery Center in SharePoint 2013 to search Exchange mailboxes.
Unsearchable items in Exchange eDiscovery	Learn about mailbox items that can't be indexed by Exchange Search and are returned in eDiscovery search results as unsearchable items.

For more information about eDiscovery in Office 365, Exchange 2013, SharePoint 2013, and Lync 2013, see the eDiscovery FAQ.

Return to top

Message properties and search operators for In-Place eDiscovery

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-08-05*

This topic describes the properties of Exchange Exchange email messages that you can search by using In-Place eDiscovery & Hold in Exchange Server 2013 and Exchange Online. The topic also describes Boolean search operators and other search query techniques that you can use to refine eDiscovery search results.

In-Place eDiscovery uses Keyword Query Language (KQL). For more details, see Keyword Query Language syntax reference.

Searchable properties in Exchange

The following table lists email message properties that can be searched using an In-Place eDiscovery search or by using the **New-MailboxSearch** or the **Set-MailboxSearch** cmdlet. The table includes an example of the *property:value* syntax for each property and a description of the search results returned by the examples.

Property	Property description	Examples	Search results returned by the examples
Attachment	The names of files attached to an email message.	attachment:annualreport.ppt attachment:annual*	Messages that have an attached file named annualreport.ppt. In the second example, using the wildcard returns messages with the word "annual" in the file name of an attachment.
Bcc	The BCC field of an email message.[1]	bcc:pilarp@contoso.com	All examples return messages with Pilar

		bcc:pilarp bcc:"Pilar Pinilla"	Pinilla included in the Bcc field.
Body	Text in the body of an email message.	body:"Northwind Traders" body:north*	Messages with the exact phrase "Northwind Traders" in the body of the message. The second example returns any message that contains words that begin with the string "north", such as north, northwind, or northern.
Category	The categories to search. Categories can be defined by users by using Outlook or Outlook Web App. The possible values are: • blue • green • orange • purple • red • yellow	category:"Red Category"	Messages that have been assigned the red category in the source mailboxes.
Cc	The CC field of an email message.[1]	cc:pilarp@contoso.com cc:"Pilar Pinilla"	In both examples, messages with Pilar Pinilla specified in the CC field.
From	The sender of an email message.[1]	from:pilarp@contoso.com	Messages sent by the specified user or sent

		from:contoso.com	from a specified domain.
Importance	The importance of an email message, which a sender can specify when sending a message. By default, messages are sent with normal importance, unless the sender sets the importance as **high** or **low**.	importance:high importance:medium importance:low	Messages that are marked as high importance, medium importance, or low importance.
Kind	The message type to search. Possible values: • contacts • docs • email • faxes • im • journals • meetings • notes • posts • rssfeeds • tasks • voicemail	kind:email kind:email OR kind:im OR kind:voicemail	Email messages that meet the search criteria. The second example returns email messages, instant messaging conversations, and voice messages that meet the search criteria.
Participants	All the people fields in an email message; these fields are From, To, CC, and BCC.[1]	participants:garthf@contoso.com participants:contoso.com	Messages sent by or sent to garthf@contoso.com. The second example returns all messages sent by or sent to a

			user in the contoso.com domain.
Received	The date that an email message was received by a recipient.	received:04/15/2014 received>=01/01/2014 AND received<=03/31/2014	Messages that were received on April 15, 2014. The second example returns all messages received between January 1, 2014 and March 31, 2014.
Recipients	All recipient fields in an email message; these fields are To, CC, and BCC.[1]	recipients:garthf@contoso.com recipients:contoso.com	Messages sent to garthf@contoso.com. The second example returns messages sent to any recipient in the contoso.com domain.
Sent	The date that an email message was sent by the sender.	sent:07/01/2014 sent>=06/01/2014 AND sent<=07/01/2014	Messages that were sent on the specified date or sent within the specified date range.
Size	The size of an item, in bytes.	size>2621440 Size:1..50000	Messages larger than 25 MB. The second example returns messages from 1 through 50,000 bytes in size.
Subject	The text in the subject line of an email message.	subject:"Quarterly Financials" subject:northwind	Messages that contain the exact phrase "Quarterly Financials" in the subject line.

			The second example returns all messages that contain the word northwind in the subject line.
To	The To field of an email message.[1]	to:annb@contoso.com to:annb to:"Ann Beebe"	All examples return messages where Ann Beebe is specified in the To: line.

Note:

[1] For the value of a recipient property, you can use the SMTP address, display name, or alias to specify a user. For example, you can use annb@contoso.com, annb, or "Ann Beebe" to specify the user Ann Beebe.

Supported search operators

Boolean search operators, such as **AND**, **OR**, and **NOT**, help you define more-precise mailbox searches by including or excluding specific words in the search query. Other techniques, such as using property operators (such as >= or ..), quotation marks, parentheses, and wildcards, help you refine eDiscovery search queries. The following table lists the operators that you can use to narrow or broaden search results.

Operator	Usage	Description
AND	keyword1 AND keyword2	Returns messages that include all of the specified keywords or `property:value` expressions.
+	keyword1 + keyword2	The same as the **AND** operator.
OR	keyword1 OR keyword2	Returns messages that include one or more of the specified keywords or `property:value` expressions.
NOT	keyword1 NOT keyword2	Excludes messages specified by

	NOT from:"Ann Beebe"	a keyword or a `property:value` expression. For example, `NOT from:"Ann Beebe"` excludes messages sent by Ann Beebe.
-	keyword1 -keyword2	The same as the **NOT** operator.
NEAR	keyword1 NEAR(n) keyword2	Returns messages with words that are near each other, where n equals the number of words apart. For example, `best NEAR(5) worst` returns messages where the word "worst" is within five words of "best". If no number is specified, the default distance is eight words.
:	property:value	The colon (:) in the `property:value` syntax specifies that the property value being searched for equals the specified value. For example, `recipients:garthf@contoso.com` returns any message sent to garthf@contoso.com.
=	property=value	The same as using the `property:value` syntax.
<	property<value	Denotes that the property being searched is less than the specified value. [1]

>	property>value	Denotes that the property being searched is greater than the specified value.[1]
<=	property<=value	Denotes that the property being searched is less than or equal to a specific value.[1]
>=	property>=value	Denotes that the property being searched is greater than or equal to a specific value.[1]
..	property:value1..value2	Denotes that the property being searched is greater than or equal to value1 and less than or equal to value2.[1]
" "	"fair value" subject:"Quarterly Financials"	Use double quotation marks (" ") to search for an exact phrase or term in keyword and `property:value` search queries.
*	cat* subject:set*	Prefix wildcard searches (where the asterisk is placed at the end of a word) match for zero or more characters in keywords or `property:value` queries. For example, `subject:set*` returns messages that contain the word set, setup, and setting (and other words that start with "set") in the subject line.
( )	(fair OR free) AND	Parentheses group together

	from:contoso.com (IPO OR initial) AND (stock OR shares) (quarterly financials)	Boolean phrases, `property:value` items, and keywords. For example, `(quarterly financials)` returns items that contain the words quarterly and financials.

Note:

[1] Use this operator for properties that have date or numeric values.

Search tips and tricks

- Keyword searches are not case sensitive. For example, **cat** and **CAT** return the same results.
- The Boolean operators **AND**, **OR**, **NOT**, and **NEAR** must be uppercase.
- A space between two keywords or two `property:value` expressions is the same as using **AND**. For example, `from:"Sara Davis" subject:reorganization` returns all messages sent by Sara Davis that contain the word **reorganization** in the subject line.
- Use syntax that matches the `property:value` format. Values are not case-sensitive, and they can't have a space after the operator. If there is a space, your intended value will just be full-text searched. For example **to: pilarp** searches for "pilarp" as a keyword, rather than for messages that were sent to pilarp.
- When searching a recipient property, such as To, From, Cc, or Recipients, you can use an SMTP address, alias, or display name to denote a recipient. For example, you can use pilarp@contoso.com, pilarp, or "Pilar Pinilla".
- You can use only prefix wildcard searches—for example, **cat*** or **set***. Suffix wildcard searches (*cat) or substring wildcard searches (*cat*) aren't supported.
- When searching a property, use double quotation marks (" ") if the search value consists of multiple words. For example **subject:budget Q1** returns messages that contain **budget** in the in the subject line and that contain **Q1** anywhere in the message or in any of the message properties. Using **subject:"budget Q1"** returns all messages that contain **budget Q1** in the subject line.

Add a user to the Discovery Management role group

Exchange Server 2013 > Messaging policy and compliance > In-Place eDiscovery >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-12*

If you want users to be able to use Microsoft Exchange Server 2013 In-Place eDiscovery, you must first authorize them by adding them to the Discovery Management role group. Members of the Discovery Management role group have Full Access mailbox permissions for the Discovery mailbox that's created by Exchange Setup.

Caution:

Members of the Discovery Management role group can access sensitive message content. Specifically, these members can use In-Place eDiscovery to search all mailboxes in your Exchange organization, preview messages (and other mailbox items), copy them to a Discovery mailbox and export the copied messages to a .pst file. In most organizations, this permission is granted to legal, compliance, or Human Resources personnel.

To learn more about the Discovery Management role group, see Discovery Management. To learn more about Role Based Access Control (RBAC), see Understanding Role Based Access Control.

Interested in scenarios where this procedure is used? See the following topics:

- Create an In-Place eDiscovery search
- Create or remove an In-Place Hold

What do you need to know before you begin?

- Estimated time to complete: 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Role groups" entry in the Role management permissions topic.
- By default, the Discovery Management role group doesn't contain any members. Administrators with the Organization Management role are also unable to create or manage discovery searches without being added to the Discovery Management role group.
- In Exchange 2013, members of the Organization Management role group can create an In-Place Hold to place all mailbox content on hold. However, to create a query-based In-Place Hold, the user must be a member of the Discovery Management role group or have the Mailbox Search role assigned.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Use the EAC to add a user to the Discovery Management role group

1. Navigate to **Permissions** > **Admin roles**.
2. In the list view, select **Discovery Management** and then click **Edit**
3. In **Role Group**, under **Members**, click **Add +**.
4. In **Select Members**, select one or more users, click **Add**, and then click **OK**.

5. In **Role Group**, click **Save**.

Use the Shell to add a user to the Discovery Management role group

This example adds the user Bsuneja to the Discovery Management role group.

```
Add-RoleGroupMember -Identity "Discovery Management" -
Member Bsuneja
```

For detailed syntax and parameter information, see Add-RoleGroupMember.

How do you know this worked?

To verify that you've added the user to the Discovery Management role group, do the following:

1. Navigate to **Permissions** > **Admin roles**.
2. In the list view, select **Discovery Management**.
3. In the details pane, verify that the user is listed under **Members**.

You can also run this command to list the members of the Discovery Management role group.

```
Get-RoleGroupMember -Identity "Discovery Management"
```

Tip:

Create a discovery mailbox

Exchange Server 2013 > Messaging policy and compliance > In-Place eDiscovery >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-04-21*

Microsoft Exchange Server 2013 Setup creates a discovery mailbox by default. In Exchange Online, a discovery mailbox is also created by default. Discovery mailboxes are used as target mailboxes for In-Place eDiscovery searches in the Exchange Admin Center (EAC). You can create additional discovery mailboxes as required. After you create a new discovery mailbox, you will have to assign Full Access permissions to the appropriate users so they can access eDiscovery search results that are copied to the discovery mailbox.

Caution:

After a discovery manager copies the results of an eDiscovery search to a discovery mailbox, the mailbox can potentially contain sensitive information. You should control access to discovery mailboxes and make sure only authorized users can access them.

For more information, see Discovery mailboxes.

What do you need to know before you begin?

- Estimated time to complete: 3 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Creating discovery mailboxes" entry in Messaging policy and compliance permissions topic.
- Discovery mailboxes have a mailbox storage quota of 50 gigabytes (GB). This storage quota can't be increased.
- You can't use the EAC to create a discovery mailbox or assign permissions to access it. You have to use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Create a discovery mailbox

This example creates a discovery mailbox named SearchResults.

```
New-Mailbox -Name SearchResults -Discovery
```

For detailed syntax and parameter information, see New-Mailbox.

To display a list of all discovery mailboxes in an Exchange organization, run the following command:

```
Get-Mailbox -Resultsize unlimited -Filter
{RecipientTypeDetails -eq "DiscoveryMailbox"}
```

For detailed syntax and parameter information, see Get-Mailbox.

Assign permissions to a discovery mailbox

You have to explicitly assign users or groups the necessary permissions to open a discovery mailbox

that you've created. Run the following command to assign a user or group permissions to open a discovery mailbox and view search results:

```
Add-MailboxPermission <Name of the discovery mailbox> -User
<Name of user or group> -AccessRights FullAccess -
InheritanceType all
```

For example, the following command assigns the Full Access permission to the Litigation Managers group, so members of the group can open the Fabrikam Litigation discovery mailbox.

```
Add-MailboxPermission "Fabrikam Litigation" -User
"Litigation Managers" -AccessRights FullAccess -
InheritanceType all
```

For detailed syntax and parameter information, see Add-MailboxPermission.

More information

- By default, members of the Discovery Management role group only have Full Access permission to the default Discovery Search Mailbox. You will have to explicitly assign the Full Access permission to the Discovery Management role group if you want members to open a discovery mailbox that you've created.
- Although visible in Exchange address lists, users can't send email to a discovery mailbox. Email delivery to discovery mailboxes is prohibited with delivery restrictions. This preserves the integrity of search results copied to a discovery mailbox.
- A discovery mailbox can't be repurposed or converted to another type of mailbox.
- You can remove a discovery mailbox as you would any other type of mailbox.

Create an In-Place eDiscovery search

Exchange Server 2013 > Messaging policy and compliance > In-Place eDiscovery >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-08-27*

Use In-Place eDiscovery to search across all mailbox content, including deleted items and original versions of modified items for users placed on In-Place Hold.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To

see what permissions you need, see the "In-Place eDiscovery" entry in the Messaging policy and compliance permissions topic.

- To create eDiscovery searches, you have to have an SMTP address in the organization that you're creating the searches in. So in Exchange Online, you must have a licensed Exchange Online mailbox to create eDiscovery searches. In an Exchange hybrid organization, your on-premises Exchange mailbox must have a corresponding mail user account in your Office 365 organization so that you can search Exchange Online mailboxes. Or, if you sign in with an account that only exists in Office 365, such as the tenant administrator account, that account must be assigned an Exchange Online license.
- Exchange 2013 Setup creates a Discovery mailbox called **Discovery Search Mailbox** to copy search results. The Discovery Search Mailbox is also created by default in Exchange Online. You can create additional Discovery mailboxes. For details, see Create a discovery mailbox.
- When you create an In-Place eDiscovery search, messages returned in search results aren't copied automatically to a discovery mailbox. After you create the search, you can use the Exchange Admin Center (EAC) to estimate and preview search results or copy them to a discovery mailbox. For details, see:
  - Estimate or preview search results (later in this topic)
  - Copy eDiscovery search results to a discovery mailbox
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Create an In-Place eDiscovery search

Use the EAC to create an In-Place eDiscovery search

As previously explained, to create eDiscovery searches, you have to sign in to a user account that has an SMTP address in your organization.

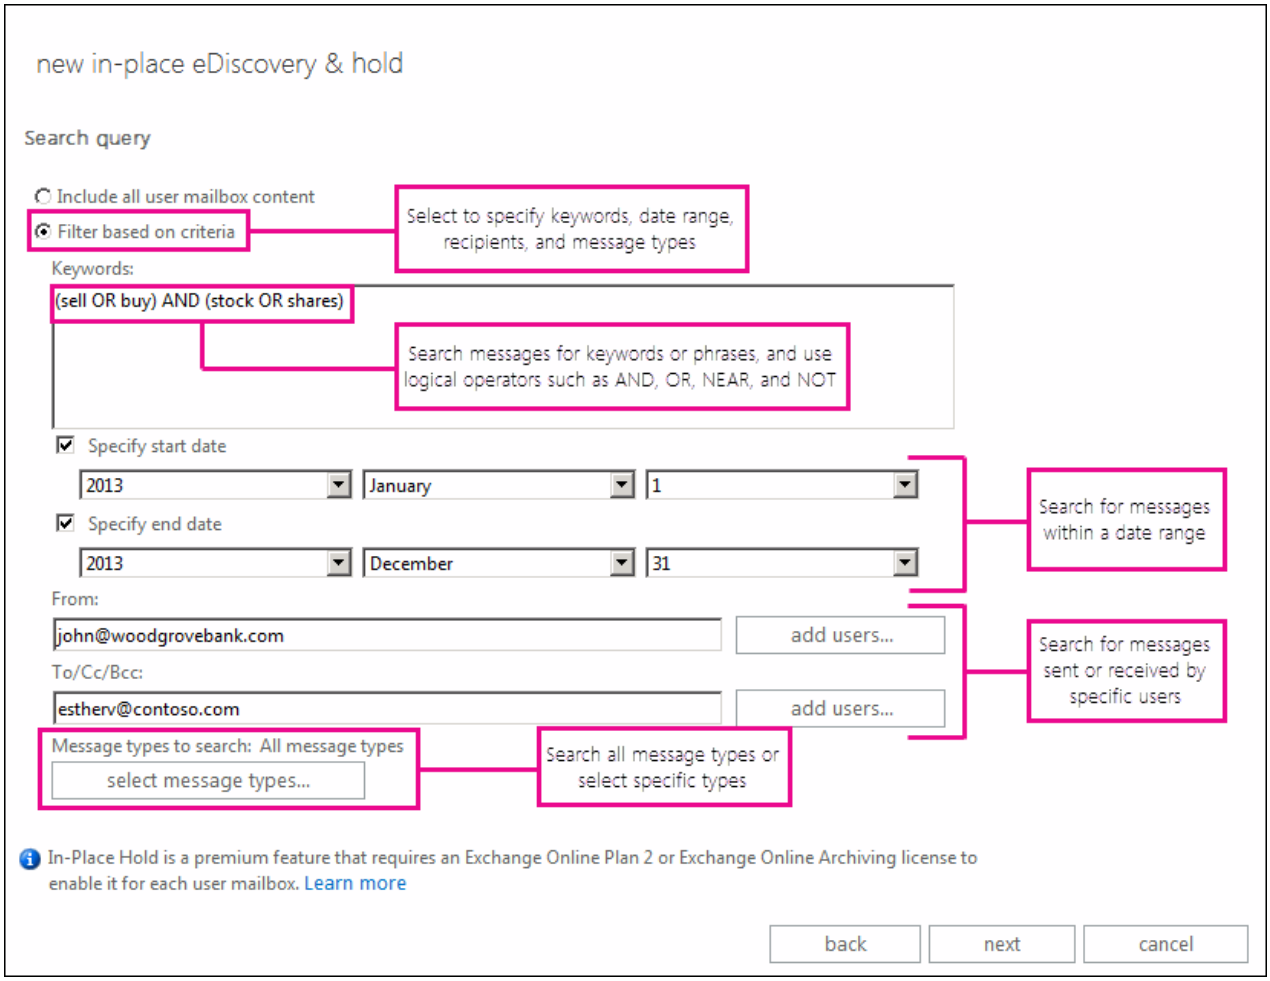
1. Go to **Compliance management** > **In-place eDiscovery & hold**.
2. Click **New +**.
3. In **In-Place eDiscovery & Hold**, on the **Name and description** page, type a name for the search, add an optional description, and then click **Next**.
4. On the **Mailboxes** page, select the mailboxes to search. You can search across all mailboxes or select specific ones to search.

Important:

You can't use the **Search all mailboxes** option to place all mailboxes on hold. To create an In-Place Hold, you must select **Specify mailboxes to search**. For more details, see Create or

remove an In-Place Hold.

5. On the **Search query** page, complete the following fields:
   - **Include all user mailbox content** Select this option to place all content in the selected mailboxes on hold. If you select this option, you can't specify additional search criteria.
   - **Filter based on criteria** Select this option to specify search criteria, including keywords, start and end dates, sender and recipient addresses, and message types.



6. On the **In-place hold settings** page, you can select the **Place content matching the search query in selected mailboxes on hold** check box, and then select one of the following options to place items on In-Place Hold:
   - **Hold indefinitely** Select this option to place the returned items on an indefinite hold. Items on hold will be preserved until you remove the mailbox from the search or remove the search.
   - **Specify number of days to hold items relative to their received date** Use this option to hold items for a specific period. For example, you can use this option if your organization requires that all messages be retained for at least seven years. You can use a *time-based* In-Place Hold along with a retention policy to make sure items are deleted in seven years.

Important:

When placing mailboxes or items on In-Place Hold for legal purposes, it is generally recommended to hold items indefinitely and remove the hold when the case or investigation is completed.

7. Click **Finish** to save the search and return an estimate of the total size and number of items that will be returned by the search based on the criteria you specified. Estimates are displayed in the

details pane. Click **Refresh** to update the information displayed in the details pane.

Use the Shell to create an In-Place eDiscovery search

This example creates the In-Place eDiscovery search Discovery-CaseId012 for items containing the keywords Contoso and ProjectA that also meet the following criteria:

- Start date: 1/1/2009
- End date: 12/31/2011
- Source mailbox: DG-Finance
- Target mailbox: Discovery Search Mailbox
- Message types: Email
- Log level: Full

Important:

If you don't specify additional search parameters when running an In-Place eDiscovery search, all items in the specified source mailboxes are returned in the results. If you don't specify mailboxes to search, all mailboxes in your Exchange or Exchange Online organization are searched.

```
New-MailboxSearch "Discovery-CaseId012" -StartDate
"1/1/2009" -EndDate "12/31/2011" -SourceMailboxes "DG-
Finance" -TargetMailbox "Discovery Search Mailbox" -
SearchQuery '"Contoso" AND "Project A"' -MessageTypes Email
-IncludeUnsearchableItems -LogLevel Full
```

Note:

When using the *StartDate* and *EndDate* parameters, you have to use the date format of mm/dd/yyyy, even if your local machine settings are configured to use a different date format, such as dd/mm/yyyy. For example, to search for messages sent between April 1, 2013 and July 1, 2013, you would use **04/01/2013** and **07/01/2013** for the start and end dates.

After using the Shell to create an In-Place eDiscovery search, you have to start the search by using the **Start-MailboxSearch** cmdlet to copy messages to the discovery mailbox specified in the *TargetMailbox* parameter. For details, see Copy eDiscovery search results to a discovery mailbox.

For detailed syntax and parameter information, see New-MailboxSearch.

Estimate or preview search results

After you create an In-Place eDiscovery search, you can use the EAC to get an estimate and preview of the search results. If you created a new search using the **New-MailboxSearch** cmdlet, you can use the Shell to start the search to get an estimate of the search results. You can't use the Shell to preview messages returned in search results.

Use the EAC to estimate or preview search results

1. Navigate to **Compliance management** > **In-place eDiscovery & hold**.

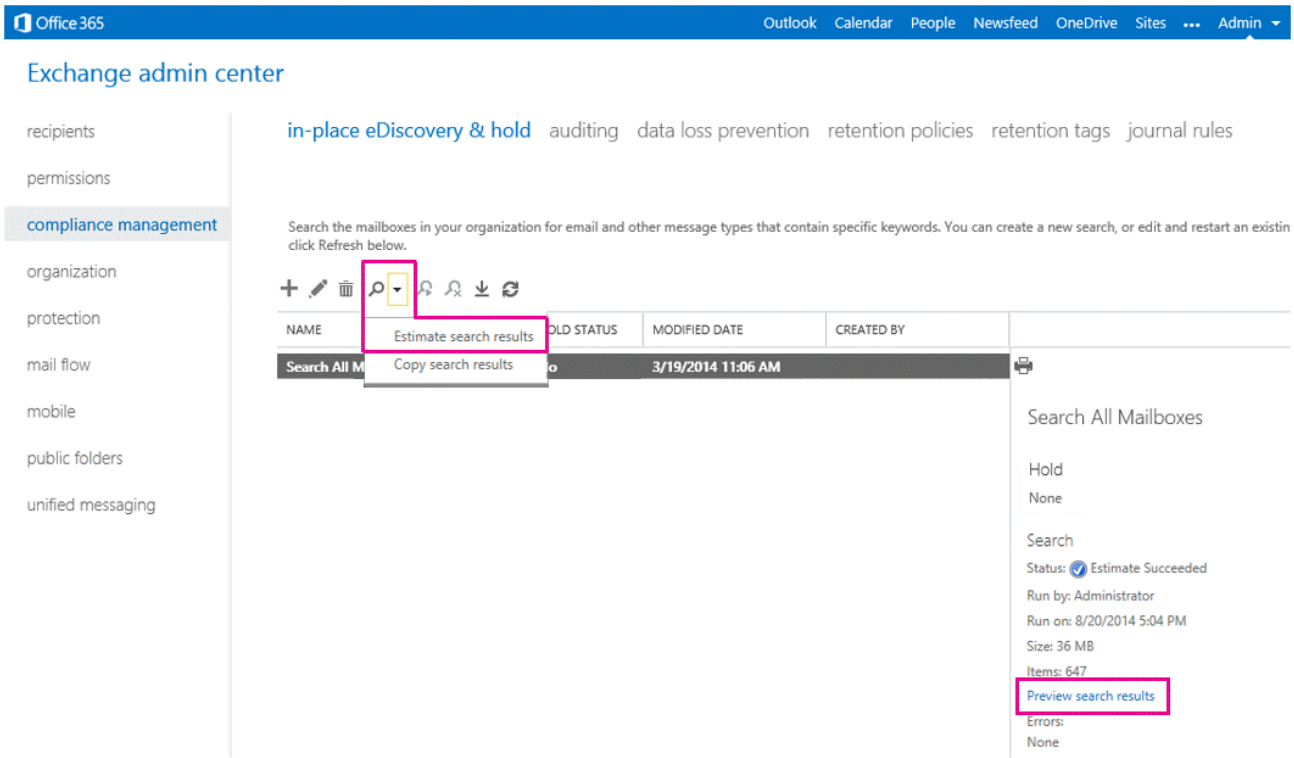
2. In the list view, select the In-Place eDiscovery search, and then do one of the following:
   - Click **Search** > **Estimate search results** to return an estimate of the total size and number of items that will be returned by the search based on the criteria you specified. Selecting this option restarts the search and performs an estimate.

Search Estimates are displayed in the details pane. Click **Refresh** to update the information displayed in the details pane.

   - Click **Preview search results** in the details pane to preview the results after the search estimate is completed. Selecting this option opens the **eDiscovery search preview** window. All messages returned from the mailboxes that were searched are displayed.

Note:

The mailboxes that were searched are listed in the right pane in the **eDiscovery search preview** window. For each mailbox, the number of items returned and the total size of these items is also displayed. All items returned by the search are listed in the right pane, and can be sorted by newest or oldest date. Items from each mailbox can't be displayed in the right pane by clicking a mailbox in the left pane. To view the items returned from a specific mailbox, you can copy the search results and view the items in the discovery mailbox.



Use the Shell to estimate search results

You can use the *EstimateOnly* switch to return only get an estimate of the search results and not copy the results to a discovery mailbox. You have to start an estimate-only search with the **Start-MailboxSearch** cmdlet. Then you can retrieve the estimated search results by using the **Get-MailboxSearch** cmdlet.

For example, you would run the following commands to create a new eDiscovery search and then display an estimate of the search results:

```
New-MailboxSearch "FY13 Q2 Financial Results" -StartDate
```

```
"04/01/2013" -EndDate "06/30/2013" -SourceMailboxes "DG-
Finance" -SearchQuery '"Financial" AND "Fabrikam"' -
EstimateOnly -IncludeKeywordStatistics

Start-MailboxSearch "FY13 Q2 Financial Results"

Get-MailboxSearch "FY13 Q2 Financial Results"
```

To display specific information about the estimated search results from the previous example, you could run the following command:

```
Get-MailboxSearch "FY13 Q2 Financial Results" | FL
Name,Status,LastRunBy,LastStartTime,LastEndTime,Sources,Sea
rchQuery,ResultSizeEstimate,ResultNumberEstimate,Errors,Key
wordHits
```

More information about eDiscovery searches

- After you create a new eDiscovery search, you can copy search results to the discovery mailbox and export those search results to a PST file. For more information, see:
  - Copy eDiscovery search results to a discovery mailbox
  - Export eDiscovery search results to a PST file
- After you run an eDiscovery search estimate (that includes keywords in the search criteria), you can view keyword statistics by clicking **View keyword statistics** in the details pane for the selected search. These statistics show details about the number of items returned for each keyword used in the search query. However, if more than 100 source mailboxes are included in the search, an error will be returned if you try to view keyword statistics. To view keyword statistics, no more than 100 source mailboxes can be included in the search.
- If you use **Get-MailboxSearch** in Exchange Online to retrieve information about an eDiscovery search, you have to specify the name of a search to return a complete list of the search properties; for example, `Get-MailboxSearch "Contoso Legal Case"`. If you run the **Get-MailboxSearch** cmdlet without using any parameters, the following properties aren't returned:
  - SourceMailboxes
  - Sources
  - SearchQuery
  - ResultsLink
  - PreviewResultsLink
  - Errors

The reason is that it requires a lot of resources to return these properties for all eDiscovery searches in your organization.

Start or stop an In-Place eDiscovery search

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-07-14*

You can stop or restart an In-Place eDiscovery search at any time. For example, if you want to modify search properties such as keywords or mailboxes searched, you must first stop a search. You can then restart the search after making the required changes.

Caution:

If you restart an In-Place eDiscovery search, search results copied to the Discovery mailbox specified in the search are removed.

What do you need to know before you begin?

- Estimated time to complete: 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "In-Place eDiscovery" entry in Messaging policy and compliance permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to start or stop an In-Place eDiscovery search

1. Navigate to **Compliance management** > **In-place eDiscovery & hold**.
2. To stop a search that's in progress, select the search, and then click **Stop search**.
3. To start a search that was stopped, select the search, and then click **Resume search**.

Use the Shell to start or stop an In-Place eDiscovery search

For an example of how to start an In-Place eDiscovery search, see "Example 1" in Start-MailboxSearch.

For an example of how to stop an In-Place eDiscovery search, see “Example 1” in Stop-MailboxSearch.

Modify an In-Place eDiscovery search

Exchange Server 2013 > Messaging policy and compliance > In-Place eDiscovery >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-08-27*

After you create an In-Place eDiscovery search, you can modify it to change the search parameters. For example, you can change the mailboxes to be searched, date ranges, key words, logging options, or you can specify a different Discovery mailbox to store search results. Any changes you make to the search properties will be used when you restart the search.

Caution:

If an In-Place eDiscovery search is running, you must stop it before modifying it. When you restart the search, the results from the last time the search was run are removed from the Discovery mailbox. However, the logs from previous searches are saved.

What do you need to know before you begin?

- Estimated time to complete: 2-5 minutes.
- An In-Place eDiscovery search has been created and isn't running.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "In-Place eDiscovery" entry in the Messaging policy and compliance permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

What do you want to do?

Use the EAC to modify an In-Place eDiscovery search

1. Navigate to **Compliance management** > **In-place eDiscovery & hold**.
2. In the list view, select the In-Place eDiscovery search you want to modify, and then click **Edit** ✎.
3. In **In-Place eDiscovery & Hold**, you can modify the following settings:
   - On **Name** page, modify the name for the search and the optional description.
   - On the **Mailboxes** page, modify the mailboxes to search. You can search across all mailboxes or select specific ones to search.

Important:

You can't use the **Search all mailboxes** option to place all mailboxes on Exchange 2013 Mailbox servers on hold. To create an In-Place Hold, you must select **Specify mailboxes to search**. For more details, see Create or remove an In-Place Hold.

- On the **Search query** page, modify the following fields:
  - **Include all user mailbox content** Select this option to place all content in the selected mailboxes on hold.
  - **Filter based on criteria** Select this option to specify search criteria, including keywords, start and end dates, sender and recipient addresses, and message types.
- On the **In-Place Hold** page, select the **Place content matching the search query in selected mailboxes on hold** check box, and then select one of the following options to place items on In-Place Hold:
  - **Hold indefinitely** Select this option to place the returned items on an indefinite hold. Items on hold will be preserved until you remove the mailbox from the search or remove the search.
  - **Specify number of days to hold items relative to their received date** Use this option to hold items for a specific period. For example, you can use this option if your organization requires that all messages be retained for at least seven years. You can use a *time-based* In-Place Hold along with a retention policy to make sure items are deleted in seven years.

Important:

When placing mailboxes or items on In-Place Hold for legal purposes, it is generally recommended to hold items indefinitely and remove the hold when the case or investigation is completed.

4. Click **Save**.

Use the Shell to modify an In-Place eDiscovery search

This example modifies the In-Place eDiscovery search Search-Project Contoso to search mailboxes belonging to members of the DG-ProjectManagers distribution group.

```
Set-MailboxSearch -Identity "Search-Project Contoso" -
SourceMailboxes "DG-ProjectManagers"
```

How do you know this worked?

To verify that you have successfully modified an In-Place eDiscovery search, do one of the following:

- Use the EAC to check properties of the search.
- Use the **Get-MailboxSearch** cmdlet from the Shell to check the properties of the search. For examples of how to check the properties of a mailbox search, see the "Examples" section in Get-MailboxSearch.

Note:

If you use **Get-MailboxSearch** in Exchange Online to retrieve information about an eDiscovery search, you have to specify the name of a search to return a complete list of the search properties; for example, `Get-MailboxSearch "Contoso Legal Case"`. If you run the **Get-MailboxSearch** cmdlet without using any parameters, the following properties aren't returned:

- SourceMailboxes
- Sources
- SearchQuery
- ResultsLink
- PreviewResultsLink
- Errors

The reason is that it requires a lot of resources to return these properties for all eDiscovery searches in your organization.

Copy eDiscovery search results to a discovery mailbox

Exchange Server 2013 > Messaging policy and compliance > In-Place eDiscovery >

Topic Last Modified: *2014-02-24*

After you create an In-Place eDiscovery search, you can use the EAC to copy the results to a discovery mailbox. You can also use the Shell to start an eDiscovery search that was created using the **New-MailboxSearch** cmdlet, which will copy the results to the discovery mailbox that was specified when you created the search.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes or longer depending on the number of mailbox items returned in the search results
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "In-Place eDiscovery" entry in the Messaging policy and compliance permissions topic.
- An eDiscovery search has to be created, by using the EAC or the Shell, before you can copy the search results. For details, see Create an In-Place eDiscovery search.
- Exchange 2013 Setup creates a discovery mailbox called **Discovery Search Mailbox** to copy search results. The Discovery Search Mailbox is also created by default in Exchange Online. You can create additional discovery mailboxes. For details, see Create a discovery mailbox.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

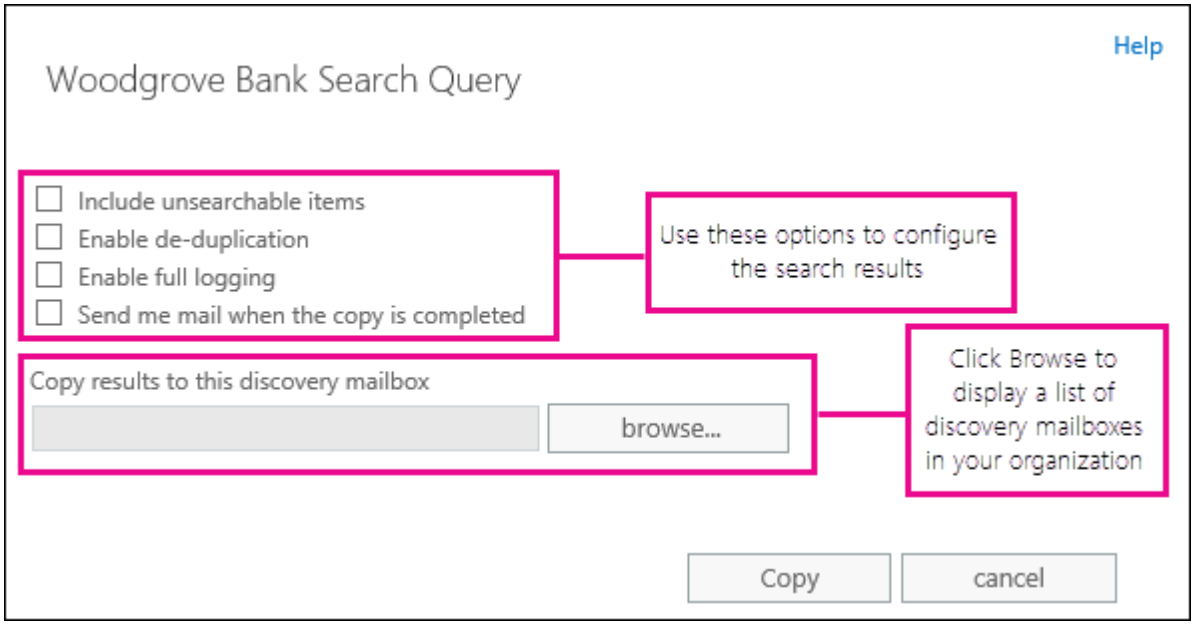
Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to copy search results

1. In the EAC, go to **Compliance management** > **In-place eDiscovery & hold**.
2. In the list view, select an eDiscovery search.
3. Click **Search**, and then click **Copy search results** from the drop-down list.
4. In **Copy Search Results**, select from the following options:
   - **Include unsearchable items** Select this check box to include mailbox items that couldn't be searched (for example, messages with attachments of file types that couldn't be indexed by Exchange Search). For more information, see Unsearchable items in Exchange eDiscovery.
   - **Enable de-duplication** Select this check box to exclude duplicate messages. Only a single instance of a message will be copied to the discovery mailbox.
   - **Enable full logging** Select this check box to include a full log in search results.
   - **Send me mail when the copy is completed** Select this check box to get an email notification when the search is completed.
   - **Copy results to this discovery mailbox** Click **Browse** to select the discovery mailbox where you want the search results copied to.



5. Click **Copy** to start the process to copy the search results to the specified discovery mailbox.
6. Click **Refresh** to update the information about the copying status that is displayed in the details pane.
7. When copying is complete, click **Open** to open the discovery mailbox to view the search results.

Use the Shell to copy search results

After using the **New-MailboxSearch** cmdlet to create an In-Place eDiscovery search, you must start the search to copy messages to the discovery mailbox you specified in the *TargetMailbox* parameter. For information about creating eDiscovery searches using the Shell, see:

- Use the Shell to create an In-Place eDiscovery search
- New-MailboxSearch

For example, you would run the following command to start an eDiscovery search named *Fabrikam Investigation* to copy the search results to the specified discovery mailbox.

```
Start-MailboxSearch "Fabrikam Investigation"
```

If you used the *EstimateOnly* switch to get an estimate of the search results, you have to remove the switch before you can copy the search results. You also have to specify a discovery mailbox to copy to search results to. For example, say you created an estimate-only search by using the following command:

```
New-MailboxSearch "FY13 Q2 Financial Results" -StartDate
"04/01/2013" -EndDate "06/30/2013" -SourceMailboxes "DG-
Finance" -SearchQuery '"Financial" AND "Fabrikam"' -
EstimateOnly -IncludeUnsearchableItems
```

To copy the results of this search to a discovery mailbox, you would run the following commands:

```
Set-MailboxSearch "FY13 Q2 Financial Results" -EstimateOnly
$false -TargetMailbox "Discovery Search Mailbox"

Start-MailboxSearch "FY13 Q2 Financial Results"
```

More information about copying search results

- After you copy search results to the discovery mailbox, you can export those search results to a PST file. For more information, see Export eDiscovery search results to a PST file.
- For more information about unsearchable items, see Unsearchable items in Exchange eDiscovery.
- If you're copying all mailbox content within a specific date range (by not specifying any keywords in the search criteria), then all unsearchable items within that date range will be automatically included in the search results. Therefore, don't select the **Include unsearchable items** checkbox when copying search results. Otherwise, a duplicate copy of all unsearchable items will be copied to the discovery mailbox.
- In addition to copying the search results to a discovery mailbox, you can also estimate or preview the search results for a selected search.
  - **Estimate search results** This option returns an estimate of the total size and number of items that will be returned by the search based on the criteria you specified. Estimates are displayed in the details pane in the EAC.

- **Preview search results** This option lets you preview the search results returned by the search instead of having to copy them to a discovery mailbox to view. This lets you quickly determine whether the search results are relevant. After you preview the results, you can revise your search query to narrow the search results and rerun the search. Items in the preview page are read-only versions of the actual search results, so you can't move, edit, delete or forward on the preview page.

For more information, see Estimate or preview search results.

Export eDiscovery search results to a PST file

Exchange Server 2013 > Messaging policy and compliance > In-Place eDiscovery >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-04-25*

You can use the eDiscovery Export tool in the EAC to export the results of an In-Place eDiscovery search to an Outlook Data File, which is also called a PST file. This lets you distribute the results to other people within your organization, such as a human resources manager or records manager, or to opposing counsel in a legal case. After search results are exported to a PST file, you or other users can open them in Outlook to review or print messages returned in the search results. PST files can also be opened in third-party eDiscovery and reporting applications.

What do you need to know before you begin?

- Estimated time to complete: Time will vary based on the amount and size of the search results that will be exported.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "In-Place eDiscovery" entry in the Messaging policy and compliance permissions topic.
- The computer you use to export search results to a PST file has to meet the following system requirements:
  - 32- and 64-bit versions of Windows 7 and later versions
  - Microsoft .NET Framework 4.5
  - A supported browser:
    - Internet Explorer 8 and later versions

OR

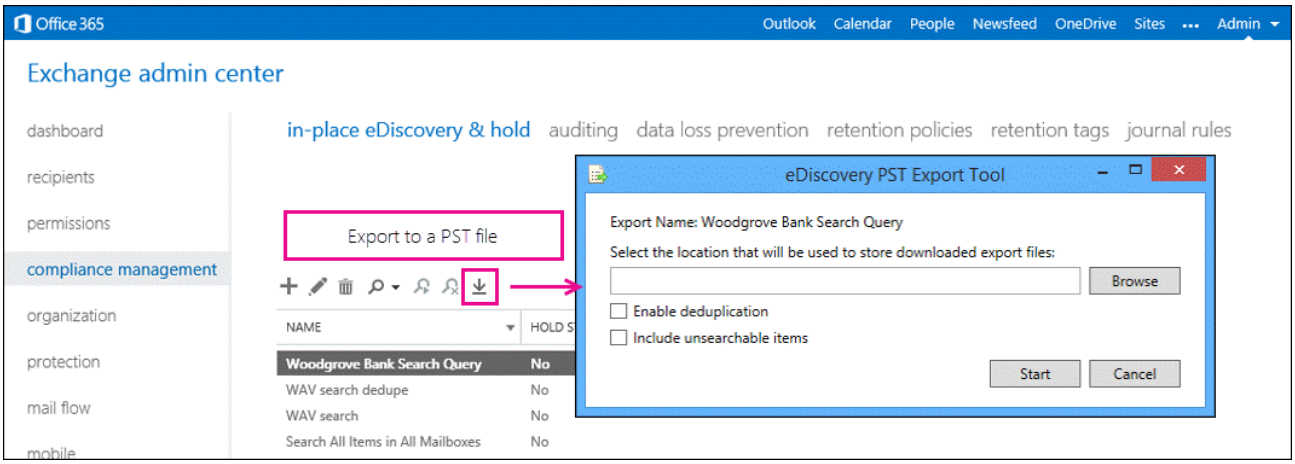
    - Mozilla Firefox or Google Chrome, with the ClickOnce add-in installed
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the EAC to export search results

1. Go to **Compliance management** > **In-place eDiscovery & hold**.
2. In the list view, select the In-Place eDiscovery search you want to export the results of, and then click **Export to a PST file**.



3. In the **eDiscovery PST Export Tool** window, do the following:
   - Click **Browse** to specify the location where you want to download the PST file.
   - Click the **Enable deduplication** checkbox to exclude duplicate messages. Only a single instance of a message will be included in the PST file.
   - Click the **Include unsearchable items** checkbox to include mailbox items that couldn't be searched (for example, messages with attachments of file types that couldn't be indexed by Exchange Search). Unsearchable items are exported to a separate PST file.

Important:

Including unsearchable items when you export eDiscovery search results takes longer when mailboxes contain a lot of unsearchable items. To reduce the time it takes to export search results and prevent large PST export files, consider the following recommendations:

- Create multiple eDiscovery searches that each search a fewer number of source mailboxes.
- If you're exporting all mailbox content within a specific date range (by not specifying any keywords in the search criteria), then all unsearchable items within that date range will be automatically included in the search results. Therefore, don't select the **Include unsearchable items** checkbox.

1. Click **Start** to export the search results to a PST file.

A window is displayed that contains status information about the export process.

More information

- Another way to reduce the size of PST export files is to export only the unsearchable items for an

eDiscovery search. To do this, create or edit a search, specify a start date in the future, and then remove any keywords from the **Keywords** box. This will result in no search results being returned. When you copy or export the search results and select the **Include unsearchable items** checkbox, only the unsearchable items will be copied to the discovery mailbox or exported to a PST file.

- If you enable de-duplication, all search results are exported in a single PST file. If you don't enable de-duplication, a separate PST file is exported for each mailbox included in the search. And as previously stated, unsearchable items are exported to a separate PST file.
- In addition to the PST files that contain the search results, two other files are also exported:
  - A configuration file (.txt file format) that contains information about the PST export request, such as the name of the eDiscovery search that was exported, the date and time of the export, whether de-duplication and unsearchable items were enabled, the search query, and the source mailboxes that were searched.
  - A search results log (.csv file format) that contains an entry for each message returned in the search results. Each entry identifies the source mailbox where the message is located. If you've enabled de-duplication, this helps you identify all mailboxes that contain a duplicate message.
- The name of the search is the first part of the filename for each file that is exported. Also, the date and time of the export request is appended to the filename of each PST file and the results log.
- For more information about de-duplication and unsearchable items, see:
  - Estimate, preview, and copy search results
  - Unsearchable items in Exchange eDiscovery
- To export eDiscovery search results from the eDiscovery Center in SharePoint or SharePoint Online, see Export eDiscovery content and create reports.

Create a custom management scope for In-Place eDiscovery searches

Exchange Server 2013 > Messaging policy and compliance > In-Place eDiscovery >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-05-14*

You can use a custom management scope to let specific people or groups use In-Place eDiscovery to search a subset of mailboxes in your Exchange 2013 or Exchange Online organization. For example, you might want to let a discovery manager search only the mailboxes of users in a specific location or department. You can do this by creating a custom management scope. This custom management scope uses a recipient filter to control which mailboxes can be searched. Recipient filter scopes use filters to target specific recipients based on recipient type or other recipient properties.

For In-Place eDiscovery, the only property on a user mailbox that you can use to create a recipient

filter for a custom scope is distribution group membership (the actual property name is *MemberOfGroup*). If you use other properties, such as *CustomAttributeN*, *Department*, or *PostalCode*, the search fails when it's run by a member of the role group that's assigned the custom scope.

To learn more about management scopes, see:

- Understanding management role scopes
- Understanding management role scope filters

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- As previously stated, you can only use group membership as the recipient filter to create a custom recipient filter scope that is intended to be used for eDiscovery. Any other recipient properties can't be used to create a custom scope for eDiscovery searches. Note that membership in a dynamic distribution group can't be used either.
- Perform steps 1 through 3 to let a discovery manager export the search results for an eDiscovery search that uses a custom management scope.
- If your discovery manager doesn't need to preview the search results, you can skip step 4.
- If your discovery manager doesn't need to copy the search results, you can skip step 5.

Step 1: Organize users into distribution groups for eDiscovery

To search a subset of mailboxes in your organization or to narrow the scope of source mailboxes that a discovery manager can search, you'll need to group the subset of mailboxes into one or more distribution groups. When you create a custom management scope in step 2, you'll use these distribution groups as the recipient filter to create a custom management scope. This allows a discovery manager to search only the mailboxes of the users who are members of a specified group.

You might be able to use existing distribution groups for eDiscovery purposes, or you can create new ones. See More information at the end of this topic for tips on how to create distribution groups that can be used to scope eDiscovery searches.

Step 2: Create a custom management scope

Now you'll create a custom management scope that's defined by the membership of a distribution group (using the *MemberOfGroup* recipient filter). When this scope is applied to a role group used for eDiscovery, members of the role group can search the mailboxes of users who are members of the distribution group that was used to create the custom management scope.

This procedure uses Exchange Management Shell commands to create a custom scope named Ottawa Users eDiscovery Scope. It specifies the distribution group named Ottawa Users for the

recipient filter of the custom scope.

1. Run this command to get and save the properties of the Ottawa Users group to a variable, which is used in the next command.

```
$DG = Get-DistributionGroup -Identity "Ottawa Users"
```

2. Run this command to create a custom management scope based on the membership of the Ottawa Users distribution group.

```
New-ManagementScope "Ottawa Users eDiscovery Scope" -
RecipientRestrictionFilter "MemberOfGroup -eq
'$($DG.DistinguishedName)'"
```

The distinguished name of the distribution group, which is contained in the variable **$DG**, is used to create the recipient filter for the new management scope.

Step 3: Create a management role group

In this step, you create a new management role group and assign the custom scope that you created in step 2. Add the Legal Hold and Mailbox Search roles so that role group members can perform In-Place eDiscovery searches and place mailboxes on In-Place Hold or Litigation Hold. You can also add members to this role group so they can search the mailboxes of the members of the distribution group used to create the custom scope in step 2.

In the following examples, the Ottawa Users eDiscovery Managers security group will be added as members this role group. You can use either the Shell or the EAC for this step.

Use the Shell to create a management role group

Run this command to create a new role group that uses the custom scope created in step 2. The command also adds the Legal Hold and Mailbox Search roles, and adds the Ottawa Users eDiscovery Managers security group as members of the new role group.

```
New-RoleGroup "Ottawa Discovery Management" -Roles "Mailbox
Search","Legal Hold" -CustomRecipientWriteScope "Ottawa
Users eDiscovery Scope" -Members "Ottawa Users eDiscovery
Managers"
```

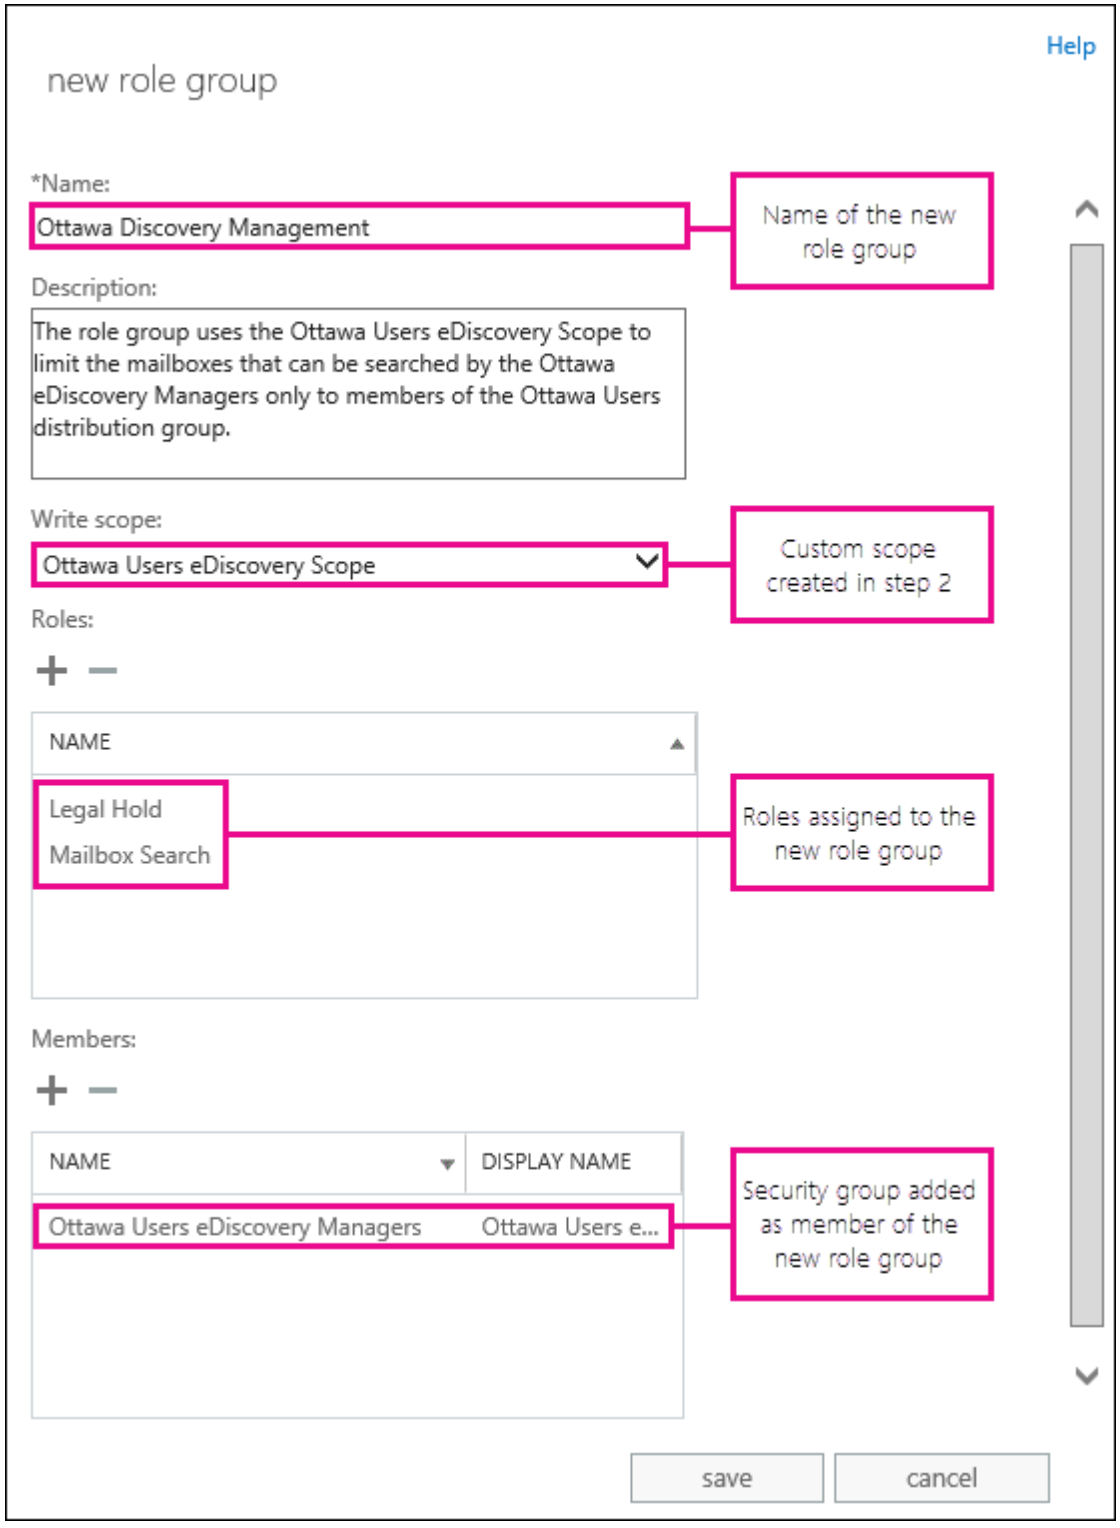
Use the EAC to create a management role group

1. In the EAC, go to **Permissions** > **Admin roles**, and then click **New +**.
2. In **New role group**, provide the following information:
   - **Name** Provide a descriptive name for the new role group. For this example, you'd use **Ottawa Discovery Management**.

- **Write scope** Select the custom management scope that you created in step 2. This scope will be applied to the new role group.
- **Roles** Click **Add +**, and add the **Legal Hold** and **Mailbox Search** roles to the new role group.
- **Members** Click **Add +**, and select the users, security group, or role groups that you want add as members of the new role group. For this example, the members of the **Ottawa Users eDiscovery Managers** security group will be able to search only the mailboxes of users who are members of the **Ottawa Users** distribution group.

3. Click **Save** to create the role group.

Here's an example of what the **New role group** window will look like when you're done.



(Optional) Step 4: Add discovery managers as members of the distribution group used to create the custom management scope

You only need to perform this step if you want to let a discovery manager preview eDiscovery search results.

Run this command to add the Ottawa Users eDiscovery Managers security group as a member of the Ottawa Users distribution group.

```
Add-DistributionGroupMember -Identity "Ottawa Users" -
Member "Ottawa Users eDiscovery Managers"
```

You can also use the EAC to add members to a distribution group. For more information, see Manage Distribution Groups.

(Optional) Step 5: Add a discovery mailbox as a member of the distribution group used to create the custom management scope

You only need to perform this step if you want to let a discovery manager copy eDiscovery search results.

Run this command to add a discovery mailbox named Ottawa Discovery Mailbox as a member of the Ottawa Users distribution group.

```
Add-DistributionGroupMember -Identity "Ottawa Users" -
Member "Ottawa Discovery Mailbox"
```

Note:

To open a discovery mailbox and view the search results, discovery managers must be assigned Full Access permissions for the discovery mailbox. For more information, see Create a discovery mailbox.

How do you know this worked?

Here are some ways to verify if you've successfully implemented custom management scopes for eDiscovery. When you verify, be sure that the user running the eDiscovery searches is a member of the role group that uses the custom management scope.

- Create an eDiscovery search, and select the distribution group that was used to create the custom management scope as the source of mailboxes to be searched. All mailboxes should be successfully searched.
- Create an eDiscovery search, and search the mailboxes of any users who aren't members of the distribution group that was used to create the custom management scope. The search should fail because the discovery manager can only search mailboxes for users who are members of the distribution group that was used to create the custom management scope. In this case, an error such as "Unable to search mailbox *<name of mailbox>* because the current user does not have permissions to access the mailbox" will be returned.
- Create an eDiscovery search, and search the mailboxes of users who are members of the distribution group that was used to create the custom management scope. In the same search, include the mailboxes of users who aren't members. The search should partially succeed. The mailboxes of members of the distribution group used to create the custom management scope should be successfully searched. The search of mailboxes for users who aren't members of the group should fail.

More information

- Because distribution groups are used in this scenario to scope eDiscovery searches and not for message delivery, consider the following when you create and configure distribution groups for eDiscovery:
  - Create distribution groups with a closed membership so that members can be added to or removed from the group only by the group owners. If you're creating the group in the Shell, use the syntax `MemberJoinRestriction closed` and `MemberDepartRestriction closed`.
  - Enable group moderation so that any message sent to the group is first sent to the group moderators who can approve or reject the message accordingly. If you're creating the group in the Shell, use the syntax `ModerationEnabled $true`. If you're using the EAC, you can enable moderation after the group is created.
  - Hide the distribution group from the organization's shared address book. Use the EAC or the **Set-DistributionGroup** cmdlet after the group is created. If you're using the Shell, use the syntax `HiddenFromAddressListsEnabled $true`.

In the following example, the first command creates a distribution group with closed membership and moderation enabled. The second command hides the group from the shared address book.

```
New-DistributionGroup -Name "Vancouver Users eDiscovery
Scope" -Alias VancouverUserseDiscovery -
MemberJoinRestriction closed -MemberDepartRestriction
closed -ModerationEnabled $true

Set-DistributionGroup "Vancouver Users eDiscovery Scope" -
HiddenFromAddressListsEnabled $true
```

For more information about creating and managing distribution groups, see Manage Distribution

Groups.

- Though you can use only distribution group membership as the recipient filter for a custom management scope used for eDiscovery, you can use other recipient properties to add users to that distribution group. Here are some examples of using the **Get-Mailbox** and **Get-Recipient** cmdlets to return a specific group of users based on common user or mailbox attributes.

```
Get-Recipient -RecipientTypeDetails UserMailbox -ResultSize
unlimited -Filter 'Department -eq "HR"'

Get-Mailbox -RecipientTypeDetails UserMailbox -ResultSize
unlimited -Filter 'CustomAttribute15 -eq
"VancouverSubsidiary"'

Get-Recipient -RecipientTypeDetails UserMailbox -ResultSize
unlimited -Filter 'PostalCode -eq "98052"'

Get-Recipient -RecipientTypeDetails UserMailbox -ResultSize
unlimited -Filter 'StateOrProvince -eq "WA"'

Get-Mailbox -RecipientTypeDetails UserMailbox -ResultSize
unlimited -OrganizationalUnit
"namsr01a002.sdf.exchangelabs.com/Microsoft Exchange Hosted
Organizations/contoso.onmicrosoft.com"
```

- You can then use the examples from the previous bullet to create a variable that can be used with the **Add-DistributionGroupMember** cmdlet to add a group of users to a distribution group. In the following example, the first command creates a variable that contains all user mailboxes that have the value **Vancouver** for the *Department* property in their user account. The second command adds these users to the Vancouver Users distribution group.

```
$members = Get-Recipient -RecipientTypeDetails UserMailbox
-ResultSize unlimited -Filter 'Department -eq "Vancouver"'

$members | ForEach {Add-DistributionGroupMember "Ottawa
Users" -Member $_.Name}
```

- You can use the **Add-RoleGroupMember** cmdlet to add a member to an existing role group that's used to scope eDiscovery searches. For example, the following command adds the user admin@ottawa.contoso.com to the Ottawa Discovery Management role group.

```
Add-RoleGroupMember "Vancouver Discovery Management" -
Member paralegal@vancouver.contoso.com
```

You can also use the EAC to add members to a role group. For more information, see Add members to a role group.

Remove an In-Place eDiscovery search

Exchange Server 2013 > Messaging policy and compliance > In-Place eDiscovery >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-07-14*

In Microsoft Exchange Server 2013, you can use In-Place eDiscovery to search mailbox content. You can remove an In-Place eDiscovery search at any time. When you remove an In-Place eDiscovery search, search results are removed from the Discovery mailbox.

Caution:
Deleting an In-Place eDiscovery search will remove any search results copied to a Discovery mailbox.

What do you need to know before you begin?

- Estimated time to completion: 2-5 minutes.
- To remove an In-Place eDiscovery search that has In-Place Hold enabled, you must first remove the In-Place Hold from the search. For details, see Create or remove an In-Place Hold.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "In-Place eDiscovery" entry in the Messaging policy and compliance permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

What do you want to do?

Use the EAC to remove an In-Place eDiscovery search

1. Navigate to **Compliance management** > **In-place eDiscovery & hold**.
2. In the list view, select the In-Place eDiscovery search you want to remove, and then click **Delete** .

Use the Shell to remove an In-Place eDiscovery search

For an example of how to remove an In-Place eDiscovery search, see the “Examples” section in Remove-MailboxSearch.

How do you know this worked?

To verify that you have successfully removed an In-Place eDiscovery search, do one of the following:

- Use the EAC to verify that the search is no longer displayed in the list view of the **In-place eDiscovery & hold** tab.
- Use the **Get-MailboxSearch** cmdlet to retrieve In-Place eDiscovery searches. For an example of how to retrieve In-Place eDiscovery searches, see the "Examples" section in Get-MailboxSearch.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Search and delete messages

Exchange Server 2013 > Messaging policy and compliance > In-Place eDiscovery >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-07-14*

You can use the **Search-Mailbox** cmdlet to search and delete messages from a mailbox.

To search and delete messages in one step, run the **Search-Mailbox** cmdlet with the *DeleteContent* switch. However, when you do this, you can't preview search results or generate a log of messages that will be returned by the search, and you may inadvertently delete messages that you didn't intend to. To preview a log of the messages found in the search before they're deleted, run the **Search-Mailbox** cmdlet with the *LogOnly* switch.

As an additional safeguard, you can first copy the messages to another mailbox by using the *TargetMailbox* and *TargetFolder* parameters. By doing this, you retain a copy of the deleted messages in case you need to access them again.

What do I need to know before I begin?

- Estimated time to complete: 10 minutes. The actual time may vary depending on the size of the mailbox and the search query.
- You need to be assigned the following management roles to search for and delete messages in users' mailboxes:
  - **Mailbox Search** This role allows you to search for messages across multiple mailboxes in your organization. Administrators aren't assigned this role by default. To assign yourself this role so that you can search mailboxes, add yourself as a member of the Discovery Management role group. See Add a user to the Discovery Management role group.

- **Mailbox Import Export** This role allows you to delete messages from a user's mailbox. By default, this role isn't assigned to any role group. To delete messages from users' mailboxes, you can add the Mailbox Import Export role to the Organization Management role group. For more information, see Add a role to a role group.

- If the mailbox from which you want to delete messages has single item recovery enabled, you must first disable the feature.
- If the mailbox from which you want to delete messages is placed on litigation hold, we recommend that you check with your records management or legal department before removing the hold and deleting the mailbox content. After you obtain approval, follow the steps listed in the topic Clean up the Recoverable Items folder.
- You can't use the Exchange admin center (EAC) to perform these procedures. You must use the Shell.

What do you want to do?

Search messages and log the search results

This example searches April Stewart's mailbox for messages that contain the phrase "Your bank statement" in the Subject field and logs the search results in the SearchAndDeleteLog folder of the administrator's mailbox. Messages aren't copied to or deleted from the target mailbox.

```
Search-Mailbox -Identity "April Stewart" -SearchQuery
"Subject:'Your bank statement'" -TargetMailbox
"administrator" -TargetFolder "SearchAndDeleteLog" -LogOnly
-LogLevel Full
```

For detailed syntax and parameter information, see Search-Mailbox.

Search and delete messages

This example searches April Stewart's mailbox for messages that contain the phrase "Your bank statement" in the Subject field and deletes the messages from the source mailbox without copying the search results to another folder. As previously explained, you need to be assigned the Mailbox Import Export management role to delete messages from a user's mailbox.

Caution:

When you use the **Search-Mailbox** cmdlet with the *DeleteContent* switch, messages are permanently deleted from the source mailbox. Before you permanently delete messages, we recommend that you either use the *LogOnly* switch to generate a log of the messages found in the search before they're deleted or copy the messages to another mailbox before deleting them from the source mailbox.

```
Search-Mailbox -Identity "April Stewart" -SearchQuery
```

```
"Subject:'Your bank statement'" -DeleteContent
```

This example searches April Stewart's mailbox for messages that contain the phrase "Your bank statement" in the Subject field, copies the search results to the folder AprilStewart-DeletedMessages in the mailbox BackupMailbox, and deletes the messages from April's mailbox.

```
Search-Mailbox -Identity "April Stewart" -SearchQuery
"Subject:'Your bank statement'" -TargetMailbox
"BackupMailbox" -TargetFolder "AprilStewart-
DeletedMessages" -LogLevel Full -DeleteContent
```

For detailed syntax and parameter information, see Search-Mailbox.

Reduce the size of a discovery mailbox in Exchange

Exchange Server 2013 > Messaging policy and compliance > In-Place eDiscovery >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-05-30*

Have a discovery mailbox that's exceeded the 50 GB limit? You can fix this issue by creating new discovery mailboxes and copying the search results from the large discovery mailbox to the new ones.

Why would I want to do this?

In Exchange Server 2013 and Exchange Online, the maximum size of discovery mailboxes, which are used to store In-Place eDiscovery search results, is 50 GB. Prior to the current size limit, you were able to increase the storage quota to more than 50 GB, which resulted in having discovery mailboxes much larger than 50 GB. There are three issues with discovery mailboxes that are larger than 50 GB:

- They're not supported.
- They can't be migrated to Office 365.
- If they're discovery mailboxes in Exchange Server 2010, they can't be upgraded to Exchange Server 2013.

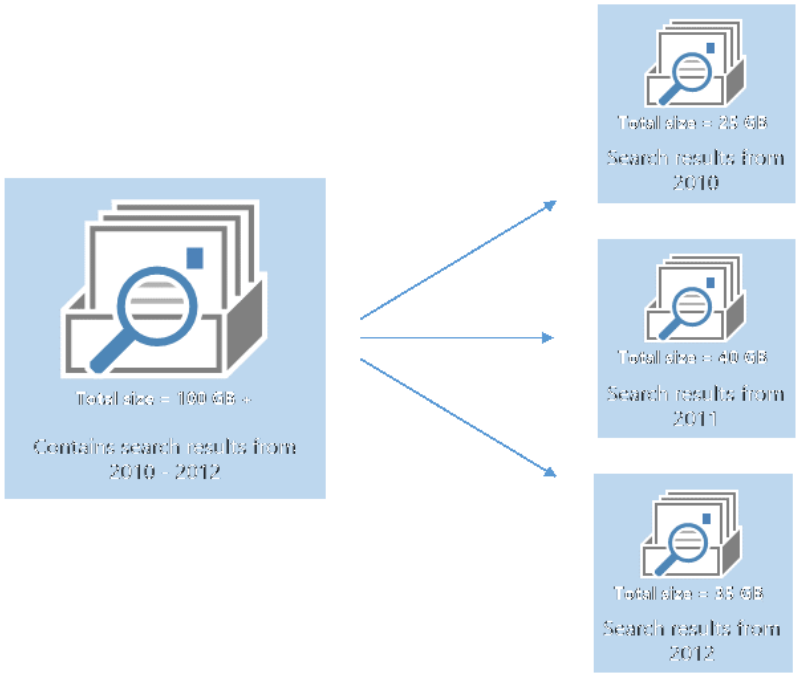
The process at a glance

Here's a quick look at what you'll need to do to reduce the size of a discovery mailbox that's

exceeded the 50 GB limit:

1. Create additional discovery mailboxes to distribute the search results to.
2. Copy the search results from the existing discovery mailbox to one or more of the new discovery mailboxes.
3. Delete eDiscovery searches from the original discovery mailbox to reduce its size.

The strategy presented here groups the search results from the original discovery mailbox into separate eDiscovery searches that are based on date ranges. This is a quick way to copy many search results to a new discovery mailbox. The following graphic illustrates this approach.



What do you need to know before you begin?

- Estimated time to complete this task: Time will vary based on the amount and size of the search results that will be copied to different discovery mailboxes.
- Run the following command to determine the size of the discovery mailboxes in your organization.

```
Get-Mailbox -RecipientTypeDetails DiscoveryMailbox | Get-MailboxStatistics | FL DisplayName,TotalItemSize
```

- Determine if you need to keep some or all of the search results from the discovery mailbox that's exceeded the 50 GB limit. Follow the steps in this topic to retain search results by copying them to a different discovery mailbox. If you don't need to keep the results of a specific eDiscovery search, you can delete the search, as explained in step 3. Deleting a search will delete the search results from the discovery mailbox.

- If you don't need any of the search results from a discovery mailbox that's exceeded the 50 GB limit, you can delete it. If this is the default discovery mailbox that was created when your Exchange organization was provisioned, you can re-create it. For more information, see Delete and re-create the default discovery mailbox in Exchange.
- For current legal cases, you might want to export the results of selected eDiscovery searches to .pst files. Doing this keeps the results from a specific search intact. In addition to the .pst files that contain the search results, a search results log (.csv file format) that contains an entry for each message returned in the search results is also exported. Each entry in this file identifies the source mailbox where the message is located. For more information, see Export eDiscovery search results to a PST file.

After you export search results to .pst files, you'll need to use Outlook if you want to import them to a new discovery mailbox.

Step 1: Create discovery mailboxes

The first step is to create additional discovery mailboxes so that you can copy the search results from the discovery mailbox that's exceeded the size limit. Based on the 50 GB size limit for discovery mailboxes, determine how many additional discovery mailboxes you'll need and create them. You'll then need to assign users or groups the necessary permissions to open these new discovery mailboxes.

1. Run the following command to create a new discovery mailbox.

```
New-Mailbox -Name <discovery mailbox name> -Discovery
```

2. Run the following command to assign a user or group permissions to open the discovery mailbox and view search results.

```
Add-MailboxPermission <discovery mailbox name> -User <name
of user or group> -AccessRights FullAccess -InheritanceType
all
```

Step 2: Copy search results to a discovery mailbox

The next step is to use the **New-MailboxSearch** cmdlet to copy the search results from the existing discovery mailbox to a new discovery mailbox that you created in the previous step. This procedure uses the *StartDate* and *EndDate* parameters to scope the search results into batches that are no larger than 50 GB. This may require some testing (by estimating the search results) to size the search results appropriately.

1. Run the following command to create a new eDiscovery search.

```
New-MailboxSearch -Name "Search results from 2010" -
SourceMailboxes "Discovery Search Mailbox" -StartDate
```

```
"01/01/2010" -EndDate "12/31/2010" -TargetMailbox
"Discovery Mailbox Backup 01" -EstimateOnly -
StatusMailRecipients admin@contoso.com
```

This example uses the following parameters:

- *Name* This parameter specifies the name of the new eDiscovery search. Because the search is scoped by sent and received dates, it's useful that the name of the search includes the date range.
- *SourceMailboxes* This parameter specifies the default discovery mailbox. You can also specify the name of another discovery mailbox that's exceeded the size limit.
- *StartDate* and *EndDate* These parameters specify the date range of the search results in the default discovery mailbox to include in the search results.

Note:

For dates, use the short date format, mm/dd/yyyy, even if the Regional Options settings on the local computer are configured with a different format, such as dd/mm/yyyy. For example, use **03/01/2014** to specify March 1, 2014.

- *TargetMailbox* This parameter specifies that search results should be copied to the discovery mailbox named "Discovery Mailbox Backup 01".
- *EstimateOnly* This switch specifies that only an estimate of the number of items that will be returned is provided when the search is started. If you don't include this switch, messages are copied to the target mailbox when the search is started. Using this switch lets you adjust the date ranges if necessary to increase or decrease the number of search results.
- *StatusMailRecipients* This parameter specifies that the status message should be sent to the specified recipient.

2. After the search is created, start it by using the Shell or the Exchange admin center (EAC).
   - **Using the Shell:** Run the following command to start the search created in the previous step. Because the *EstimateOnly* switch was included when the search was created, the search results won't be copied to the target discovery mailbox.

```
Start-MailboxSearch "Search results from 2010"
```

   - **Using the EAC:** Go to **Compliance management** > **In-Place eDiscovery & hold**. Select the search created in the previous step, click **Search**, and then click **Estimate search results**.
3. If necessary, adjust the date range to increase or decrease the amount of search results that are returned. If you change the date range, run the search again to get a new estimate of the results. Consider changing the name of the search to reflect the new date range.
4. When you're finished testing the search, use the Shell or the EAC to copy the search results to the target discovery mailbox.
   - **Using the Shell:** Run the following commands to copy the search results. You have to remove the *EstimateOnly* switch before you can copy the search results.

```
Set-MailboxSearch "Search results from 2010" -EstimateOnly
$false
```

```
Start-MailboxSearch "Search results from 2010"
```

- **Using the EAC:** Go to **Compliance management** > **In-Place eDiscovery & hold**. Select the search, click **Search** 🔍, and then click **Copy search results**.

For more information, see Copy eDiscovery search results to a discovery mailbox.

5. Repeat steps 1 through 4 to create new searches for additional date ranges. Include the date range in the name of the new search to indicate the range of the results. To make sure none of the discovery mailboxes exceeds the 50 GB limit, use different discovery mailboxes as the target mailbox.

Step 3: Delete eDiscovery searches

After you've copied search results from the original discovery mailbox to another discovery mailbox, you can delete the original eDiscovery searches. Deleting an eDiscovery search will delete the search results from the discovery mailbox where those search results are stored.

Before deleting a search, you can run the following command to identify the size of the search results that have been copied to a discovery mailbox for all searches in your organization.

```
Get-MailboxSearch | FL Name,TargetMailbox,ResultSizeCopied
```

You can use the Shell or the EAC to delete an eDiscovery search.

- **Using the Shell:** Run the following command.

```
Remove-MailboxSearch -Identity <name of search>
```

- **Using the EAC:** Go to **Compliance management** > **In-Place eDiscovery & hold**. Select the search that you want to delete, and then click **Delete** 🗑.

How do you know this worked?

After you've deleted the eDiscovery searches to remove the results from the discovery mailbox where they were stored, run the following command to display the size of a selected discovery mailbox.

```
Get-Mailbox <name of discovery mailbox> | Get-
MailboxStatistics | FL TotalItemSize
```

Delete and re-create the default discovery mailbox in Exchange

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-05-23*

You can use the Exchange Management Shell to delete the default discovery mailbox, re-create it, and then assign permissions to it.

Why would I want to do this?

In Exchange Server 2013 and Exchange Online, the maximum size of the default discovery mailbox is 50 GB. It's used to store In-Place eDiscovery search results. Before the size limit was changed, organizations could increase the storage quota to more than 50 GB. As a result, discovery mailboxes could grow to more than 50 GB. There are three issues with a default discovery mailbox that is larger than 50 GB:

- It's not supported.
- It can't be migrated to Office 365.
- If it's the default discovery mailbox in Exchange Server 2010, it can't be upgraded to Exchange Server 2013.

How you resolve this depends on whether you want to save the search results from a default discovery mailbox that's exceeded 50 GB.

Do you want to save the search results?	Do this
No	Follow the steps in this topic to delete, and then re-create the default discovery mailbox.
Yes	Follow the steps in Reduce the size of a discovery mailbox in Exchange.

Use the Shell to delete and re-create the default discovery mailbox

Note:
You can't use the Exchange admin center (EAC) because discovery mailboxes aren't displayed in the EAC.

1. Run the following command to delete the default discovery mailbox.

```
Remove-Mailbox "DiscoverySearchMailbox{D919BA05-46A6-415f-80AD-7E09334BB852}"
```

2. In the message asking you to confirm that you want to delete the mailbox and the corresponding

Active Directory user object, type **Y**, and then press Enter.

A new user object is created in Active Directory when you create the discovery mailbox in the next step.

3. Run the following command to re-create the default discovery mailbox.

```
New-Mailbox -Name "DiscoverySearchMailbox{D919BA05-46A6-415f-80AD-7E09334BB852}" -Alias "DiscoverySearchMailbox{D919BA05-46A6-415f-80AD-7E09334BB852}" -DisplayName "Discovery Search Mailbox" -Discovery
```

4. Run the following command to assign the Discovery Management role group permissions to open the default discovery mailbox and view search results.

```
Add-MailboxPermission "DiscoverySearchMailbox{D919BA05-46A6-415f-80AD-7E09334BB852}" -User "Discovery Management" -AccessRights FullAccess -InheritanceType all
```

Re-create the Discovery system mailbox

Exchange Server 2013 > Messaging policy and compliance > In-Place eDiscovery >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-07-14*

In-Place eDiscovery uses a system mailbox to store In-Place eDiscovery search metadata. This Discovery system mailbox has the display name **SystemMailbox{e0dc1c29-89c3-4034-b678-e6c29d823ed9}**. Because system mailboxes aren't visible in the Exchange Administration Center (EAC) or in Exchange address lists, they are rarely deleted inadvertently.

However, if the Discovery system mailbox is deleted accidentally, discovery managers will be unable to perform In-Place eDiscovery searches or manage existing searches. In this case, to enable eDiscovery functionality, you must re-create the Discovery system mailbox.

What you should know before you begin

- Estimated time to complete: 10 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Use the Shell to re-create the Discovery system mailbox

1. Delete the SystemMailbox{e0dc1c29-89c3-4034-b678-e6c29d823ed9} user account from Active Directory, if it exists. By default, Exchange Server 2013 Setup creates the mailbox in the Users container in Active Directory. For details about how to delete a user account from Active Directory, see Delete a User Account.
2. Prepare Active Directory by running Microsoft Exchange 2013 Setup with the **/PrepareAD** switch in the root domain of your Active Directory forest. For details, see Prepare Active Directory and domains.
3. Use the Shell to enable the Discovery system mailbox.

Note:
You can't use the EAC to enable the Discovery system mailbox.

This example enables the Discovery system mailbox. You must specify the fully qualified domain name (FQDN) of a global catalog server in the root domain of the Active Directory forest.

```
Enable-Mailbox -Arbitration -DomainController <FQDN of root global catalog server> -Identity "SystemMailbox{e0dc1c29-89c3-4034-b678-e6c29d823ed9}"
```

For detailed syntax and parameter information, see Enable-Mailbox.

How do I know this worked?

To verify that you have successfully re-created the Discovery system mailbox, use the **Get-Mailbox** cmdlet with the *Arbitration* switch to retrieve system mailboxes. View the results of the command to verify that the system mailbox `SystemMailbox{e0dc1c29-89c3-4034-b678-e6c29d823ed9}` has been re-created.

Using OAuth authentication to support eDiscovery in an Exchange hybrid deployment

Exchange Server 2013 > Messaging policy and compliance > In-Place eDiscovery >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-05-07*

To successfully perform cross-premises eDiscovery searches in an Exchange 2013 hybrid organization, you will have to configure OAuth (Open Authorization) authentication between your Exchange on-premises and Exchange Online organizations so that you can use In-Place eDiscovery to search on-premises and cloud-based mailboxes. OAuth authentication supports the following eDiscovery scenarios in an Exchange hybrid deployment:

- Search on-premises mailboxes that use Exchange Online Archiving for cloud-based archive mailboxes.
- Search on-premises and cloud-based mailboxes in the same eDiscovery search.

For step-by-step instructions for configuring OAuth authentication to support eDiscovery, see Configure OAuth authentication between Exchange and Exchange Online organizations.

What is OAuth authentication?

OAuth authentication is a server-to-server authentication protocol that allows applications to authenticate to each other. With OAuth authentication, user credentials and passwords are not passed from one computer to another. Instead, authentication and authorization is based on the exchange of security tokens, which grant access to a specific set of resources for a specific amount of time.

OAuth authentication typically involves three parties: a single authorization server and the two realms that need to communicate with one another. Security tokens are issued by the authorization server (also known as a security token server) to the two realms that need to communicate; these tokens verify that communications originating from one realm should be trusted by the other realm. When using OAuth authentication between an on-premises Exchange organization and Exchange Online, the function of the authorization server is provided by Microsoft Azure Active Directory Access Control Services (ACS) in your Office 365 organization. For example, during a cross-premises eDiscovery search, Azure ACS issues tokens that verify that an administrator or compliance officer from the Exchange on-premises organization is able to access mailboxes in the Exchange Online organization, and vice-versa.

eDiscovery scenarios in a hybrid deployment

The follow table identifies the eDiscovery scenarios in an Exchange hybrid deployment that require OAuth authentication.

eDiscovery scenario	Requires OAuth authentication?
Search Exchange on-premises mailboxes and Exchange Online mailboxes in the same eDiscovery search initiated from the Exchange	Yes

on-premises organization. For example, searching all mailboxes in the organization in a single eDiscovery search.	
Search Exchange on-premises mailboxes that use Exchange Online Archiving for cloud-based archive mailboxes. When you use In-Place eDiscovery, both the primary and archive mailboxes are searched.	Yes
Search Exchange Online mailboxes from an eDiscovery search initiated from the Exchange on-premises organization by an administrator or compliance officer.	Yes
Search on-premises mailboxes using an eDiscovery search initiated from the Exchange on-premises organization by an administrator or compliance officer.	No **Note:** As previously discussed, OAuth authentication would be required if the on-premises mailboxes were configured with cloud-based archive mailboxes.
Search Exchange Online mailboxes from an eDiscovery search initiated from Exchange Online or the eDiscovery Center in SharePoint Online by an Office 365 tenant administrator or a compliance officer signed in to an Office 365 user account.	No

Configuring OAuth authentication to support eDiscovery

As previously stated, see Configure OAuth authentication between Exchange and Exchange Online organizations for instructions to configure OAuth authentication to support eDiscovery in an Exchange hybrid deployment.

If OAuth isn't configured for your Exchange hybrid deployment, you can't use eDiscovery to search Exchange on-premises and Exchange Online mailboxes in the same eDiscovery search. You will have to search on-premises mailboxes from an eDiscovery search initiated from your on-premises

organization. Similarly, you can only search Exchange Online mailboxes from an eDiscovery search initiated from your Exchange Online organization or by using the eDiscovery Center in SharePoint Online. Additionally, you won't be able to search primary on-premises mailboxes if their corresponding archive mailbox resides in Exchange Online or in an Exchange Online Archiving organization.

More information

- You can also use OAuth authentication to allow other applications, such as SharePoint 2013 and Lync Server 2013, to authenticate to Exchange 2013. For more information, see Configure OAuth authentication with SharePoint 2013 and Lync 2013.
- You can configure server-to-server authentication between Exchange 2013 and SharePoint 2013 so administrators and compliance officers can use the eDiscovery Center in SharePoint 2013 to search Exchange 2013 mailboxes. For more information, see Configure Exchange for SharePoint eDiscovery Center.
- You can configure an Exchange hybrid deployment using the Hybrid Configuration Wizard in Exchange 2013. For a customized, step-by-step hybrid deployment configuration checklist, see the Exchange Server Deployment Assistant.

Configure Exchange for SharePoint eDiscovery Center

Exchange Server 2013 > Messaging policy and compliance > In-Place eDiscovery >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-09-06*

Microsoft Exchange Server 2013 includes features that work with Microsoft SharePoint Server 2013 and Microsoft Lync Server 2013, known as *partner applications*. To make sure these partner applications can access each other's resources, you need to configure server-to-server authentication.

This topic shows you how to configure server-to-server authentication between Exchange 2013 and SharePoint 2013 so users can use the eDiscovery Center in SharePoint 2013 to search Exchange Server 2013 mailbox content. To fully enable this functionality, you must complete additional steps in SharePoint 2013. For details, see Configure eDiscovery in SharePoint 2013 .

What do you need to know before you begin?

- Estimated time to complete this task: 30 minutes.
- Procedures in this topic require specific permissions. See each procedure for its permissions

information.

- It's supported to install Exchange 2013 and SharePoint 2013 in different domains or forests. A Windows trust relationship between Exchange and SharePoint forests isn't required, because in that circumstance, Exchange and SharePoint will rely on the OAuth 2.0 protocol to trust one another.
- The SharePoint 2013 site must be configured to use Secure Sockets Layer (SSL).
- The Exchange Web Services Managed API must be installed on every server that is running SharePoint 2013. Reset Internet Information Server (IIS) after installation.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

How do you do this?

Step 1: Configure server-to-server authentication for Exchange 2013 on a server running SharePoint Server 2013

Run the following command to create Exchange 2013 as a trusted security token issuer in SharePoint 2013.

```
New-SPTrustedSecurityTokenIssuer -Name Exchange -
MetadataEndPoint https://<Exchange Server Name or FQDN>/
autodiscover/metadata/json/1
```

Step 2: Configure server-to-server authentication for SharePoint 2013 on a server running Exchange 2013

Perform this step on an Exchange 2013 server. You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Partner applications - configure" entry in the Sharing and collaboration permissions topic.

Run this command to configure the SharePoint partner application.

```
cd c:\'Program Files'\Microsoft\'Exchange Server'\V15
\Scripts
.\Configure-EnterprisePartnerApplication.ps1 -
AuthMetadataUrl <path to SharePoint AuthMetadataUrl> -
```

```
ApplicationType SharePoint
```

Step 3: Add authorized users to the Discovery Management role group

Add users who need to perform an eDiscovery search using SharePoint 2013 to the Discovery Management role group in Exchange 2013. For details, see Add a user to the Discovery Management role group.

Caution:
Adding users to the Discovery Management role group allows them to use In-Place eDiscovery to search all Exchange 2013 mailboxes and access potentially sensitive email content in user mailboxes. By default, this permission isn't assigned to any user, including members of the Organization Management role group. Check with your organization's legal or HR departments before assigning this permission to any user.

Unsearchable items in Exchange eDiscovery

Exchange Server 2013 > Messaging policy and compliance > In-Place eDiscovery >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-01-29*

In In-Place eDiscovery for Exchange Server 2013 and Exchange Online, unsearchable items are mailbox items that can't be indexed by Exchange Search or that have been only partially indexed. An unsearchable item typically contains a file, which can't be indexed, attached to an email message. Here are a few reasons why files can't be indexed for search and are returned as an unsearchable item when attached to an email message:

- The file type is unsupported for indexing because a search filter (also known as an *IFilter*) to index the file format isn't installed.
- The file type is disabled for indexing.
- The file type is supported for indexing but an indexing error occurred for a specific file.
- A file is encrypted with non-Microsoft technologies.
- A file is password-protected.

For a successful eDiscovery search, your organization may be required to review unsearchable items. You can specify whether to include unsearchable items when you copy eDiscovery search results to a discovery mailbox or export results to a PST file.

File types not supported for search

Certain types of files, such as Bitmap or MP3 files, don't contain content that can be indexed. As a result, Exchange Search doesn't perform full-text indexing on these types of files. These types of files are considered as unsupported file types. There are also file types for which full-text indexing has been disabled, either by default or by an administrator. Unsupported and disabled file types are considered unsearchable items in eDiscovery searches. These types of files, which are typically attached to an email message, are included in the result set when you include unsearchable items when copying or exporting search results. For a list of supported and disabled file formats, see File formats indexed by Exchange Search. In Exchange Server 2013, administrators can disable indexing for a supported file format by using the Set-SearchDocumentFormat cmdlet. This cmdlet isn't available in Exchange Online.

To identify the unsearchable items in a specific mailbox, you can run the Get-FailedContentIndexDocuments cmdlet to get a list of items that would be copied or exported when you choose to include unsearchable items with the search results.

Messages with unsupported file types returned in search results

Not every message with an unsupported file attachment is automatically returned as an unsearchable item. That's because other file properties, such as the filename, are indexed and available to be searched. For example, a keyword search for "financial" will return a message with an unsupported file attachment if that keyword appears in the file name. If the keyword only appears in the body of the attached file, the message would be returned as an unsearchable item.

Similarly, messages with unsupported file attachments are included in search results when other properties of a mailbox item, which are indexed and searchable, meet the search criteria. Message properties that are indexed for search include sent and received dates, sender and recipient, the file name of an attachment, and text in the message body. So even though a message attachment may be unsearchable, the message will be included in the regular search results if the value of other message properties matches the search criteria. In fact, it's common that messages with unsearchable attachments are included in the regular search results.

For a list of email message properties indexed for search, see Message properties indexed by Exchange Search.

Including unsearchable items in the search results

Your organization may be required to identify and perform additional processing on unsearchable items to determine what they are, what they contain, and whether they're relevant. To include unsearchable items with the eDiscovery search results, you can use the unsearchable items option

when you copy or export search results. To include unsearchable items when using In-Place eDiscovery in Exchange or Exchange Online, select the **Include unsearchable items** option when copying search results to a discovery mailbox or exporting them to a PST file. To include unsearchable items when using the eDiscovery Center in SharePoint or SharePoint Online, select the **Include items that are encrypted or have an unrecognized format** option.

Keep the following in mind when copying or exporting unsearchable items:

- When you copy unsearchable items to a discovery mailbox, any unsearchable items are copied to a separate folder named **Unsearchable**, which is located under the folder that contains the search results. When you export search results and include unsearchable items, the unsearchable items are exported to a separate PST file.
- When you include unsearchable items in the search results, all unsearchable items in the mailboxes that are searched will be returned, regardless of the search criteria.
- If you choose to include all mailbox items in the search results or if a search query doesn't specify any keywords or only specifies a date range, unsearchable items may not be copied to the **Unsearchable** folder if you select the option to include unsearchable items. This is because all items, including any unsearchable items, will be automatically included in the regular search results.
- As previously stated, because message properties and metadata are indexed, a keyword search may return results if that keyword appears in the properties or metadata of a message with an unsearchable file attached to it. In this case, two copies of the same mailbox item will also be included in the search results. To prevent this type of duplication and only include one copy of the item in the regular search results, you can select the **Enable deduplication** option when you copy or export the search results.
- Including unsearchable items in the search results can also affect the estimated search results that are displayed. If you include unsearchable items when copying search results, the total estimated item count and the total estimated size will include the unsearchable items.

For more information about including unsearchable items in search results, see:

- Create an In-Place eDiscovery search
- Export eDiscovery search results to a PST file
- SharePoint: Export eDiscovery content and create reports

More information about unsearchable items

- Although a file type supported by Exchange Search and is full-text indexed, there can be indexing or search errors that will cause a file to be returned as an unsearchable item. For example, searching a very large Excel file might be partially successful, but will then fail as the size limit is exceeded. In this case, it's possible that the same file is returned with the search results and as an unsearchable item.
- Attached files encrypted with Microsoft technologies are indexed by Exchange Search and will be searched. Files encrypted with non-Microsoft technologies are returned as unsearchable.
- Email messages encrypted with S/MIME aren't indexed and are considered unsearchable items. This includes encrypted messages with or without file attachments.

- Messages protected using Information Rights Management (IRM) are indexed by Exchange Search and included in the search results if they match query parameters. For more information about IRM, see Information Rights Management.
- As previously stated, because message properties and metadata are indexed, a keyword search may return results if that keyword appears in the indexed metadata. However, that same keyword search may not return the same item if the keyword only appears in the content of an attached item with an unsupported file type. In this case, the item would be returned only as an unsearchable item.
- In eDiscovery in Exchange 2010, there is the concept of a *safelist*. These are file types that contain content that isn't searchable and so aren't indexed by Exchange Search; for example, Windows Media Video (.wmv) and Waveform Audio (.wav) files. Because these types of files don't contain searchable content, they aren't considered unsearchable items in Exchange 2010. Mailbox items containing these file types weren't returned as unsearchable items and weren't copied to a discovery mailbox.

There is no longer a safelist in Exchange 2013 or Exchange Online. File types are either enabled or disabled for indexing or they are unsupported. Disabled and unsupported file types are considered unsearchable items.

Messaging records management

Exchange Server 2013 > Messaging policy and compliance >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-11-20*

Users send and receive email every day. If left unmanaged, the volume of email generated and received each day can inundate users, impact user productivity, and expose your organization to risks. As a result, email lifecycle management is a critical component for most organizations.

Messaging records management (MRM) is the records management technology in Microsoft Exchange Server 2013 that helps organizations manage email lifecycle and reduce the legal risks associated with email. Deploying MRM can help your organization in several ways:

- **Meet business requirements** Depending on your organization's messaging policies, you may need to retain important email messages for a certain period. For example, a user's mailbox may contain critical messages related to business strategy, transactions, product development, or customer interactions.
- **Meet legal and regulatory requirements** Many organizations have a legal or regulatory requirement to store messages for a designated period and remove messages older than that period. Storing messages longer than necessary may increase your organization's legal or financial risks.
- **Increase user productivity** If left unmanaged, the ever-increasing volume of email in your users'

mailboxes can also impact their productivity. For example, although newsletter subscriptions and automated notifications may have informational value when they're received, users may not remove them after reading (often they're never read). Many of these types of messages don't have a retention value beyond a few days. Using MRM to remove such messages can help reduce information clutter in users' mailboxes, thereby increasing productivity.

- **Improve storage management** Due to expectations driven by free consumer email services, many users keep old messages for a long period or never remove them. Maintaining large mailboxes is increasingly becoming a standard practice, and users shouldn't be forced to change their work habits based on restrictive mailbox quotas. However, retaining messages beyond the period that's necessary for business, legal, or regulatory reasons also increases storage costs.

Looking for management tasks related to MRM? See Messaging Records Management Procedures.

MRM in Exchange 2013

In Exchange 2013 (and also in Exchange 2010), MRM is accomplished through the use of retention tags and retention policies. Retention tags are used to apply retention settings to an entire mailbox and default mailbox folders such as Inbox and Deleted Items. You can also create and deploy retention tags that Outlook 2010 and later and Outlook Web App users can use to apply to folders or individual messages. After they're created, you add retention tags to a retention policy and then apply the policy to users. The Managed Folder Assistant, a mailbox assistant that runs on Exchange 2013 Mailbox servers, processes mailboxes and applies retention settings in the user's retention policy. To learn more about retention policies, see Retention tags and retention policies.

When a message reaches its retention age specified in the applicable retention tag, the Managed Folder Assistant takes the retention action specified by the tag. Messages can then be deleted permanently or deleted with the ability to recover them. If an archive has been provisioned for the user, you can also use retention tags to move items to the user's In-Place Archive. To learn more about In-Place Archiving in Exchange 2013, see In-Place Archiving.

Note:

Managed folders, the MRM feature available in Exchange 2007 and deprecated in Exchange 2010, isn't available in Exchange 2013. You must port your managed folder policy settings to retention policies.

MRM strategies

You can use retention policies to enforce basic message retention for an entire mailbox or for specific default folders. Although there are several strategies for deploying MRM, here are some of the most common:

Remove all messages after a specified period. In this strategy, you implement a single MRM policy that removes all messages after a certain period. In this strategy, there's no classification of messages. You can implement this policy by creating a single default policy tag (DPT) for the mailbox. However, this doesn't ensure that messages are retained for the specified period. Users

can still delete messages before retention period is reached.

Remove messages based on folder location. In this strategy, you implement MRM policies based on email location. For example, you can specify that messages in the Inbox are retained for one year and messages in the Junk Email folder are retained for 60 days. You can implement this policy by using a combination of retention policy tags (RPTs) for each default folder you want to configure and a DPT for the entire mailbox. The DPT applies to all custom folders and all default folders that don't have an RPT applied.

Note:
In Exchange 2013, you can create RPTs for the Calendar and Tasks folders. If you don't want items in these folders or other default folders to expire, you can create a disabled retention tag for that default folder.

Allow users to classify messages. In this strategy, you implement MRM policies that include a baseline retention setting for all messages but allow users to classify messages based on business or regulatory requirements. In this case, users become an important part of your records management strategy - often they have the best understanding of a message's retention value.

In Exchange 2013, users can apply different retention settings to messages that need to be retained for a longer or shorter period. You can implement this policy using a combination of the following:

- A DPT for the mailbox
- Personal tags that users can apply to custom folders or individual messages
- (Optional) Additional RPTs to expire items in specific default folders

For example, you can use a retention policy with personal tags that have a shorter retention period (such as two days, one week, or one month), as well as personal tags that have a longer retention period (such as one, two, or five years). Users can apply personal tags with the shorter retention periods for items such as newsletter subscriptions that may lose their value within days of receiving them, and apply the tags with longer periods to preserve items that have a high business value. They can also automate the process by using Inbox rules in Outlook and Outlook Web App.

Retain messages for eDiscovery purposes. In this strategy, you implement MRM policies that remove messages from mailboxes after a specified period but also retain them in the Recoverable Items folder for In-Place eDiscovery purposes, even if the messages were deleted by the user or another process.

In Exchange 2013, you can meet this requirement by using a combination of retention policies and In-Place Hold. Retention policies remove messages from the mailbox after the specified period. A time-based In-Place Hold preserves messages that were deleted or modified before that period. For example, to retain messages for seven years, you can create a retention policy with a DPT that deletes messages in seven years and an In-Place Hold to hold messages for seven years. Messages that aren't removed by users will be deleted after seven years; messages deleted by users before the seven year period will be retained in the Recoverable Items folder for seven years. To learn more about this folder, see Recoverable Items folder.

Optionally, you can use RPTs and personal tags to allow users to clean up their mailboxes. However,

In-Place Hold continues to retain the deleted messages until the hold period expires.

Note:
A time-based In-Place Hold is similar to what was informally referred to as a *rolling legal hold* in Exchange 2010. Rolling legal hold was implemented by configuring the deleted item retention period for a mailbox database or individual mailbox. However, deleted item retention retains deleted and modified items based on the date deleted. In-Place Hold preserves items based on the date they're received or created. This ensures that messages are preserved for at least the specified period.

Move messages to archive mailboxes. In this strategy, you implement MRM policies that move items to the user's archive mailbox. An archive mailbox provides additional storage for users to maintain old and infrequently accessed content. Retention tags that move items are also known as *archive policies*. Within the same retention policy, you can combine a DPT and personal tags to move items, and a DPT, RPTs, and personal tags to delete items. To learn more about archiving policies, see In-Place Archiving.

In Exchange 2013, MRM provides the flexibility to implement the records management policy that best meets your organization's requirements. With a good understanding of MRM, In-Place Archiving, and In-Place Hold, you can help meet your goals of managing mailbox storage and meeting regulatory retention requirements.

Messaging records management terminology in Exchange 2013

Retention tags and retention policies

Messaging records management terminology in Exchange 2013

Exchange Server 2013 > Messaging policy and compliance > Messaging records management >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-30*

This topic defines the core components associated with messaging records management (MRM) in Microsoft Exchange Server 2013. MRM is a records management technology in Exchange 2013 that helps organizations reduce the risks associated with e-mail and other communications. MRM makes it easier to keep messages needed to comply with company policy, government regulations, or legal needs, and to remove content that has no legal or business value.

default policy tag (DPT)

A DPT is a retention tag that applies to all items in a mailbox that don't already have a retention tag applied. You can have only one DPT in a retention policy.

filer user or filer

A user who regularly files mailbox items into folders.

Compare to piler user or piler.

journaling

The ability to record communications, including e-mail communications, in an organization for use in the organization's e-mail retention or archival strategy. In MRM, journaling commonly refers to the process of sending a journal report about messages in a managed folder to the specified SMTP address. This process is performed by the Managed Folder Assistant.

managed content settings

The retention information created for managed folders, the MRM feature available in Exchange Server 2007 and Exchange Server 2010. A managed folder can have multiple content settings for different message types such as e-mail messages, voice mail, and calendar items. Message retention settings defined in content settings for a managed folder apply to messages in that managed folder.

managed folder

Used for the MRM functionality in Exchange Server 2007 and Exchange Server 2010, a managed folder is an Active Directory object that represents a mailbox folder in order to apply managed content settings to it. In a mailbox, a managed folder is a folder to which managed content settings have been applied.

Managed Folder Assistant

One of the Microsoft Exchange Mailbox Assistants in Exchange 2013. The Managed Folder Assistant is responsible for archiving, message expiration, and compliance. It processes mailboxes and applies retention policies.

managed folder mailbox policy

A logical grouping of managed folders. In Exchange 2010 and Exchange 2007, when a managed folder mailbox policy is applied to a user's mailbox, all managed folders linked to the policy are deployed in a single operation.

personal tag

A personal tag is a retention tag available to Outlook Web App and Outlook 2010 and later users for applying retention settings to custom folders and individual items, such as e-mail messages.

piler user or piler

A user who doesn't file mailbox items regularly. Piler users tend to have a large Inbox and rely on search to find messages.

Compare to filer user or filer.

policy

See *retention policy* or *managed folder mailbox policy*.

retention policy tag (RPT)

A RPT is a retention tag that's applied to default folders such as Inbox and Deleted Items.

retention policy

A retention policy is logical grouping of retention tags. When a retention policy is applied to a user's mailbox, all retention tags linked to the policy are deployed in a single operation.

retention tag

Retention tags are used to apply retention settings to messages and folders in user mailboxes. There are three types of retention tags:
- Default policy tags (DPTs)
- Retention policy tags (RPTs)
- Personal tags

Retention tags and retention policies

Exchange Server 2013 > Messaging policy and compliance > Messaging records management >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-09-03*

In Microsoft Exchange Server 2013 and Exchange Online, Messaging records management (MRM) helps organizations to manage email lifecycle and reduce legal risks associated with e-mail and other communications. MRM makes it easier to keep messages needed to comply with company policy, government regulations, or legal needs, and to remove content that has no legal or business value.

Looking for management tasks related to MRM? See Messaging Records Management Procedures.

Contents

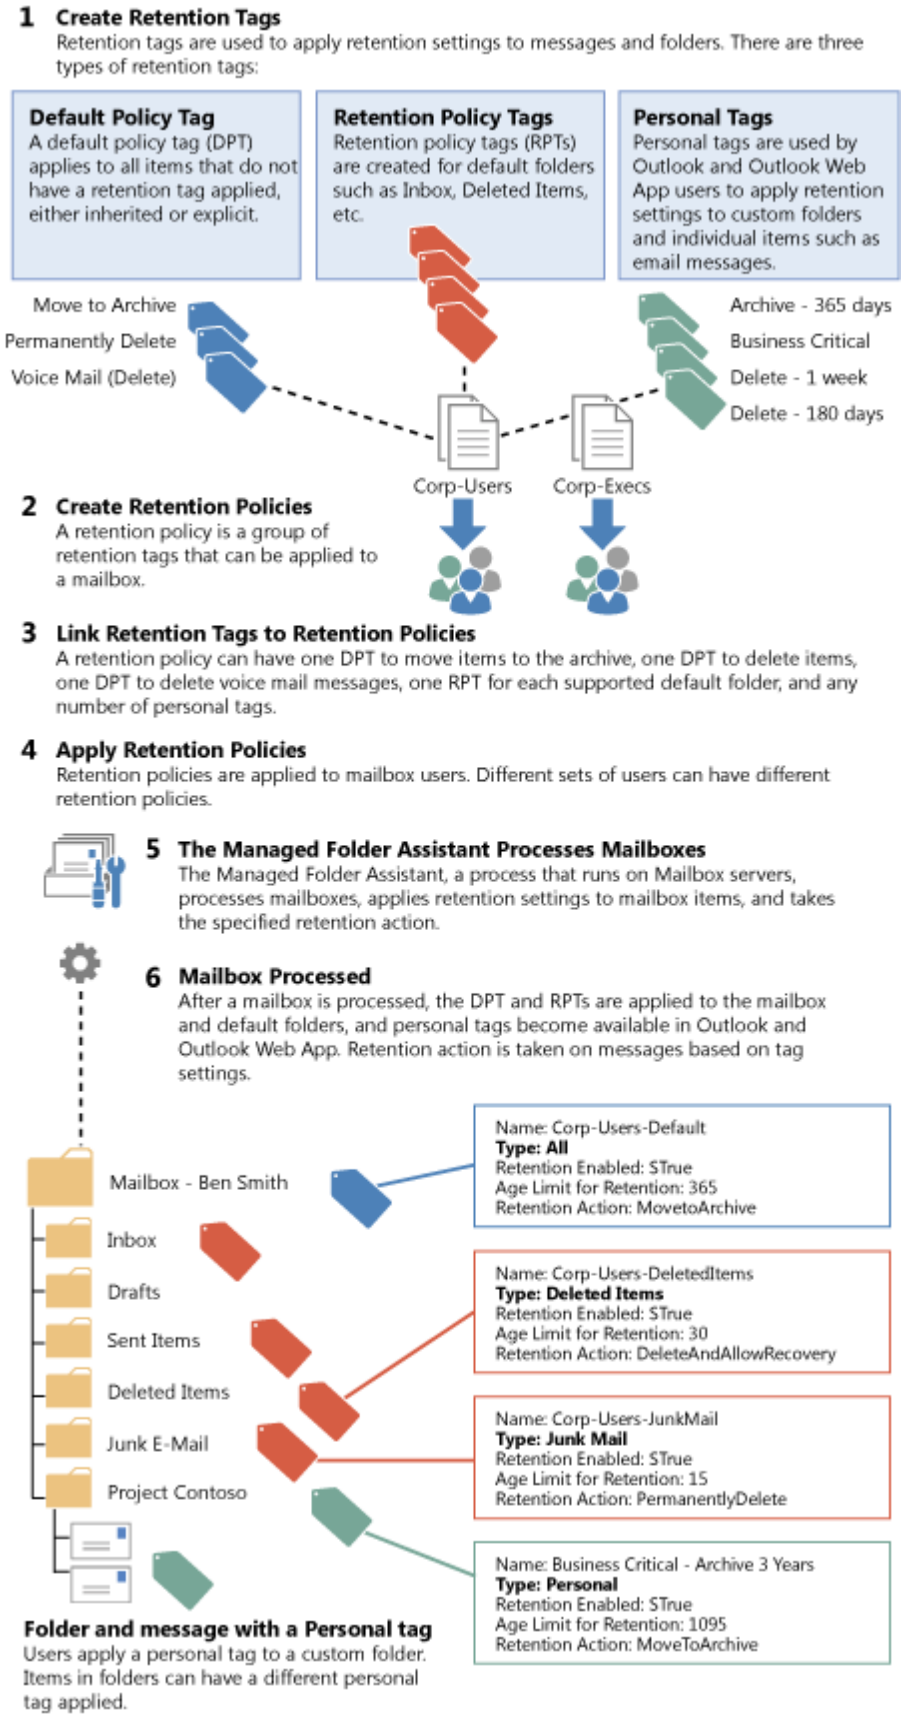
Messaging Records Management strategy

MRM in Exchange 2013 and Exchange Online is accomplished by using *retention tags* and *retention policies*. Before discussing the details about each of these retention features, it's important to learn how the features are used in the overall MRM strategy. This strategy is based on:

- Assigning *retention policy tags* (RPTs) to default folders, such as the Inbox and Deleted Items.
- Applying *default policy tags* (DPTs) to mailboxes to manage the retention of all untagged items.
- Allowing the user to assign *personal tags* to custom folders and individual items.
- Separating MRM functionality from users' Inbox management and filing habits. Users aren't required to file messages in managed folders based on retention requirements. Individual messages can have a different retention tag than the one applied to the folder in which they're located.

The following figure illustrates the tasks involved in implementing this strategy.

Messaging records management strategy



Return to top

Requirements

The following table shows requirements for the Mailbox server and client application.

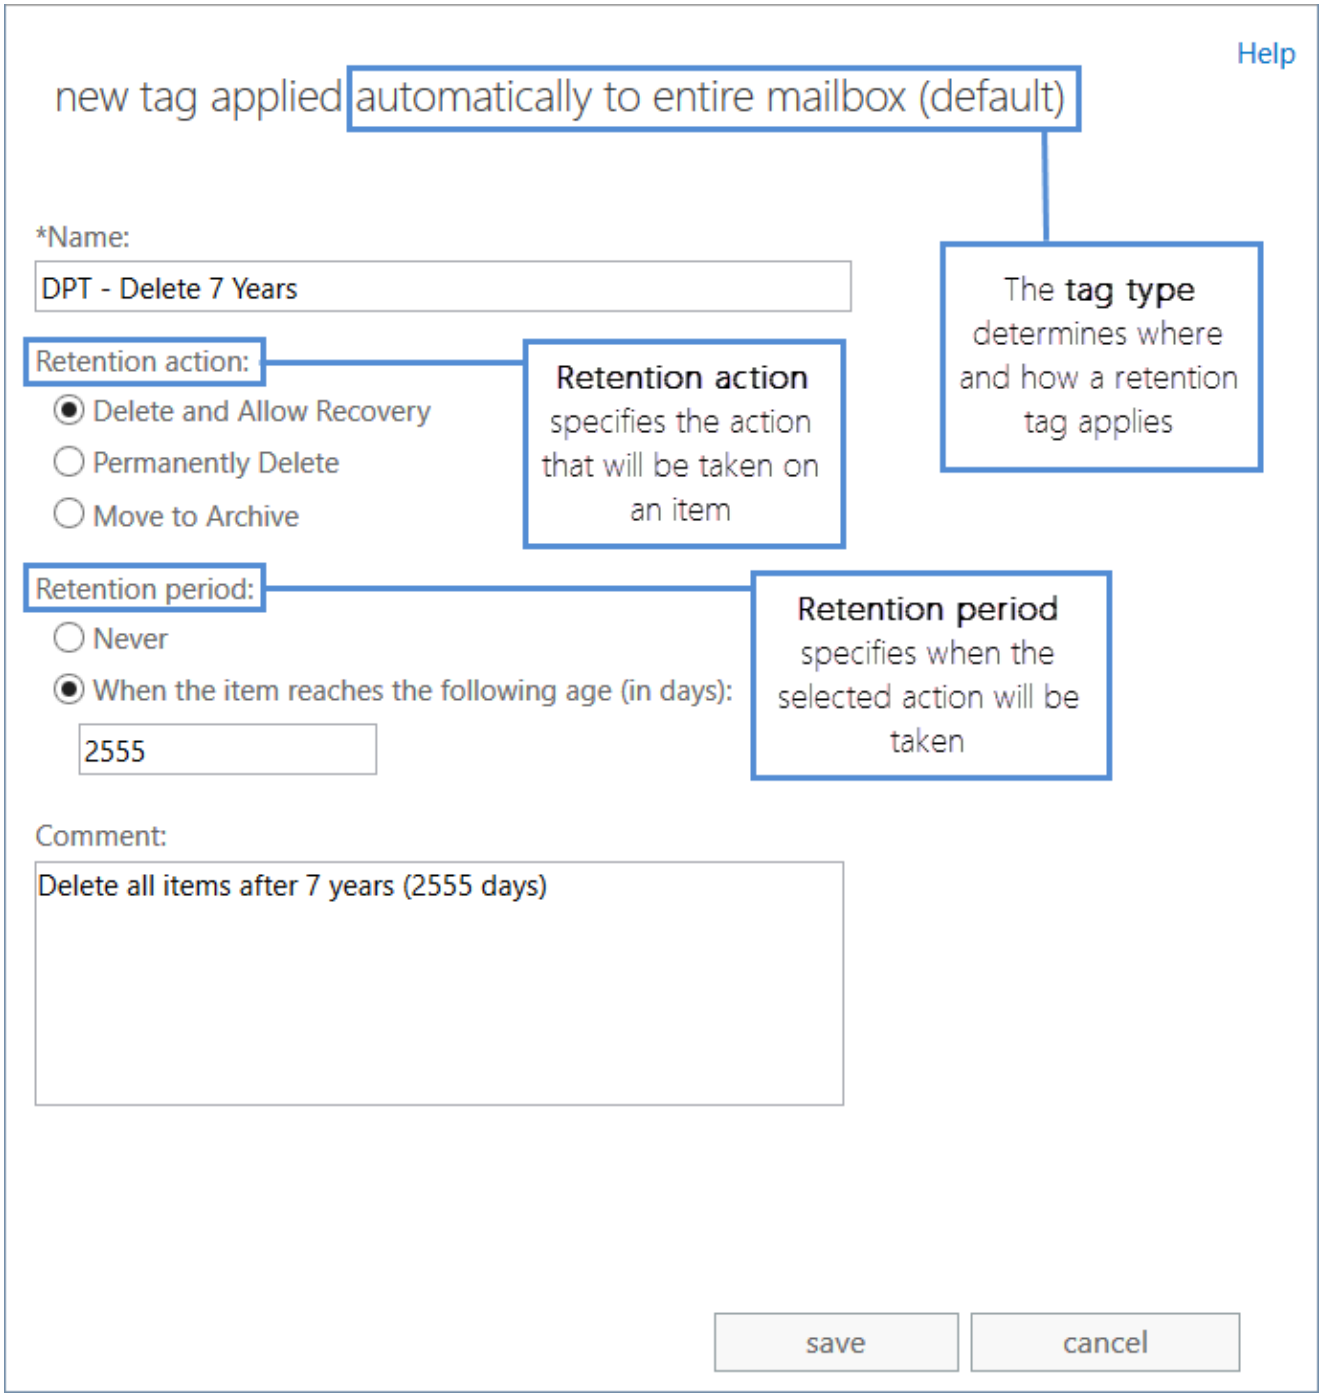
Retention tag and retention policy requirements

Location	Requirement
Mailbox server	Exchange 2010 or later is required.
Client application (to view retention tags and apply personal tags)	Only Microsoft Outlook 2010 and later, and Microsoft Office Outlook Web App users apply personal tags and view the retention tags applied to their mailbox folders or items. **Note:** Because retention policies are processed on Mailbox servers, they're independent of the Outlook version used by the users in your organization. You can still apply retention policies to user mailboxes running Microsoft Office Outlook 2007 and earlier. In these cases, RPTs in the policy apply to the default folders in their mailbox, and the DPT applies to untagged mailbox items.

Return to top

Retention tags

As illustrated in the preceding figure, retention tags are used to apply retention settings to folders and individual items such as e-mail messages and voice mail. These settings specify how long a message remains in a mailbox and the action to be taken when the message reaches the specified retention age. When a message reaches its retention age, it's moved to the user's In-Place Archive or deleted.



Retention tags allow users to tag their own mailbox folders and individual items for retention. Users no longer have to file items in managed folders provisioned by an administrator based on message retention requirements.

Types of retention tags

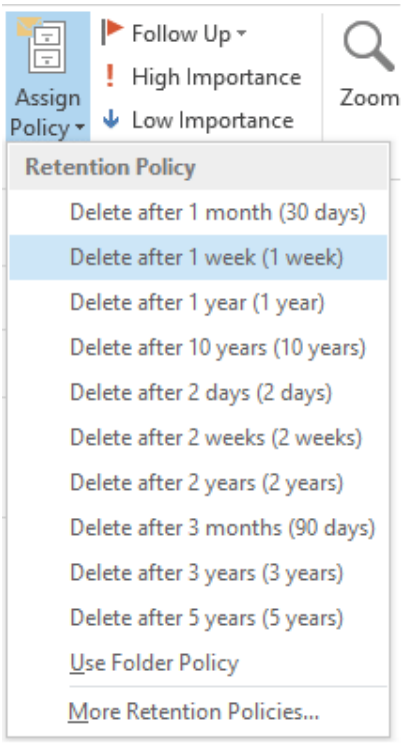
Retention tags are classified into the following three types based on who can apply them and where in a mailbox they can be applied.

Type of retention tag	Applied..	Applied by..	Action to take...	Details
Default Policy Tag (DPT)	Automatically to entire mailbox	Administrator	• Move to archive • Delete and allow	Users can't change DPTs

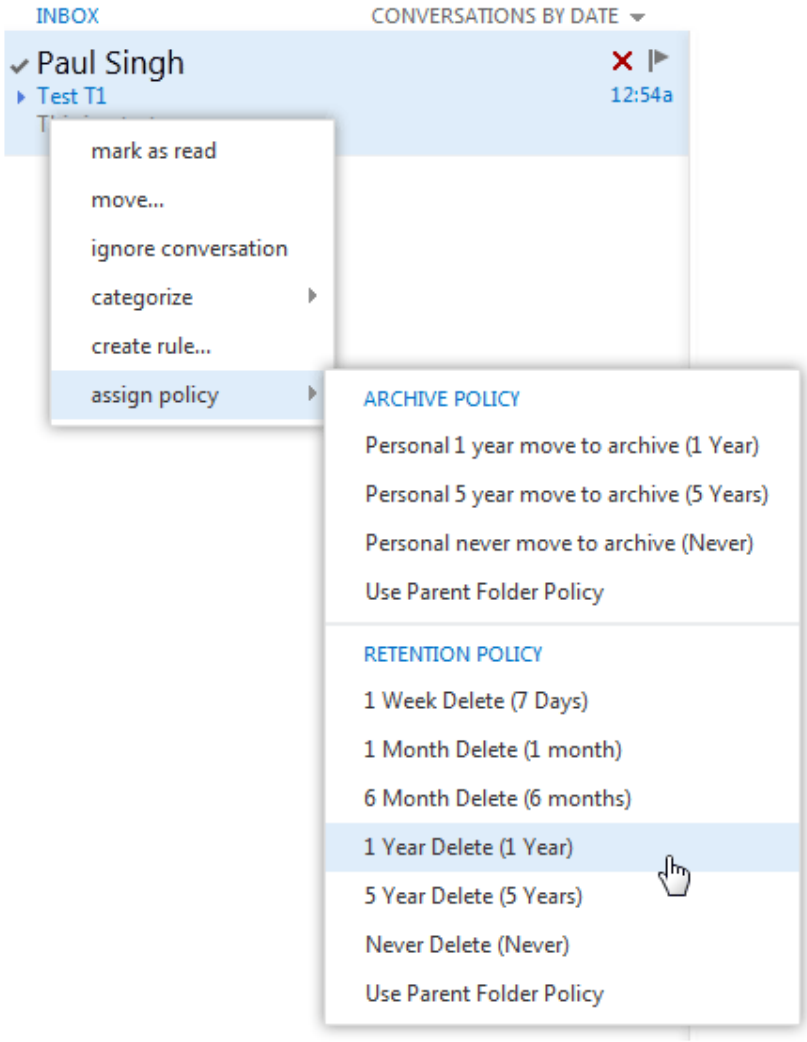
	A DPT applies to *untagged* items - items that don't have a retention tag applied directly or by inheritance from the folder.		recovery • Permanently delete	applied to a mailbox.
Retention Policy Tag (RPT)	Automatically to a default folder Default folders are folders created automatically in all mailboxes, for example: **Inbox**, **Deleted Items**, and **Sent Items**. See the list of supported default folders in Default folders that support Retention Policy Tags.	Administrator	• Delete and allow recovery • Permanently delete	Users can't change the RPT applied to a default folder.
Personal Tag	Manually to items and folders Users can automate tagging by using Inbox rules to either move a message	Users	• Move to archive • Delete and allow recovery • Permanently delete	Allow your users to determine how long an item should be retained. For example, the mailbox can have a DPT to delete

	to a folder that has a particular tag or to apply a personal tag to the message.			items in seven years, but a user can create an exception for an item or items in a folder by applying a personal tag that deletes an item such as newsletters and automated notifications in three days.

Personal tags Personal tags are available to Outlook 2010 and Outlook Web App users as part of their retention policy. Users can apply personal tags to folders they create or to individual items, even if those items already have a different tag applied. In Outlook 2010 and Outlook Web App, personal tags with the **Move to Archive** action appear as **Archive Policy**, and personal tags with the **Delete and Allow Recovery** or **Permanently Delete** actions appear as **Retention Policy**, as shown in the following figure.



Outlook 2013



OWA 2013

Messages that have a personal tag applied are always processed based on the personal tag's settings. Users can apply a personal tag to a message so that it's moved or deleted sooner or later than the settings specified in the DPT or RPTs applied to that user's mailbox. You can also create personal tags with retention disabled. This allows users to tag items so they're never moved to an archive or never expire.

Note:

Users can apply archive policies to default folders, user-created folders or subfolders, and individual items. Users can apply a retention policy to user-created folders or subfolders and individual items (including subfolders and items in a default folder), but not to default folders.

Users can also use the Exchange Administration Center (EAC) to select additional personal tags that aren't linked to their retention policy. The selected tags then become available in Outlook 2010 and Outlook Web App. To enable users to select additional tags from the EAC, you must add the MyRetentionPolicies role to the user's role assignment policy. To learn more about role assignment policies for users, see Understanding management role assignment policies. If you allow users to select additional personal tags, all personal tags in your Exchange organization become available to them.

Note:

Personal tags are a premium feature. Mailboxes with policies that contain these tags (or as a result of users adding the tags to their mailbox) require an Exchange Enterprise client access license (CAL).

Retention age limit and retention actions

When you enable a retention tag, you must specify a retention age for the tag. This age indicates the number of days to retain a message after it arrives in the user's mailbox.

The retention age for non-recurring items (such as email messages) is calculated differently than items that have an end date or recurring items (such as meetings and tasks). To learn how retention age is calculated for different types of items, see How retention age is calculated.

You can also create retention tags with retention disabled or disable tags after they're created. Because messages that have a disabled tag applied aren't processed by the Managed Folder Assistant, no retention action is taken. As a result, users can use a disabled personal tag as a **Never Move** tag or a **Never Delete** tag to override a DPT or RPT that would otherwise apply to the message.

When creating or configuring an RPT, you can select from one of the following actions to specify what retention action should be taken when a mailbox item reaches its retention age:

- **Move to Archive** This action moves a message to the user's archive mailbox. Tags that have this action applied are known as *archive tags*. Messages are moved to a folder in the archive mailbox that has the same name as the source folder in the user's primary mailbox. This allows users to easily locate messages in their archive mailbox. The **Move to Archive** action is available only for DPTs and personal tags. You can't create an RPT with the **Move to Archive** action. If the mailbox user doesn't have an archive mailbox, no action is taken. To learn more about archive mailboxes, see In-Place Archiving.
- **Delete and Allow Recovery** This action emulates the behavior when the Deleted Items folder is emptied. Tags that have this action applied are known as *deletion tags*. When this action occurs, and deleted item retention is configured for the mailbox database or the user, messages move to the Recoverable Items folder. The Recoverable Items folder (previously known as the dumpster) provides the user another chance to recover deleted messages. To do so, the user would access the **Recover Deleted Items** dialog box in Outlook 2010 or Outlook Web App. To learn more about recoverable items, see Recoverable Items folder.
- **Permanently Delete** This action permanently deletes a message. Like tags with the **Delete and Allow Recovery** action, tags that have this action applied are known as deletion tags. When this action is applied to a message, it's purged from the mailbox. This action is like a deleted message being removed from the Recoverable Items folder. After this happens, the user can no longer recover the message.
- **Mark as Past Retention Limit** This action isn't available in the Exchange Administration Center (EAC); you must use the Shell. This action marks a message as expired after it reaches its retention age. In Outlook 2010 or later, and Outlook Web App, expired items are displayed with the notification stating 'This item has expired' and 'This item will expire in 0 days'. In Outlook 2007,

items marked as expired are displayed by using strikethrough text.

Important:

If In-Place Hold or litigation hold is enabled for a mailbox user, permanently deleted items are retained in the Recoverable Items store until hold is removed. In-Place eDiscovery will still return permanently deleted messages in search results. To learn more, see In-Place Hold and In-Place eDiscovery.
If single item recovery is enabled for the mailbox, permanently deleted items are retained in the Recoverable Items store until the deleted item retention period for the mailbox database (or the deleted item retention period for the mailbox, if specified) is reached. To learn more, see Recoverable Items folder.

For details about how to create retention tags, see Create a Retention Policy.

Return to top

Retention policies

To apply one or more retention tags to a mailbox, you must add them to a retention policy and then apply the policy to mailboxes. A mailbox can't have more than one retention policy. Retention tags can be linked to or unlinked from a retention policy at any time, and the changes automatically take effect for all mailboxes that have the policy applied.

A retention policy can have the following retention tags:

- One RPT for each supported default folder

Note:

You can't link more than one RPT for a particular default folder (such as **Deleted Items**) to the same retention policy.

- One DPT with the **Move to Archive** action
- One DPT with the **Delete and Allow Recovery** or **Permanently Delete** actions
- One DPT for voice mail messages with the **Delete and Allow Recovery** or **Permanently Delete** actions
- Any number of personal tags

Although you can add any number of personal tags to a retention policy, having many personal tags with different retention settings can confuse users. We recommend linking no more than 10 personal tags to a retention policy.

Note:

Although a retention policy doesn't need to have any retention tags linked to it, we don't recommend using this scenario. If mailboxes with retention policies don't have retention tags linked to them, this may cause mailbox items to never expire.

A retention policy can contain both archive tags (tags that move items to the personal archive mailbox) and deletion tags (tags that delete items). A mailbox item can also have both types of tags applied. Archive mailboxes don't have a separate retention policy. The same retention policy is applied to the primary and archive mailbox.

When planning to create retention policies, you must consider whether they'll include both archive and deletion tags. As mentioned earlier, a retention policy can have one DPT that uses the **Move to Archive** action and one DPT that uses either the **Delete and Allow Recovery** or **Permanently Delete** action. The DPT with the **Move to Archive** action must have a lower retention age than the DPT with a deletion action. For example, you can use a DPT with the **Move to Archive** action to move items to the archive mailbox in two years, and a DPT with a deletion action to remove items from the mailbox in seven years. Items in both primary and archive mailboxes will be deleted after seven years.

For a list of management tasks related to retention policies, see Messaging Records Management Procedures.

Default Retention Policy

Exchange Setup creates the retention policy **Default MRM Policy**. The Default MRM Policy is applied automatically to new mailboxes in Exchange Online. In Exchange Server, the policy is applied automatically if you create an archive for the new user and don't specify a retention policy

You can modify tags included in the Default MRM Policy, for example by changing the retention age or retention action, disable a tag or modify the policy by adding or removing tags from it. The updated policy is applied to mailboxes the next time they're processed by the Managed Folder Assistant.

For more details, including a list of retention tags linked to the policy, see Default Retention Policy in Exchange Online and Exchange Server.

Note:
In Exchange 2010, the Default MRM Policy was named Default Archive and Retention Policy.

Return to top

Managed Folder Assistant

The Managed Folder Assistant, a mailbox assistant that runs on Mailbox servers, processes mailboxes that have a retention policy applied.

The Managed Folder Assistant applies the retention policy by inspecting items in the mailbox and determining whether they're subject to retention. It then stamps items subject to retention with the appropriate retention tags and takes the specified retention action on items past their retention age.

The Managed Folder Assistant is a throttle-based assistant. Throttle-based assistants are always running and don't need to be scheduled. The system resources they can consume are throttled. You can configure the Managed Folder Assistant to process all mailboxes on a Mailbox server within a certain period (known as a *work cycle*). Additionally, at a specified interval (known as the *work cycle checkpoint*), the assistant refreshes the list of mailboxes to be processed. During the refresh, the

assistant adds newly created or moved mailboxes to the queue. It also reprioritizes existing mailboxes that haven't been processed successfully due to failures and moves them higher in the queue so they can be processed during the same work cycle.

You can also use the Start-ManagedFolderAssistant cmdlet to manually trigger the assistant to process a specified mailbox. To learn more, see Configure the Managed Folder Assistant.

Note:
The Managed Folder Assistant doesn't take any action on messages that aren't subject to retention, specified by disabling the retention tag. You can also disable a retention tag to temporarily suspend items with that tag from being processed.

Moving items between folders

A mailbox item moved from one folder to another inherits any tags applied to the folder to which it's moved. If an item is moved to a folder that doesn't have a tag assigned, the DPT is applied to it. If the item has a tag explicitly assigned to it, the tag always takes precedence over any folder-level tags or the default tag.

Applying a retention tag to a folder in the archive

When the user applies a personal tag to a folder in the archive, if a folder with the same name exists in the primary mailbox and has a different tag, the tag on that folder in the archive changes to match the one in the primary mailbox. This is by design to avoid any confusion about items in a folder in the archive having a different expiry behavior than the same folder in the user's primary mailbox. For example, the user has a folder named Project Contoso in the primary mailbox with a *Delete – 3 years* tag and a Project Contoso folder also exists in the archive mailbox. If the user applies a *Delete – 1 year* personal tag to delete items in the folder after 1 year. When the mailbox is processed again, the folder reverts to the Delete – 3 Years tag.

Removing or deleting a retention tag from a retention policy

When a retention tag is removed from the retention policy applied to a mailbox, the tag is no longer available to the user and can't be applied to items in the mailbox.

Existing items that have been stamped with that tag continue to be processed by the Managed Folder Assistant based on those settings and any retention action specified in the tag is applied to those messages.

However, if you delete the tag, the tag definition stored in Active Directory is removed. This causes the Managed Folder Assistant to process all items in a mailbox and restamp the ones that have the removed tag applied. Depending on the number of mailboxes and messages, this process may

significantly consume resources on all Mailbox servers that contain mailboxes with retention policies that include the removed tag.

Important:

If a retention tag is removed from a retention policy, any existing mailbox items with the tag applied will continue to expire based on the tag's settings. To prevent the tag's settings from being applied to any items, you should delete the tag. Deleting a tag removes it from any retention policies in which it's included.

Disabling a retention tag

If you disable a retention tag, the Managed Folder Assistant ignores items that have that tag applied. Items that have a retention tag for which retention is disabled are either never moved or never deleted, depending on the specified retention action. Because these items are still considered tagged items, the DPT doesn't apply to them. For example, if you want to troubleshoot retention tag settings, you can temporarily disable a retention tag to stop the Managed Folder Assistant from processing messages with that tag.

Note:

The retention period for a disabled retention tag is displayed to the user as **Never**. If a user tags an item believing it will never be deleted, enabling the tag later may result in unintentional deletion of items the user didn't want to delete. The same is true for tags with the **Move to Archive** action.

Return to top

Retention hold

When users are temporarily away from work and don't have access to their e-mail, retention settings can be applied to new messages before they return to work or access their e-mail. Depending on the retention policy, messages may be deleted or moved to the user's personal archive. You can temporarily suspend retention policies from processing a mailbox for a specified period by placing the mailbox on retention hold. When you place a mailbox on retention hold, you can also specify a retention comment that informs the mailbox user (or another user authorized to access the mailbox) about the retention hold, including when the hold is scheduled to begin and end. Retention comments are displayed in supported Outlook clients. You can also localize the retention hold comment in the user's preferred language.

Note:

Placing a mailbox on retention hold doesn't affect how mailbox storage quotas are processed. Depending on the mailbox usage and applicable mailbox quotas, consider temporarily increasing the mailbox storage quota for users when they're on vacation or don't have access to e-mail for an extended period. For more information about mailbox storage quotas, see Configure storage quotas for a mailbox.

During long absences from work, users may accrue a large amount of e-mail. Depending on the

volume of e-mail and the length of absence, it may take these users several weeks to sort through their messages. In these cases, consider the additional time it may take the users to catch up on their mail before removing them from retention hold.

If your organization has never implemented MRM, and your users aren't familiar with its features, you can also use retention holds during the initial *warm up and training* phase of your MRM deployment. You can create and deploy retention policies and educate users about the policies without the risk of having items moved or deleted before users can tag them. A few days before the warm up and training period ends, you should remind users of the warm-up deadline. After the deadline, you can remove the retention hold from user mailboxes, allowing the Managed Folder Assistant to process mailbox items and take the specified retention action.

For details about how to place a mailbox on retention hold, see Place a mailbox on retention hold.

Return to top

Default Retention Policy in Exchange Online and Exchange Server

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-08-05*

Exchange creates the retention policy Default MRM Policy in your Exchange Online and on-premises Exchange organization. The policy is auomatically applied to new users in Exchange Online. In on-premises organizations, the policy is applied when you create an archive for the mailbox. You can change the retention policy applied to a user at any time.

You can modify tags included in the Default MRM Policy, for example by changing the retention age or retention actions, disable a tag, or modify the policy by adding or removing tags from it. The updated policy is applied to mailboxes the next time they're processed by the Managed Folder Assistant

Retention tags linked to the Default MRM Policy

The following table lists the default retention tags linked to the Default MRM Policy.

Name	Type	Retention age (days)	Retention action
Default 2 years move to archive	Default Policy Tag (DPT)	730	Move to Archive

Recoverable Items 14 days move to archive	Recoverable Items folder	14	Move to Archive
Personal 1 year move to archive	Personal tag	365	Move to Archive
Personal 5 year move to archive	Personal tag	1,825	Move to Archive
Personal never move to archive	Personal tag	Not applicable	Move to Archive
1 Week Delete	Personal tag	7	Delete and Allow Recovery
1 Month Delete	Personal tag	30	Delete and Allow Recovery
6 Month Delete	Personal tag	180	Delete and Allow Recovery
1 Year Delete	Personal tag	365	Delete and Allow Recovery
5 Year Delete	Personal tag	1,825	Delete and Allow Recovery
Never Delete	Personal tag	Not applicable	Delete and Allow Recovery

What you can do with the Default MRM Policy

You can...	In Exchange Online...	In Exchange Server...
Apply the Default MRM Policy automatically to new users	Yes, applied by default. No action is required.	Yes, applied by default if you also create an archive for the new user. If you create an archive for the

		user later, the policy is applied automatically only if the user doesn't have an existing Retention Policy.
Modify the retention age or retention action of a retention tag linked to the policy	Yes	Yes
Disable a retention tag linked to the policy	Yes	Yes
Add a retention tag to the policy	Yes	Yes
Remove a retention tag from the policy	Yes	Yes
Set another policy as the default retention policy to be applied automatically to new users	No	No

More Info

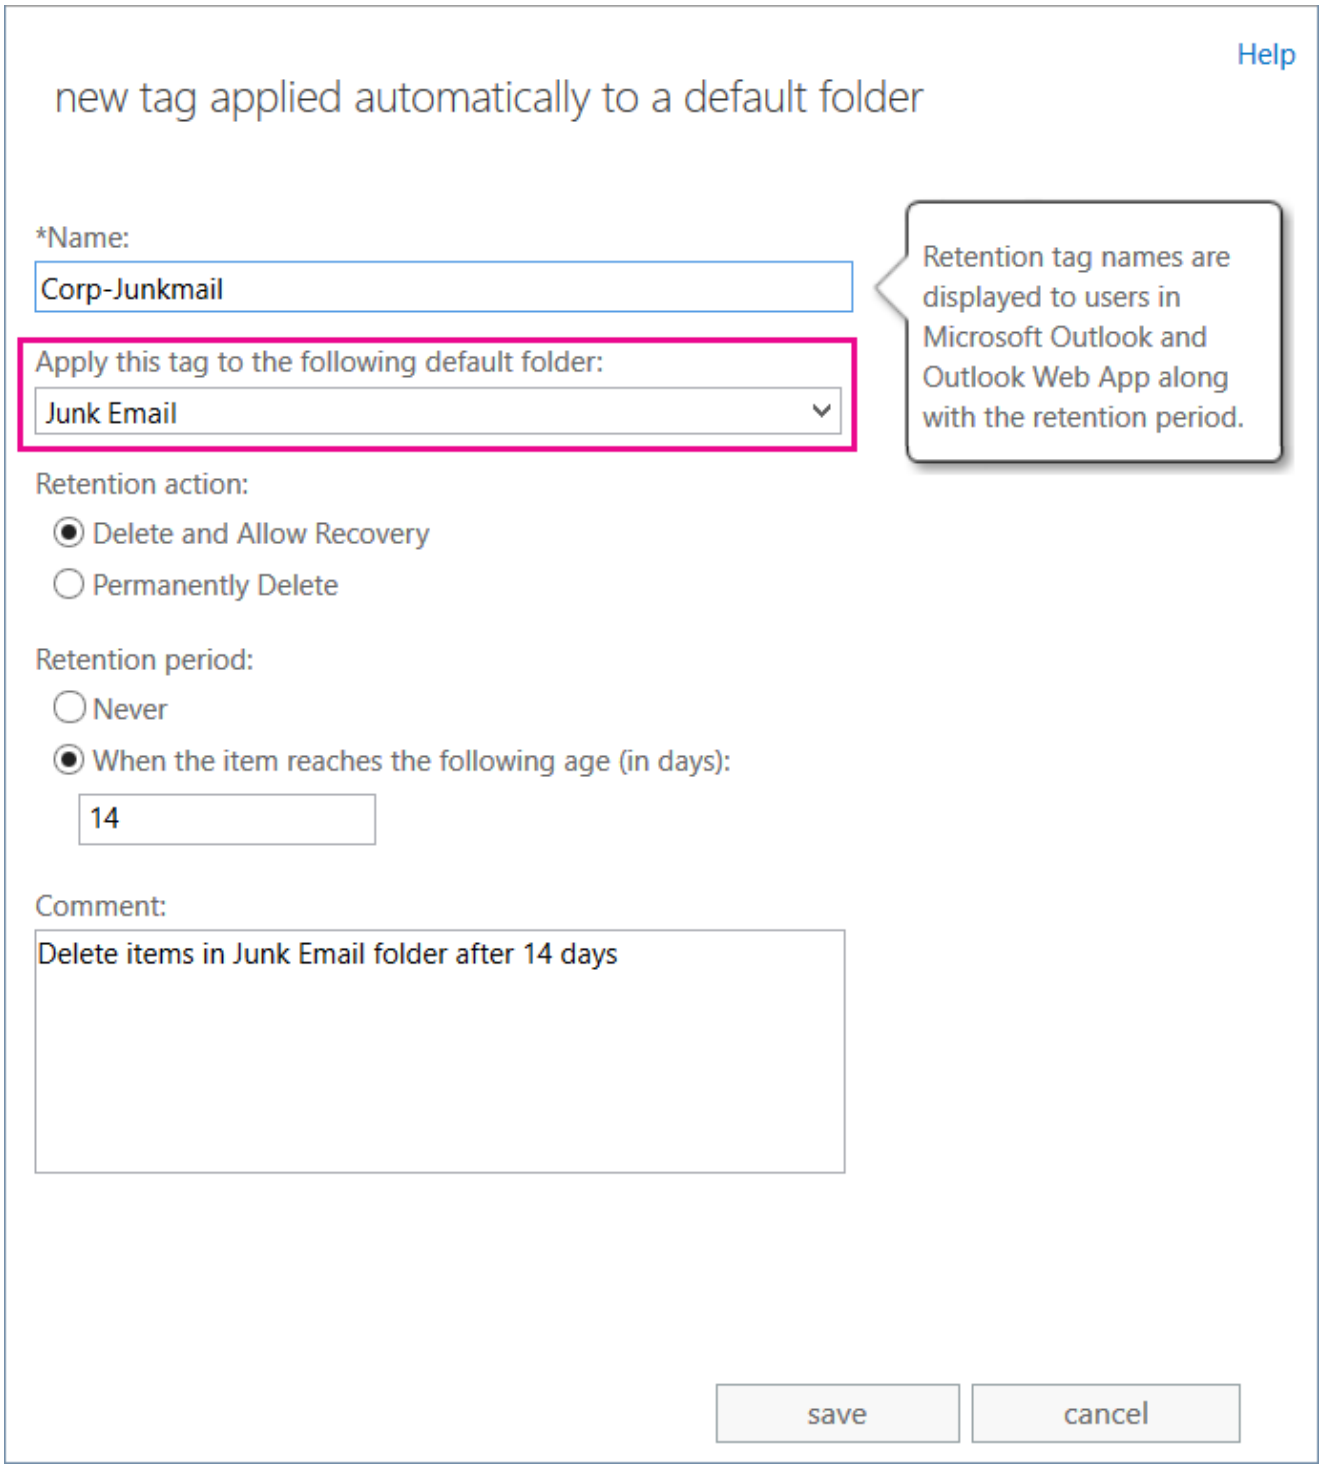
- A Retention Tag can be linked to more than one Retention Policy. For details about managing Retention tags and retention policies, see Messaging Records Management Procedures.
- The Default MRM Policy does not include a DPT to automatically delete items. If you want to automatically delete items after a specified period, create a DPT with the required delete action and add it to the policy. For details, see Create a Retention Policy and Add retention tags to or remove retention tags from a retention policy.
- Retention policies are applied to mailbox users. The same policy applies to the user's mailbox and archive.

Default folders that support Retention Policy Tags

Topic Last Modified: *2014-08-29*

You can use Retention tags and retention policies to manage email lifecycle. Retention Policies contain Retention Tags, which are settings you can use to specify when a message should be automatically moved to the archive or when it should be deleted.

A Retention Policy Tag (RPT) is a type of retention tag that you can apply to default folders in a mailbox, such as **Inbox** and **Deleted Items**.



Supported default folders

You can create RPTs for the default folders shown in the following table.

Folder name	Details
Calendar	This default folder is used to store meetings and appointments.
Conversation History	This folder is created by Microsoft Lync (previously Microsoft Office Communicator). Although not treated as a default folder by Outlook, it's treated as a special folder by Exchange and can have RPTs applied.
Deleted Items	This default folder is used to store items deleted from other folders in the mailbox. Outlook and Outlook Web App users can manually empty this folder. Users can also configure Outlook to empty the folder upon closing Outlook.
Drafts	This default folder is used to store draft messages that haven't been sent by the user. Outlook Web App also uses this folder to save messages that were sent by the user but not submitted to the Hub Transport server.
Inbox	This default folder is used to store messages delivered to a mailbox.
Journal	This default folder contains actions selected by the user. These actions are automatically recorded by Outlook and placed in a timeline view.
Junk E-mail	This default folder is used to save messages marked as junk e-mail by the content filter on an Exchange server or by the anti-spam filter in Outlook.
Notes	This folder contains notes created by users in Outlook. These notes are also visible in Outlook Web App.
Outbox	This default folder is used to temporarily store messages sent by the user until they're submitted to a Hub Transport server. A

	copy of sent messages is saved in the Sent Items default folder. Because messages usually remain in this folder for a brief period, it isn't necessary to create an RPT for this folder.	
RSS Feeds	This default folder contains RSS feeds.	
Recoverable Items	This is a hidden folder in the Non-IPM sub-tree. It contains the Deletions, Versions, Purges, and Audits sub-folders. Retention tags for this folder move items from the Recoverable Items folder in the user's primary mailbox to the Recoverable Items folder in the user's archive mailbox. You can assign only the **Move To Archive** retention action to tags for this folder. To learn more, see Recoverable Items folder.	
Sent Items	This default folder is used to store messages that have been submitted to a Hub Transport server.	
Sync Issues	This folder contains synchronization logs. To learn more, see Synchronization error folders.	
Tasks	This default folder is used to store tasks.	

More Info

- RPTs are retention tags for default folders. You can only select a delete action for RPTs – either **delete and allow recovery** or **permanently delete**.
- You can't create an RPT to move messages to the archive. To move old items to archive, you can create a *Default Policy Tag* (DPT), which applies to the entire mailbox, or *Personal Tags*, which are displayed in Outlook and Outlook Web App (OWA) as Archive Policies. Your users can apply them to folders or individual messages.
- You can't apply RPTs to the Contacts folder.
- You can only add one RPT for a particular default folder to a Retention Policy. For example, if a retention policy has an Inbox tag, you can't add another RPT of type Inbox to that retention policy.
- To learn how to create RPTs or other types of retention tags and add them to a retention policy, see Create a Retention Policy.
- In Exchange 2013 and Exchange Online, a DPT also applies to the **Calendar** and **Tasks** default folders. This may result in items being deleted or moved to the archive based on the DPT settings.

To prevent the DPT settings from deleting items in these folders , create RPTs with retention disabled. To prevent the DPT settings from moving items in a default folder, you can create a disabled Personal Tag with the move to archive action, add it to the retention policy, and then have users apply it to the default folder. For details, see Prevent archiving of items in a default folder in Exchange 2010.

How retention age is calculated

Messaging policy and compliance > Messaging records management > Retention tags and retention policies >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-06-16*

The Managed Folder Assistant (MFA) is one of many *mailbox assistant* processes that runs on mailbox servers. Its job is to process mailboxes that have a Retention Policy applied, add the Retention Tags included in the policy to the mailbox, and process items in the mailbox. If the items have a retention tag, the assistant tests the age of those items. If an item has exceeded its *retention age*, it takes the specified *retention action*. Retention actions include moving an item to the user's archive, deleting the item and allowing recovery, or deleting the item permanently.

See Retention tags and retention policies for more information.

Determining the age of different types of items

The retention age of mailbox items is calculated from the date of delivery or the date of creation for items such as drafts that are not delivered but created by the user. When the Managed Folder Assistant processes items in a mailbox, it stamps a start date and an expiration date for all items that have retention tags with the **Delete and Allow Recovery** or **Permanently Delete** retention action. Items that have an archive tag are also stamped with a move date.

Items in the Deleted Items folder and items which may have a start and end date, such as calendar items (meetings and appointments) and tasks, are handled differently as shown in this table.

If the item type is...	And the item is...	The retention age is calculated based on...
• Email message • Contact • Document • Fax • Journal item • Meeting request, response,	Not in the Deleted Items folder	• Delivery date or date of creation

or cancellation • Missed call		
• Email message • Contact • Document • Fax • Journal item • Meeting request, response, or cancellation • Missed call	In the Deleted Items folder	• Date of delivery or creation unless the item was deleted from a folder that does not have an inherited or implicit retention tag. • If an item is in a folder that doesn't have an inherited or implicit retention tag applied, the item isn't processed by the MFA and therefore doesn't have a start date stamped by it. When the user deletes such an item, and the MFA processes it for the first time in the Deleted Items folder, it stamps the current date as the start date.
Calendar	Not in the Deleted Items folder	• Non-recurring calendar items expire according to their end date. • Recurring calendar items expire according to the end date of their last occurrence. Recurring calendar items with no end date don't expire.
Calendar	In the Deleted Items folder	1. A calendar item expires according to its `message-received date`, if one exists. 2. If a calendar item doesn't have a `message-received date`, it expires according to its `message-creation date`. 3. If a calendar item has neither a `message-received date` nor a

		message-creation date, it doesn't expire.
Task	Not in the Deleted Items folder	• Non-recurring tasks: 1. A non-recurring task expires according to its message-received date, if one exists. 2. If a non-recurring task doesn't have a message-received date, it expires according to its message-creation date. 3. If a non-recurring task has neither a message-received date nor a message-creation date, it doesn't expire. • A recurring task expires according to the end date of its last occurrence. If a recurring task doesn't have an end date, it doesn't expire. • A regenerating task (which is a recurring task that regenerates a specified time after the preceding instance of the task is completed) doesn't expire.
Task	In the Deleted Items folder	1. A task expires according to its message-received date, if one exists. 2. If a task doesn't have a message-received date, it expires according to its message-creation date. 3. If a task has neither a message-received date nor a message-creation date, it doesn't expire.

Corrupted	Any folder	• Corrupted items are skipped by the Managed Folder Assistant and don't expire.

Examples

If the user..	The retention tags on folder...	The Managed Folder Assistant...
1. Receives a message in the Inbox on 01/26/2013. 2. Deletes the message on 2/27/2013.	• Inbox: Delete in 365 days • Deleted Items: Delete in 30 days	1. Processes the message in the Inbox on 1/26/2013, stamps it with a *start date* of 01/26/2013 and an *expiration date* of 01/26/2014. 2. Processes the message again in the Deleted Items folder on 2/27/2013. It recalculates the expiration date based on the same start date (01/26/2013). 3. Because the item is older than 30 days, it is expired immediately.
1. Receives a message in the Inbox on 01/26/2013. 2. Deletes the message on 2/27/2013.	• Inbox: None (inherited or implicit) • Deleted Items: Delete in 30 days	1. Processes the message in the Deleted Items folder on 02/27/2013 and determines the item doesn't have a start date. It stamps the current date as the start date, and 03/27/2013 as the expiration date. 2. The item is expired on 3/27/2013, which is 30 days after the user deleted or moved it to the Deleted Items

		folder.

More Info

- In Exchange Online, the Managed Folder Assistant may process a mailbox once in seven days. This may result in items being expired up to seven days after the expiration date stamped on the item.
- Items in mailboxes placed on Retention Hold are not removed until the hold is removed.
- If a mailbox is placed on In-Place Hold or Litigation Hold, expiring items are removed from the Inbox but preserved in the Recoverable Items folder until the mailbox is removed from In-Place Hold.
- In hybrid deployments, the same retention tags and retention policies must exist in your on-premises and Exchange Online organizations in order to consistently move and expire items across both organizations. See Export and import retention tags for more information.

Checklist: Deploying retention policies

Messaging policy and compliance > Messaging records management > Retention tags and retention policies >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-17*

Use this checklist to deploy retention policies in your Microsoft Exchange Server 2013 organization. Before you start working with this checklist, make sure you're familiar with the concepts in the following topics:

- Messaging records management
- Retention tags and retention policies

Checklist for deploying retention policies

Done?	Tasks	Topic
	Assess messaging records management (MRM) requirements for different sets of users.	Messaging records management
	Determine which Microsoft Outlook client versions are in use.	**Get-LogonStatistics**

	Create retention tags.	Create a Retention Policy
	Create retention policies.	Create a Retention Policy
	Add retention tags to retention policies.	Add retention tags to or remove retention tags from a retention policy
	Place mailboxes on retention hold.	Place a mailbox on retention hold
	Apply a retention policy to a single mailbox for testing purposes.	Apply a retention policy to mailboxes
	Optional: Implement client blocking to block legacy Outlook clients.	Configure Outlook Client Blocking for Messaging Records Management
	Begin user communication and training activities. Include a deadline when retention policies will be processed, and items moved or deleted.	Not applicable
	Apply retention policy to additional mailboxes.	Apply a retention policy to mailboxes
	A few days in advance, remind users about the deadline.	Not applicable
	At the deadline, remove the retention hold from mailboxes.	Place a mailbox on retention hold

Create a Retention Policy

Add retention tags to or remove retention tags from a retention policy

Apply a retention policy to mailboxes

Configure the Managed Folder Assistant

Place a mailbox on retention hold

Create a Retention Policy

Messaging records management > Retention tags and retention policies > Messaging Records Management Procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-12-11*

In Exchange Server 2013, you can use retention policies to manage email lifecycle. Retention policies are applied by creating retention tags, adding them to a retention policy, and applying the policy to mailbox users.

For additional management tasks related to retention policies, see Messaging Records Management Procedures.

What do you need to know before you begin?

- Estimated time to complete this task: 30 minutes.
- Procedures in this topic require specific permissions. See each procedure for its permissions information.
- Mailboxes to which you apply retention policies must reside on Exchange Server 2010 or later servers.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

How do you do this?

Step 1: Create a retention tag

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Messaging records management" entry in the Messaging policy and compliance permissions topic.

Use the EAC to create a retention tag

1. Navigate to **Compliance management** > **Retention tags**, and then click **Add +**
2. Select one of the following options:
   - **Applied automatically to entire mailbox (default)** Select this option to create a default policy tag (DPT). You can use DPTs to create a default deletion policy and a default archive policy, which applies to all items in the mailbox.

Note:
You can't use the EAC to create a DPT to delete voice mail items. For details about how to create a DPT to delete voice mail items, see the Shell example below.

   - **Applied automatically to a specific folder** Select this option to create a retention policy tag (RPT) for a default folder such as **Inbox** or **Deleted Items**.

Note:
You can only create RPTs with the **Delete and allow recovery** or **Permanently delete** actions.

   - **Applied by users to items and folders (Personal)** Select this option to create personal tags. These tags allow Outlook and Outlook Web App users to apply archive or deletion settings to a message or folders that are different from the settings applied to the parent folder or the entire mailbox.
3. The **New retention tag** page title and options will vary depending on the type of tag you selected. Complete the following fields:
   - **Name** Enter a name for the retention tag. The tag name is for display purposes and doesn't have any impact on the folder or item a tag is applied to. Consider that the personal tags you provision for users are available in Outlook and Outlook Web App.
   - **Apply this tag to the following default folder** This option is available only if you selected **Applied automatically to a specific folder**.
   - **Retention action** Select one of the following actions to be taken after the item reaches its retention period:
     - **Delete and Allow Recovery** Select this action to delete items but allow users to recover them using the **Recover Deleted Items** option in Outlook or Outlook Web App. Items are retained until the deleted item retention period configured for the mailbox database or the mailbox user is reached.
     - **Permanently Delete** Select this option to permanently delete the item from the mailbox database.

Important:
Mailboxes or items subject to In-Place Hold or litigation hold will be retained and returned in

In-Place eDiscovery searches. To learn more, see In-Place Hold.

- **Move to Archive** This action is available only if you're creating a DPT or a personal tag. Select this action to move items to the user's In-Place Archive.

- **Retention period** Select one of the following options:
  - **Never** Select this option to specify that items should never be deleted or moved to the archive.
  - **When the item reaches the following age (in days)** Select this option and specify the number of days to retain items before they're moved or deleted. The retention age for all supported items except Calendar and Tasks is calculated from the date an item is received or created. Retention age for Calendar and Tasks items is calculated from the end date.
- **Comment** User this optional field to enter any administrative notes or comments. The field isn't displayed to users.

Use the Shell to create a retention tag

Use the **New-RetentionPolicyTag** cmdlet to create a retention tag. Different options available in the cmdlet allow you to create different types of retention tags. Use the *Type* parameter to create a DPT (`All`), RPT (specify a default folder type, such as `Inbox`) or a personal tag (`Personal`).

This example creates a DPT to delete all messages in the mailbox after 7 years (2,556 days).

```
New-RetentionPolicyTag -Name "DPT-Corp-Delete" -Type All -
AgeLimitForRetention 2556 -RetentionAction
DeleteAndAllowRecovery
```

This example creates a DPT to move all messages to the In-Place Archive in 2 years (730 days).

```
New-RetentionPolicyTag -Name "DPT-Corp-Move" -Type All -
AgeLimitForRetention 730 -RetentionAction MoveToArchive
```

This example creates a DPT to delete voice mail messages after 20 days.

```
New-RetentionPolicyTag -Name "DPT-Corp-Voicemail" -Type All
-MessageClass Voicemail -AgeLimitForRetention 20 -
RetentionAction DeleteAndAllowRecovery
```

This example creates a RPT to permanently delete messages in the Junk EMail folder after 30 days.

```
New-RetentionPolicyTag -Name "RPT-Corp-JunkMail" -Type
JunkEmail -AgeLimitForRetention 30 -RetentionAction
PermanentlyDelete
```

This example creates a personal tag to never delete a message.

```
New-RetentionPolicyTag -Name "Never Delete" -Type Personal
```

```
-RetentionAction DeleteAndAllowRecovery -RetentionEnabled
$false
```

Step 2: Create a retention policy

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Messaging records management" entry in the Messaging policy and compliance permissions topic.

Use the EAC to create a retention policy

1. Navigate to **Compliance management** > **Retention policies**, and then click **Add +**
2. In **New Retention Policy**, complete the following fields:
   - **Name** Enter a name for the retention policy.
   - **Retention tags** Click **Add +** to select the tags you want to add to this retention policy.

A retention policy can contain the following tags:

- One DPT with the **Move to Archive** action
- One DPT with the **Delete and Allow Recovery** or **Permanently Delete** actions
- One DPT for voice mail messages with the **Delete and Allow Recovery** or **Permanently Delete** actions
- One RPT per default folder such as **Inbox** to delete items
- Any number of personal tags

Note:

Although you can add any number of personal tags to a retention policy, having many personal tags with different retention settings can confuse users. We recommend linking no more than ten personal tags to a retention policy.

You can create a retention policy without adding any retention tags to it, but items in the mailbox to which the policy is applied won't be moved or deleted. You can also add and remove retention tags from a retention policy after it's created.

Use the Shell to create a retention policy

This example creates the retention policy RetentionPolicy-Corp and uses the *RetentionPolicyTagLinks* parameter to associate five tags to the policy.

```
New-RetentionPolicy "RetentionPolicy-Corp"  -
RetentionPolicyTagLinks "DPT-Corp-Delete","DPT-Corp-
Move","DPT-Corp-Voicemail","RPT-Corp-JunkMail","Never
Delete"
```

For detailed syntax and parameter information, see New-RetentionPolicy.

Step 3: Apply a retention policy to mailbox users

After you create a retention policy, you must apply it to mailbox users. You can apply different retention policies to different set of users. For detailed instructions, see Apply a retention policy to mailboxes.

How do you know this task worked?

After you create retention tags, add them to a retention policy, and apply the policy to a mailbox user, the next time the MRM mailbox assistant processes the mailbox, messages are moved or deleted based on settings you configured in the retention tags.

To verify that you have applied the retention policy, do the following:
1. Run the following Shell command to run the MRM assistant manually against a single mailbox.

```
Start-ManagedFolderAssistant -Identity <mailbox identity>
```

2. Log on to the mailbox using Outlook or Outlook Web App and verify that messages are deleted or moved to an archive in accordance with the policy configuration.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Add retention tags to or remove retention tags from a retention policy

Messaging records management > Retention tags and retention policies > Messaging Records Management Procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-14*

You can add retention tags to a retention policy when the policy is created or any time thereafter. For details about how to create a retention policy, including how to simultaneously add retention tags, see Create a Retention Policy.

A retention policy can contain the following retention tags:
- One or more retention policy tags (RPTs) for supported default folders
- One default policy tag (DPT) with the **Move to Archive** action
- One DPT with the **Delete and Allow Recovery** or the **Permanently Delete** action
- One DPT for voice mail
- Any number of personal tags

For additional management tasks related to messaging records management (MRM), see

Messaging Records Management Procedures.

What do you need to know before you begin?

- Estimated time to completion: 10 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Messaging records management" entry in the Recipients Permissions topic.
- Retention tags aren't applied to a mailbox until they're linked to a retention policy and the Managed Folder Assistant processes the mailbox. To learn more about the Managed Folder Assistant, see Configure the Managed Folder Assistant.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to add retention tags to or remove retention tags from a retention policy

1. Navigate to **Compliance management** >**Retention policies**.
2. In the list view, select the retention policy to which you want to add retention tags and then click **Edit** .
3. In **Retention Policy**, use the following settings:
   - **Add +** Click this button to add a retention tag to the policy.
   - **Remove −** Select a tag from the list, and then click this button to remove the tag from the policy.

Use the Shell to add retention tags to or remove retention tags from a retention policy

This example adds the retention tags VPs-Default, VPs-Inbox, and VPs-DeletedItems to the retention policy RetPolicy-VPs, which doesn't already have retention tags linked to it.

Caution:

If the policy has retention tags linked to it, this command replaces the existing tags.

```
Set-RetentionPolicy -Identity "RetPolicy-VPs" -
```

```
RetentionPolicyTagLinks "VPs-Default","VPs-Inbox","VPs-
DeletedItems"
```

This example adds the retention tag VPs-DeletedItems to the retention policy RetPolicy-VPs, which already has other retention tags linked to it.

```
$TagList = (Get-RetentionPolicy "RetPolicy-
VPs").RetentionPolicyTagLinks
$TagList.Add((Get-RetentionPolicyTag 'VPs-
DeletedItems').DistinguishedName)
Set-RetentionPolicy "RetPolicy-VPs" -
RetentionPolicyTagLinks $TagList
```

This example removes the retention tag VPs-Inbox from the retention policy RetPolicy-VPs.

```
$TagList = (Get-RetentionPolicy "RetPolicy-
VPs").RetentionPolicyTagLinks
$TagList.Remove((Get-RetentionPolicyTag 'VPs-
Inbox').DistinguishedName)
Set-RetentionPolicy "RetPolicy-VPs" -
RetentionPolicyTagLinks $TagList
```

For detailed syntax and parameter information, see Set-RetentionPolicy and Get-RetentionPolicy.

How do you know this worked?

To verify that you have successfully added or removed a retention tag from a retention policy, use the Get-RetentionPolicy cmdlet to verify the *RetentionPolicyTagLinks* property.

This example use the **Get-RetentionPolicy** cmdlet to retrieve retention tags added to the Default MRM Policy and pipes them to the **Format-Table** cmdlet to output only the name property of each tag.

```
(Get-RetentionPolicy "Default MRM
Policy").RetentionPolicyTagLinks | Format-Table name
```

Apply a retention policy to mailboxes

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-04-25*

You can use retention policies to group one or more retention tags and apply them to mailboxes to enforce message retention settings. A mailbox can't have more than one retention policy.

Caution:

Messages are expired based on settings defined in the retention tags linked to the policy. These settings include actions such moving messages to the archive or permanently deleting them. Before applying a retention policy to one or more mailboxes, we recommended that you test the policy and inspect each retention tag associated with it.

For additional management tasks related to messaging records management (MRM), see Messaging Records Management Procedures.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Applying retention policies" entry in the Messaging policy and compliance permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to apply a retention policy to a single mailbox

1. Navigate to **Recipients** > **Mailboxes**.
2. In the list view, select the mailbox to which you want to apply the retention policy, and then click **Edit** .
3. In **User Mailbox**, click **Mailbox features**.
4. In the **Retention policy** list, select the policy you want to apply to the mailbox, and then click **Save**.

Use the EAC to apply a retention policy to multiple mailboxes

1. Navigate to **Recipients** > **Mailboxes**.
2. In the list view, use the Shift or Ctrl keys to select multiple mailboxes.

3. In the details pane, click **More options**.
4. Under **Retention Policy**, click **Update**.
5. In **Bulk Assign Retention Policy**, select the retention policy you want to apply to the mailboxes, and then click **Save**.

Use the Shell to apply a retention policy to a single mailbox

This example applies the retention policy RP-Finance to Bharat's mailbox.

```
Set-Mailbox "Bharat" -RetentionPolicy "RP-Finance"
```

For detailed syntax and parameter information, see Set-Mailbox.

Use the Shell to apply a retention policy to multiple mailboxes

This example applies the new retention policy New-Retention-Policy to all mailboxes that have the old policy Old-Retention-Policy.

```
$OldPolicy={Get-RetentionPolicy "Old-Retention-
Policy"}.distinguishedName
Get-Mailbox -Filter {RetentionPolicy -eq $OldPolicy} -
Resultsize Unlimited | Set-Mailbox -RetentionPolicy "New-
Retention-Policy"
```

This example applies the retention policy RetentionPolicy-Corp to all mailboxes in the Exchange organization.

```
Get-Mailbox -ResultSize unlimited | Set-Mailbox -
RetentionPolicy "RetentionPolicy-Corp"
```

This example applies the retention policy RetentionPolicy-Finance to all mailboxes in the Finance organizational unit.

```
Get-Mailbox -OrganizationalUnit "Finance" -ResultSize
Unlimited | Set-Mailbox -RetentionPolicy "RetentionPolicy-
Finance"
```

For detailed syntax and parameter information, see Get-Mailbox and Set-Mailbox.

How do you know this worked?

To verify that you have applied the retention policy, run the Get-Mailbox cmdlet to retrieve the retention policy for the mailbox or mailboxes.

This example retrieves the retention policy for Bharat's mailbox.

```
Get-Mailbox Bharat | Select RetentionPolicy
```

This command retrieves all mailboxes that have the retention policy RP-Finance applied.

```
Get-Mailbox -ResultSize unlimited | Where-Object
{$_.RetentionPolicy -eq "RP-Finance"} | Format-Table
Name,RetentionPolicy -Auto
```

Configure the Managed Folder Assistant

Messaging records management > Retention tags and retention policies > Messaging Records Management Procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-14*

The *Managed Folder Assistant* is a Microsoft Exchange Mailbox Assistant that applies message retention settings configured in retention policies.

For additional management tasks related to messaging records management (MRM), see Messaging Records Management Procedures.

What do you need to know before you begin?

- Time to complete: 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Messaging records management" entry in the Messaging policy and compliance permissions topic.
- You can't use the Exchange Administration Center (EAC) to configure the Managed Folder Assistant. You must use the Shell
- In Exchange 2013, the Managed Folder Assistant is a throttle-based assistant. Throttle-based assistants are always running and don't need to be scheduled. The system resources they can consume are throttled. You can configure the Managed Folder Assistant to process all mailboxes

on a Mailbox server within a certain period (known as a *work cycle)*. The work cycle is set to one day by default.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to configure the Managed Folder Assistant

This example configures the Managed Folder Assistant to process all mailboxes within one day.

```
Set-MailboxServer MyMailboxServer -ManagedFolderWorkCycle 1
```

For detailed syntax and parameter information, see Set-MailboxServer.

How do I know this worked?

To verify that you have successfully configured the Managed Folder Assistant, use the Get-MailboxServer cmdlet to check the *ManagedFolderWorkCycle* parameter.

This command retrieves all Mailbox servers in the organization and outputs the Managed Folder Assistant's workcycle properties from each server in a table format. The *Auto* switch is used to automatically fit column width.

```
Get-MailboxServer | Format-Table
Name,ManagedFolderWorkCycle* -Auto
```

Use the Shell to start the Managed Folder Assistant

This example triggers the Managed Folder Assistant to immediately process Bharat Suneja's mailbox.

```
Start-ManagedFolderAssistant -Identity
bharat.suneja@contoso.com
```

For detailed syntax and parameter information, see Start-ManagedFolderAssistant.

Place a mailbox on retention hold

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-14*

Placing a mailbox on retention hold suspends the processing of a retention policy or managed folder mailbox policy for that mailbox. Retention hold is designed for situations such as a user being on vacation or away temporarily.

During retention hold, users can log on to their mailbox and change or delete items. When you perform a mailbox search, deleted items that are past the deleted item retention period aren't returned in search results. To make sure items changed or deleted by users are preserved in legal hold scenarios, you must place a mailbox on legal hold. For more information, see Create or remove an In-Place Hold.

You can also include retention comments for mailboxes you place on retention hold. The comments are displayed in supported versions of Microsoft Outlook.

For additional management tasks related to messaging records management (MRM), see Messaging Records Management Procedures.

What do you need to know before you begin?

- Estimated time to complete: 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Messaging records management" entry in the Messaging policy and compliance permissions topic.
- You can't use the Exchange Administration Center (EAC) to place a mailbox on retention hold. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to place a mailbox on retention hold

This example places Michael Allen's mailbox on retention hold.

```
Set-Mailbox "Michael Allen" -RetentionHoldEnabled $true
```

For detailed syntax and parameter information, see Set-Mailbox.

Use the Shell to remove retention hold for a mailbox

This example removes the retention hold from Michael Allen's mailbox.

```
Set-Mailbox "Michael Allen" -RetentionHoldEnabled $false
```

For detailed syntax and parameter information, see Set-Mailbox.

How do you know this worked?

To verify that you have successfully placed a mailbox on retention hold, use the Get-Mailbox cmdlet to retrieve the *RetentionHoldEnabled* property of the mailbox.

This command retrieves the *RetentionHoldEnabled* property for Michael Allen's mailbox.

```
Get-Mailbox "Michael Allen" | Select RetentionHoldEnabled
```

This command retrieves all mailboxes in the Exchange organization, filters the mailboxes that are placed on retention hold, and lists them along with the retention policy applied to each.

Important:
Because *RetentionHoldEnabled* isn't a filterable property in Exchange 2013, you can't use the *Filter* parameter with the **Get-Mailbox** cmdlet to filter mailboxes that are placed on retention hold on the server-side. This command retrieves a list of all mailboxes and filters on the client running the Shell session. In large environments with thousands of mailboxes, this command may take a long time to complete.

```
Get-Mailbox -ResultSize unlimited | Where-Object
{$_.RetentionHoldEnabled -eq $true} | Format-Table
Name,RetentionPolicy,RetentionHoldEnabled -Auto
```

Export and import retention tags

Messaging records management > Retention tags and retention policies > Messaging Records Management Procedures >

Applies to: *Exchange Online*

Topic Last Modified: *2013-02-21*

There are several scenarios in which you may want to export or import retention tags, including:

- Applying the same retention policies across all servers in a multi-forest Exchange organization

- Applying the same retention policies in a hybrid deployment where some mailboxes reside in your on-premises Exchange organization and some reside in Exchange Online.
- Applying retention policies in an Exchange Online Archiving scenario, where users with on-premises Exchange 2010 or later mailboxes have a cloud-based archive.

In these scenarios, the Managed Folder Assistant can correctly process an item that has a retention tag applied after the item or the mailbox is moved to another organization.

Caution:

To keep retention tags and retention policies synchronized between two organizations, every time you make changes to a retention tag or policy in the source organization, you must perform this procedure to export retention tags and policies from the source organization and import them in the destination organization.
You can't select specific retention tags or policies to export. The Export-RetentionTags.ps1 script exports all retention tags and policies from an organization.

For additional management tasks related to Messaging Records Management, see Messaging Records Management Procedures.

What do you need to know before you begin?

- Estimated time to complete each procedure: 10 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Messaging Records Management" entry in the Messaging policy and compliance permissions topic.
- You can't select specific retention tags or policies to export or import. The Export-RetentionTags.ps1 script exports all retention tags and policies from an organization. The Import-RetentionTags.ps1 script imports all retention tags and policies in the XML file being imported, replacing all existing retention tags and policies in an Exchange organization.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Export retention tags from an on-premises Exchange organization

1. Run this Exchange Management Shell command to change directory to the **Scripts** subdirectory in your Exchange installation path.

```
Cd "<Exchange Server installation path>\Scripts"
```

2. Run the Export-RetentionTags.ps1 script to export retention tags to an XML file.

Important:
If you're importing or exporting retention tags and retention policies to Exchange Online, you must connect your Windows PowerShell session to Exchange Online. For details, see **Connect to Exchange Online using remote PowerShell**.

```
Export-RetentionTags.ps1 "c:\docs
\ExportedRetentionTags.xml"
```

How do you know this worked?

To verify that you have successfully exported retention tags and retention policies, do the following:

1. Navigate to the path you specified in the command to export and verify that the XML file with the name you specified has been created.
2. Optionally, you can open the XML file in a text editor to review its contents.

Import retention tags to an Exchange organization

1. Run this Shell command to change the directory to the **Scripts** subdirectory in your Exchange installation path.

```
Cd "<Exchange Server installation path>\Scripts"
```

2. Run the Import-RetentionTags.ps1 script to import retention tags from a previously exported XML file.

Important:
If you're importing or exporting retention tags and retention policies to Exchange Online, you must connect your Windows PowerShell session to Exchange Online. For details, see **Connect to Exchange Online using remote PowerShell**.

Note:
When running this script against Exchange Online, you may be prompted to confirm that you want to run software from an untrusted publisher. Verify that the name of the publisher appears as `CN=Microsoft Corporation, OU=MOPR, O=Microsoft Corporation, L=Redmond, S=Washington, C=US`, and then click **R** to allow the script to be run once or **A** to always run.

```
Import-RetentionTags.ps1 "c:\docs
\ExportedRetentionTags.xml"
```

How do you know this worked?

To verify that you have successfully imported retention tags and retention policies, do the following:

1. In the EAC, navigate to **Compliance Management** > **Retention tags**, and verify that the

retention tags have been imported successfully. Navigate to **Compliance Management** > **Retention policies**, and verify that the retention policies have been imported successfully.

2. Use the **Get-RetentionPolicy** and **Get-RetentionPolicyTag** cmdlets to verify that the tags and policies have been created. For an example about how to retrieve retention tags and retention policies, see Examples in Get-RetentionPolicyTag and Get-RetentionPolicy.

Configure Outlook client blocking

Messaging records management > Retention tags and retention policies > Messaging Records Management Procedures >

Applies to: *Exchange Server 2010 Service Pack 2 (SP2)*

Topic Last Modified: *2013-02-14*

In Exchange Server 2013, you can use retention policies or managed folders for messaging records management (MRM). Only users running Microsoft Outlook 2010 and later have access to all client features for retention policies. However, retention policies are applied on the Mailbox server by the Managed Folder Assistant, regardless of the Outlook client version used by the user. Older Outlook clients do not expose the MRM functionality of these features. For example, because Outlook 2007 does not support retention policies, users can't apply personal tags to items or folders.

You can block users who are running older versions of Outlook from accessing their Exchange mailboxes. You can also block access on a per-mailbox or on a per-Client Access server basis.

For other management tasks related to MRM, see Messaging Records Management Procedures.

MRM Feature Availability by Client Application and Version

The following table lists the MRM features available in various client applications and versions.

MRM features

Client application	Available MRM client features
Outlook 2013 and Outlook 2010	All
Outlook 2007	Managed folders
Outlook 2003 and older	Not supported
Other e-mail client software	None

The following table shows version numbers for Outlook.

Outlook versions

Outlook version	Version number
Outlook 2013	15
Outlook 2010	14
Outlook 2007	12
Outlook 2003	11
Outlook 2002	10
Outlook 2000	9
Outlook 98	8.5
Outlook 97	8

Note:

Before making any changes, note that hotfixes and service pack releases may affect the client version string. Be careful when you restrict client access because server-side Exchange components must also use MAPI to log on. Some components report their client version as the component name (such as SMTP or OLE DB), while others report the Exchange build number (such as 6.0.4712.0). For this reason, avoid restricting clients that have version numbers that start with 6.<*x.x.*>. For example, to prevent MAPI access completely, instead of specifying **0.0.0-6.5535.65535.65535**, specify the two ranges so that the server components can log on. For example, specify the following: **0.0.0-5.9.9; 7.0.0-**.

After you perform these procedures, be aware that when users are blocked from accessing their mailboxes, they will receive the following warning message.

> Your Exchange Server administrator has blocked the version of Outlook that you are using.
>
> Contact your administrator for assistance.

To bypass the warning that MRM features aren't supported for e-mail clients running versions of Outlook earlier than Outlook 2010, you can use the *ManagedFolderMailboxPolicyAllowed* parameter of the **New-Mailbox**, **Enable-Mailbox**, and **Set-Mailbox** cmdlets in the Shell. When a managed folder mailbox policy is assigned to a mailbox by using the *ManagedFolderMailboxPolicy* parameter, the warning appears by default unless you use the *ManagedFolderMailboxPolicyAllowed* parameter.

What do you need to know before you begin?

- Estimated time to complete: 1 minute.
- You can't use the Exchange admin center (EAC) to perform these procedures. You must use the Shell.

- Procedures in this topic require specific permissions. See each procedure for its permissions information.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Block versions of Outlook on a per-mailbox basis

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "User mailboxes" entry in the Recipients Permissions topic.

This example blocks all Outlook versions earlier than 11.8010.8036.

```
Set-CASMailbox -Identity adam@contoso.com -
MAPIBlockOutlookVersions "-11.8010.8036"
```

This example restores access to a mailbox that's blocked by a version of Outlook.

```
Set-CASMailbox -Identity adam@contoso.com -
MAPIBlockOutlookVersions $null
```

For detailed syntax and parameter information, see Set-CASMailbox.

Block Outlook versions on a Client Access server

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "RPC Client Access settings" entry in the Clients and mobile devices permissions topic.

This example blocks Outlook clients prior to version 12.0.0 from accessing the mailbox on an Exchange 2010 or later Client Access server.

Important:
The value used for the *BlockedClientVersions* parameter in this command is an example. You must determine the correct client version numbers. You can use the **Get-LogonStatistics** cmdlet to retrieve the versions of MAPI clients that are connected to the mailbox database.

```
Set-RpcClientAccess -Server CAS01 -BlockedClientVersions
"0.0.0-5.65535.65535;7.0.0;8.02.4-11.65535.65535"
```

For detailed syntax and parameter definition, see Set-RpcClientAccess.

Migrate from managed folders

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-14*

In Microsoft Exchange Server 2013, messaging records management (MRM) is performed by using retention tags and retention policies. A retention policy is a group of retention tags that can be applied to a mailbox. For more details, see Retention tags and retention policies. Managed folders, the MRM technology introduced in Exchange Server 2007, aren't supported.

A mailbox that has a managed folder mailbox policy applied can be migrated to use a retention policy. To do so, you must create retention tags that are equivalent to the managed folders linked to the user's managed folder mailbox policy.

Important:

Before you migrate from managed folders to retention policies in your production environment, we recommend that you test the process in a test environment.

Tip:

You can place mailboxes on retention hold to halt processing of retention policies or managed folder mailbox policies. Placing mailboxes on retention hold can be helpful in migration scenarios to avoid deleting messages or moving them to archive until new policy settings have been tested on test mailboxes or a small number of production mailboxes. For details, see Place a mailbox on retention hold.

For other management tasks related to MRM, see Messaging Records Management Procedures.

Comparing retention tags to managed folders

Unlike managed folders, which require users to move items to a managed folder based on retention settings, retention tags can be applied to a folder or an individual item in the mailbox. This process has minimal impact on the user's workflow and email organization methods. When a folder has retention tags applied, all items in that folder inherit the retention settings. Users can further specify retention settings by applying different retention tags to individual items in that folder.

Managed folders support different managed content settings for a folder, each with a different message class (such as email items or calendar items). Retention tags don't require a separate managed content settings object because the retention settings are specified in the tag's properties. It isn't supported to create retention tags for particular message classes, with the exception of a default policy tag (DPT) for voicemail messages. Retention tags also don't allow you to use journaling performed by the Managed Folder Assistant.

Note:

Journal rules, which are used to send copies of messages with a journal report to a journaling mailbox, are enforced in the transport pipeline by the Journaling agent and are independent of MRM. For more details, see Journaling.

The following table compares the MRM functionality available when using retention tags or managed folders.

Retention tags vs. managed folders

Functionality	Retention tags	Managed folders
Specify retention settings for default folders (such as Inbox)	Use retention policy tags (RPTs)	Use managed default folders
Specify retention settings for entire mailbox	Use a default policy tag (DPT)	Use managed default folders
Use retention settings for custom folders	Use personal tags	Using managed custom folders
Require managed content settings	No (retention settings included in a retention tag)	Yes
Use retention settings for different message classes (such as e-mail messages, voice mail, or calendar items)	No	Yes
Support the Move To Archive action, which moves items to the user's archive mailbox	Yes	No
Support the Move To Managed Folder action	No	Yes
Allow journaling using the Managed Folder Assistant	No	Yes
Policy applied to user	Retention policy	Managed folder mailbox policy
Maximum number of policies	1	1

that can be applied to a mailbox user		
Processed by the Managed Folder Assistant	Yes	Yes
Client support	Microsoft Outlook 2010 and Office Outlook Web App	Outlook 2010, Office Outlook 2007, and Outlook Web App

What do you need to know before you begin?

- Estimated time to complete: 20 minutes.
- Procedures in this topic require specific permissions. See each procedure for its permissions information.
- You can't use the Exchange admin center (EAC) to create retention tags based on retention policies.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Migrate mailbox users from managed folders

The following are general steps for migrating users from this managed folder mailbox policy to a retention policy. Each step is detailed later in this topic:

1. Gather information about managed folder mailbox policies applied to all Exchange 2010 and Exchange 2007 mailboxes, managed folders in each policy and managed content settings for each managed folder. You can use the EMC or the Shell on an Exchange 2010 or Exchange 2007 server to obtain this information.
2. Create retention tags for the migration.
3. Create a retention policy and link the newly created retention tags to the policy.
4. Remove the managed folder mailbox policy and then apply the retention policy to user mailboxes.

Important:
After you apply the retention policy to a user and the Managed Folder Assistant runs, the managed folders in the user's mailbox become unmanaged.

For the following procedures, Contoso mailboxes have a managed folder mailbox policy applied containing the following managed folders.

Managed folders for Contoso

Managed folder	Managed content settings	Retention enabled	Retention age	Retention action
Corp-DeletedItems	CS-Corp-DeletedItems	Yes	30 days	Delete and Allow Recovery
Corp-SentItems	CS-Corp-SentItems	Yes	1,825 days	Move to Deleted Items
Corp-JunkMail	CS-Corp-JunkMail	Yes	30 days	Permanently Delete
Corp-EntireMailbox	CS-Corp-EntireMailbox	Yes	365 days	Move to Deleted Items
30 Days	CS-30Days	Yes	30 days	Move to Deleted Items
5 Years	CS-5Years	Yes	1,825 days	Move to Deleted Items
Never Expire	CS-NeverExpire	No	365 days	Not applicable

How do you do this?

Step 1: Create retention tags for the migration

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Messaging records management" entry in the Messaging policy and compliance permissions topic.

There are two methods you can use for this step:

- **Create retention tags based on the managed folders and their corresponding managed content settings** With this method, you use the **New-RetentionPolicyTag** cmdlet with the *ManagedFolderToUpgrade* parameter. When you specify this parameter, the corresponding retention tag is automatically applied to the managed folder.

Important:
If the managed folder you want to port has multiple managed content settings for different message classes, only one retention tag is created, and the highest retention age of all the managed content settings is used as the retention age for the ported tag, irrespective of the message class of the managed content settings. For example, review the following managed content settings for the managed folder Corp-

DeletedItems.

- **Create retention tags by manually specifying the retention settings** With this method, you use the **New-RetentionPolicyTag** cmdlet without the *ManagedFolderToUpgrade* parameter. When you don't specify this parameter, any retention policy tags you add to the policy are applied to the default folders, and the default policy tag is applied to the entire mailbox. However, any personal tags you add to the policy aren't automatically applied to the managed folders.

Note:

If you are in a mixed environment with Exchange 2013 and Exchange 2010 servers, you can use the **Port Managed Folder** wizard in the Exchange Management Console (EMC) on an Exchange 2010 server to easily port managed folder and corresponding managed content setting to retention tags.

Create retention tags based on managed folders

This example creates retention tags based on the corresponding managed content settings shown in the Contoso managed folder mailbox policy.

```
New-RetentionPolicyTag Corp-DeletedItems -
ManagedFolderToUpgrade Corp-DeletedItems
New-RetentionPolicyTag Corp-SentItems -
ManagedFolderToUpgrade Corp-SentItems
New-RetentionPolicyTag Corp-JunkMail -
ManagedFolderToUpgrade Corp-JunkMail
New-RetentionPolicyTag Corp-EntireMailbox -
ManagedFolderToUpgrade Corp-EntireMailbox
New-RetentionPolicyTag 30Days -ManagedFolderToUpgrade
30Days
New-RetentionPolicyTag 5Years -ManagedFolderToUpgrade
5Years
New-RetentionPolicyTag NeverExpire -ManagedFolderToUpgrade
NeverExpire
```

For detailed syntax and parameter information, see New-RetentionPolicyTag.

Create retention tags manually

Note:

You can also use the EAC to create retention tags manually (not based on settings in managed folders). For details, see Create a Retention Policy.

This example creates retention tags based on the managed folders and corresponding managed content settings shown in the Contoso managed folder mailbox policy. The retention settings are specified manually without using the *ManagedFolderToUpgrade* parameter.

```
New-RetentionPolicyTag Corp-DeletedItems -Type DeletedItems
-RetentionEnabled $true -AgeLimitForRetention 30 -
RetentionAction DeleteAndAllowRecovery
New-RetentionPolicyTag Corp-SentItems -Type SentItems -
RetentionEnabled $true -AgeLimitforRetention 1825 -
RetentionAction MoveToDeletedItems
New-RetentionPolicyTag Corp-JunkMail -Type JunkMail -
RetentionEnabled $true -AgeLimitforRetention 30 -
RetentionAction PermanentlyDelete
New-RetentionPolicyTag Corp-EntireMailbox -Type All -
RetentionEnabled $true -AgeLimitForRetention 365 -
RetentionAction MoveToDeletedItems
New-RetentionPolicyTag 30Days -Type Personal -
RetentionEnabled $true -AgeLimitForRetention 30 -
RetentionAction MoveToDeletedItems
New-RetentionPolicyTag 5Years -Type Personal -
RetentionEnabled $true -AgeLimitForRetention 1825 -
RetentionAction MoveToDeletedItems
New-RetentionPolicyTag NeverExpire -Type Personal -
RetentionEnabled $false
```

For detailed syntax and parameter information, see New-RetentionPolicyTag.

Step 2: Create a retention policy

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Messaging records management" entry in the Messaging policy and compliance permissions topic.

Note:
You can also use the EAC to create a retention policy and add retention tags to the policy. For details, see Create a Retention Policy.

This example creates the retention policy RP-Corp and links the newly created retention tags to the policy.

```
New-RetentionPolicy RP-Corp -RetentionPolicyTagLinks Corp-
DeletedItems,Corp-SentItems,Corp-JunkMail,Corp-
EntireMailbox,30Days,NeverExpire
```

For detailed syntax and parameter information, see New-RetentionPolicy.

Step 3: Remove the managed folder mailbox policy from user mailboxes

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Applying retention policies" entry in the Messaging policy and compliance permissions topic.

This example removes the managed folder mailbox policy and any managed folders from Ken Kwok's mailbox. Managed folders that have any messages are not removed.

```
Set-Mailbox -Identity Kwok -RemoveManagedFolderAndPolicy
RP-Corp
```

Step 4: Apply the retention policy to user mailboxes

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Applying retention policies" entry in the Messaging policy and compliance permissions topic.

Note:

You can also use the EAC to apply a retention policy to users. For details, see Apply a retention policy to mailboxes.

This example applies the newly created retention policy RP-Corp to the mailbox user Ken Kwok.

```
Set-Mailbox -Identity Kwok -RetentionPolicy RP-Corp
```

For detailed syntax and parameter information, see Set-Mailbox.

How do you know this task worked?

To verify that you have migrated from managed folders to retention policies, do the following:

- Generate a report of all user mailboxes and the retention policy applied to them.

This command retrieves the retention policy applied to all mailboxes in an organization, and their retention hold status.

```
Get-Mailbox -ResultSize unlimited -Filter {Name -NotLike
"DiscoverySearch*"} | Format-Table
Name,RetentionPolicy,RetentionHoldEnabled -Auto
```

- After the Managed Folder Assistant has processed a mailbox with a retention policy, use the Get-RetentionPolicyTag cmdlet to retrieve the retention tags provisioned in the user mailbox.

This command retrieves the retention tags actually applied to April Stewart's mailbox.

```
Get-RetentionPolicyTag -Mailbox astewart
```

Turn off or suspend messaging records management

Applies to: *Exchange Server 2010 Service Pack 2 (SP2)*

Topic Last Modified: *2013-02-14*

To meet individual, IT, or business requirements, you may need to turn off or temporarily suspend messaging records management (MRM) for an individual user or for a Mailbox server. Reasons you may need to turn off or suspend MRM include:

- If a mailbox user is away from the office or is otherwise unable to access e-mail, you can temporarily disable MRM for the mailbox by placing it on retention hold. When a mailbox is on retention hold, it's no longer processed by the Managed Folder Assistant. When the mailbox user returns or is able to access the mailbox again, you can remove the retention hold from the mailbox.
- If you need to test or troubleshoot performance issues, you can temporarily turn off MRM on that server by clearing the schedule for the Managed Folder Assistant.
- If you need to remove a retention tag from mailboxes (which have a retention policy with that tag applied), you can remove the tag from the policy.
- If you want a retention policy or a managed folder mailbox policy to no longer apply to a mailbox, you can remove the policy from the mailbox.
- If your organization decides not to use MRM features, you can turn off MRM permanently for the entire organization. If you later decide to deploy MRM, you have the ability to do so.

What do you need to know before you begin?

- Estimated time to complete: 1 minute
- Procedures in this topic require specific permissions. See each procedure for its permissions information.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Place mailboxes on retention hold

You can place mailboxes on retention hold to turn off MRM temporarily (for example when users are on vacation). This suspends the processing of retention policies for the mailbox until retention hold is disabled. This is different from placing mailboxes on In-Place Hold or litigation hold.

For details about how to place a mailbox on retention hold, see Place a mailbox on retention hold.

To learn more about In-Place Hold and litigation hold, see In-Place Hold.

Remove retention tags from mailboxes

To remove a retention tag from a mailbox, you unlink the tag from the retention policy. When you unlink a retention policy tag (RPT) for a default folder, the default mailbox tag applies to all items in that folder. When you unlink a personal tag, it's no longer available to the user. Tags applied to existing messages will continue to be processed unless you remove the tag from the Exchange organization.

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Messaging records management" entry in the Messaging policy and compliance permissions topic.

This Shell example unlinks the retention tag Delete - 3 Days from the retention policy Corp-Users.

```
$tags = (Get-RetentionPolicy "Corp-
Users").RetentionPolicyTagLinks
$tags -= "Deleted Items - 3 Days"
Set-RetentionPolicy "Corp-Users" -RetentionPolicyTagLinks
$tags
```

For detailed syntax and parameter information, see Get-RetentionPolicy and Set-RetentionPolicy.

Remove retention policies from mailboxes

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Apply retention policies" entry in the Messaging policy and compliance permissions topic.

You can stop a retention policy from applying to a mailbox by removing the policy from the mailbox user's properties.

This Shell example removes the retention policy from the mailbox jpeoples.

```
Set-Mailbox jpeoples -RetentionPolicy $null.
```

This Shell example removes the retention policy from all mailboxes in the Exchange organization.

```
Get-Mailbox -ResultSize unlimited -Filter {RetentionPolicy
-ne $null} | Set-Mailbox -RetentionPolicy $null
```

This Shell example removes the retention policy Corp-Finance from all mailbox users who have the policy applied.

```
Get-Mailbox -ResultSize unlimited -Filter {RetentionPolicy
-eq "Corp-Finance"} | Set-Mailbox -RetentionPolicy $null
```

For detailed syntax and parameter information, see Set-Mailbox and Get-Mailbox.

Turn off MRM permanently for an entire organization

To turn off MRM for an organization, delete all retention tags and retention policies except for the ArbitrationMailbox policy, which is created by Exchange Setup. After this is complete, retention policies aren't enforced.

Caution:

Retention policies also include Move to Archive tags, which move messages to the user's archive mailbox. If you remove a retention policy that has a Move to Archive tag, users who had the policy applied will no longer have messages moved to the archive by the Managed Folder Assistant.
To avoid this, remove only the Delete and Allow Recovery and Permanently Delete tags from your organization and keep the policies that have the Move to Archive tags applied.
Alternatively, users who have and archive enabled could manually move items to their archive mailbox using Outlook or Outlook Web App.
Before removing retention tags or retention policies, we recommend that you check the settings of the tags being removed. Don't delete tags with the Move to Archive retention action.

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Messaging records management" entry in the Messaging policy and compliance permissions topic.

Note:

Include the *Whatlf* switch in the following commands to simulate the action taken by a command.

This example removes all delete tags from an Exchange organization except the Never Delete tag, which is used in the ArbitrationMailbox policy created by Exchange Setup.

```
Get-RetentionPolicyTag | ? {$_.RetentionAction -ne
```

```
"MoveToArchive" -and $_.Name -ne "Never Delete"} | Remove-RetentionPolicyTag
```

This example removes all retention tags except the Never Delete tag.

```
Get-RetentionPolicyTag | ? {$_.Name -ne "Never Delete"} | Remove-RetentionPolicyTag
```

This command removes the Corp-Users retention policy from an Exchange organization.

```
Remove-RetentionPolicy Corp-Users
```

For detailed syntax and parameter information, see the following topics:

- Get-RetentionPolicyTag
- Remove-RetentionPolicyTag
- Remove-RetentionPolicy

Monitoring messaging records management

You can use Windows Reliability and Performance Monitor (Perfmon.exe) to select and view performance counters for messaging records management (MRM). By using performance counters, you can monitor the Managed Folder Assistant while it runs resource-intensive MRM processes.

For a list of performance counters for MRM, see Performance counters for messaging records management.

Looking for other tasks related to monitoring MRM? Check out Monitoring messaging records management.

Use Windows Reliability and Performance Monitor to view performance counters for MRM

To perform this procedure, the account you use must be delegated membership in the local Administrators group.

1. To start Windows Reliability and Performance Monitor, click **Start**, click **Run**, and then type **perfmon**.
2. In the console tree, navigate to **Monitoring Tools** > **Performance Monitor**.
3. Click the plus sign (+) button on the toolbar. The **Add Counters** dialog box appears.
4. From the **Select counter from computer** list, select one of the following options:
   - If you are performing this procedure on a local computer, select **<Local computer>**. This is the default selection.
   - If you are performing this procedure remotely, select the server you want to monitor.
5. In the list of performance counters, expand **MSExchange Assistants - Per Database** or the **MSExchange Managed Folder Assistant**.
6. Select the performance counters you want to monitor.
7. For performance counters under **MSExchange Assistants - Per Database**, to view the counters for all mailbox databases, in **Instances of selected object**, click **All instances**. Or, to specify one or more mailbox databases, select instances from the list.
8. To add the selected counters so that the counters appear in Windows Reliability and Performance Monitor, and to begin collecting performance data, click **Add**.

Performance counters for messaging records management

Messaging policy and compliance > Messaging records management > Monitoring messaging records management >

Applies to: *Exchange Server 2010 Service Pack 2 (SP2)*

Topic Last Modified: *2010-11-23*

The performance counters in this topic monitor the Managed Folder Assistant as it implements messaging records management (MRM) for Microsoft Exchange Server 2010. Because running the Managed Folder Assistant is a resource-intensive process, you should run it only when your server can tolerate the additional load. You should also monitor server performance when the Managed Folder Assistant is running. In addition to the performance counters listed in this topic, you may also want to monitor additional performance counters that monitor items such as disk performance and CPU usage.

For more information about monitoring computers running MRM, see Monitoring messaging records management.

Performance Counters for MRM

The following table describes performance counters for MRM.

Performance counters, performance objects, and description

Performance counter	Performance object	Description
Average Mailbox Processing Time In Seconds	MSExchange Assistants	Counts the average processing time of mailboxes for time-based assistants.
Mailboxes Processed	MSExchange Assistants	Counts the number of mailboxes processed by time-based assistants since the service started.
Mailboxes processed/sec	MSExchange Assistants	Determines the rate of mailboxes processed by time-based assistants per second.
Items Deleted but Recoverable	MSExchange Managed Folder Assistant	Counts the number of items deleted by the Managed Folder Assistant since the start of the most recent schedule interval. (The items are still recoverable through the Recoverable Items

		folder.) The number includes items in the mailboxes scheduled for processing during the schedule interval and items in any mailboxes that you specified for processing. This counter is reset to zero at the start of each schedule interval.
Items Journaled	MSExchange Managed Folder Assistant	Counts the number of items journaled by the Managed Folder Assistant since the start of the most recent schedule interval. The number includes items in the mailboxes scheduled for processing during the current work cycle and items in any mailboxes you specified for processing. This counter is reset to zero at the start of each work cycle.
Items Marked as Past Retention Date	MSExchange Managed Folder Assistant	Counts the number of items marked as past their retention date by the Managed Folder Assistant since the start of the most recent schedule interval. The number includes items in mailboxes scheduled for processing during the schedule interval and items in any mailboxes you specified for processing. This counter is reset to zero at the start of each

		schedule interval.
Items Moved	MSExchange Managed Folder Assistant	Counts the number of items moved by the Managed Folder Assistant since the start of the most recent schedule interval. The number includes items in the mailboxes scheduled for processing during the schedule interval and items in any mailboxes you specified for processing. This counter is reset to zero at the start of each schedule interval.
Items Permanently Deleted	MSExchange Managed Folder Assistant	Counts the number of items permanently deleted by the Managed Folder Assistant since the beginning of the most recent schedule interval. The number includes items in the mailboxes scheduled for processing during the schedule interval and items in any mailboxes you specified for processing. This counter is reset to zero at the beginning of each schedule interval.
Items Subject to Retention Policy	MSExchange Managed Folder Assistant	Counts the number of items subject to retention policy by the Managed Folder Assistant since the start of the most recent schedule interval. The number includes items in the mailboxes scheduled for processing during

		the schedule interval and items in any mailboxes you specified for processing. This counter is reset to zero at the start of each schedule interval. This counter is the sum of the following four expiration-related counters: • Items Journaled • Items Marked as Past Retention Date • Items Moved • Items Permanently Deleted
TotalSizeItemsExpired - Size of Items subject to Retention Policy (In Bytes)	MSExchange Managed Folder Assistant	Indicates the total size of items expired by the Managed Folder Assistant (SoftDelete, HardDelete, MoveToArchive). The following items are included: • Messages subject to deletion or move to a managed custom folder by a managed folder mailbox policy • Messages subject to deletion or move to archive by the user's retention policy • Messages expired by dumpster policy • Messages cleaned up by system cleanup tags This counter is reset to zero at every work cycle checkpoint of the Managed Folder Assistant work cycle.

TotalSizeItemsSoftDeleted - Size of Items Deleted but Recoverable (In Bytes)	MSExchange Managed Folder Assistant	Indicates the total size of items soft deleted by the Managed Folder Assistant. The following items are included: • Messages soft deleted by a managed folder mailbox policy • Messages soft deleted by a retention policy This counter is reset to zero at every work cycle checkpoint of the Managed Folder Assistant work cycle.
TotalSizeItemsPermanentlyDeleted - Size of Items Permanently Deleted (In Bytes)	MSExchange Managed Folder Assistant	Indicates the total size of items soft deleted by the Managed Folder Assistant. The following items are included: • Messages hard deleted by a managed folder mailbox policy • Messages hard deleted by a retention policy • Messages hard deleted by the Recoverable Items policy This counter is reset to zero at every work cycle checkpoint of the Managed Folder Assistant work cycle.
TotalSizeItemsMoved - Size of Items Moved due to an Archive policy tag (In Bytes)	MSExchange Managed Folder Assistant	Indicates the total size of items moved to a folder or moved to archive by the Managed Folder Assistant. The following items are included:

		• Messages moved to a managed custom folder by a managed folder mailbox policy • Messages moved to the personal archive by a retention policy This counter is reset to zero at every work cycle checkpoint of the Managed Folder Assistant work cycle.
TotalItemsWithPersonalTag - Items stamped with Personal Tag (Expiry or Archive)	MSExchange Managed Folder Assistant	Indicates the number of times a user tags items with a personal tag. This includes both Deletion and Archive tags. For example: • An item is tagged with a personal tag. • An item with a personal tag is retagged with another personal tag. If a folder is tagged with a personal tag, the counter is incremented by the total number of items in the folder.
TotalItemsWithDefaultTag - Items stamped with Default Tag (Expiry or Archive)	MSExchange Managed Folder Assistant	Indicates the number of items assigned a default policy tag (DPT) based on a user action, for example, when a user selects a message with a personal tag and selects **Use folder policy**.

		If a new user is assigned a retention policy with a DPT, the counter is incremented by the number of items that will be assigned the DPT due to the retention policy. **Note:** If a user has a retention policy with a DPT, new messages that arrive through transport get a default tag, and this isn't tracked by this counter.
TotalItemsWithSystemCleanupTag - Items stamped with System Cleanup Tag	MSExchange Managed Folder Assistant	Indicates the number of items tagged with the system cleanup tag. This includes mailbox metadata items that aren't visible to users.
TotalItemsExpiredByDefaultExpiryTag - Items expired due to a default Expiry Tag	MSExchange Managed Folder Assistant	Indicates the number of items expired (soft or hard deleted) by the Managed Folder Assistant due to any non-personal (default or system) tag in a retention policy. This doesn't include the items expired by Recoverable Items clean up or system clean up.
TotalItemsExpiredByPersonalExpiryTag - Items expired due to a personal Expiry Tag	MSExchange Managed Folder Assistant	Indicates the number of items expired (soft or hard deleted) by the Managed Folder Assistant due to a personal tag in the retention policy.
TotalItemsMovedByDefaultArchiveTag - Items moved due	MSExchange Managed Folder Assistant	Indicates the number of items moved to the archive by the

to a default Archive Tag		Managed Folder Assistant due to any non-personal (default or system) archive tag in a retention policy. This doesn't include the items moved to the Recoverable Items folder in archive by Recoverable Items cleanup.
TotalItemsMovedByPersonalArchiveTag - Items Moved due to an Archive Tag	MSExchange Managed Folder Assistant	Indicates the number of items moved to the archive by the Managed Folder Assistant due to a personal archive tag in a retention policy.

Messaging records management errors and events

Messaging policy and compliance > Messaging records management > Monitoring messaging records management >

Applies to: *Exchange Server 2010 Service Pack 2 (SP2)*

Topic Last Modified: *2013-02-15*

Messaging records management (MRM) generates events that you can view in Event Viewer. This allows you to troubleshoot and verify the performance of the Managed Folder Assistant. Event Viewer tracks the following kinds of events in the following order, based on importance:

1. Error events
2. Warning events
3. Informational events

MRM Errors and Events

The following tables provide lists of events that you can use to troubleshoot MRM. The logging types include the following:

- Events labeled as **LogAlways** are always logged individually.
- Events labeled as **LogPeriodic** are logged only once in any five-minute period, not every time they occur. This helps to prevent excessive log entries.

MRM events in the Managed Folder Assistant category

Event ID	Category	Event type	Logging	Value or description
10003	Managed Folder Assistant	Error	LogPeriodic	Could not get the server configuration object from Active Directory. *<Exception details>*. Check for domain controller network connectivity issues or incorrect DNS configuration.
10004	Managed Folder Assistant	Error	LogAlways	The retention policy for folder *<folder>* in mailbox *<mailbox>* will not be applied. The managed folder assistant is unable to process managed content setting *<content*

				setting> for the managed folder <*managed folder*>. The RetentionAction is MoveToFolder but a destination folder was not specified. Please specify a destination folder.
10005	Managed Folder Assistant	Error	LogAlways	Retention policy will not be applied to folder <*folder*> in mailbox <*mailbox*>. Unable to process Managed Content Setting <*content setting*> for the Managed Folder <*managed folder*>. The RetentionAction is MoveToFolder but the destination folder <*folder*> is the same as the source folder <*folder*>. Please specify a destination folder

				that is different from the source folder.
10009	Managed Folder Assistant	Error	LogAlways	The managed folder assistant skipped processing all databases on the local server because it could not read the audit log parameters from Active Directory. It will try again later in the schedule window. Current database: *<database>*
10010	Managed Folder Assistant	Error	LogAlways	The managed folder assistant skipped processing all databases on the local server because the audit log is enabled but the path to the audit log is missing in Active Directory. It will try again later in the schedule window.

				Current database: *<database>*
10011	Managed Folder Assistant	Error	LogAlways	The managed folder assistant could not configure the audit log. It will stop processing the current database: '%1'. It will try again later in the schedule window. Exception details: *<details>*
10012	Managed Folder Assistant	Error	LogAlways	The managed folder assistant did not write to the audit log. It will stop processing the current database: *<database>*. It will try to write to the audit log again later in the schedule window. Exception details: *<details>*
10017	Managed Folder Assistant	Error	LogAlways	An exception occurred in the Managed Folder

				Assistant while it was processing Mailbox: <*mailbox*> Folder: Name: <*folder name*> Id: <*folder ID*> Item: Ids: <*IDs*>. Exception: <*exception*>.

MRM events in the Assistants category

Event ID	Category	Event type	Logging	Value or description
9004	Assistants	Warning	LogAlways	Service <*service*>. <*service*> failed to process mailbox <*mailbox*>. The following exception caused the failure: <*exception*>
9014	Assistants	Warning	LogAlways	Service <*service*>. Unable to process schedule changes. The following exception caused the failure: <*exception*>
9017	Assistants	Information	LogAlways	Service <*service*>. <*service*> for database <*database*> is entering a

				scheduled time window. There are *<number>* mailboxes to process.
9018	Assistants	Information	LogAlways	Service *<service>*. *<service>* for database *<database>* is exiting a scheduled time window. *<number>* out of *<number>* mailboxes were successfully processed. *<number>* mailboxes were skipped due to errors. *<number>* mailboxes were processed separately. *<number>* mailboxes were not processed due to insufficient time. **Note:** The Managed Folder Assistant will resume where it left off the next time it runs.

9019	Assistants	Warning	LogPeriodic	Service <*service*>. Unable to save progress for <*service*> on database <*database*>. (The assistant was unable to save where it stopped so that it could resume there when it restarts.) The following exception caused the failure: <*exception*>
9020	Assistants	Warning	LogAlways	Service <*service*>. <*assistant name*> failed to start for database <*database*>. The following exception caused the failure: <*exception*>
9021	Assistants	Information	LogAlways	Service <*service*>. <*service*> for database <*database*> is processing an on-demand request. There are <*number*> mailboxes to

				process.
9022	Assistants	Information	LogAlways	Service <*service*>. <*service*> for database <*database*> has finished an on-demand request. <*number*> out of <*number*> mailboxes were successfully processed. <*number*> mailboxes were skipped due to errors.
9023	Assistants	Warning	LogAlways	Service <*service*>. <*service*> failed to start time window processing on database <*database*>. The following exception caused the failure: <*exception*>
9025	Assistants	Information	LogAlways	Service <*service*>. <*service*> skipped <*number*> mailboxes on database <*database*>.

				Mailboxes: <*mailboxes*>
9026	Assistants	Warning	LogAlways	Service <*service*>. <*service*> failed to start on-demand processing on database <*database*>. The following exception caused the failure: <*exception*>
9027	Assistants	Error	LogAlways	Service <*service*>. <*service*> caused the process to terminate <*number*> times while processing mailbox <*mailbox*> on database <*database*>. This mailbox will no longer be processed in the requested time window or on-demand request. The following exception caused the failure: <*exception*>

9028	Assistants	Warning	LogAlways	Service <*service*>. <*service*> caused the process to terminate <*number*> times while processing mailbox <*mailbox*> on database <*database*>. The following exception caused the failure: <*exception*>
9033	Assistants	Warning	LogAlways	Service <*service*>. <*service*> for database <*database*> received an on-demand request. However, there are no mailboxes to process.
9034	Assistants	Information	LogAlways	Service <*service*> halted time based operations for managed folder assistant on database <*database*>.
9035	Assistants	Warning	LogAlways	Service <*service*>. <*assistant name*>

				was unable to process <*number*> mailboxes because insufficient time.
9037	Assistants	Error	LogAlways	Service <*service*>. An exception was encountered while processing a RPC. Method: <*method*>, Exception: <*exception*>

Journaling

Exchange Server 2013 > Messaging policy and compliance >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-05-20*

Journaling can help your organization respond to legal, regulatory, and organizational compliance requirements by recording inbound and outbound email communications. When planning for messaging retention and compliance, it's important to understand journaling, how it fits in your organization's compliance policies, and how Microsoft Exchange Server 2013 helps you secure journaled messages.

Contents

Why journaling is important

First, it's important to understand the difference between journaling and archiving:

- *Journaling* is the ability to record all communications, including email communications, in an organization for use in the organization's email retention or archival strategy. To meet an increasing number of regulatory and compliance requirements, many organizations must maintain records of communications that occur when employees perform daily business tasks.
- *Archiving* refers to backing up the data, removing it from its native environment, and storing it elsewhere, therefore reducing the strain of data storage. You can use Exchange journaling as a tool in your email retention or archival strategy.

Although journaling may not be required by a specific regulation, compliance may be achieved through journaling under certain regulations. For example, corporate officers in some financial sectors may be held liable for the claims made by their employees to their customers. To verify that the claims are accurate, a corporate officer may set up a system where managers review some part of employee-to-client communications regularly. Every quarter, the managers verify compliance and approve their employees' conduct. After all managers report approval to the corporate officer, the corporate officer reports compliance, on behalf of the company, to the regulating body. In this example, email messages might be one type of the employee-to-client communications that managers must review; therefore, journaling can be used to collect all email messages sent by client-facing employees. Other client communication mechanisms may include faxes and telephone conversations, which may also be subject to regulation. The ability to journal all classes of data in an enterprise is a valuable functionality of the IT architecture.

The following list shows some of the more well-known U.S. and international regulations where journaling may help form part of your compliance strategies:

- Sarbanes-Oxley Act of 2002 (SOX)
- Security Exchange Commission Rule 17a-4 (SEC Rule 17 A-4)
- National Association of Securities Dealers 3010 & 3110 (NASD 3010 & 3110)
- Gramm-Leach-Bliley Act (Financial Modernization Act)
- Financial Institution Privacy Protection Act of 2001
- Financial Institution Privacy Protection Act of 2003
- Health Insurance Portability and Accountability Act of 1996 (HIPAA)
- Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism Act of 2001 (Patriot Act)
- European Union Data Protection Directive (EUDPD)
- Japan's Personal Information Protection Act

Return to top

Journaling agent

In an Exchange 2013 organization, all email traffic is routed by Mailbox servers. All messages

traverse at least one server running the Transport service in their lifetime. The *Journaling agent* is a compliance-focused transport agent that processes messages on Mailbox servers. It fires on the **OnSubmittedMessage** and **OnRoutedMessage** transport events.

Note:

In Exchange 2013, the Journaling agent is a built-in agent. Built-in agents aren't included in the list of agents returned by the **Get-TransportAgent** cmdlet. For more details, see Transport agents.

Exchange 2013 provides the following journaling options:

- **Standard journaling** Standard journaling is configured on a mailbox database. It enables the Journaling agent to journal all messages sent to and from mailboxes located on a specific mailbox database. To journal all messages to and from all recipients and senders, you must configure journaling on all mailbox databases on all Mailbox servers in the organization.
- **Premium journaling** Premium journaling enables the Journaling agent to perform more granular journaling by using journal rules. Instead of journaling all mailboxes residing on a mailbox database, you can configure journal rules to match your organization's needs by journaling individual recipients or members of distribution groups. You must have an Exchange Enterprise client access license (CAL) to use premium journaling.

When you enable standard journaling on a mailbox database, this information is saved in Active Directory and is read by the Journaling agent. Similarly, journal rules configured with premium journaling are also saved in Active Directory and applied by the Journaling agent. For more information about how to configure standard and premium journaling, see Manage journaling.

Return to top

Journal rules

The following are key aspects of journal rules:

- **Journal rule scope** Defines which messages are journaled by the Journaling agent.
- **Journal recipient** Specifies the SMTP address of the recipient you want to journal.
- **Journaling mailbox** Specifies one or more mailboxes used for collecting journal reports.

Journal rule scope

You can use a journal rule to journal only internal messages, only external messages, or both. The following list describes these scopes:

- **Internal messages only** Journal rules with the scope set to journal internal messages sent between the recipients inside your Exchange organization.
- **External messages only** Journal rules with the scope set to journal external messages sent to recipients or received from senders outside your Exchange organization.
- **All messages** Journal rules with the scope set to journal all messages that pass through your organization regardless of origin or destination. These include messages that may have already

been processed by journal rules in the Internal and External scopes.

Journal recipient

You can implement targeted journaling rules by specifying the SMTP address of the recipient you want to journal. The recipient can be an Exchange mailbox, distribution group, mail user, or contact. These recipients may be subject to regulatory requirements, or they may be involved in legal proceedings where email messages or other communications are collected as evidence. By targeting specific recipients or groups of recipients, you can easily configure a journaling environment that matches your organization's processes and meets regulatory and legal requirements. Targeting only the specific recipients that need to be journaled also minimizes storage and other costs associated with retention of large amounts of data.

All messages sent to or from the journaling recipients you specify in a journaling rule are journaled. If you specify a distribution group as the journaling recipient, all messages sent to or from members of the distribution group are journaled. If you don't specify a journaling recipient, all messages sent to or from recipients that match the journal rule scope are journaled.

Unified Messaging-enabled journal recipients

Many organizations that implement journaling may also use Unified Messaging (UM) to consolidate their email, voice mail, and fax infrastructure. However, you may not want the journaling process to generate journal reports for messages generated by Unified Messaging. In these cases, you can decide whether to journal voice mail messages and missed call notification messages handled by an Exchange 2013 server running the Unified Messaging service or to skip such messages. If your organization doesn't require journaling of such messages, you can reduce the amount of hard disk storage space required to store journal reports by skipping these messages.

Note:

Messages that contain faxes generated by a the Unified Messaging service are always journaled, even if you disable the journaling of Unified Messaging voice mail and missed call notification messages.

For more information about how to enable or disable voice mail and missed call notification messages, see Disable or enable journaling of voice mail and missed call notifications.

Journaling mailbox

The journaling mailbox is used to collect journal reports. How you configure the journaling mailbox depends on your organization's policies, regulatory requirements, and legal requirements. You can specify one journaling mailbox to collect messages for all the journal rules configured in the organization, or you can use different journaling mailboxes for different journal rules or sets of journal rules.

Important:

You can't designate an Office 365 mailbox as a journaling mailbox. You can deliver journal reports to an on-premises archiving system or a third-party archiving service. If you're running a hybrid deployment with your mailboxes split between on-premises servers and Office 365, you can designate an on-premises mailbox as the journaling mailbox for your Office 365 and on-premises mailboxes.

Important:

Journaling mailboxes contain very sensitive information. You must secure journaling mailboxes because they collect messages that are sent to and from recipients in your organization. These messages may be part of legal proceedings or may be subject to regulatory requirements. Various laws require that messages remain tamper-free before they're submitted to an investigatory authority. We recommend that you create policies that govern who can access the journaling mailboxes in your organization, limiting access to only those individuals who have a direct need to access them. Speak with your legal representatives to make sure that your journaling solution complies with all the laws and regulations that apply to your organization.

Alternate journaling mailbox

When the journaling mailbox is unavailable, you may not want the undeliverable journal reports to collect in mail queues on Mailbox servers. Instead, you can configure an alternate journaling mailbox to store those journal reports. The alternate journaling mailbox receives the journal reports as attachments in the non-delivery reports (NDRs) generated when the journaling mailbox or the server on which it's located refuses delivery of the journal report or becomes unavailable.

When the journaling mailbox becomes available again, you can use the **Send Again** feature of Office Outlook to submit journal reports for delivery to the journaling mailbox.

When you configure an alternate journaling mailbox, all the journal reports that are rejected or can't be delivered across your entire Exchange 2013 organization are delivered to the alternate journaling mailbox. Therefore, it's important to make sure that the alternate journaling mailbox and the Mailbox server where it's located can support many journal reports.

Caution:

If you configure an alternate journaling mailbox, you must monitor the mailbox to make sure that it doesn't become unavailable at the same time as the journal mailboxes. If the alternate journaling mailbox also becomes unavailable or rejects journal reports at the same time, the rejected journal reports are lost and can't be retrieved.

Because the alternate journaling mailbox collects all the rejected journal reports for the entire Exchange 2013 organization, you must make sure that this doesn't violate any laws or regulations that apply to your organization. If laws or regulations prohibit your organization from allowing journal reports sent to different journaling mailboxes from being stored in the same alternate journaling mailbox, you may be unable to configure an alternate journaling mailbox. Discuss this with your legal representatives to determine whether you can use an alternate journaling mailbox.

When you configure an alternate journaling mailbox, you should use the same criteria that you used when you configured the journaling mailbox.

Important:

The alternate journaling mailbox should be treated as a special dedicated mailbox. Any messages addressed directly to the alternate journaling mailbox aren't journaled.

Return to top

Journal rule replication

Journal rules are stored in Active Directory and applied by all Mailbox servers in the Exchange 2013 organization. When you create, modify, or remove a journal rule, the change is replicated to all Active Directory servers in the organization. All Mailbox servers in the organization then retrieve the updated journal rule configuration from the Active Directory servers and apply the new or modified journal rules.

By replicating all the journal rules across the organization, Exchange 2013 enables you to provide a consistent set of journal rules across the organization. All messages that pass through your Exchange 2013 organization are subject to the same journal rules.

Important:

Replication of journal rules across an organization is dependant on Active Directory replication. Replication time between Active Directory domain controllers varies depending on the number of sites in the organization and the speed of links and other factors outside the control of Microsoft Exchange. Consider replication delays when you implement journal rules in your organization. For more information about Active Directory replication, see Introduction to Active Directory Replication and Topology Management Using Windows PowerShell.

Important:

Each Mailbox server caches distribution group membership to avoid repeated round trips to Active Directory. The expanded groups cache reduces the number of requests that each Mailbox server must make to an Active Directory domain controller. By default, entries in the expanded groups cache expire in four hours. Therefore, if you specify a distribution group as the journal recipient, changes to distribution group membership may not be applied to journal rules until the expanded groups cache is updated. To force an immediate update of the recipient cache, you must stop and start the Microsoft Exchange Transport service. You must do this for each Mailbox server where you want to forcibly update the recipient cache.

Return to top

Journal reports

A *journal report* is the message that the Journaling agent generates when a message matches a journal rule and is to be submitted to the journaling mailbox. The original message that matches the journal rule is included unaltered as an attachment to the journal report. The body of a journal report contains information from the original message such as the sender email address, message subject, message-ID, and recipient email addresses. This is also referred to as envelope journaling, and is the only journaling method supported by Exchange 2013.

Journal reports and IRM-protected messages

When implementing journaling in an Exchange 2013 environment, you must consider journaling reports and IRM-protected messages. IRM-protected messages will affect the search and discovery capabilities of third-party archiving systems that don't have RMS support built-in. In Exchange 2013, you can configure Journal Report Decryption to save a clear-text copy of the message in a journal report.

Return to top

Interoperability with Exchange 2007

There isn't much difference between journaling functionality in Exchange 2013, Exchange 2010, and Exchange 2007. However, in Exchange 2010 and later, Setup creates a separate container in Active Directory to store journal rules. When you set up the first Exchange 2010 or later server in an Exchange 2007 organization, Setup creates a copy of the existing journal rules in Exchange 2007 and stores them in the new container. When Setup completes, the journal rules in both versions of Exchange are consistent.

After Setup, if you change the journal rule configuration on Exchange 2010 (or later), you must make the same change on Exchange 2007 servers to make sure they're consistent. Similarly, changes made to Journal rules on Exchange 2007 must be also be made in Exchange 2010 or later. You can also export journal rules from Exchange 2007 and import them to Exchange 2013.

Troubleshooting

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.. If you're having trouble with the **JournalingReportDNRTo** mailbox, see Transport and Mailbox Rules in Exchange Online don't work as expected.

Manage journaling

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-11-20*

Journaling can help your organization respond to legal, regulatory, and organizational compliance

requirements by recording inbound and outbound e-mail communications. This topic shows you how to perform basic tasks related to managing journaling in Exchange 2013.

Standard journaling is configured on a mailbox database. It enables the Journaling agent to journal all messages sent to and from mailboxes located on a specific mailbox database. You can also use premium journaling enables the Journaling agent to perform more granular journaling by using journal rules. Instead of journaling all mailboxes residing on a mailbox database, you can configure journal rules to match your organization's needs by journaling individual recipients or members of distribution groups. You must have an Exchange Enterprise client access license (CAL) to use premium journaling.

To learn more about journaling, see Journaling.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Journaling" entry in the Messaging policy and compliance permissions topic.
- A journaling mailbox has been created, or an existing mailbox is available for use as the journaling mailbox.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection. If you're having trouble with the **JournalingReportDNRTo** mailbox, see Transport and Mailbox Rules in Exchange Online don't work as expected.

What do you want to do?

Create a journal rule

Use the EAC to create a journal rule

1. Navigate to **Compliance management** > **Journal rules**, and then click **Add +**.
2. In **Journal rule**, provide a name for the journal rule and then compete the following fields:
   - **If the message is sent to or received from** Specify the recipient that the rule will target. You can either select a specific recipient or apply the rule to all messages.
   - **Journal the following messages** Specify the scope of the journal rule. You can journal only the internal messages, only the external messages, or all messages regardless of origin or destination.
   - **Send journal reports to** Type the address of the journaling mailbox that will receive all the journal reports.

3. Click **Save** to create the journal rule.

Use the Shell to create a journal rule

This example creates the journal rule Discovery Journal Recipients to journal all messages sent from and received by the recipient user1@contoso.com.

```
New-JournalRule -Name "Discovery Journal Recipients" -
Recipient user1@contoso.com -JournalEmailAddress "Journal
Mailbox" -Scope Global -Enabled $True
```

How do you know this worked?

To verify that you have successfully created the journal rule, do one of the following:

- From the EAC, verify that the new journal rule you created is listed on the **Journal rules** tab.
- From the Shell, verify that the new journal rule exists by running the following command (the example below verifies the rule created in the Shell example above):

```
Get-JournalRule "Discovery Journal Recipients"
```

View or modify a journal rule

Use the EAC to view or modify a journal rule

1. Navigate to **Compliance management** > **Journal rules**.
2. In the list view, you'll see all the journal rules in your organization.
3. Double-click the rule you want to view or modify.
4. In **Journal Rule**, modify the settings you want. For more information about the settings in this dialog box, see the procedure Use the EAC to create a journal rule earlier in this topic.

Use the Shell to view or modify a journal rule

This example displays a summary list of all journal rules in the Exchange organization:

```
Get-JournalRule
```

This example retrieves the journal rule Brokerage Journal Rule, and pipes the output to the **Format-List** command to display rule properties in a list format:

```
Get-JournalRule "Brokerage Journal Rule" | Format-List
```

If you want to modify the properties of a specific rule, you need to use the Set-JournalRule cmdlet. This example changes the name of the journal rule `JR-Sales` to `TraderVault`. The following rule settings are also changed:

- Recipient
- JournalEmailAddress
- Scope

```
Set-JournalRule JR-Sales -Name TraderVault -Recipient
traders@woodgrovebank.com -JournalEmailAddress
tradervault@woodgrovebank.com -Scope Internal
```

How do you know this worked?

To verify that you have successfully modified a journal rule, do one of the following:

- From the EAC, navigate to **Compliance management**, > **Journal rules**. Double-click the rule you modified and verify your changes were saved.
- From the Shell, verify that you modified the journal rule successfully by running the following command. This command will list the properties you modified along with the name of the rule (the example below verifies the rule modified in the Shell example above):

```
Get-TransportRule "TraderVault" | Format-List
Name,Recipient,JournalEmailAddress,Scope
```

Enable or disable a journal rule

Important:
When you disable a journal rule, the journaling agent will stop journaling messages targeted by that rule. While a journal rule is disabled, any messages that would have normally been journaled by the rule aren't journaled. Make sure that you don't compromise the regulatory or compliance requirements of your organization by disabling a journaling rule.

Use the EAC to enable or disable a journal rule

1. Navigate to **Compliance management** > **Journal rules**.
2. In the list view, in the **On** column next to the rule's name, select the check box to enable the rule or clear it to disable the rule.

Use the Shell to enable or disable a journal rule

This example enables the rule Contoso.

```
Enable-JournalRule "Contoso Journal Rule"
```

This example disables the rule Contoso.

```
Disable-JournalRule "Contoso Journal Rule"
```

How do you know this worked?

To verify that you have successfully enabled or disabled a journal rule, do one of the following:

- From the EAC, view the list of journal rules check the status of the check box in the **On** column.
- From the Shell, run the following command to return a list of all journal rules in your organization along, including their status:

```
Get-JournalRule | Format-Table Name,Enabled
```

Remove a journal rule

Use the EAC to remove a journal rule

1. Navigate to **Compliance management** > **Journal rules**.
2. In the list view, select the rule you want to remove, and then click **Delete** 🗑.

Use the Shell to remove a journal rule

This example removes the rule Brokerage Journal Rule.

```
Remove-JournalRule "Brokerage Journal Rule"
```

How do you know this worked?

To verify that you have successfully removed the journal rule, do one of the following:

- From the EAC, verify that the rule you removed is no longer listed on the **Journal rules** tab.
- From the Shell, run the following command to verify that the rule you remove is no longer listed:

```
Get-JournalRule
```

Enable or disable per-mailbox database journaling

Caution:
Disabling message journaling on a mailbox database may result in your organization being out of compliance with any applicable messaging retention policies. When you disable message journaling on a mailbox database, journal receipts are no longer sent for messages sent or received by mailboxes on that mailbox database.

Use the EAC enable or disable per-mailbox database journaling

1. Navigate to **Servers** > **Databases**.
2. In the list view, double-click the mailbox database for which you want to enable journaling.
3. Click **Maintenance**, and then click **Browse** next to the **Journal recipient** box to select the journaling mailbox. Specifying a journal recipient enables journaling for the database.

To disable journaling, remove the journal recipient by clicking **Remove X**.

Use the Shell to enable or disable per-mailbox database journaling

This example enables journaling for the mailbox database Sales Database and sets Sales Database journal mailbox as the journal recipient.

```
Set-MailboxDatabase "Sales Database" -JournalRecipient
"Sales Database Journal Mailbox"
```

This example disables per-mailbox database journaling on the Sales Database mailbox database.

```
Set-MailboxDatabase "Sales Database" -JournalRecipient
$Null
```

This example disables per-mailbox database journaling on all mailbox databases in the Exchange organization. The Get-MailboxDatabase cmdlet is used to retrieve all mailbox databases in the Exchange organization, and results from the cmdlet are piped to the Set-MailboxDatabase cmdlet.

```
Get-MailboxDatabase | Set-MailboxDatabase -JournalRecipient
$Null
```

How do you know this worked?

To verify that you have successfully enabled or disabled per-mailbox database journaling, do one of the following:

1. From the EAC, navigate to **Servers** > **Databases**.
2. Double click the database you want to verify, and then select the **Maintenance** tab.
3. If the correct journaling recipient is listed in the **Journal recipient** box, you have successfully enabled journaling for the mailbox database. If there is no journaling recipient listed, journaling is disabled for the database.

- From the Shell, run the following command to return a list of all mailbox databases in your organization, including the journal recipients associated with them. Journaling is enabled for databases that have a journal recipient listed, otherwise it's disabled.

```
Get-MailboxDatabase | Format-Table Name,JournalRecipient
```

Disable or enable journaling of voice mail and missed call notifications

New-JournalRule

Get-JournalRule

Set-JournalRule

Enable-JournalRule

Disable-JournalRule

Remove-JournalRule

Set-MailboxDatabase

Disable or enable journaling of voice mail and missed call notifications

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-01-10*

In Microsoft Exchange Server 2013, when you create a journal rule to journal email messages sent to or from recipients or senders in an Exchange organization, voice mail and missed call notifications generated by the Unified Messaging (UM) service are included. Use the procedures in this topic to turn this feature on or off for your entire organization.

Looking for other management tasks related to journaling? Check out Manage journaling.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Journaling" entry in the Messaging policy and compliance permissions topic.
- You can only use the Shell to perform this procedure.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to disable or enable journaling of voice mail and missed call notifications

This example disables journaling of voice mail and missed call notifications by setting the *VoicemailJournalingEnabled* parameter to `$false`.

```
Set-TransportConfig -VoicemailJournalingEnabled $false
```

This example enables the journaling of voice mail and missed call notifications by setting the same parameter to `$true`.

```
Set-TransportConfig -VoicemailJournalingEnabled $true
```

For detailed syntax and parameter information, see Set-TransportConfig.

Transport rules

Exchange Server 2013 > Messaging policy and compliance >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-01-23*

Using transport rules, you can look for specific conditions in messages that pass through your organization and take action on them. Transport rules let you apply messaging policies to email messages, secure messages, protect messaging systems, and prevent information leakage.

Many organizations today are required by law, regulatory requirements, or company policies to apply messaging policies that limit the interaction between recipients and senders, both inside and outside the organization. In addition to limiting interactions among individuals, departmental groups inside the organization, and entities outside the organization, some organizations are also subject to the following messaging policy requirements:

- Preventing inappropriate content from entering or leaving the organization
- Filtering confidential organization information
- Tracking or archiving copying messages that are sent to or received from specific individuals
- Redirecting inbound and outbound messages for inspection before delivery
- Applying disclaimers to messages as they pass through the organization

Looking for management tasks related to managing transport rules? See Manage Transport Rules.

For each rule, you have the option of enforcing it, testing it and notifying the sender, or just testing the rule. You can notify the sender that they might be violating one of the rules—even before they send an offending message. You can accomplish this by configuring Policy Tips and setting the mode of the rule. Policy Tips are similar to MailTips, and can be configured to present a brief note in the Microsoft Outlook 2013 client that provides information about possible policy violations to a person creating a message. For more information, see Policy Tips.

Contents

Overview of transport rules

Transport rules are similar to the Inbox rules that are available in many email clients. The main difference between transport rules and rules you would set up in a client application such as Outlook is that transport rules take action on messages while they're in transit as opposed to after the message is delivered. Transport rules also contain a richer set of conditions, exceptions, and actions, which provides you with the flexibility to create a customized rule.

The following list summarizes the basic workflow for transport rules:

1. You use the Exchange admin center (EAC),the Shell, or a DLP policy to create a transport rule. After you create your rule, it's stored in Active Directory.
2. As messages go through the transport pipeline, the Transport rules agent is invoked. The Transport rules agent is a special Transport agent that processes the Transport rules you create.
3. The Transport rules agent scans the message, and if the message fits the conditions you specify in a transport rule, it takes the specified action on that message based on the mode of the rule.

The following sections provide detailed information about transport rule components, transport rule modes, the Transport rules agent, and how the transport rules are applied.

Return to top

Transport rule components

Transport rules consist of the following components:

- **Conditions** Conditions specify the characteristics of messages to which you want to apply a transport rule action. Some conditions examine message fields or headers, such as the To, From, or Cc fields. Other conditions examine message characteristics such as message subject, body, attachments, message size, and message classification. Most conditions require that you specify a comparison operator, such as equals, doesn't equal, or contains, and a value to match. If there are no conditions or exceptions, the rule is applied to all messages.
- **Exceptions** Exceptions are based on the same characteristics used to build conditions. However, unlike conditions, exceptions identify messages to which transport rule actions shouldn't be applied. Exceptions override conditions and prevent actions from being applied to an email message, even if the message matches all configured conditions.
- **Actions** Actions are applied to messages that match all the conditions and don't match any of the exceptions. There are many actions available, such as rejecting, deleting, or redirecting messages, adding additional recipients, adding prefixes in the message subject, or inserting disclaimers in the message body.

For a complete list of transport rule conditions, see Transport rule conditions (predicates). The list of conditions is also available in the **Transport rule** dialog in the EAC. If you use the Shell, you can

retrieve the list of conditions by using the Get-TransportRulePredicate cmdlet.

For a complete list of transport rule actions available, see Transport rule actions. The list of actions is also available in the **Transport rule** dialog box in the EAC. If you use the Shell, you can retrieve the list of actions by using the Get-TransportRuleAction cmdlet.

Return to top

Transport rule modes

There are three modes for each transport rule that define how the rule will be implemented:

- **Enforce**: All actions on the rule will be enforced.
- **Test with Policy Tips**: Any Policy Tip actions will be sent, but other enforcement actions will not be acted on
- **Test without Policy Tips**: Actions will be listed in a log file, but senders will not be notified in any way, and enforcement actions will not be acted on

In order to make sure rules work as you intend, we recommend testing rules before setting them to **Enforce**.

How transport rules are applied

All transport rules are processed by the Transport rules agent on Exchange servers. The Transport rules agent is a built-in agent that fires on the **OnResolvedMessage** transport event. All messages in an Exchange 2013 organization are processed by the Transport service.

Differences in processing based on message type

There are several types of messages that pass through an organization. The following table shows which messages types can be processed by transport rules.

Type of message	Can a rule be applied?
Regular messages Messages that contain a single rich text format (RTF), HTML, or plain text message body or a multipart or alternative set of message bodies.	Yes
Encrypted messages (Office 365 Message Encryption) Messages that are encrypted using Office	Rules can always access envelope headers contained in encrypted messages and process messages based on conditions that inspect headers.

365 Message Encryption.	For a rule to inspect or modify Office 365 message encrypted content, your organization must: • Use Exchange Server or Exchange Online. • Have transport decryption set to **Mandatory** or **Optional**. Transport decryption is set to **Optional** by default. • Have the encryption key. You can also create a rule that automatically decrypts encrypted messages.
Encrypted messages (S/MIME) Messages that are encrypted using S/MIME.	Rules can access only envelope headers contained in S/MIME encrypted messages and process messages based on conditions that inspect headers. Rules with conditions that require inspection of message content, or actions that modify content, can't be processed.
Protected messages Messages that are protected by applying an Active Directory Rights Management Services (AD RMS) rights policy template.	Rules can always access envelope headers contained in protected messages and process messages based on conditions that inspect headers. For a rule to inspect or modify protected message content, your organization must: • Use Exchange Server or Exchange Online. • Have transport decryption set to **Mandatory** or **Optional**. Transport decryption is set to **Optional** by default. • Have the encryption key.
Clear-signed messages Messages that have been signed but not encrypted.	Yes

Unified messaging email messages Messages that are created or processed by the Unified Messaging service, such as voice mail, fax, missed call notifications, and messages created or forwarded by using Microsoft Outlook Voice Access.	Yes
Anonymous	Yes
Messages sent by anonymous senders.	Yes
Read reports Reports that are generated in response to read receipt requests by senders. Read reports have a message class of `IPM.Note*.MdnRead` or `IPM.Note*.MdnNotRead`.	Yes

Return to top

How the Transport rules agent evaluates messages

The Transport rules agent evaluates the following elements when processing rules for a message:

- **Message scope** The first check performed by rules agents is whether a message falls within the scope of the agent. Transport rules aren't applied to all types of messages.
- **Priority** For messages that fall within the scope of the rules agent, the agent starts processing rules based on rule priority in ascending order. The rule with a priority of 0 is processed first, followed by the rule with a priority of 1 and so on. Transport rule priority values range from `0` to `n-1`, where `n` is the total number of transport rules. Only enabled rules are processed. You can change the rule priority.
- **Rules with no conditions or exceptions** If a rule has no conditions and no exceptions, it's applied to all messages.
- **Conditions** The conditions describe the type of message for which the rule is intended, and the rules agent applies the rules to the messages that match the criteria specified in the rule conditions.
- **Rules with multiple conditions** It may be necessary to use more than one condition to specify a rule. For a rule's action to be applied to a message, it must match all the conditions selected in the rule. For example, if a rule uses the conditions **The sender is a member of this group** and **The subject includes any of these words**, the message must match both conditions. It must be

sent by a member of the specified distribution group, and the message subject must contain the specified word.

- **Conditions with multiple values** Some conditions allow you to specify more than one value. If one condition allows you to enter multiple values, the message must match any value specified for that condition. For example, if an email message has the subject **Stock price information**, and the **The subject includes any of these words** condition on a transport rule is configured to match the words **Contoso** and **stock**, the condition is satisfied because the subject contains at least one of the condition values.
- **Exceptions** A rule isn't applied to messages that match any of the exceptions defined in the rule. This is exactly opposite of how the rules agent treats conditions. For example, if the exceptions **Except if the sender is this person** and **Except if the subject or body includes any of these words** are selected, the message fails to match the rule condition if the message is sent from any of the specified senders, or if the message contains any of the specified words.
- **Actions** Messages that match the rules conditions get all actions specified in the rule applied to them. For example, if the actions **Prepend the subject of the message with** and **Add recipients to the Bcc box** are selected, both actions are applied to the message. The message will get the specified string prefixed to the message subject, and the recipients specified will be added as Bcc recipients.

Keep in mind that some actions, such as the **Delete the message without notifying anyone** action, prevent subsequent rules from being applied to a message. You can also configure a rule so that when that rule is applied, the rules agent stops processing any subsequent rules.

Return to top

Transport rules and group membership

When you define a transport rule using a condition that expands membership of a distribution group, the resulting list of recipients is cached by the Transport service on the Mailbox server that applies the rule. This is known as the *Expanded Groups Cache* and is also used by the Journaling agent for evaluating group membership for journal rules. By default, the Expanded Groups Cache stores group membership for four hours. Recipients returned by the recipient filter of a dynamic distribution group are also stored. The Expanded Groups Cache makes repeated round-trips to Active Directory and the resulting network traffic from resolving group memberships unnecessary.

In Exchange 2013, this interval and other parameters related to the Expanded Groups Cache are configurable. You can lower the cache expiration interval, or disable caching altogether, to ensure group memberships are refreshed more frequently. You must plan for the corresponding increase in load on your Active Directory domain controllers for distribution group expansion queries. You can also clear the cache on a Mailbox server by restarting the Microsoft Exchange Transport service on that server. You must do this on each Mailbox server where you want to clear the cache. When creating, testing, and troubleshooting transport rules that use conditions based on distribution group membership, you must also consider the impact of Expanded Groups Cache.

Return to top

Rule storage and replication

The Transport rules you create are stored in Active Directory and are available after Active Directory replication on all Exchange servers in your Exchange 2013 organization. This allows you to apply a consistent set of rules across the entire Exchange organization.

When a transport rule is created or an existing transport rule is modified or deleted, the change is replicated to all Active Directory domain controllers in the organization. All the Exchange servers in the organization then read the new configuration from the Active Directory servers and apply the new or modified transport rules.

Important:

Replication of transport rules across an organization depends on Active Directory replication. Replication time between Active Directory domain controllers varies depending on the number of sites in the organization, slow links, and other factors outside the control of Exchange. When you configure transport rules in your organization, make sure that you consider replication delays. For more information about Active Directory replication, see Active Directory Replication Technologies.

Important:

The Transport service on each Mailbox server maintains a recipient cache that's used to look up recipient and distribution list information. The recipient cache reduces the number of requests that each Mailbox server must make to an Active Directory domain controller. The recipient cache updates every four hours. You can't modify the recipient cache update interval. Therefore, changes to transport rule recipients, such as the addition or removal of distribution list members, may not be applied to transport rules until the recipient cache is updated. To force an immediate update of the recipient cache, you must stop and start the Microsoft Exchange Transport service. You must do this for each Mailbox server where you want to forcibly update the recipient cache.

Note:

Each time the Transport service on the Mailbox server retrieves a new transport rule configuration, an event is logged in the Security log in Event Viewer.

Rule replication and storage in mixed environments

There are two mixed environment scenarios that are common: hybrid deployments where part of your organization resides on Office 365, and Exchange 2013 coexisting with Exchange 2010 or Exchange 2007.

In the hybrid scenario, there is no replication of rules between your on-premises deployment and Office 365. Therefore, when you create a rule in your on-premises Exchange organization, you need to create a matching rule in Office 365. The rules you create in Office 365 are stored in the cloud, along with the rest of your Office 365 organization configuration, whereas the rules you create in your on-premises Exchange organization are stored locally in Active Directory. When managing rules in a hybrid scenario, you need to make sure that you keep the two sets of rules synchronized

by making the change in both places, or making the change in one environment and then exporting the rules and importing them in the other environment.

Important:
Even though there is a substantial overlap between the conditions and actions available in Office 365 and on-premises Exchange, there are differences. If you plan on creating the same rule in both locations, make sure that all conditions and actions you plan to use are available. To see the list of available conditions and actions for each deployment, see the following topics: **Transport Rule Conditions (Predicates)** in Office 365 Transport rule conditions (predicates) in on-premises Exchange **Transport rule actions** in Office 365 Transport rule actions in on-premises Exchange

When you coexist with Exchange 2010 or Exchange 2007, all transport rules are stored in Active Directory and replicated across your organization regardless of the Exchange Server version you used to create the rules. However, all transport rules are associated with the Exchange server version that was used to create them and are stored in a version-specific container in Active Directory. When you first deploy Exchange 2013 in your organization, any existing rules are imported to Exchange 2013 as part of the setup process. However, any changes afterwards would need to be made with both versions. For example, if you change an existing rule using the Exchange 2013 EAC, you need to make the same change using the Exchange 2010 or Exchange 2007 EMC.

Exchange Server 2013 > Messaging policy and compliance > Transport rules >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-07-31*

Transport rule conditions and exceptions are used to define when a transport rule is applied. For example, when adding a disclaimer, you could define the conditions to only add the disclaimer to messages containing specific words, to messages from a specific person or group, or to all messages except those from a specific group.

Conditions and Condition Properties for a Mailbox Server

To determine whether a transport rule should be applied to a message, most conditions have one or more properties for which you must specify a value. For example, the **The sender is** condition requires that you specify the sender for the message. Some conditions have two properties. For example, the **A message header includes any of these words** condition requires one property to specify the header to examine, such as To, From, Received, or Content-Type, and a second property for the text to look for in the specified message header. Others don't have properties. For example, the **Any attachment has executable content** condition simply inspects whether any attachment in a message has executable content, and therefore doesn't require any values.

To assign a value to a condition in the Exchange admin center (EAC), you can use the drop-down lists and secondary dialog boxes that are displayed in the **Transport rule** page. These help you select the correct property types and valid values for those property types. If you're using the Shell to define conditions, see the descriptions in Condition properties.

The following table lists the conditions that can be used with transport rules in Exchange 2013 Mailbox Server.

Note:

Each condition listed in the following table also has an equivalent exception that can be selected in the EAC. In the Shell, conditions that can be used as exceptions start with `ExceptIf`. For example, for the `FromMemberOf` condition, the parameter that can be used as an exception in transport rule cmdlets is called *ExceptIfFromMemberOf*.
The same condition object contains the logic for use in both transport rule conditions and exceptions. Therefore, when you use the Get-`TransportRuleCondition` cmdlet to list conditions, exceptions aren't listed as separate conditions.

Condition name in EAC	Condition name in Shell	Condition property type	Description
The sender is	`From`	Addresses	This condition matches

			messages sent by the specified mailboxes, mail-enabled users, or contacts.
The sender is located	`FromScope`	FromUserScope	This condition matches messages that are sent by senders within the specified scope.
The sender is a member of	`FromMemberOf`	Addresses	This condition matches messages where the sender is a member of the specified distribution group.
The sender address includes	`FromAddressContainsWords`	Words	This condition matches messages that contain the specified words in the sender's address.
The sender address matches	`FromAddressMatchesPatterns`	Patterns	This condition matches messages that contain text patterns in the sender's address that match the specified regular expression.
The sender's specified properties include any of these words	`SenderADAttributeContainsWords`	Words	This condition matches messages where the specified attribute of the sender contains specified words. **Note:** When matching a country using

			CountryOrRegion, you must use the ISO country code, rather than the country name. For example, to match all senders from Germany: `Set-TransportRule`
The sender's specified properties match these text patterns	`SenderADAttributeMatchesPatterns`	Patterns	This condition matches messages where the specified attribute of the sender contains text patterns that match the specified regular expression.
The sender has overridden the Policy Tip	`HasSenderOverride`	Not applicable	This condition matches messages where the sender has chosen to override a DLP policy.
Sender's IP address is in the range	`SenderIPRanges`	IPRanges	This condition matches messages where the sender's IP address falls within the specified ranges.
The sender's domain is	`SenderDomainIs`	Domain name	This condition matches messages where the sender's domain matches the specified domain name.
The recipient is	`SentTo`	Addresses	This condition matches messages where one of the recipients is the

			specified mailbox, mail-enabled user, or contact. The specified recipients can be listed in the **To**, **Cc**, or **Bcc** fields. **Note:** You can't specify a distribution group with this condition. If you need to create a rule that takes action on messages sent to a distribution group, use the **To box contains** (**AnyOfToHeader**) condition instead.
The recipient is located	`SentToScope`	ToUserScope	This condition matches messages that are sent to recipients within the specified scope.
The recipient is a member of	`SentToMemberOf`	Addresses	This condition matches messages that contain recipients who are members of the specified distribution group. The distribution group can be listed in the **To**, **Cc**, or **Bcc** fields.
The recipient address includes	`RecipientAddressContainsWords`	Words	This condition matches messages where a recipient's address contains any of the

			specified words.
The recipient address matches	`RecipientAddressMatchesPatterns`	Patterns	This condition matches messages where a recipient's address matches a specified regular expression.
The recipient's specified properties include any of these words	`RecipientADAttributeContainsWords`	Words	This condition matches messages where the specified attribute of a recipient contains any of the specified words..
The recipient's specified properties match these text patterns	`RecipientADAttributeMatchesPatterns`	Patterns	This condition matches messages where the specified attribute of a recipient matches the specified regular expression.
A recipient's domain is	`RecipientDomainIs`	Domain Name	This condition matches messages where the domain of any recipient of the message matches the specified domain name.
The subject or body includes	`SubjectOrBodyContainsWords`	Words	This condition matches messages that have the specified words in the **Subject** field or message body.
The subject or body matches	`SubjectOrBodyMatchesPatterns`	Patterns	This condition matches messages where text

			patterns in the **Subject** field or message body match a specified regular expression.
The subject includes	`SubjectContainsWords`	Words	This condition matches messages that have the specified words in the **Subject** field.
The subject matches	`SubjectMatchesPatterns`	Patterns	This condition matches messages where text patterns in the **Subject** field match a specified regular expression.
Any attachment's content includes	`AttachmentContainsWords`	Words	This condition matches messages with attachments that contain a specified string.
Any attachment's content matches	`AttachmentMatchesPatterns`	Patterns	This condition matches messages with attachments that contain a text pattern that matches a specified regular expression. **Note:** Only the first 150 KB of the attachment is scanned when trying to match a pattern.
Any attachment's	`AttachmentIsUnsupported`	Not applicable	This condition matches

content can't be inspected			messages with attachments that aren't supported.
Any attachment's file name matches	`AttachmentNameMatchesPatterns`	Patterns	This condition matches messages that contain text patterns in an attachment file name that matches a specified regular expression.
Any attachment's file extension matches	`AttachmentExtensionMatchesWords`	Words	This condition matches messages that contain an attachment whose extension matches any of the specified words.
Any attachment size is greater than or equal to	`AttachmentSizeOver`	Size	This condition matches messages that contain attachments greater than or equal to the specified value.
The message didn't complete scanning	`AttachmentProcessingLimitExceeded`	Not applicable	This condition matches messages for which the rules engine couldn't complete scanning of the attachments. This condition can be used to create rules that work together with other attachment processing rules and gives you the ability to

			handle messages whose content couldn't be fully scanned.
Any attachment has executable content	`AttachmentHasExecutableContent`	Not applicable	This condition matches messages that contain executable files as attachments. The system uses auto-detection of file types by inspecting file properties rather than the actual file extension, thus preventing spammers from being able to bypass transport rule filtering by renaming the file extension.
Any attachment is password protected	`AttachmentIsPasswordProtected`	Not applicable	This condition matches messages that contain compressed archive attachments that are password protected, and therefore cannot be scanned.
The message contains sensitive information	`MessageContainsDataClassifications`	SensitiveInformation	This condition matches messages that contain sensitive information. This condition is required for rules using the `NotifySender`

			(Notify the sender with a Policy Tip) action.
The To box contains	`AnyOfToHeader`	Addresses	This condition matches messages where the **To** field includes any of the specified recipients.
The To box contains a member of	`AnyOfToHeaderMemberOf`	Addresses	This condition matches messages where the **To** field contains a recipient who is a member of the specified distribution group.
The Cc box contains	`AnyOfCcHeader`	Addresses	This condition matches messages where the **Cc** field includes any of the specified recipients.
The Cc box contains a member of	`AnyOfCcHeaderMemberOf`	Addresses	This condition matches messages where the **Cc** field contains a recipient who is a member of the specified distribution group.
The To or Cc box contains	`AnyOfToCcHeader`	Addresses	This condition matches messages where the **To** or **Cc** fields include any of the specified recipients.

The To or Cc box contains a member of	`AnyOfToCcHeaderMemberOf`	Addresses	This condition matches messages where the **To** or **Cc** fields contains a recipient who is a member of the specified distribution group.
The message size is greater than or equal to	`MessageSizeOver`	Size	This condition matches messages whose overall size is greater than or equal to the specified value.
The message character set name includes any of these words	`ContentCharacterSetContainsWords`	Character Sets	This condition matches messages that have any of the character set names specified.
The sender is one of the recipients'	`SenderManagementRelationship`	ManagementRelationship	This condition matches messages where the sender has the specified management relationship with a recipient.
The message is between members of these groups	`BetweenMemberOf1` and `BetweenMemberOf2`	First property: Addresses (`BetweenMemberOf1`) Second property: Addresses (`BetweenMemberOf2`)	This condition matches messages that are sent between members of two distribution groups.
The manager of the sender or recipient is	`ManagerForEvaluatedUser` and `ManagerAddress`	First property: EvaluatedUser	This condition matches messages where the

		(`ManagerForEvaluatedUser`) Second property: Addresses (`ManagerAddresses`)	specified user's (sender or recipient) manager exists in the list of specified addresses.
The sender's and any recipient's property compares as	`ADAttributeComparisonAttribute` and `ADComparisonOperator`	First property: ADAttribute (`ADComparisonAttribute`) Second property: Evaluation (`ADComparisonOperator`)	This condition matches messages where the sender's specified Active Directory attribute matches or doesn't match (as specified in the **Evaluation** property) the same attribute of any recipient.
The message type is	`MessageTypeMatches`	MessageType	This condition matches messages of the specified type.
The message is classified as	`HasClassification`	Classification	This condition matches messages that have the specified classification.
The message isn't marked with any classifications	`HasNoClassification`	Not applicable	This condition matches messages that don't have a message classification.
The message has an SCL greater than or equal to	`SCLOver`	SclValue	This condition matches messages that are assigned a spam confidence level (SCL) matching or exceeding

			the specified value.
The message importance is set to	`WithImportance`	Importance	This condition matches messages marked with the specified priority.
A message header includes	`HeaderContainsMessageHeader` and `HeaderContainsWords`	First property: MessageHeader (`HeaderContainsMessageHeader`) Second property: Words (`HeaderContainsWords`)	This condition matches messages where the specified message header contains one of the specified words.
A message header matches	`HeaderMatchesMessageHeader` and `HeaderMatchesPatterns`	First property: MessageHeader (`HeaderMatchesMessageHeader`) Second property: Patterns (`HeaderMatchesPatterns`)	This condition matches messages where the specified message header contains a text pattern that matches a specified regular expression.

Condition property values for a Mailbox server

Each property that you use to define a transport rule condition requires a value. Here's a list of values for each condition property available in Exchange 2013 Mailbox servers.

Property type	Valid values	Description
ADAttribute	One of the Active Directory attributes available for use	`ADAttribute` accepts the name of one of the following Active Directory attributes: • `DisplayName` • `FirstName` • `Initials` • `LastName` • `Office` • `PhoneNumber` • `OtherPhoneNumber` • `Email`

		• Street • POBox • City • State • ZipCode • Country • UserLogonName • HomePhoneNumber • OtherHomePhoneNumber • PagerNumber • MobileNumber • FaxNumber • OtherFaxNumber • Notes • Title • Department • Company • Manager • CustomAttribute1 - CutomAttribute15 When you use the Shell to create a Transport rule that contains a condition which uses an Active Directory attribute, you must specify an attribute name from the preceding list followed by a colon (:) and the word or text pattern you want to match in the specified attribute. The entire notation should be enclosed in quotation marks ("). For example, to specify the attribute City and the values San Francisco or Palo Alto, you must use City:San Francisco, Palo Alto. You can also specify multiple Active Directory attributes and value pairs. For example, "City:San Francisco, Palo Alto","Department:Sales, Finance". In this case, the

		recipient's `City` attribute should contain either `San Francisco` or `Palo Alto`, and the `Department` attribute should contain either `Sales` or `Finance`.
Addresses	Array of Active Directory mailbox, contact, or distribution group objects	`Addresses` accepts one or more mailbox, contact, mail-enabled user, or distribution group object.
Character Sets	Array of valid character set names	`Character Sets` is a list of names of specific content character sets that can be found in a message. For example, if you wanted to create a rule that checks messages for character sets used in Microsoft ForeFront Online Protection for Exchange, you would use the following list: • Arabic/iso-8859-6 • Chinese/big5 • Chinese/euc-cn • Chinese/euc-tw • Chinese/gb2312 • Chinese/iso-2022-cn • Cyrillic/iso-8859-5 • Cyrillic/koi8-r • Cyrillic/windows-1251 • Greek/iso-8859-7 • Hebrew/iso-8859-8 • Japanese/euc-jp • Japanese/iso-022-jp • Japanese/shift-jis • Korean/euc-kr • Korean/johab • Korean/ks_c_5601-1987

		• Turkish/windows-1254 • Turkish/iso-8859-9 • Vietnamese/tcvn
Classification	Message classification object	`Classification` accepts a message classification object. To see what message classifications are available, you can use the Get-MessageClassification cmdlet.
Domain Name	Any valid SMTP domain name	`Domain Name` is the FQDN for any valid SMTP domain.
EvaluatedUser	Single value of `Sender` or `Recipient`	`EvaluatedUser` is used to determine whether the value specified in the *ManagerAddresses* parameter is the manager of the sender or one of the recipients.
Evaluation	Single value of `Equal` or `NotEqual`	`Evaluation` is used when comparing the Active Directory attributes of the sender and recipients.
FromUserScope	Single value of `InOrganization` or `NotInOrganization`	`FromUserScope` specifies whether the message is sent by a sender who is considered to be inside the organization or external to the organization. The following values can be used: • **InOrganization** A sender is considered to be inside the organization if either of the following conditions is true: ○ The sender is a mailbox, mail-enabled user, distribution group, or public folder that exists in the organization's Active Directory. ○ The domain of the sender is an accepted domain in the Exchange organization, but

		isn't an `ExternalRelay` domain. Also, the message must be sent or received by using an authenticated connection. • **NotInOrganization** A sender is considered to be outside the organization if the sender's domain isn't an accepted domain in the Exchange organization, or is in an accepted domain that is configured as an `ExternalRelay` domain.
Importance	Single value of `High`, `Low`, or `Normal`	`Importance` specifies the message priority.
IPRanges	Array of IP ranges	`IPRanges` is used to specify one or more IP address ranges.
ManagementRelationship	Single value of `Manager` or `DirectReport`	`ManagementRelationship` specifies the relationship between two evaluated users, for example the sender and the recipient. The evaluated user's Active Directory information is located to determine the manager and direct reports.
MessageHeader	Single string	`MessageHeader` accepts a string that can be used to specify the SMTP message header to examine. This property is used together with the `Words` or `Patterns` properties, which specify the value of the header field to match.
MessageType	Single message type name	`MessageType` accepts one of the following message types: • OOF

		• AutoForward • Encrypted • Calendaring • PermissionControlled • Voicemail • Signed • ApprovalRequest • ReadReceipt – Does not match for a read receipt to a meeting request.
Patterns	Array or regular expressions	`Patterns` accepts one or more regular expressions that can be used to match text that follows an identifiable pattern. Enclose the expression in quotation marks (").
SclValue	Single integer	`SclValue` accepts an integer that can be used to match the spam confidence level (SCL) assigned to a message. SCL values range from -1 through 9.
SensitiveInformation	Sensitive Information Types	`SensitiveInformation` accepts the sensitive information types defined in your organization. For a list of built-in sensitive information types in Exchange 2013, see Sensitive information types inventory.
Size	Single integer with quantifier such as KB or MB	`Size` accepts an integer that specifies the size of an email attachment or the overall message. When using the EAC, the value specified is in kilobytes. When using the Shell, you can enter an integer value qualified by one of the following units: • B (bytes) • KB (kilobytes)

		• MB (megabytes) • GB (gigabytes) For example, `20MB`
ToUserScope	One of the following values: • `InOrganization` • `NotInOrganization` • `ExternalPartner` • `ExternalNonPartner`	`ToUserScope` specifies the scope of the recipients. The `InOrganization` and `NotInOrganization` values are evaluated similar to the `FromUserScope` property, but in the context of the recipient. The following is a description of the other possible values: • **ExternalPartner** These domains are configured to send mail to an external domain by using Domain Secure security • **ExternalNonPartner** These represent all other domains that aren't considered `ExternalPartner` domains.
Words	Array of strings	`Words` accepts one string or an array of strings. It's used in all conditions that inspect different parts of a message for specific words or strings. In Exchange 2013, only instances of the word without a prefix or suffix are matched. For example, if you specify the word "contoso", the rule will fire only if an exact match is found. The following variations where the word appears as a suffix, a prefix, or between other characters (other than the space character) aren't

		considered an exact match: • Acontoso • Contosoa • Acontosob The property isn't case-sensitive. The asterisk (*) is treated as a literal character, and not used as a wildcard character.

Conditions and Condition Properties for an Edge Transport Server

The following table lists the conditions that can be used with transport rules in Exchange 2013 Edge Transport Server. These can only be managed in the Exchange Management Shell and not in the EAC. To learn how to open the Shell in your on-premises Exchange organization, see Open the Shell.

In the Exchange Management Shell, the properties are available as parameters of the New-TransportRule and Set-TransportRule cmdlets. Property values are specified after the property name. You don't instantiate conditions and actions by using the Get-TransportRulePredicate or Get-TransportRuleAction cmdlets because these cmdlets only allow you to list the conditions and actions available for use on Edge Transport servers on which the cmdlets are used. The New-TransportRule and Set-TransportRule cmdlets have all the conditions and actions available as parameters, allowing you to create or modify a transport rule using a single command.

Note:

Each condition listed below also has an equivalent exception that can be selected. In the Shell, the conditions that can be used as exceptions start with `ExceptIf`. For example, for the `FromAddressMatches` condition, the parameter that can be used as an exception in transport rule cmdlets is called `ExceptIfFromAddressMatches`. The same condition object contains the logic for use in a transport rule condition and exception. Therefore, when you use the `Get-TransportRulePredicate` cmdlet to list conditions, exceptions aren't listed as separate conditions.

Conditions available only on Edge Transport servers

Condition name in Shell	Condition property type	Description
`SubjectContains`	Words	This condition matches messages that contain the specified words in the **Subject**

		field.
SubjectOrBodyContains	Words	This condition matches messages that contain the specified words in the **Subject** field or message body.
HeaderContains	First property: MessageHeader Second property: Words	This condition matches messages where the value of the specified message header contains the specified words.
FromAddressContains	Words	This condition matches messages that contain the specified words in the **From** field.
AnyOfRecipientAddressContains	Words	This condition matches messages that contain the specified words in the **To**, **Cc**, or **Bcc** fields of the message.
SubjectMatches	Patterns	This condition matches messages where text patterns in the **Subject** field match a specified regular expression.
SubjectOrBodyMatches	Patterns	This condition matches messages where text patterns in the **Subject** field or message body match a specified regular expression.
HeaderMatches	First property: MessageHeader Second property: Patterns	This condition matches messages where the specified message header field contains

		text patterns that match a specified regular expression.
`FromAddressMatches`	Patterns	This condition matches messages that contain text patterns in the **From** field of the messages that match a specified regular expression.
`AnyOfRecipientAddressMatches`	Patterns	This condition matches messages where text patterns in the **To**, **Cc**, or **Bcc** fields of the message match a specified regular expression.
`SCLOver`	SclValue	This condition matches messages with an SCL that's equal to or greater than the value specified.
`AttachmentSizeOver`	Size	This condition matches messages that contain attachments larger than the specified value.
`FromScope`	Scope	This condition matches messages that are sent from the specified scope.
`MessageSizeOver`	Size	This condition matches messages when the message size is larger than or equal to the specified value.

Condition property values for an Edge Transport Server

The following table lists the property types used in transport rule conditions for the Edge Server-

only conditions.

Property types used in Edge server transport rule conditions

Condition type	Valid values	Description
ADAttribute	One of the Active Directory attributes available for use	`ADAttribute` accepts the name of one of the following Active Directory attributes available for use with this property type in transport rules: • `DisplayName` • `FirstName` • `Initials` • `LastName` • `Office` • `PhoneNumber` • `OtherPhoneNumber` • `Email` • `Street` • `POBox` • `City` • `State` • `ZipCode` • `Country` • `UserLogonName` • `HomePhoneNumber` • `OtherHomePhoneNumber` • `PagerNumber` • `MobileNumber` • `FaxNumber` • `OtherFaxNumber` • `Notes` • `Title` • `Department` • `Company` • `Manager` • `CustomAttribute1` - `CutomAttribute15` When you use the Shell to create a transport rule consisting of the `RecipientAddressContains` or `RecipientAddressMatches` predicates, you must specify an attribute name from the preceding list followed by a colon (:) and the word or text pattern you want to match in the specified attribute. The entire

		notation should be enclosed in quotation marks ("). For example, to specify the attribute `City` and the values `San Francisco` or `Palo Alto`, you must use `City:San Francisco, Palo Alto`. You can also specify multiple Active Directory attributes and value pairs. For example, `"City:San Francisco, Palo Alto","Department:Sales, Finance"`. In this case, the recipient's `City` attribute should contain either `San Francisco` or `Palo Alto`, and the `Department` attribute should contain either `Sales` or `Finance`.
Addresses and Addresses2	Array of Active Directory mailbox, contact, or distribution group objects	`Addresses` and `Addresses2` accept a single mailbox, contact, mail-enabled user, or distribution group object.
Classification	Message classification object	`Classification` accepts a message classification object. To specify a message classification object, you must use the Get-MessageClassification cmdlet. For example, use the following command to search for messages with the `ExCompanyInternal` classification and prepend the message subject with CompanyInternal. `New-TransportRule "Rule Name" -HasClassification @(Get-MessageClassification`

		`ExCompanyInternal).Identity -PrependSubject "CompanyInternal"`
EvaluatedUser	Single value of `Sender` or `Recipient`	`ManagementRelationship` accepts an `EvaluatedUser` value for the `ManagerForEvaluatedUser` property. It instructs the Transport Rules agent whether the predicate should inspect a message's sender or the recipient.
Evaluation	Single value of `Equal` or `NotEqual`	`ADAttributeComparison` accepts a value of type `Evaluation` for the `ADComparisonOperator` property. This allows you to compare the specified Active Directory attribute values for the sender and recipient.
FromUserScope	Single value of `InOrganization` or `NotInOrganization`	`FromScope` accepts a scope value of type `FromUserScope`. This specifies whether the message is sent by a sender who is considered to be inside the organization. The following values can be used: • **InOrganization** A sender is considered to be inside the organization if either of the following conditions is true: ○ The sender is a mailbox, mail-enabled user, distribution group, or public folder that exists in the organization's Active Directory. ○ The domain of the sender is an accepted domain in the Exchange organization, but isn't an `ExternalRelay` domain. Also, the message must be sent or received by using an authenticated

		connection. **Note:** To determine whether mail contacts are considered to be inside or outside the organization, the domain part of the sender's address is compared with the configured accepted domains. • **NotInOrganization** A sender is considered to be outside the organization if the sender's domain isn't an accepted domain in the Exchange organization and is an `ExternalRelay` domain.
Importance	Single value of `High`, `Low`, or `Normal`	`Importance` accepts the message priority.
ManagementRelationship	Single value of `Manager` or `DirectReport`	`ManagementRelationship` specifies the relationship between two evaluated users, for example the sender and the recipient. The evaluated user's Active Directory information is located to determine the manager and direct reports.
MessageHeader	Single string	`MessageHeader` accepts a string that can be used to specify the SMTP message header to examine. This property is used together with the `Words` or `Patterns` properties, which specify the value of the header field to match. You don't need to add a colon (`:`) in the header name.
MessageType	Single message type name	`MessageType` accepts one of the following message types: • OOF

		• AutoAccept • AutoForward • Encrypted • Calendaring • PermissionControlled • Voicemail • RSS • Signed • ApprovalRequest • ReadReceipt
Patterns	Array or regular expressions	`Patterns` accepts a regular expression that can be used to match text that follows an identifiable pattern. Enclose the expression in quotation marks (").
SclValue	Single integer	`SclValue` accepts an integer that can be used to match the spam confidence level (SCL) assigned to a message. SCL values range from -1 through 9.
Size	Single integer with quantifier such as KB or MB	`Size` accepts an integer that specifies the size of an email attachment. You can enter an integer value qualified by one of the following units: • B (bytes) • KB (kilobytes) • MB (megabytes) • GB (gigabytes) For example, `20MB`
ToUserScope	One of the following values: • `InOrganization` • `NotInOrganization` • `ExternalPartner` • `ExternalNonPartner`	`SentToScope` accepts a scope value of type `ToUserScope`. The `InOrganization` and `NotInOrganization` values are evaluated similar to the `FromUserScope` property, but in the context of the recipient. The

		following is a description of the other possible values: • **ExternalPartner** These domains are configured to send mail to an external domain by using Domain Secure security • **ExternalNonPartner** These represent all other domains that aren't considered `ExternalPartner` domains.
Words	Array of strings	`Words` accepts one string or an array of strings. It's used in all predicates that inspect different parts of a message for specific words or strings. Only instances of the word without a prefix or suffix are matched. For example, if you specify the word "contoso", the rule will fire only if an exact match is found. The following variations where the word appears as a suffix, a prefix, or between other characters (other than the space character) aren't considered an exact match: • Acontoso • Contosoa • Acontosob The property isn't case-sensitive. The asterisk (*) is treated as a literal character, and not used as a wildcard character.

Transport Rule Conditions (Predicates) for Exchange Online

Transport rule conditions (predicates) for Exchange Online Protection

New-TransportRule

Transport rule actions

Exchange Server 2013 > Messaging policy and compliance > Transport rules >

Applies to: *Exchange Server 2013, Exchange Online Protection, Exchange Online*

Topic Last Modified: *2014-03-12*

Transport rule actions let you apply messaging policies to email messages flowing through your organization that match conditions and exceptions defined in Transport rule conditions (predicates). For example, you could define a transport rule action to forward an email message to an approving manager, or add a disclaimer or personalized signature.

- Management tasks related to transport rules? See Manage Transport Rules
- Exchange Online version of this topic? See **Transport rule actions**
- Exchange Online Protection version of this topic? See **Transport rule actions**

Contents

Transport rule actions and properties

Each transport rule action contains the action, and any information needed for the action. For example, when you use the **Redirect the Message to** action, you must specify the email address of the person you're redirecting the message to. Sometimes two pieces of information are needed. For example, when you add a disclaimer, you need the disclaimer text plus information about what to do if the disclaimer can't be sent.

Here's a list of the information required for each action in Exchange 2013. When you add these

actions using the Exchange admin center, you're prompted for the required information. When you add them using the Shell, you must specify them on the command line. Valid values for each property are described in Property values.

Action name in Exchange admin center	Action name in Shell	Properties	Description
Forward the message for approval to	`ModerateMessageByUser`	`Addresses`	Forwards the message to the specified moderators as an attachment wrapped in an approval request. See Forward a message to a manager for approval for more information.
Forward to the sender's manager for approval	`ModerateMessageByManager`	Not applicable	Forwards the message to the sender's manager for approval, if the manager attribute is populated in Active Directory. **Important:** If the sender's manager attribute isn't populated in Active Directory, the message is delivered to recipients without moderation.
Redirect the message to	`RedirectMessageTo`	`Addresses`	Redirects the email message to one or more specified recipients. The message isn't delivered to the original recipients, and no notification is sent to the sender or the original recipients.
Reject the message	`RejectReason`	`RejectReason`	Deletes the email message

with the explanation			and sends a non-delivery report to the sender with the specified text as the rejection reason. The recipient doesn't receive the message or notification.
Reject the message with the enhanced status code	`RejectMessageEnhancedStatusCode`	`EnhancedStatusCode`	Deletes the email message and sends a non-delivery receipt to the sender with the specified status code. The recipient doesn't receive the message or notification.
Delete the message without notifying anyone	`DeleteMessage`	Not applicable	Deletes the email message without sending a notification to either the recipient or the sender.
Bcc the message to	`BlindCopyTo`	`Addresses`	Adds one or more recipients as blind carbon copy (Bcc) recipients. The original recipients aren't notified and can't see the Bcc addresses.
Add these recipients to the To box	`AddToRecipient`	`Addresses`	Adds one or more recipients to the To field of the message. The original recipients can see the additional address.
Cc the message to	`CopyTo`	`Addresses`	Adds one or more recipients to the carbon

			copy (Cc) field of the message. The original recipients can see the Cc address.
Add the sender's manager as a recipient type	`AddManagerAsRecipientType`	`AddedRecipientType`	Adds the sender's manager, if defined in the manager attribute in Active Directory, as the specified recipient type.

Append the disclaimer	`ApplyHtmlDisclaimerText`
	`ApplyHtmlDisclaimerTextLocation`
	`ApplyHtmlDisclaimerFallbackAction`
		First property: `DisclaimerText`
		Second property: `FallbackAction`
			Applies an HTML disclaimer to the message. There are three parameters in the Shell that correspond to this action. When you append the disclaimer, the property `ApplyHtmlDisclaimerTextLocation` is set to **Append**.

Prepend the disclaimer	`ApplyHtmlDisclaimerText`
	`ApplyHtmlDisclaimerTextLocation`
	`ApplyHtmlDisclaimerFallbackAction`
		First property: `DisclaimerText`
		Second property: `FallbackAction`
			Applies an HTML disclaimer to the message. There are three parameters in the Shell that correspond to this action. When you prepend the disclaimer, the property `ApplyHtmlDisclaimerTextLocation` is set to **Prepend**.

Remove this header	`RemoveHeader`	`MessageHeader`	Removes the specified message header from a message.
Set the message	`SetHeaderName` `SetHeaderValue`	First property: `MessageHeader`	Creates a new message

header to this value		Second property: `HeaderValue`	header or modifies an existing message header and sets the value of that message header to the specified value. There are two parameters in the Shell that correspond to this action.
Apply a message classification	`ApplyClassification`	`Classification`	Applies a message classification to the message.
Set the spam confidence level (SCL) to	`SetScl`	`SclValue`	This action sets the spam confidence level (SCL) on an email message.
Prepend the subject of the message with	`PrependSubject`	`Prefix`	Prepends the Subject of the message with the specified text.
Apply rights protection to the message with	`ApplyRightsProtectionTemplate`	`RMSTemplateIdentity`	Applies the specified Rights Management Services (RMS) template to the message.

Require TLS encryption	`RouteMessageOutboundRequireTls`	Either of the following:
		`Not applicable`
		`Applicable`
			Forces the outbound messages to be routed over TLS encrypted connections.

Notify the sender with a Policy Tip	`NotifySender`	`NotifySenderType`	Notifies the sender when the message goes against a DLP policy configured in the organization. • When you use this action, you must use the

			`MessageContainsDataClassification` (**The message contains sensitive information**) condition. • You can also use the following conditions: ○ `SentTo` (**The recipient is**) ○ `SentToScope` (**The recipient is located**) ○ `From` (**The sender is**) ○ `FromMemberOf` (**The sender is a member of**) ○ `FromScope` (**The sender is located**) • Some actions can't be combined with `NotifySender`: ○ `RejectMessageReasonText` (**Reject the message and include an explanation**) ○ `RejectMessageEnhancedStatusCode` (**Reject the message with the enhanced status code of**) ○ `DeletedMessage` (**Delete the message without notifying anyone**)
Generate incident report and send it to	`GenerateIncidentReport`	First property: `Addresses` Second property: `IncidentReportContent`	Generates an incident report and sends it to the specified recipients.
Stop processing more rules	`StopRuleProcessing`	Not applicable	Specifies whether the processing of subsequent rules should be stopped for

			this message.

Property values

Each property that you use to define a transport rule action requires a value. Here's a list of values for each action property in Exchange 2013.

Property	Valid values	Description
`AddedRecipientType`	One of the following values: • **To** • **Cc** • **Bcc** • **Redirect**	`AddedRecipientType` accepts a single value: • `To`, `Cc`, and `Bcc` values are self-explanatory and correspond to the addressing fields of email messages. • `Redirect` delivers the message only to the specified recipient. The message isn't delivered to any of the original recipients.
`Addresses`	Either a single or an array of valid recipients.	`Addresses` accepts an array of mailbox, mail-enabled contact, mail-enabled user, or distribution group objects.
`Classification`	Single message classification object	`Classification` accepts a single message classification object. To see what message classification objects are available, you can use the Get-MessageClassification cmdlet.
`DisclaimerText`	HTML string	`DisclaimerText` can be any text you want to insert to the message as a disclaimer. HTML tags and cascade style sheet (CSS) tags.
`EnhancedStatusCode`	Single DSN code of `5.7.1`, or any value from `5.7.10` through `5.7.999`	`EnhancedStatusCode` specifies the DSN code and related DSN message to display to the senders of messages rejected by a Transport rule action. The DSN message associated with the specified DSN status code is displayed in the user

		information portion of the NDR displayed to the sender. The specified DSN code must be an existing default DSN code or a customized DSN status code that you can create by using the **New-SystemMessage** cmdlet.
`FallbackAction`	One of the following values: • `Wrap` • `Ignore` • `Reject`	`FallbackAction` specifies what the Transport rule should do if a disclaimer can't be applied to a message. There can be cases where the contents of a message can't be altered, for example if a message is encrypted. The default fallback action is `Wrap`. The following list describes each fallback action: • **Wrap** If the disclaimer can't be inserted into the original message, Exchange encloses, or *wraps*, the original message in a new message envelope. Then the disclaimer is inserted into the new message. **Important:** If an original message is wrapped in a new message envelope, subsequent Transport rules are applied to the new message envelope, and not to the original message. Therefore, you must configure Transport rules with disclaimer actions that wrap original messages in a new message body with a lower priority than other Transport rules. **Note:** If the original message can't be wrapped in a new message envelope, the original message

		isn't delivered. The sender of the message receives an NDR that explains why the message wasn't delivered. • **Ignore** If the disclaimer can't be inserted into the original message, Exchange lets the original message continue unmodified. No disclaimer is added. • **Reject** If the disclaimer can't be inserted into the original message, Exchange doesn't deliver the message. The sender of the message receives an NDR that explains why the message wasn't delivered.
`HeaderValue`	Single string	`HeaderValue` accepts a single string that's applied to the header specified header.
`IncidentReportContent`	One of the following values: • Sender • Recipients • Subject • CC • BCC • Severity • Override • RuleDetections • FalsePositive • DataClassifications • IdMatch • AttachOriginalMail	`IncidentReportContent` specifies the list of properties of the original message to be included in the incident report. You can choose to include any combination of these properties. In addition to the properties you specify, the message ID is always included in the incident report. The following list describes these properties: • **Sender**, **Subject**, and **AttachOriginalMail** Self-explanatory values. The first two correspond to the message properties with the

		same name. The third property specifies that the entire message that triggered the rule is attached to the incident report. • **Recipients**, **CC**, and **BCC** Designate the recipients the message was sent to, and correspond to the To, Cc, and Bcc boxes respectively. For each of these properties, only the first 10 recipients are included in the incident report. If the message was addressed to more than 10 recipients, the report will also include the count of additional recipients. For example, if the message included 22 people in the To: box, the incident report will list the first 10 of these recipients and specify that there were 12 additional recipients. • **Severity** Specifies the audit severity of the rule that was triggered. If the message was processed by more than one rule, the highest severity is included in the incident report. • **Override** Specifies the override if the sender has chosen to override a Policy Tip. If the sender has provided a justification, the first 100

		characters of the justification are also included. • **RuleDetections** Specifies the list of rules that the message triggered. • **FalsePositive** Specifies the false positive if the sender marked the message as a false positive for a Policy Tip. • **DataClassifications** Specifies the list of sensitive information types detected in the message. • **IdMatch** Specifies the sensitive information type detected, the exact matched content from the message, and the 150 characters before and after the matched sensitive information.
`MessageHeader`	Single string	`MessageHeader` accepts a string that can be used to specify the SMTP message header to modify.
`NotifySenderType`	One of the following values: • NotifyOnly • RejectMessage • RejectUnlessFalsePositiveOverride • RejectUnlessSilentOverride • RejectUnlessExplicitOverride	`NotifySenderType` specifies the type of Policy Tip the sender will receive if a message they sent goes against a DLP policy configured in the organization. The following list describes each notification type: • **NotifyOnly** Notifies sender, but delivers the message normally. • **RejectMessage** Notifies

		sender, and rejects the message. • **RejectUnlessFalsePositiveOverride** RejectsThe message unless the sender has marked it with a false positive. • **RejectUnlessSilentOverride** Rejects the message unless the sender has chosen to override the policy restriction. • **RejectUnlessExplicitOverride** This is similar to **RejectUnlessSilentOverride** type, but the sender also provides a justification for overriding the policy restriction.
`Prefix`	Single string	`Prefix` accepts a string that's prepended to the subject of the email message. **Tip:** To prevent the string that's specified with the `Prefix` Transport rule action from being added to the subject every time that a reply to the message encounters the Transport rule, add the `SubjectContains` exception to the Transport rule. The `SubjectContains` exception should contain the string that you specified with the `Prefix` Transport rule action. If you add the `SubjectContains` exception to the Transport rule, the Transport rule doesn't add another instance of the `Prefix` string to the subject if the `Prefix` string already appears in

		the subject.
`RejectReason`	Single string	`RejectReason` accepts a string that's used to populate the administrator information portion of the NDR returned to the email sender if an email message is rejected.
`RMSTemplateIdentity`	RMS Template identity	`RMSTemplateIdentity` accepts an RMS Template identity. You can get a list of RMS templates available on an Active Directory RMS server in the Active Directory forest using the **Get-RMSTemplate** cmdlet.
`SclValue`	Single integer	`SclValue` accepts a single integer from `-1` through `9`, which is used to configure the SCL of the email message.

Using transport rules to inspect message attachments

Exchange Server 2013 > Messaging policy and compliance > Transport rules >

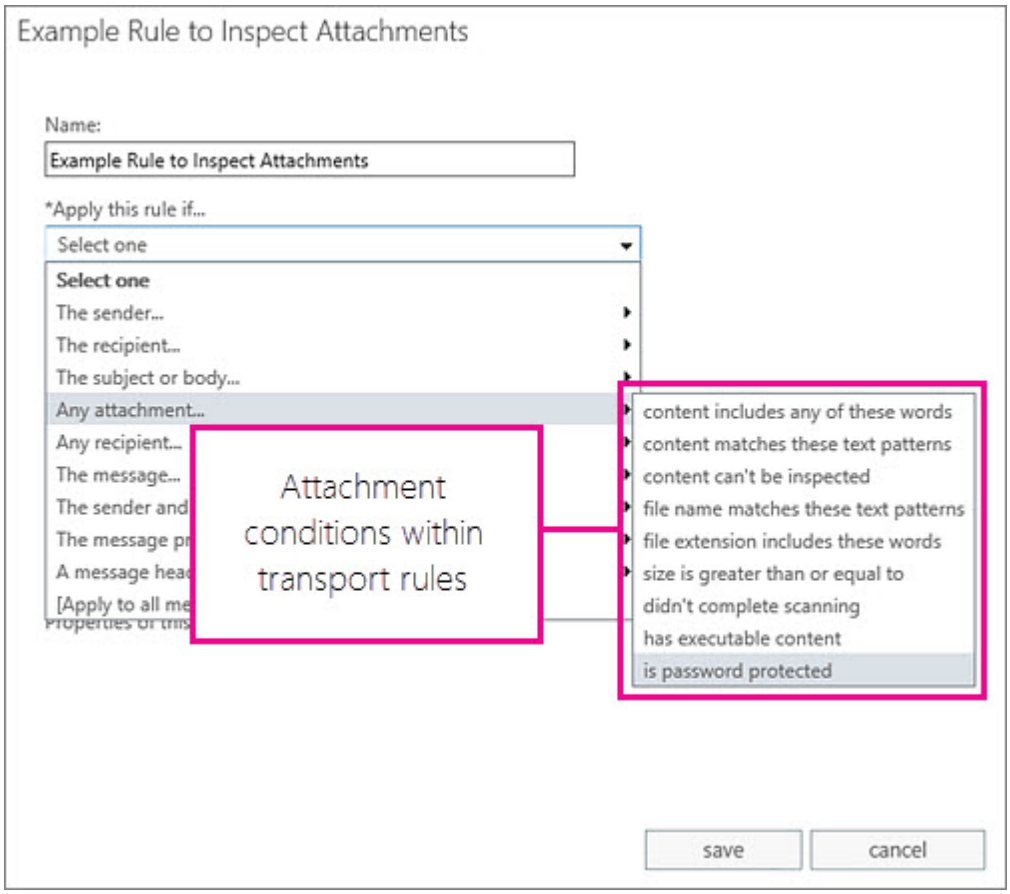
Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-06-10*

You can inspect email attachments in your organization by setting up transport rules. Exchange offers transport rules that provide the ability to examine email attachments as a part of your messaging security and compliance needs. When you inspect attachments, you can then take action on the messages that were inspected based on the content or characteristics of those attachments. Here are some attachment-related tasks you can do by using transport rules:

- Search files in compressed attachments such as .zip and .rar files and, if there's any text that matches a pattern you specify, add a disclaimer to the end of the message.
- Inspect content within attachments and, if there are any keywords you specify, redirect the message to a moderator for approval before it's delivered.
- Check for messages with attachments that can't be inspected and then block the entire message from being sent.
- Check for attachments that exceed a certain size and then notify the sender of the issue if you choose to prevent the message from being delivered.
- Create notifications that alert users if they send a message that has matched a transport rule.

Exchange administrators can create transport rules by going to **Exchange Admin Center** > **Mail flow** > **Rules**. You need to be assigned permissions before you can perform this procedure. After you start to create a new rule, you can see the full list of attachment-related conditions by clicking **More options** > **Any attachment** under **Apply this rule if**. The attachment-related options are shown in the following diagram.



For more information about transport rules, including the full range of conditions and actions that you can choose, see Transport rules. Exchange Online Protection (EOP) and hybrid customers can benefit from the transport rules best practices provided in **Best practices for configuring EOP**. If

you're ready to start creating rules, see Manage Transport Rules.

Inspect the content within attachments

You can use the transport rule conditions in the following table to examine the content of attachments to messages. For these conditions, only the first 150 KB of an attachment is inspected. In order to start using these conditions when inspecting messages, you need to add them to a transport rule. Learn about creating or changing rules at Manage Transport Rules.

Condition name in EAC	Condition name in the Shell	Description
Any attachment content includes any of these words	`AttachmentContainsWords`	This condition matches messages with supported file type attachments that contain a specified string or group of characters.
Any attachment content matches these text patterns	`AttachmentMatchesPatterns`	This condition matches messages with supported file type attachments that contain a text pattern that matches a specified regular expression.

The Exchange Management Shell names for the conditions listed here are parameters that require the `TransportRule` cmdlet.

Learn more about the cmdlet at New-TransportRule.

Learn more about property types for these conditions at Conditions and Condition Properties for a Mailbox Server.

Transport rules can inspect only the content of supported file types. If the transport rules agent encounters an attachment that isn't in the list of supported file types, the `AttachmentIsUnsupported` condition is triggered. The supported file types are listed in the following section. Any file not listed will trigger the `AttachmentIsUnsupported` condition.

Compressed archive files

If the message contains a compressed archive file such as a .zip or .cab file, the transport rules agent will inspect the files contained within that attachment. Such messages are processed in a manner similar to messages that have multiple attachments. The properties of compressed archive files aren't inspected. For example, if the container file type supports comments, that field isn't

inspected.

Supported file types for transport rule content inspection

The following table lists the file types supported by transport rules. The system automatically detects file types by inspecting file properties rather than the actual file name extension, thus helping to prevent malicious hackers from being able to bypass transport rule filtering by renaming a file extension. A list of file types with executable code that can be checked within the context of transport rules is listed later in this topic.

Category	File extension	Notes
Office 2013, Office 2010, and Office 2007	.docm, .docx, .pptm, .pptx, .pub, .one, .xlsb, .xlsm, .xlsx	Microsoft OneNote and Microsoft Publisher files aren't supported by default. You can enable support for these file types by using IFilter integration. For more information, see Register Filter Pack IFilters with Exchange 2013. The contents of any embedded parts contained within these file types are also inspected. However, any objects that aren't embedded—for example, linked documents—aren't inspected.
Office 2003	.doc, .ppt, .xls	None
Additional Office files	.rtf, .vdw, .vsd, .vss, .vst	None
Adobe PDF	.pdf	None
HTML	.html	None
XML	.xml, .odp, .ods, .odt	None

Text	.txt, .asm, .bat, .c, .cmd, .cpp, .cxx, .def, .dic, .h, .hpp, .hxx, .ibq, .idl, .inc, inf, .ini, inx, .js, .log, .m3u, .pl, .rc, .reg, .txt, .vbs, .wtx	None
OpenDocument	.odp, .ods, .odt	No parts of .odf files are processed. For example, if the .odf file contains an embedded document, the contents of that embedded document aren't inspected.
AutoCAD Drawing	.dxf	AutoCAD 2013 files aren't supported.
Image	.jpg, .tiff	Only the metadata text associated with these image files is inspected. There is no optical character recognition.

Inspect the file properties of attachments

The following transport rule conditions inspect the properties of a file that is attached to a message. In order to start using these conditions when inspecting messages, you need to add them to a transport rule. A list of supported file types with executable code that can be checked within the context of transport rules is listed here. For more information about creating or changing rules, see Manage Transport Rules.

Condition name in EAC	Condition name in the Shell	Description
Any attachment file name matches these text patterns	`AttachmentNameMatchesPatterns`	This condition matches messages with supported file type attachments when those attachments have a name that contains the characters you specify.
Any attachment file	`AttachmentExtensionMatchesWords`	This condition matches

extension includes these words		messages with supported file type attachments when the file name extension matches what you specify.
Any attachment size is greater than or equal to	`AttachmentSizeOver`	This condition matches messages with supported file type attachments when those attachments are larger than the size you specify.
Any attachment didn't complete scanning	`AttachmentProcessingLimitExceeded`	This condition matches messages when an attachment is not inspected by the transport rules agent.
Any attachment has executable content	`AttachmentHasExecutableContent`	This condition matches messages that contain executable files as attachments. The supported file types are listed here.
Any attachment is password protected	`AttachmentIsPasswordProtected`	This condition matches messages with supported file type attachments when those attachments are protected by a password.

The Exchange Management Shell names for the conditions listed here are parameters that require the `TransportRule` cmdlet.

Learn more about the cmdlet at New-TransportRule.

Learn more about property types for these conditions at Conditions and Condition Properties for a Mailbox Server.

Supported executable file types for transport rule

inspection

The transport agent uses true type detection by inspecting file properties rather than merely the file extensions. This helps to prevent malicious hackers from being able to bypass your rule by renaming a file extension. The following table lists the executable file types supported by these conditions. If a file is found that is not listed here, the `AttachmentIsUnsupported` condition is triggered.

Type of file	Native extension
Self-extracting archive file created with the WinRAR archiver.	.rar
32-bit Windows executable file with a dynamic link library extension.	.dll
Self-extracting executable program file.	.exe
Java archive file.	.jar
Uninstallation executable file.	.exe
Program shortcut file.	.exe
Compiled source code file or 3-D object file or sequence file.	.obj
32-bit Windows executable file.	.exe
Microsoft Visio XML drawing file.	.vxd
OS/2 operating system file.	.os2
16-bit Windows executable file.	.w16
Disk-operating system file.	.dos
European Institute for Computer Antivirus Research standard antivirus test file.	.com
Windows program information file.	.pif
Windows executable program file.	.exe

Extending the number of supported file types

The supported file types listed in this topic can be revised at any time using IFilter integration. For more information, see Register Filter Pack IFilters with Exchange 2013.

The file types you add using this process become supported file types and no longer trigger the `AttachmentIsUnsupported` condition.

Data loss prevention policies and attachment transport rules

To help you manage important business information in email, you can include any of the attachment-related conditions along with the rules of a data loss prevention (DLP) policy. For example, you might want to allow messages with passport numbers to be sent but only if the passport numbers are in a password-protected attachment. To accomplish this, do the following:

- Create a DLP policy that inspects mail for passport-related sensitive information. Learn more at DLP procedures.
- Add the **Any attachment is password protected** exception in the **Except if...** transport rule area.
- Define an action to take on mail that contains passport numbers that are not in the protected file.

DLP policies and attachment-related conditions can help you enforce your business needs by defining those needs as transport rule conditions, exceptions, and actions. When you include the sensitive information inspection in a DLP policy, any attachments to messages are scanned for that information only. However, attachment-related conditions such as size or file type are not included until you add the conditions listed in this topic. DLP is not available with all versions of Exchange; learn more at Data loss prevention.

Data loss prevention

Transport rules

Transport rule conditions (predicates)

Using transport rules to inspect message attachments in Exchange Online

Organization-wide disclaimers, signatures, footers, or headers

Applies to: *Exchange Online Protection*

Topic Last Modified: *2014-01-31*

You can add an email disclaimer, legal disclaimer, disclosure statement, signature, or other information to the top or bottom of email messages that enter or leave your organization. This might be needed for legal, business, or regulatory requirements, to identify potentially unsafe e-mail messages, or for other reasons unique to your organization.

To set up a disclaimer, you create a transport rule that includes the conditions, such when the sender is in a specific group or when the message includes specific text patterns, and the text to add. To apply multiple disclaimers to a single email message, you use multiple transport rules.

Important:
• If you want the information to be added only to outgoing messages, you must add a condition such as recipients located outside the organization. By default, transport rules are applied to both incoming and outgoing messages.

Contents

Looking for procedures? See Add an email disclaimer, legal disclaimer, common signature, or email footer or header.

Examples

Here are a few ideas for how to use disclaimers.

Type	Sample text added
Legal – outgoing messages	This email and any files transmitted with it are confidential and intended solely for the use of the individual or entity to whom they are addressed. If you have received this email in error, please notify the system manager.
Legal – incoming messages	Employees are expressly required not to make

	defamatory statements and not to infringe or authorize any infringement of copyright or any other legal right by email communications. Employees who receive such an email must notify their supervisor immediately.
Notice that message was sent to an alias	This message was sent to the Sales discussion group.
Signature – pulls in data for each employee	Kathleen Mayer Sales Department Contoso www.contoso.com kathleen@contoso.com cell: 111-222-1234
Advertisement	Click here for March specials

The examples in this article are not intended for use as-is. Modify them for your needs.

Scoping your disclaimer

As you work on your disclaimers, consider which messages they should apply to. For example, you might want different disclaimers for internal and external messages or for messages sent by users in specific departments. To make sure only the first message in a conversation gets a disclaimer, add an exception that looks for unique text in your disclaimer.

Here are some examples of the conditions and exceptions you can use.

Description	Conditions and exceptions in EAC	Conditions and exceptions in the Shell
Outside your organization, if the original message doesn't include text from your disclaimer, such as "CONTOSO LEGAL NOTICE"	Condition: **The recipient is located** > **Outside the organization** Exception: **The subject or body** > **Subject or body matches these text patterns** > **CONTOSO LEGAL NOTICE**	`-FromScope NotInOrgani`

Incoming messages with executable attachments	Condition 1: **The sender is located** > **Outside the organization** Condition 2: **Any attachment** > **has executable content**	`-FromScope NotInOrgani`
Sender is in the marketing department	Condition: **The sender** > **is a member of this group** > **group name**	`-FromMemberOf "Marketi`
Every message that comes from an external sender to the sales discussion group	Condition 1: **The sender is located** > **Outside the organization** Condition 2: **The message** > **To or Cc box contains this person** > **group name**	`-FromScope NotInOrgani`
Prepend an advertisement to outgoing messages for one month	Condition 1: **The recipient is located** > **Outside the organization** Specify the dates at the bottom of the **New rule** dialog.	-ApplyHtmlDisclaimerLocation 'Prepend' -SentToScope 'NotInOrganization' –ActivationDate '03/1/2014' –ExpiryDate '03/31/2014'

For a complete list of transport rule conditions you can use to target the disclaimer, see one of the following:

- **Transport Rule Conditions (Predicates)** (Exchange Online)
- Transport rule conditions (predicates) (Exchange 2013)
- **Transport Rule Conditions (Predicates)** (Exchange Online Protection)

Formatting your disclaimer

You can format your disclaimer as needed. Here's what can be included in your disclaimer text.

Type of information	Description
Text	The maximum length is 5,000 characters, including any HTML tags and inline Cascading Style Sheets (CSS).

HTML and inline CSS	You can use HTML and inline CSS styles to format the text. For example, use the `<HR>` tag to add a line before the disclaimer. HTML in a disclaimer is ignored if the disclaimer is added to a plain text message.
Add Images	Use the `<IMG>` tag to point to an image available on the internet. For example, `<IMG src="http://contoso.com/images/companylogo.gif" alt="Contoso logo">` Keep in mind that Outlook Web App and Outlook block external web content, including images, by default. Users may need to perform a specific action if they want to view the blocked external content. This means that images added by using the `IMG` tag may not be visible by default. We recommend that you test a disclaimer with `IMG` tags in the email clients your recipients are likely to use to make sure it displays well.
Add information for personalized signatures	If you want everyone to have signatures formatted the same way with the same information, you can add unique information for each employee, such as `DisplayName`, `FirstName`, `LastName`, `PhoneNumber`, `Email`, `FaxNumber`, and `Department`. This information must be enclosed in two percent signs (%%) on each side of the information. For example, to use `DisplayName`, you must use **%% DisplayName%%** in your disclaimer. When a disclaimer rule is triggered, the corresponding values for that user are inserted. The data comes from the sender's Active

	Directory user account (for on-premises Exchange Server), or from the sender's Office 365 account for Exchange Online. For a complete list of attributes that can be used in disclaimers and personalized signatures, see the description for the `ADAttribute` property in Transport rule conditions (predicates) (Exchange Server), **Transport Rule Conditions (Predicates)** (Exchange Online), or **Transport rule conditions (predicates)** (Exchange Online Protection).

For example, here's an example of an HTML disclaimer that includes a signature, an `IMG` tag, and embedded CSS.

```
<div style="font-size:9pt;  font-family: 'Calibri',sans-
serif;">
%%displayname%%</br>
%%title%%</br>
%%company%%</br>
%%street%%</br>
%%city%%, %%state%% %%zipcode%%</div>
 </br>
<div style="background-color:#D5EAFF; border:1px dotted
#003333; padding:.8em; ">
<div><img alt="Fabrikam"  src="http://fabrikam.com/images/
fabrikamlogo.png"></div>
<span style="font-size:12pt;  font-family: 'Cambria','times
new roman','garamond',serif; color:#ff0000;">HTML
Disclaimer Title</span></br>
<p style="font-size:8pt; line-height:10pt; font-family:
'Cambria','times roman',serif;">This message contains
confidential information and is intended only for the
individual(s) addressed in the message. If you are not the
named addressee, you should not disseminate, distribute, or
copy this e-mail. If you are not the intended recipient,
```

```
you are notified that disclosing, distributing, or copying
this e-mail is strictly prohibited.  </p>
<span style="padding-top:10px; font-weight:bold;
color:#CC0000; font-size:10pt; font-family:
'Calibri',Arial,sans-serif; "><a href="http://
www.fabrikam.com">Fabrikam, Inc. </a></span></br></br>
</div>
```

Fallback options if the disclaimer can't be added

Some messages, such as encrypted messages, prevent Exchange from modifying the content of the original message. You can control how your organization handles these messages. You specify whether to wrap a message that can't be modified in a message envelope that contains the disclaimer, reject the message if a disclaimer can't be added, or ignore the disclaimer action and deliver the message without a disclaimer.

The following list describes each fallback action:

- **Wrap** If the disclaimer can't be inserted into the original message, Exchange encloses, or "wraps," the original message in a new message envelope. Then the disclaimer is inserted into the new message. If the original message can't be wrapped in a new message envelope, the original message is not delivered. The sender of the message receives a non-delivery report (NDR) that explains why the message was not delivered.

Important:
If an original message is wrapped in a new message envelope, subsequent transport rules are applied to the new message envelope, not to the original message. Therefore, you must configure transport rules with disclaimer actions that wrap original messages in a new message body after you configure other transport rules.

- **Reject** If the disclaimer can't be inserted into the original message, Exchange doesn't deliver the message. The sender of the message receives an NDR that explains why the message wasn't delivered.
- **Ignore** If the disclaimer can't be inserted into the original message, Exchange delivers the original message unmodified. No disclaimer is added.

Add an email disclaimer, legal disclaimer, common signature, or email footer or header

Transport rules (Exchange Server 2013)

Transport rules (Exchange Online)

Transport rules (Exchange Online Protection)

Transport rule procedures

Exchange Server 2013 > Messaging policy and compliance > Transport rules >

Applies to: *Exchange Server*

Topic Last Modified: *2014-01-31*

You can begin using transport rules by using the following procedures. To learn about concepts and objectives for transport rules, see Transport rules.

Add an email disclaimer, legal disclaimer, common signature, or email footer or header Information to help you set up a legal disclaimer, email disclaimer, consistent signature, email header, or email footer by using transport rules.

Create a domain or user-based safe sender or blocked sender list using transport rules Information to help you create domain or user-based safe sender and blocked sender lists by using transport rules.

Register Filter Pack IFilters with Exchange 2013 Information to help you register additional file types for attachments so that transport rules that apply to attachments can scan these file types.

Manage Transport Rules Information to help you create, view, modify, enable, disable, or remove a transport rule, and information about importing and exporting transport rule collections.

Add an email disclaimer, legal disclaimer, common signature, or email footer or header

Messaging policy and compliance > Transport rules > Transport rule procedures >

Applies to: *Exchange Online Protection*

Topic Last Modified: *2014-01-31*

You can add an HTML or text legal disclaimer, disclosure statement, signature, or other information to the top or bottom of email messages that enter or leave your organization. To do this, you create a transport rule that adds the required information when specific conditions are met.

For examples and information about how to scope and format disclaimers, signatures, and other additions to email messages, see Organization-wide disclaimers, signatures, footers, or headers.

Important:

- If you want the information to be added only to outgoing messages, you must add a condition such as recipients located outside the organization. By default, transport rules are applied to incoming and outgoing messages.
- To avoid multiple disclaimers being added in an email conversation, add an exception that looks for unique text in your disclaimer. That way the disclaimer is only added to the original message.
- Test each disclaimer. When you create the transport rule, you have the option to start using it immediately (**Enforce**), or to test it first and view the results in the messaging log. We recommend testing all transport rules prior to setting them to **Enforce**.

What do you need to know before you begin?

- Estimated time to complete each procedure: 15 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport Rules" entry in the Messaging policy and compliance permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to add a disclaimer or other email header or footer

1. Go to **Mail flow** > **Rules**.
2. Click **Add +**, and then click **Apply disclaimers**.
3. In **New rule**, name the rule.
4. In the **Apply this rule if** box, select the conditions for displaying the disclaimer. For example, select **The recipient is located** condition, and then select **Outside the organization**.
   - If you want this rule to apply to every message that enters or leaves your organization, select **[Apply to all messages]**.
   - If you have additional conditions or exceptions, select **More options** at the bottom of the page.

For example, to add an exception that looks for text from your disclaimer:

a. Select **Add exception**.

b. Select **The subject or body**, select **Subject or body matches these text patterns**, and then specify the words or phrases in your disclaimer.

Tip:

To put your disclaimer at the top of the email message:

- Select **More options**.
- In the **Do the following list**, select **Apply a disclaimer to the message** > **prepend a disclaimer**.

1. Next to the **Do the following** box, select **Enter text** to enter the text of your disclaimer. For information about what can be added, see Enter and format your disclaimer.
2. Click **Select one**, and select one of the Fallback options if the disclaimer can't be added.
3. Specify the audit severity level to assign the severity level that appears in the message log.
4. Select the mode for the rule. Select **Enforce** to turn on the disclaimer immediately, or select **Test without Policy Tips** to put a message in the message tracking log instead of adding the disclaimer.
5. Click **Save** to complete creating the rule.

For more examples of how to scope your disclaimer, see Scoping your disclaimer.

Use the Shell to add a disclaimer or other email header or footer

Use New-TransportRule to create a disclaimer, with parameters for each condition and exception. For detailed parameter information, see Transport rule conditions (predicates) for Exchange Server, **Transport Rule Conditions (Predicates)** for Exchange Online, or **Transport rule conditions (predicates)** for Exchange Online Protection.

This example creates a new transport rule that adds a disclaimer with an image to the end of all email messages sent outside the organization.

```
New-TransportRule -Name ExternalDisclaimer -SentToScope
'NotInOrganization'  -ApplyHtmlDisclaimerText
"<h3>Disclaimer Title</h3><p>This is the disclaimer text.</
p><img alt='Contoso logo' src='http://www.contoso.com/
images/logo.gif'>"
```

This example creates a new transport rule that adds an advertisement for one month to the beginning of all outgoing messages.

```
New-TransportRule -Name MarchSpecial -Enabled $true -
SentToScope 'NotInOrganization' -
ApplyHtmlDisclaimerLocation 'Prepend' -ActivationDate
```

```
'03/1/2014' -ExpiryDate '03/31/2014'-
ApplyHtmlDisclaimerText "<table align=center width=200
border=1 bordercolor=blue bgcolor=green cellpadding=10
cellspacing=0><tr><td nowrap><a href=http://
www.contoso.com/marchspecials.htm>Click to see March
specials</a></td></tr></table>"
```

For more examples of how to scope your disclaimer, see Scoping your disclaimer.

How do you know this worked?

To verify that your disclaimer works as expected, do the following:

- Send yourself both a plain text email and an HTML email that match the conditions and exceptions you defined, and verify that the text appears as you intended.
- If you added an exception to avoid adding the disclaimer to successive messages in a conversation, forward your test messages to yourself to make sure that they don't get an extra copy of the disclaimer.
- Send yourself some messages that should not get the disclaimer and verify that the disclaimer is not included.

For more information

After you configure a disclaimer or email header or footer, see Manage Transport Rules for information about how to view, modify, enable, disable, or remove a rule.

Create a domain or user-based safe sender or blocked sender list using transport rules

Messaging policy and compliance > Transport rules > Transport rule procedures >

Applies to: *Exchange Online Protection, Exchange Online*

Topic Last Modified: *2014-01-27*

If you want to be sure that you receive mail from a particular sender, because you trust them and their messages, you can create an Exchange transport rule that serves as a domain or user-based safe sender list. Any messages sent from the domain or user you specify bypasses spam filtering.

Conversely, if you want to block messages sent from a particular domain or user, you can create an

Exchange transport rule that serves as a domain or user-based blocked sender list. Any messages sent from the domain or user you specify will be blocked.

Tip:
A domain-based list isn't as secure as an IP address-based list, because domains can be spoofed. Also, if the sending IP address is on a Block list, it will still be blocked even if filtering for the domain or user is being bypassed. This is because a transport rule on a domain or user does not override the global IP Block list. We recommend using an IP address-based list in most cases. To create an IP address-based list, you can use the IP Allow list or IP Block list in the connection filter. Any messages sent from these IP addresses aren't checked by the content filter. For instructions on how to configure the connection filter policy by adding IP addresses to the IP Allow list or IP Block list, see **Configure the Connection Filter Policy**.

For additional management tasks related to transport rules, see **Transport rules**.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport rules" entry in the Messaging policy and compliance permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the EAC to bypass spam filtering for a domain or user

1. In the EAC, navigate to **Mail flow** > **Rules**. Choose **Add +** and then choose **Bypass spam filtering**.
2. Give the rule a name. Under **Apply this rule if**, choose **The sender** and then select one of the following conditions:
   - If you want to specify a domain, choose **domain is**. In the **Specify domain** dialog box, enter the domain of the sender you want to designate as safe, such as contoso.com. **Add +** to move it to the list of phrases. Repeat this step if you want to add additional domains, and click **OK** when you are finished.
   - If you want to specify a user, choose **is this person**. In the **Select members** dialog box, add the user from the list or type the user and click **Check names**. Repeat this step if you want to add additional users, and click **OK** when you are finished.
3. If you'd like, you can make selections to audit the rule, test the rule, activate the rule during a specific time period, and other selections. We recommend selecting the Stop processing more rules check box to ensure that no other rule can reverse the bypass action. We also recommend testing the rule for a period of time before you enforcing it in your organization. For more

information about these selections, see Manage Transport Rules.

4. Choose **Save** to save the rule.

After you create and enforce the rule, spam filtering is bypassed for the domain or user you specified.

Use the EAC to block messages sent from a domain or user

1. In the EAC, navigate to **Mail flow** > **Rules**. Choose **Add +** and then choose **Create a new rule**.
2. Give the rule a name and then click **More options**.
3. Under **Apply this rule if**, choose **The sender** and then select one of the following conditions:
   - If you want to specify a domain, choose **domain is**. In the Specify domain dialog box, enter the sender domain from which you want to block messages, such as contoso.com. Click **Add +** to move it to the list of phrases. Repeat this step if you want to add additional domains, and click **OK** when you are finished.
   - If you want to specify a user, choose **is this person**. In the **Select members** dialog box, add the user from the list or type the user and click **Check names**. Repeat this step if you want to add additional users, and click **OK** when you are finished.
4. Under **Do the following**, choose **Block the message** and then click one of the other options such as **Delete the message without notifying anyone**.
5. If you'd like, you can make selections to audit the rule, test the rule, activate the rule during a specific time period, and other selections. We recommend testing the rule for a period of time before you enforcing it in your organization. For more information about these selections, see Manage Transport Rules.
6. Choose **Save** to save the rule.

After you create and enforce the rule, any messages sent from the domain or user you specify will be blocked.

Register Filter Pack IFilters with Exchange 2013

Messaging policy and compliance > Transport rules > Transport rule procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-01-24*

Transport rules with attachment scanning conditions perform text extraction when analyzing the content of attachments. Exchange 2013 can scan most commonly used attachment types natively.

Additional attachment types can be included by registering IFilters with Exchange 2013. This topic shows you how to register IFilters released by Microsoft and third-party providers.

After you register an IFilter for a specific file type, transport rules with attachment processing conditions will be able to scan these attachments. As a result, these file types will no longer trigger the *AttachmentIsUnsupported* condition.

Caution:

The procedures listed in this topic involve modifying the registry on your Exchange servers. Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.
These procedures also require you to stop and restart the Microsoft Exchange Transport service on your Mailbox servers.

For additional management tasks related to Transport rules, see Manage Transport Rules.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes per server.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Exchange server configuration settings" entry in the Exchange and Shell infrastructure permissions topic.
- You must perform the procedures below on servers that already have Exchange 2013 Mailbox server role installed. If you add additional Mailbox servers after you perform these procedures, you must perform them again on the newly provisioned servers.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Register the Microsoft Office 2010 Filter Pack

By default, the following Office file types aren't supported by Exchange transport rules:

- Office OneNote
- Office Publisher

If you want to support these files, you must deploy the Microsoft Office 2010 Filter Pack. This Filter Pack isn't deployed during Exchange 2013 Setup and isn't a prerequisite for deployment.

Deploy the Microsoft Office 2010 Filter Pack

Deploying the Office 2010 Filter Pack consists of two main steps:

- Downloading and installing the Filter Pack, which registers the IFilters with Windows (Search).
- Modifying the registry so the IFilters are also registered with Exchange 2013. This allows Exchange to support attachment scanning for the file formats.

Important:
You must perform this procedure on all Mailbox servers in your organization.

1. Download and save the Microsoft Office 2010 Filter Pack (`FilterPack64bit.exe`) from the Microsoft Download Center.
2. Run the `FilterPack64bit.exe` file on your Mailbox server and follow the instructions to complete the installation.
3. Start Registry Editor and locate the following registry subkey:

`HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ExchangeServer\v15\HubTransportRole\CLSID`

4. Under **CLSID**, add a subkey for OneNote files as follows:
   a. Right-click **CLSID**, point to **New**, and then click **Key**.
   b. Change the name of the new key to `{B8D12492-CE0F-40AD-83EA-099A03D493F1}`.
   c. Click the key you just created and set the **(Default)** value to where you installed the Office 2010 Filter Pack. By default, the filter pack gets installed at `C:\Program Files\Common Files\Microsoft Shared\Filters\ONIFilter.dll`.
   d. Right click **{B8D12492-CE0F-40AD-83EA-099A03D493F1}**, point to **New**, and then click **String Value**.
   e. Name the new string value `ThreadingModel` and set it to `Both`.
5. Under **CLSID**, add a subkey for Publisher files as follows:
   a. Right-click **CLSID**, point to **New**, and then click **Key**.
   b. Change the name of the new key to `{A7FD8AC9-7ABF-46FC-B70B-6A5E5EC9859A}`.
   c. Click the key you just created and set the **(Default)** value to where you installed the Office 2010 Filter Pack. By default, the filter pack gets installed at `C:\Program Files\Common Files\Microsoft Shared\Filters\PUBFILT.dll`.
   d. Right-click **{A7FD8AC9-7ABF-46FC-B70B-6A5E5EC9859A}**, point to **New**, and then click **String Value**.
   e. Name the new string value `ThreadingModel` and set it to `Both`.
6. Locate the following registry key:

`HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ExchangeServer\v15\HubTransportRole\filters`

7. Under **filters**, add a subkey for .one extensions as follows.
   a. Right-click **filters**, point to **New**, and then click **Key**.
   b. Change the name of the new key to `.one`.
   c. Click the key you just created and set the **(Default)** value to `{B8D12492-CE0F-40AD-83EA-099A03D493F1}`.

8. Under **filters**, add a subkey for .pub extensions as follows:
   a. Right-click **filters**, point to **New** and then click **Key**.
   b. Change the name of the new key to `.pub`.
   c. Click the key you just created and set the **(Default)** value to `{A7FD8AC9-7ABF-46FC-B70B-6A5E5EC9859A}`.
9. Close Registry Editor.
10. On your Mailbox server, stop and then restart the following services in the specified order:
   a. Stop the Microsoft Exchange Transport service.
   b. Stop the Microsoft Filtering Management Service.
   c. Start the Microsoft Filtering Management Service.
   d. Start the Microsoft Exchange Transport service.

How do you know this worked?

To verify that you have successfully registered the Microsoft Office 2010 Filter Pack IFilters, do the following:

1. Create a Transport rule with the following properties. For detailed instructions about how to create Transport rules, see Manage Transport Rules.
   - The sender is your mailbox.
   - Any attachment's content includes "Testing IFilters".
   - Generate an incident report and send it to your mailbox.
2. Create a OneNote file that contains the phrase "Testing IFilters", attach it to a new email message, and send it to yourself.
3. Verify that you receive a Transport rule incident report for the rule you just created. This confirms that the rules engine was able to analyze the contents of the OneNote file.
4. Repeat Steps 2 and 3 with a Publisher file.

Register third-party IFilters to support additional file formats

You can extend the attachment scanning capability for additional file types by registering additional third-party IFilters. Support for additional files can be added by installing and registering the file type's IFilter on each of your Mailbox servers.

Important:
Microsoft hasn't tested third-party IFilters with transport rules, therefore we recommend that you deploy and test any third-party IFilters in a test environment before deploying into your production environment.

Deploy the Adobe PDF IFilter

This procedure shows how to deploy the Adobe PDF IFilter to support processing of PDF attachments in transport rules.

Note:

By default, Exchange 2013 supports the scanning of PDF files in transport rules. The PDF example here is used simply to illustrate how you can extend support for additional file types using third-party IFilters.

1. Download the Adobe PDF IFilterand then follow the installation instructions.
2. Start Registry Editor and locate the following subkey:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ExchangeServer\v15
\HubTransportRole\CLSID
```

3. Under **CLSID**, add a subkey for PDF files as follows:
   a. Right-click **CLSID**, point to **New**, and then click **Key**.
   b. Change the name of the new key to `{E8978DA6-047F-4E3D-9C78-CDBE46041603}`.

Note:

Each IFilter has a unique class ID (CLSID). You can find the CLSID in the installation documentation for the IFilter you're registering or by searching for the file extension under the `HKEY_CLASSES_ROOT\CLSID` key in the registry.

   c. Click the key you just created and set the **(Default)** value to where you installed the PDF IFilter. By default, the PDF IFilter is installed at `C:\Program Files\Adobe\Adobe PDF IFilter 9 for 64-bit platforms\bin\PDFFilter.dll`.
4. Locate the following registry key:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ExchangeServer\v15
\HubTransportRole\filters
```

5. Under **filters**, add a subkey for .pdf extensions as follows:
   a. Right-click **filters**, point to **New**, and then click **Key**.
   b. Change the name of the new key to `.pdf`.
   c. Click the key you just created and set the **(Default)** value to `{E8978DA6-047F-4E3D-9C78-CDBE46041603}`.
6. Close Registry Editor.
7. On your Mailbox server, stop and restart the following services in the specified order:
   a. Stop the Microsoft Exchange Transport service.
   b. Stop the Microsoft Filtering Management Service.
   c. Start the Microsoft Filtering Management Service.
   d. Start the Microsoft Exchange Transport service.

How do you know this worked?

Use the same procedure listed in the How do you know this worked? section earlier in this topic, substituting Publisher files with Adobe PDF files.

Transport rule actions

Manage Transport Rules

Messaging policy and compliance > Transport rules > Transport rule procedures >

Applies to: *Exchange Server 2013, Exchange Online Protection, Exchange Online*

Topic Last Modified: *2014-08-08*

You can use transport rules to look for specific conditions on messages that pass through your organization and take action on them. This topic shows you how to create, copy, adjust the order, enable or disable, delete, or import or export rules, and how to monitor rule usage.

Tip:

To make sure your rules work the way you expect, be sure to thoroughly test each rule and interactions between rules.

Interested in scenarios where these procedures are used? See the following topics:

- Organization-wide disclaimers, signatures, footers, or headers
- Using transport rules to inspect message attachments
- **Use transport rules to aggressively filter bulk email messages**
- Define rules to encrypt or decrypt messages
- Create a domain or user-based safe sender or blocked sender list using transport rules

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport rules" entry in Messaging policy and compliance permissions (Exchange Server), or in **Feature permissions in Exchange Online**.
- If you are using Exchange Online or Exchange Online Protection, you can have up to 100 rules.
- When a rule is listed as **version 14**, this means that the rule is based on an Exchange Server 2010 transport rule format. All options are available for these rules.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Create a transport rule

You can create a transport rule by setting up a Data Loss Prevention (DLP) policy, creating a new rule, or by copying a rule. You can use the Exchange admin center (EAC) or the Shell.

Use a DLP policy to create transport rules

Each DLP policy is a collection of transport rules. After you create the DLP policy, you can fine-tune the rules using the procedures below.

1. Create a DLP policy. For instructions, see:
   - Exchange Server 2013 DLP Procedures
   - Exchange Online DLP procedures
2. Modify the transport rules created by the DLP policy. See View or modify a transport rule.

Use the EAC to create a transport rule

The EAC allows you to create transport rules by using a template, copying an existing rule, or from scratch.

1. Go to **Mail flow** > **Rules**.
2. Create the rule by using one of the following options:
   - To create a rule from a template, click **Add +** and select a template.
   - To copy a rule, select the rule, and then select **Copy** 🗎.
   - To create a new rule from scratch, **Add +** and then select **Create a new rule**.
3. In the **New rule** dialog box, name the rule, and then select the conditions and actions for this rule:
   - In **Apply this rule if...**, select the condition you want from the list of available conditions.
     - Some conditions require you to specify values. For example, if you select **The sender is...** condition, you must specify a sender address.
     - If the condition you want isn't listed, or if you need to add exceptions, select **More options**. Additional conditions and exceptions will be listed.
     - If you don't want to specify a condition, and want this rule to apply to every message in your organization, select **[Apply to all messages]** condition.
   - In **Do the following...**, select the action you want the rule to take on messages matching the criteria from the list of available actions.
     - Some of the actions will require you to specify values. For example, if you select the **Forward the message for approval to...** condition, you will need to select a recipient in your organization.
     - If the condition you want isn't listed, select **More options**. Additional conditions will be listed.
   - Specify how rule match data for this rule is displayed in the Data Loss Prevention (DLP) reports and the transport rule reports.

- Under **Audit this rule with severity level**, select a level to specify the severity level for this rule. The severity level has no impact on the priority in which the rule is processed: it just impacts how the report is categorized in the reports.

Note:
If you clear the **Audit this rule with severity level** checkbox, rule matches will not show up in the rule reports

- Set the mode for the rule. You can use one of the two test modes to test the rule without impacting mail flow. In both test modes, when the conditions are met, an entry is added to the message trace.
  - **Enforce** This turns on the rule and it starts processing messages immediately. All actions on the rule will be performed.
  - **Test with Policy Tips** This turns on the rule, and any Policy Tip actions (**Notify the sender with a Policy Tip**) will be sent, but no actions related to message delivery will be performed. Data Loss Prevention (DLP) is required in order to use this mode. To learn more, see Policy Tips.
  - **Test without Policy Tips** Only the Generate incident report action will be enforced. No actions related to message delivery are performed.

4. If you are satisfied with the rule, go to step 5. If you want to add more conditions or actions, or if you want to specify exceptions or set additional properties, click **More options**. After you click **More options**, complete the following fields to create your rule:
   - To add more conditions, click **Add condition**. If you have more than one condition, you can remove any one of them by clicking **Remove X** next to it. Note that there are a larger variety of conditions available once you click **More options**.
   - To add more actions, click **Add action**. If you have more than one action, you can remove any one of them by clicking **Remove X** next to it. Note that there are a larger variety of actions available once you click **More options**.
   - To specify exceptions, click **Add exception**, then select exceptions using the **Except if...** dropdown. You can remove any exceptions from the rule by clicking the **Remove X** next to it.
   - If you want this rule to take effect after a certain date, click **Activate this rule on the following date:** and specify a date. Note that the rule will still be enabled prior to that date, but it won't be processed.

Similarly, you can have the rule stop processing at a certain date. To do so, click **Deactivate this rule on the following date:** and specify a date. Note that the rule will remain enabled, but it won't be processed.

- You can choose to avoid applying additional rules once this rule processes a message. To do so, click **Stop processing more rules**. If you select this, and a message is processed by this rule, no subsequent rules are processed for that message.
- You can specify how the message should be handled if the rule processing can't be completed. By default, the rule will be ignored and the message will be processed regularly, but you can choose to resubmit the message for processing. To do so, check the **Defer the message if rule processing doesn't complete** check box.
- If your rule analyzes the sender address, it only examines the message headers by default.

However, you can configure your rule to also examine the SMTP message envelope. To specify what's examined, click one of the following values for **Match sender address in message**:

- **Header** Only the message headers will be examined.
- **Envelope** Only the SMTP message envelope will be examined.
- **Header or envelope** Both the message headers and SMTP message envelope will be examined.

- You can add comments to this rule in the **Comments** box.

5. Click **Save** to complete creating the rule.

Use the Shell to create a transport rule

This example uses the New-TransportRule cmdlet to create a new transport rule that prepends "`External message to Sales DG:`" to messages sent from outside the organization to the Sales Department distribution group.

```
New-TransportRule -Name "Mark messages from the Internet to Sales DG" -FromScope NotInOrganization -SentTo "Sales Department" -PrependSubject "External message to Sales DG:"
```

The rule parameters and action used in the above procedure are for illustration only. Review all the available transport rule conditions and actions to determine which ones meet your requirements.

How do you know this worked?

To verify that you have successfully created a new transport rule, do the following:

- From the EAC, verify that the new transport rule you created is listed in the **Rules** list.
- From the Shell, verify that you created the new transport rule successfully by running the following command (the example below verifies the rule created in the Shell example above):

```
Get-TransportRule "Mark messages from the Internet to Sales DG"
```

View or modify a transport rule

Use the EAC to view or modify a transport rule

1. From the EAC, go to **Mail flow** > **Rules**.
2. When you select a rule in the list, the conditions, actions, exceptions and select properties of that rule are displayed in the details pane. To view all the properties of a specific rule, double click it. This opens the rule editor window, where you can make changes to the rule. For more information about rule properties, see Use the EAC to create a new Transport rule section, earlier in this topic.

Use the Shell to view or modify a transport rule

The following example gives you a list of all rules configured in your organization:

```
Get-TransportRule
```

To view the properties of a specific transport rule, you provide the name of that rule or its GUID. It is usually helpful to send the output to the **Format-List** cmdlet to format the properties. The following example returns all the properties of the transport rule named **Sender is a member of Marketing**:

```
Get-TransportRule "Sender is a member of marketing" |
Format-List
```

To modify the properties of an existing rule, use the Set-TransportRule cmdlet. This cmdlet allows you to change any property, condition, action or exception associated with a rule. The following example adds an exception to the rule "Sender is a member of marketing" so that it won't apply to messages sent by the user Kelly Rollin:

```
Set-TransportRule "Sender is a member of marketing" -
ExceptIfFrom "Kelly Rollin"
```

How do you know this worked?

To verify that you have successfully modified a transport rule, do the following:

- From the rules list in the EAC, click the rule you modified in the **Rules** list and view the details pane.
- From the Shell, verify that you modified the transport rule successfully by running the following command to list the properties you modified along with the name of the rule (the example below verifies the rule modified in the Shell example above):

```
Get-TransportRule "Sender is a member of marketing" |
Format-List Name,ExceptIfFrom
```

Set the priority of a transport rule

The rule at the top of the list is processed first. This rule has a **Priority** of 0.

Use the EAC to set the priority of a rule

1. From the EAC, go to **Mail flow** > **Rules**. This displays the rules in the order in which they are processed.
2. Select a rule, and use the arrows to move the rule up or down the list.

Use the Shell to set the priority of a rule

The following example sets the priority of "Sender is a member of marketing" to 2:

```
Set-TransportRule "Sender is a member of marketing"
```

```
priority "2"
```

How do you know this worked?

To verify that you have successfully modified a transport rule, do the following:

- From the rules list in the EAC, look at the order of the rules.
- From the Shell, verify the priority of the rules (the example below verifies the rule modified in the Shell example above):

```
Get-TransportRule * | Format-List Name,Priority
```

Enable or disable a transport rule

Rules are enabled when you create them. You can disable a transport rule.

Use the EAC to enable or disable a transport rule

1. From the EAC, go to **Mail flow** > **Rules**.
2. To disable a rule, clear the check box next to its name.
3. To enable a disabled rule, select the check box next to its name.

Use the Shell to enable or disable a transport rule

The following example disables the transport rule "Sender is a member of marketing":

```
Disable-TransportRule "Sender is a member of marketing"
```

The following example enables the transport rule "Sender is a member of marketing":

```
Enable-TransportRule "Sender is a member of marketing"
```

How do you know this worked?

To verify that you have successfully enabled or disabled a transport rule, do the following:

- From the EAC, view the list of rules in the **Rules** list and check the status of the check box in the **ON** column.
- From the Shell, run the following command which will return a list of all rules in your organization along with their status:

```
Get-TransportRule | Format-Table Name,State
```

Remove a transport rule

Use the EAC to remove a transport rule

1. From the EAC, go to **Mail flow** > **Rules**.
2. Select the rule you want to remove and then click **Delete** 🗑.

Use the Shell to remove a transport rule

The following example removes the transport rule "Sender is a member of marketing":

```
Remove-TransportRule "Sender is a member of marketing"
```

How do you know this worked?

To verify that you have successfully removed the transport rule, do the following:

- From the EAC, view the rules in the **Rules** list and verify that the rule you removed is no longer shown.
- From the Shell, run the following command and verify that the rule you remove is no longer listed:

```
Get-TransportRule
```

Monitor rule usage

If you're using Exchange Online or Exchange Online Protection, you can check the number of times each rule is matched by using a rules report. In order to be included in the reports, a rule must have the **Audit this rule with severity level** check box selected. You can look at a report online, or download an Excel version of all the mail protection reports.

Note:
While most data is in the report within 24 hours, some data may take as long as 5 days to appear.

Use the Office 365 admin center to generate a rules report

1. In the Office 365 admin center, select **Reports**.
2. In the **Rules** section, select **Top rule matches for mail** or **Rule matches for mail**.

To learn more, see View mail protection reports.

Download an Excel version of the reports

1. On the Reports page in the Office 365 admin center, select **Mail protection reports (Excel)**.
2. If it is your first time using the Excel mail protection reports, a tab opens to the download page.
   a. Select **Download** to download the Microsoft Office 365 Excel Plugin for Exchange Online Reporting.
   b. Open the download.
   c. In the **Mail Protection reports for Office 365 Setup** dialog box, select **Next**, accept the terms of the license agreement, and then select **Next**.
   d. Select the service you are using, and then select **Next**.
   e. Verify the prerequisites, and then select **Next**.
   f. Select **Install**. A shortcut to the reports is placed on your desktop.
3. On your desktop, select **Office 365 Mail Protection Reports**.

4. In the report, select the **Rules** tab.

Import or export a transport rule collection

You must use the Shell to import or export a transport rule collection. For information about how to import a transport rule collection from an XML file, see Import-TransportRuleCollection. For information about how to export a transport rule collection to an XML file, see Export-TransportRuleCollection.

Managing message approval

Exchange Server 2013 > Messaging policy and compliance > Transport rules >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-25*

You can require all messages sent to specific recipients be approved by moderators by Using the moderated transport feature in Microsoft Exchange Server 2013. You can configure any type of recipient as a moderated recipient, and Exchange will ensure that all messages sent to those recipients go through an approval process.

In any type of organization, you may need to restrict access to specific recipients. The most

common scenario is the need to control messages sent to large distribution groups. Depending on your organization's requirements, you may also need to control the messages sent to executive mailboxes or partner contacts. You can use moderated recipients to accomplish these tasks.

Note:

Microsoft Exchange Server 2007 doesn't support moderated recipients. If a message sent to a moderated distribution group is expanded on an Exchange 2007 Hub Transport server, the message will bypass moderation and will be delivered to all members of the distribution group. If you have Exchange 2007 Hub Transport servers in your Exchange organization, you need to designate an Exchange 2013 Mailbox server as the expansion server for moderated distribution groups. This ensures that all messages sent to the distribution group are moderated.

Contents

Moderated transport components

The moderated transport application consists of the following components:

- **Categorizer** The categorizer in the Transport service on a Mailbox server initiates the approval process. When the categorizer detects a moderated recipient while processing a message, it reroutes the message to the arbitration mailbox.
- **Mailbox Transport service** The Mailbox Transport service on a Mailbox server processes the messages that the categorizer marks for moderation. When the Mailbox Transport service encounters such a message, it delivers the original message to the arbitration mailbox and sends approval requests to the moderators. When a moderator responds with a decision, the Mailbox Transport service marks that decision on the message that's stored in the arbitration mailbox. If an approved message is submitted again by the Information Assistant, the Mailbox Transport service removes the approval workflow wrappers so the message that's delivered is identical to the original message submitted by the sender.
- **Information Assistant** The Information Assistant process in the Mailbox Transport service monitors the arbitration mailbox. The Information Assistant resubmits any approved messages to the Transport service on a Mailbox server for delivery to the intended recipients, or it deletes rejected messages. The Information Assistant is also responsible for sending rejection notifications to the sender. In addition, it cleans up the arbitration mailbox by deleting any stale or orphaned messages from the arbitration mailbox. For example, if a moderator simply deletes an approval request instead of making a decision, the corresponding message waiting for approval in the arbitration mailbox needs to be removed by the Information Assistant.
- **Arbitration mailbox** The arbitration mailbox is used to store the original message that's

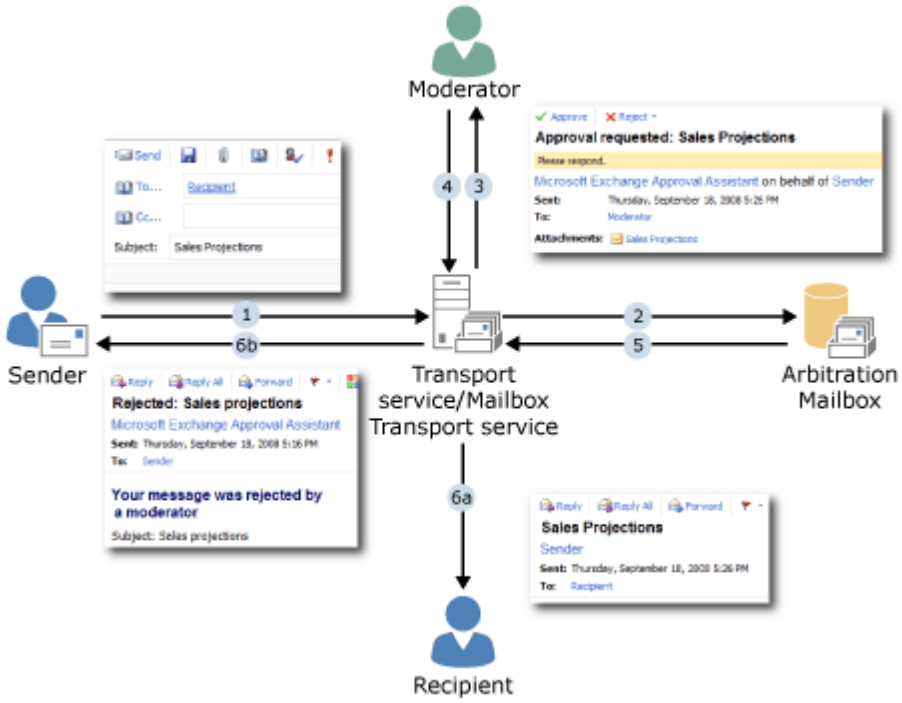
awaiting approval. By default, one arbitration mailbox is created for moderated transport during setup. It's used for all moderated recipients. You can add additional arbitration mailboxes for load balancing purposes. If you're using multiple arbitration mailboxes, you need to specify which mailbox to use for each moderated recipient.

Return to top

Message flow for moderated recipients

When a user sends a message to a moderated recipient, the message follows a path to its destination, as shown in the following figure and described in the following steps.

Moderated transport message flow



1. The sender creates a message and sends it to the moderated recipient.
2. The categorizer in the Transport service intercepts the message, marks it for moderation, and then reroutes it to the Mailbox Transport service on the Mailbox server where the arbitration mailbox resides.
3. The Mailbox Transport service delivers the message to the arbitration mailbox and sends an approval request to the moderator.
4. The moderator uses the buttons in the approval request to either accept or reject the message.
5. The Mailbox Transport service marks the moderator's decision on the original message stored in the arbitration mailbox.
6. The Information Assistant in the Mailbox Transport service reads the approval status on the message stored in the arbitration mailbox, and then processes the message depending on the moderator's decision:
   a. If the moderator has approved the message, the Information Assistant resubmits the message to the Transport service on a Mailbox server, and the message is delivered to the recipient.
   b. If the moderator has rejected the message, the Information Assistant deletes the message

from the arbitration mailbox and notifies the sender that the message was rejected.

Note:

If the moderator doesn't respond to the message within five days, the Information Assistant will delete the message from the arbitration mailbox and notify the sender that their message has expired.

Return to top

Handling multiple moderated recipients

It's possible to send a message to a group of recipients that includes both moderated recipients and recipients that aren't moderated. In this case, a separate approval process occurs for each moderated recipient.

Consider a message that's sent to 12 recipients, one of which is a moderated distribution group. The categorizer bifurcates or forks this message into two copies. One message is delivered immediately to the 11 recipients that aren't moderated, and the second message is submitted to the approval process for the moderated distribution group.

If a message is intended for more than one moderated recipient, a separate copy is created for each moderated recipient and is submitted to the approval process.

A moderated distribution group may contain other moderated recipients. In this case, after the message to the distribution group is approved, a separate approval process occurs for each moderated recipient that's a member of the distribution group. However, you can also enable the automatic approval of the distribution group members after the message to the moderated distribution group is approved. To do this, you use the *BypassNestedModerationEnabled* parameter on the **Set-DistributionGroup** cmdlet.

Return to top

Bypassing moderation

Messages from moderators are delivered to the moderated recipient immediately, bypassing the approval process. By definition, a moderator has the authority to determine what messages are appropriate for a moderated recipient.

Moderation is also bypassed for owners of distribution groups and dynamic distribution groups. The owner of a distribution group can be responsible for managing the distribution group membership, but may not be able to moderate messages sent to it. For example, the account provisioning staff may be the owners of a distribution group called All Employees, but only specific people in human resources may have moderator rights for the same distribution group.

Return to top

Forward a message to a manager for approval

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-03-15*

When you configure a recipient for moderation, all messages sent to that recipient are subject to approval by the designated moderators. For more information about how Microsoft Exchange Server 2013 handles recipient moderation, see Managing message approval.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the"Moderated Transport" entry in the Mail flow permissions topic.
- Microsoft Exchange Server 2007 doesn't support moderated recipients. If you have Exchange 2007 Hub Transport servers in your organization, you need to specify an Exchange 2013 Mailbox server as the distribution group expansion server for a moderated distribution group.
- These examples show how to configure a distribution group for moderation, but you can follow similar steps to configure any type of recipient for moderation. Note that some recipient types can only be configured for moderation using the Exchange Management Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to configure a recipient for moderation

This example configures the following moderation settings for the distribution group named All Employees:

- Enable moderation for the distribution group.
- Designate David Hamilton and Yossi Ran as moderators.
- Allow the members of the distribution group named HR to bypass moderation.

- Notify internal senders if their message to the distribution group is rejected, but do not send any notifications to external senders.

To accomplish the tasks in this example scenario, perform the following procedure:

1. In the EAC, navigate to **Recipients** > **Groups**.
2. In the result pane, select the **All employees** distribution group and click **Edit** .
3. On the properties page, click **Message approval**, and complete the following:
   a. Select the **Messages sent to this group have to be approved by a moderator** check box.
   b. In the **Group moderators** list, click **Add +**.
   c. In the **Select group moderators** dialog, find and select David Hamilton, click **Add**, find and select Yossi Ran, and click **Add**. When you are finished, click **OK**.
   d. In the **Senders who don't require message approval** list, click **Add +**.
   e. In the **Select senders** dialog, find and select HR from the list and click **Add**. When you are finished, click **OK**.
   f. In **Select moderation notifications**, select **Notify all senders when their messages aren't approved**.
4. Click **Save**.

Use the Shell to configure a recipient for moderation

Run the following command:

```
Set-<RecipientType> <Identity> -ModerationEnabled $true -
ModeratedBy <recipient1,recipient2...> -
ByPassModerationFromSendersOrMembers
<recipient1,recipient2...> -SendModerationNotifications
<Never | Always | Internal>
```

This example configures the following moderation settings for the distribution group named All Employees:

- Enable moderation for the distribution group.
- Designate David Hamilton and Yossi Ran as moderators.
- Allow the members of the distribution group named HR to bypass moderation.
- Notify internal senders if their message to the distribution group is rejected, but do not send any notifications to external senders.

To accomplish the tasks in this example scenario, run the following command:

```
Set-DistributionGroup "All Employees" -ModerationEnabled
$true -ModeratedBy "David Hamilton","Yossi Ran" -
ByPassModerationFromSendersOrMembers HR -
SendModerationNotifications Internal
```

To add or remove users from the list of moderators or recipients who bypass moderation without

affecting other entries, use the following syntax:

```
Set-<RecipientType> <Identity> -ModeratedBy
@{Add="<recipient1>","<recipient2>"...;
Remove="<recipient1>","<recipient2>"...} -
ByPassModerationFromSendersOrMembers
@{Add="<recipient1>","<recipient2>"...;
Remove="<recipient1>","<recipient2>"...}
```

This example configures the following moderation settings for the distribution group named All Employees:

- Add the user chris@contoso.com to the list of existing moderators.
- Remove the user michelle@contoso.com from the list of existing senders who bypass moderation.

```
Set-DistributionGroup "All Employees" -ModeratedBy
@{Add="chris@contoso.com"} -
ByPassModerationFromSendersOrMembers
@{Remove="michelle@contoso.com"}
```

How do you know this worked?

To verify that you have successfully configured a recipient for moderation, do the following:

1. Send a test message to the moderated recipient.
2. Verify the designated moderators receive notification.
3. Verify the recipients who bypass moderation receive the message directly.

Manage and troubleshoot message approval

Messaging policy and compliance > Transport rules > Managing message approval >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-20*

You may receive the following error when you attempt to remove an arbitration mailbox:

Can't remove the arbitration mailbox <*mailbox*> because it's being used for the approval workflow for existing recipients that have either membership restrictions or moderation

enabled. You should either disable the approval features on those recipients or specify a different arbitration mailbox for those recipients before removing this arbitration mailbox.

An arbitration mailbox can be used to handle the approval workflow for moderated recipients and distribution group membership approvals. You use PowerShell to find all the recipients that are configured to use the arbitration mailbox. After you identify the recipients, you can either configure them to use a different arbitration mailbox, or you can disable moderation for them.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Aribtration" entry in the Recipients Permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Step 1: Use the Shell to find all the recipients that use the arbitration mailbox you are trying to delete

Run the following commands:

```
$AM = Get-Mailbox "<arbitration mailbox>" -Arbitration
$AMDN = $AM.DistinguishedName
Get-Recipient -RecipientPreviewFilter {ArbitrationMailbox -
eq $AMDN}
```

For example, to find all the recipients that use the arbitration mailbox named Arbitration Mailbox01, run the following commands:

```
$AM = Get-Mailbox "Arbitration Mailbox01" -Arbitration
$AMDN = $AM.DistinguishedName
Get-Recipient -RecipientPreviewFilter {ArbitrationMailbox -
eq $AMDN}
```

Note:

The arbitration mailbox is specified using the distinguished name (DN). If you know the DN of the arbitration mailbox, you can run the single command: `Get-Recipient -RecipientPreviewFilter {ArbitrationMailbox -eq <DN>}`.

Step 2: Use the Shell to specify a different arbitration

mailbox or disable moderation for the recipients

To stop moderated recipients from using the arbitration mailbox you are trying to delete, you can either specify a different arbitration mailbox, or you can disable moderation for the recipients.

If you choose to specify a different arbitration mailbox for the recipients, run the following command:

```
Set-<RecipientType> <Identity> -ArbitrationMailbox
<different arbitration mailbox>
```

For example, to reconfigure the distribution group named All Employees to use the arbitration mailbox named Arbitration Mailbox02 for membership approval, run the following command:

```
Set-DistributionGroup "All Employees" -ArbitrationMailbox
"Arbitration Mailbox02"
```

If you choose to disable moderation for the recipients, run the following command:

```
Set-<RecipientType> <Identity> -ModerationEanbled $false
```

For example, to disable moderation for the mailbox named Human Resources, run the following command:

```
Set-Mailbox "Human Resources" -ModerationEanbled $false
```

How do you know this worked?

The procedure was successful if you can delete the arbitration mailbox without receiving the error that it's being used.

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Data loss prevention

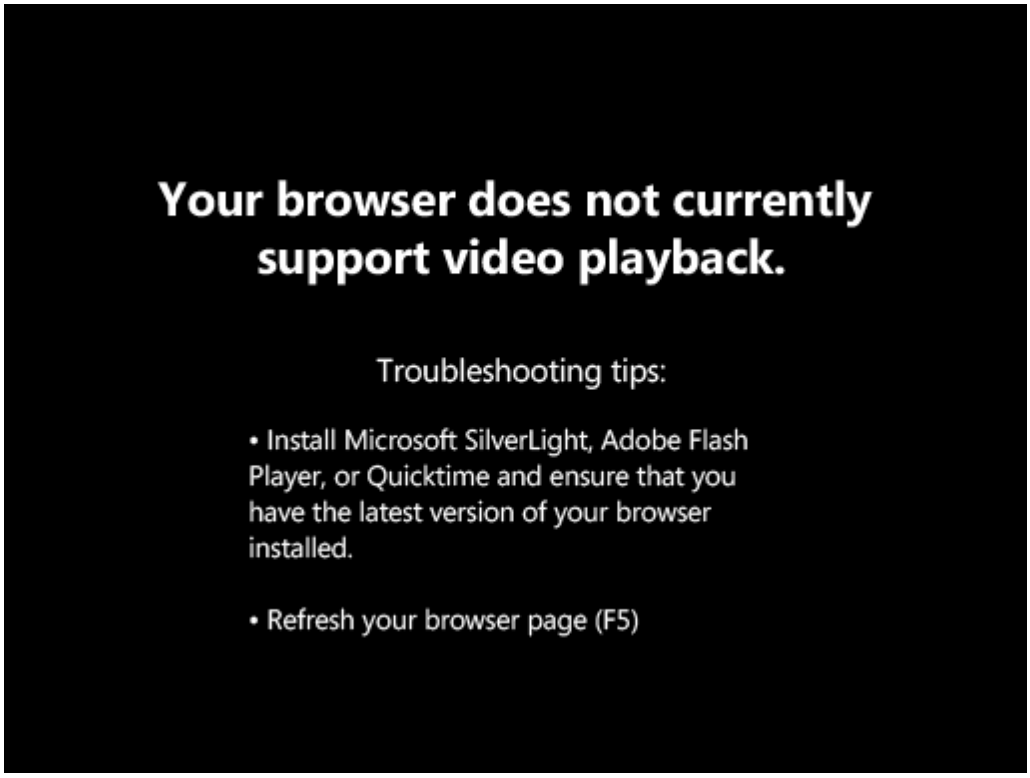
Exchange Server 2013 > Messaging policy and compliance >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-08-08*

Data loss prevention (DLP) is an important issue for enterprise message systems because of the

extensive use of email for business critical communication that includes sensitive data. In order to enforce compliance requirements for such data, and manage its use in email, without hindering the productivity of workers, DLP features make managing sensitive data easier than ever before. For a conceptual overview of DLP, watch the following video.



DLP policies are simple packages that contain sets of conditions, which are made up of transport rules, actions, and exceptions that you create in the Exchange Administration Center (EAC) and then activate to filter email messages and attachments. You can create a DLP policy, but choose to not activate it. This allows you to test your policies without affecting mail flow. DLP policies can use the full power of existing transport rules. In fact, a number of new types of transport rules have been created in Microsoft Exchange Server 2013 and Exchange Online in order to accomplish new DLP capability. One important new feature of transport rules is a new approach to classifying sensitive information that can be incorporated into mail flow processing. This new DLP feature performs deep content analysis through keyword matches, dictionary matches, regular expression evaluation, and other content examination to detect content that violates organizational DLP policies. The latest release of Exchange Online and Exchange 2013 SP1 add Document Fingerprinting, which helps you detect sensitive information in standard forms. For more information about transport rules, see Transport rules and Integrating sensitive information rules with transport rules. You can also manage your DLP policies by using Exchange Management Shell cmdlets. For more information about policy and compliance cmdlets, see Policy and compliance cmdlets.

In addition to the customizable DLP policies themselves, you can also inform email senders that they may be about to violate one of your policies—even before they send an offending message. You can accomplish this by configuring Policy Tips. Policy Tips are similar to MailTips, and can be configured to present a brief note in the Microsoft Outlook 2013 client that provides information about possible policy violations to a person creating a message. In the latest release of Exchange Online and in Exchange 2013 SP1, Policy Tips are also displayed in Outlook Web App and OWA for

Devices. For more information, see Policy Tips.

Note:

Exchange Online: DLP is a premium feature that requires an Exchange Online Plan 2 subscription. For more information, see Exchange Online Licensing.
Exchange 2013: DLP is a premium feature that requires an Exchange Enterprise Client Access License (CAL). For more information about CALs and server licensing, see Exchange Server Licensing.
Exchange Enterprise CAL with Services: There is a behavior distinction to take note of if you are an Exchange Enterprise CAL with Services customer with a hybrid deployment, where you have some mailboxes located on premises and some in Exchange Online. DLP policies are applied in Exchange Online. Therefore, messages sent from one on-premises user to another on-premises user do not have DLP policies applied, because the message doesn't leave the on-premises infrastructure.

Looking for management tasks related to Data Loss Prevention? See DLP procedures.

Contents

Establish policies to protect sensitive data

The data loss prevention features can help you identify and monitor many categories of sensitive information that you have defined within the conditions of your policies, such as private identification numbers or credit card numbers. You have the option of defining your own custom policies and transport rules or using the pre-defined DLP policy templates provided by Microsoft in order to get started quickly. For more information about the policy templates that are included, see DLP policy templates supplied in Exchange. A *policy template* includes a range of conditions, rules, and actions that you can choose from in order to create and save an actual DLP policy that will help you inspect messages. The policy templates are models from which you can select or build your own specific rules to create a policy that meets your needs for data loss prevention.

Three different methods exist for you to begin using DLP:

1. **Apply an out-of-the-box template supplied by Microsoft.** The quickest way to start using DLP policies is to create and implement a new policy using a template. This saves you the effort of building a new set of rules from nothing. You will need to know what type of data you want to

check for or which compliance regulation you are attempting to address. You will also need to know your organizations expectations for processing such data. More information at DLP policy templates supplied in Exchange and Create a DLP policy from a template.

2. **Import a pre-built policy file from outside your organization.** You can import policies that have already been created outside of your messaging environment by independent software vendors. In this way you can extend the DLP solutions to suit your business requirements. More information at Policy templates from Microsoft partners, Define your own DLP templates and information types, and Import a DLP policy from a file.
3. **Create a custom policy without any pre-existing conditions.** Your enterprise may have its own requirements for monitoring certain types of data known to exist within a messaging system. You can create a custom policy entirely on your own in order to start checking and acting upon your own unique message data. You will need to know the requirements and constraints of the environment in which the DLP policy will be enforced in order to create such a custom policy. More information at Create a custom DLP policy.

After you have added a policy, you can review and change its rules, make the policy inactive, or remove it completely. The procedures for these actions are provided in the Manage DLP policies topic.

Sensitive information types in DLP policies

When you create or change DLP policies, you can include rules that include checks for sensitive information. The sensitive information types listed in the Sensitive information types inventory topic are available to be used in your policies. The conditions that you establish within a policy, such as how many times something has to be found before an action is taken or exactly what that action is can be customized within your new custom policies in order to meet your specific policy requirements. For more information about creating DLP policies see, Create a custom DLP policy. For more information about the full suite transport rules, see Transport rules.

To make it easy for you to make use of the sensitive information-related rules, Microsoft has supplied policy templates that already include some of the sensitive information types. You cannot add conditions for all of the sensitive information types listed here to policy templates however, because the templates are designed to help you focus on the most-common types of compliance-related data within your organization. For more information about the pre-built templates, see DLP policy templates supplied in Exchange. You can create numerous DLP policies for your organization and have them all enabled so that many disparate types of information are examined. You can also create a DLP policy that is not based on an existing template. To begin creating such a policy, see Create a custom DLP policy. For more information about sensitive information types, see Sensitive information types inventory.

Detecting sensitive form data with Document

Fingerprinting

With Exchange 2013 SP1 and the latest version of Exchange Online, you can use Document Fingerprinting to easily create a sensitive information type based on a standard form. To learn how to protect form data, see Protect form data with document fingerprinting.

Policy Tips notify users about sensitive content expectations

You can use Policy Tip notification messages to inform email senders about possible compliance issues while they are composing an email message. When you configure a Policy Tip in a DLP policy, the notification message will only show up if something in the sender's email message meets the conditions described in your policy. Policy Tips are similar to MailTips that were introduced in Microsoft Exchange 2010. For more information, see Policy Tips.

Detecting sensitive information along with traditional message classification

Exchange 2013 and Exchange Online present a new method of helping you manage message and attachment data when compared with traditional message classification. A key factor in the strength of a DLP solution is the ability to correctly identify confidential or sensitive content that may be unique to the organization, regulatory needs, geography, or other business needs. Exchange 2013 can achieve this by using a new architecture for deep content analysis coupled with detection criteria that you establish through rules in your DLP policies. Helping prevent data loss in Exchange 2013 relies on configuring the correct set of sensitive information rules so that they provide a high degree of protection while minimizing inappropriate mail flow disruption with false positives and negatives. These types of rules, referred to throughout the DLP information as sensitive information detection, function within the framework offered by transport rules in order to enable DLP capabilities. To learn more about these new features, see Integrating sensitive information rules with transport rules. The traditional message classification fields can still be applied to messages in Exchange and these can be combined withthe new sensitive information detection either together within a single DLP policy or running concurrently so they are evaluated independently within Exchange. To learn more about the legacy Exchange 2010 message classifications, see Understanding Message Classifications in the TechNet Library.

Information about DLP-processed messages

To obtain information about messages and DLP policy detections in your environment, see DLP

policy detection reports. Data related to DLP detections, is highly integrated into the delivery reports message tracking tool of Exchange 2013.

Installation prerequisites

In order to make use of DLP features, you must have Exchange 2013 or Exchange Online configured with at least one sender mailbox. Data Loss Prevention is a premium feature that requires an Enterprise Client Access License (CAL). For more information about getting started with Exchange 2013, see Planning and deployment. For more information about getting started with Exchange Online, see **Exchange Online**.

Policy and compliance cmdlets

DLP policy templates

Exchange Server 2013 > Messaging policy and compliance > Data loss prevention >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-04-28*

You can use data loss prevention (DLP) policy templates to get started with your DLP solution in Microsoft Exchange Server 2013. A DLP policy template is a model for a policy. You can select a template to begin the process of building your own customized DLP policy. Within your DLP policy, you can customize the rules to ensure that it meets your business needs for data loss prevention. Several policy templates are supplied by Microsoft, but these are not the only way to implement a data loss prevention solution in Exchange.

Looking for management tasks related to DLP policy templates? See DLP procedures.

For more information

Extend the templates and information types to meet your needs

You can incorporate sensitive-content definitions and policy templates from Microsoft Partners or from files that you develop yourself as an addition to the DLP policy templates, information types, and rules already provided in Exchange 2013. Presented here are several ways in which you can add your own unique DLP content and extend DLP functionality. The templates already provided by Microsoft are a convenient method to get started with a DLP solution. In order to extend the DLP features with your own unique DLP policy template files, you must understand the XML schema requirements for policy templates that are created independent of Exchange. To learn more about the Exchange Management Shell cmdlets associated with DLP policy templates, see cmdlets related to `Get-DlpPolicyTemplate` in Policy and compliance cmdlets. Furthermore, you can define your own sensitive content types after you understand the format and procedure to incorporate them. To learn more about the Exchange Management Shell cmdlets associated with DLP policy templates, see cmdlets related to `Get-ClassificationRuleCollection` in Policy and compliance cmdlets.

Caution:
You should turn on your DLP policies in test mode before enforcing them in your production environment. During such tests, we recommended that you configure sample user mailboxes and send test messages that invoke your test policies in order to confirm the results.

Create your own new DLP policy template or your own sensitive information types in a classification rule package

You can create a DLP policy template file apart from Exchange that meets the specific XML schema definition provided by Microsoft and then import the file into your system so that you can create DLP policies from it. By creating your own template files, you can define your own model for DLP policies that Microsoft has not already provided. This is different than creating a DLP policy by using the Exchange Administration Center, which typically happens after policy templates are available. If you create a policy template independent of Exchange, you will need to import it before you can use it to scan messages. You can also create your own sensitive information definitions apart from those defined by Microsoft in Exchange. There is a separate XML schema definition for DLP policy template files and classification rule packages. To get started with this, see the following information:

Define your own DLP templates and information types

Import a DLP policy from a file

Include DLP functionality with existing transport rules

You can incorporate DLP detection capabilities with traditional transport rules without creating a new DLP policy. If you have created a complex set of rules in a previous version of Exchange, and you want to duplicate them or add sensitive information detection in Exchange 2013, then you can use the transport rules editor in the Exchange Administration Center or the Exchange management shell to incorporate these two features. To get started with this, see the following information:

Transport rules

Manage Transport Rules
Policy and compliance cmdlets

Use DLP policies created by Microsoft

Numerous DLP policies are supplied by Microsoft. This is the easiest way to get started with a DLP solution that is flexible and simple to implement. You can always use the provided policies as a starting point and customize them further to meet your requirements. To get started with this, see the following information:

- DLP policy templates supplied in Exchange
- Create a DLP policy from a template

How DLP rules are applied to evaluate messages

Messaging policy and compliance > Data loss prevention > DLP policy templates >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-11-25*

You can set up sensitive information rules within your Microsoft Exchange data loss prevention (DLP) policies to detect very specific data in email messages. This topic will help you understand how these rules are applied and how messages are evaluated. You can avoid workflow disruptions for your email users and achieve a high degree of accuracy with your DLP detections if you know how your rules are enforced. Let's use the Microsoft-supplied credit card information rule as an

example. When you activate a transport rule or DLP policy, the Exchange transport rules agent compares all messages that your users send with the rule sets that you create.

Get precise about your needs

Suppose you need to act on credit card information in messages. The actions you take once it is found are not the subject of this topic, but you can learn more about that in **Transport rule actions**. With as most certainty as possible, you need to ensure that what is detected in a message is truly credit card data and not something else that could be a legitimate use of groups of numbers that merely resemble credit card data; for example, a reservation code or a vehicle identification number. To meet this need, let's make it clear that the following information should be classified as a credit card.

Margie's Travel,
I have received updated credit card information for Spencer.
Spencer Badillo
Visa: 4111 1111 1111 1111
Expires: 2/2012
Please update his travel profile.

Let's also make it clear that the following information should not be classified as a credit card.

Hi Alex,
I expect to be in Hawaii too. My booking code is 1234 1234 1234 1234 and I'll be there on 3/2012.
Regards, Lisa

The following XML snippet shows how the needs expressed earlier are currently defined in a sensitive information rule that is provided with Exchange and it is embedded within one of the supplied DLP policy templates.

```
<Entity id="50842eb7-edc8-4019-85dd-5a5c1f2bb085"
patternsProximity="300" recommendedConfidence="85">
      <Pattern confidenceLevel="85">
        <IdMatch idRef="Func_credit_card" />
        <Any minMatches="1">
          <Match idRef="Keyword_cc_verification" />
          <Match idRef="Keyword_cc_name" />
          <Match idRef="Func_expiration_date" />
        </Any>
      </Pattern>
    </Entity>
```

Pattern-matching in your solution

The XML rule definition shown earlier includes pattern-matching, which improves the likelihood that the rule will detect only the important information and not detect vague, related information. For more information about the XML schema for DLP rules and templates, see Define your own DLP templates and information types.

In the credit card rule, there is a section of XML code for patterns, which includes a primary identifier match and some additional corroborative evidence. All three of these requirements are explained here:

1. `<IdMatch idRef="Func_credit_card" />` — This requires a match of a function, titled credit card, that is internally defined. This function includes a couple of validations as follows:
   a. It matches a regular expression—in this instance for 16 digits—that could also include variations like a space delimiter so that it also matches **4111 1111 1111 1111** or a hyphen delimiter so that it also matches **4111-1111-1111-1111**.
   b. It evaluates the Lhun's checksum algorithm against the 16-digit number in order to ensure the likelihood of this being a credit card number is high.
   c. It requires a mandatory match, after which corroborative evidence is evaluated.
2. `<Any minMatches="1">` — This section indicates that the presence of at least one of the following items of evidence is required.

3. The corroborative evidence can be a match of one of these three:

```
<Match idRef="Keyword_cc_verification" />
<Match idRef="Keyword_cc_name" />
<Match idRef="Func_expiration_date" />
```

These three simply mean a list of keywords for credit cards, the names of the credit cards, or an expiration date is required. The expiration date is defined and evaluated internally as another function.

The process of evaluating content against rules

The five steps here represent actions that Exchange takes to compare your rule with email messages. For our credit card rule example, the following steps are taken.

Step	Action
1. Get Content	Spencer Badillo Visa: 4111 1111 1111 1111 Expires: 2/2012
2. Regular Expression Analysis	4111 1111 1111 1111 -> a 16-digit number is

	detected
3. Function Analysis	• 4111 1111 1111 1111 -> matches checksum • 1234 1234 1234 1234 -> doesn't match
4. Additional Evidence	1. Keyword Visa is near the number. 2. A regular expression for a date (2/2012) is near the number.
5. Verdict	1. There is a regular expression that matches a checksum. 2. Additional evidence increases confidence.

The way this rule is set up by Microsoft makes it mandatory that corroborating evidence such as keywords are a part of the email message content in order to match the rule. So the following email content would not be detected as containing a credit card:

Margie's Travel,
I have received updated information for Spencer.
Spencer Badillo
4111 1111 1111 1111
Please update his travel profile.

You can use a custom rule that defines a pattern without extra evidence, as shown in the next example. This would detect messages with only credit card number and no corroborating evidence.

```
      <Pattern confidenceLevel="85">
         <IdMatch idRef="Func_credit_card" />
      </Pattern>
   </Entity>
```

The illustration of credit cards in this article can be extended to other sensitive information rules as well. To see the complete list of the Microsoft-supplied rules in Exchange, use the Get-ClassificationRuleCollection cmdlet in the Exchange Management Shell in the following manner:

```
$rule_collection = Get-ClassificationRuleCollection

$rule_collection[0].SerializedClassificationRuleCollection
| Set-Content oob_classifications.xml -Encoding byte
```

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-08-11*

Data loss prevention (DLP) includes 51 sensitive information type rules that are ready to use right out of the box. You can use any sensitive information type in a DLP policy, and in that policy you can use other conditions, actions, and exceptions to solve your DLP requirements. The information types provided by Microsoft and listed here can help you detect personally identifiable information (PII), financial information, and health information across a number of regions.

This topic has the following reference information to help you understand the included sensitive information types, their properties, and where they are used in the XML.

- Sensitive information type definitions
- Regex definitions contained in DLP rule pack
- Keyword list used for DLP rules
- XML rule definitions

If you would like to learn how to adjust the sensitivity of the included rules, follow the example in **Customize the built-in DLP rules to detect more credit card data**. You can also extend and customize your DLP solution with information types that you provide yourself. To learn more about creating your own specialized information types, see Define your own DLP templates and information types. For more information about modifying your DLP policies by using sensitive information detection, see Integrating sensitive information rules with transport rules and Manage DLP policies.

Sensitive information type definitions

The following table lists the properties of the included sensitive information types, such as the name, the term used in the XML, the primary geographical region that uses it, and the type of information that it detects. You can use the XML terms to find the corresponding sensitive information in the code snippets in the other sections of this topic.

Information type name	XML term	Primary region	Category
ABA Routing Number	`aba_routing`	United States	finance

Australia Bank Account Number	`australia_bank_account_number`	Australia	finance
Australia Driver's License Number	`australia_drivers_license_number`	Australia	PII
Australia Medical Account Number	`australian_medical_account_number`	Australia	health
Australia Passport Number	`australia_passport_number`	Australia	PII
Australia Tax File Number	`australian_tax_file_number`	Australia	finance
Canada Bank Account Number	`canada_bank_account_number`	Canada	finance
Canada Driver's License Number	`canada_drivers_license`	Canada	PII
Canada Health Service Number	`canada_health_service_number`	Canada	health
Canada Passport Number	`canada_passport_number`	Canada	PII
Canada Personal Health Identification Number (PHIN)	`canada_phin`	Canada	health
Canada Social Insurance Number	`canadian_sin`	Canada	PII
Credit Card Number	`credit_card`	All	finance
Drug Enforcement Agency (DEA) Number	`dea_number`	United States	PII

EU Debit Card Number	`eu_debit_card`	European Union	finance
Finland National ID[1]	`finnish_national_id`	Finland	PII
France Driver's License Number	`french_drivers_license`	France	PII
France National ID Card (CNI)	`france_cni`	France	PII
France Passport Number	`fr_passport`	France	PII
France Social Security Number (INSEE)	`french_insee`	France	PII
German Driver's License Number	`german_drivers_license`	Germany	PII
German Passport Number	`german_passport`	Germany	PII
International Banking Account Number (IBAN)	`iban`	All	finance
IP Address	`ipaddress`	All	PII
Israel Bank Account Number	`israel_bank_account_number`	Israel	finance
Israel National ID	`israeli_national_id_number`	Israel	PII
Italy Driver's License Number	`italy_drivers_license_number`	Italy	PII
Japan Bank Account Number	`jp_bank_account`	Japan	finance

Japan Driver's License Number	`jp_drivers_license_number`	Japan	PII
Japan Passport Number	`jp_passport`	Japan	PII
Japan Resident Registration Number	`jp_resident_registration_number`	Japan	PII
Japan Social Insurance Number (SIN)	`jp_sin`	Japan	PII
New Zealand Ministry of Health Number	`new_zealand_ministry_of_health_number`	New Zealand	health
Saudi Arabia National ID	`saudi_arabia_national_id`	Saudi Arabia	PII
Poland National ID (PESEL)[1]	`pesel_identification_number`	Poland	PII
Poland Identity Card[1]	`polish_national_id`	Poland	PII
Poland Passport[1]	`polish_passport_number`	Poland	PII
Spain National ID		Spain	PII
Spain Social Security Number (SSN)	`spanish_social_security_number`	Spain	PII
Sweden National ID	`swedish_national_identifier`	Sweden	PII
Sweden Passport Number	`sweden_passport_number`	Sweden	PII
SWIFT Code	`swift`	All	finance
Taiwan National ID[1]	`taiwanese_national_id`	Taiwan	PII

U.K. Driver's License Number	uk_drivers_license	United Kingdom	PII
U.K. Electoral Roll Number	uk_electoral	United Kingdom	PII
U.K. National Health Service Number	uk_nhs_number	United Kingdom	health
U.K. National Insurance Number (NINO)	uk_nino	United Kingdom	health
U.S. / U.K. Passport Number	usa_uk_passport	United States and United Kingdom	PII
U.S. Bank Account Number	usa_bank_account_number	United States	finance
U.S. Driver's License Number	us_drivers_license	United States	PII
U.S. Individual Taxpayer Identification Number (ITIN)	itin	United States	finance
U.S. Social Security Number (SSN)	ssn	United States	health

Note:

[1]Available in Exchange 2013 SP1 and Exchange Online.

Regex definitions contained in DLP rule pack

The following code snippet contains the regular expressions, or *regex*, that are used within DLP to detect common character patterns in sensitive information.

```
    <Regex id="Regex_france_cni">(^|\s)(\d{12})($|\s|\.\s)
</Regex>
    <Regex id="Regex_uk_electoral">(^|\s)([a-zA-Z]{2}
```

```
\d{1,4})($|\s|\.\s)</Regex>
    <Regex id="Regex_canada_health_service_number">(^|\s)
(\d{10})($|\s|\.\s)</Regex>
    <Regex id="Regex_canada_phin">(^|\s)(\d{9})($|\s|\.\s)
</Regex>
    <Regex id="Regex_canada_passport_number">(^|\s)(\D{2})
(\d{6})($|\s|\.\s)</Regex>
    <Regex id="Regex_canada_bank_account_number">(^|\s)
(\d{7})($|\s|\.\s)</Regex>
    <Regex id="Regex_australia_passport_number">(^|\s)([A-
Za-z]\d{7})($|\s|\.\s)</Regex>
    <Regex id="Regex_australia_drivers_license_number">(?
ix)(?:^|\s)(?=(?:[A-Z\d]{2}\d{2}[A-Z\d]{5})(?:$|\s|.\s))(?
=(?:[A-Z]{0,2}\d){4,9})(?!(?:\d{0,9}[A-Z]){3,9})[A-Z\d]{9}
</Regex>
    <Regex id="Regex_australia_bank_account_number">(^|\s)
([0-9]{6,10})($|\s|\.\s)</Regex>
    <Regex id="Regex_sweden_passport_number">(^|\s)(\d{8})
($|\s|\.\s)</Regex>

    <Regex id="Regex_usa_bank_account_number">(^|\s)
(\d{4,17})($|\s|\.\s)</Regex>
```

Keyword list used for DLP rules

The following code snippet shows the keywords that are used for each sensitive information type rule. Keyword information is valuable to help you determine why a rule might not be detecting information that you expect to be detected. However, keep in mind that the service evaluates more

than just keywords when detecting information. Confidence and proximity are also important parts of the evaluation process. For more information about how DLP rules are applied, see How DLP rules are applied to evaluate messages.

```

XML rule definitions

The following code sample includes all the default, out-of-box rules, which, to be honest, make the XML sample quite long. To make it easier to navigate the sample, use the table in Sensitive information type definitions to find the corresponding XML term for the sensitive information type that you want to locate. Then use the search feature of your web browser (usually **Ctrl+F**) to find the XML term in the sample, or you can copy the sample to a text editor and search from there. For an overview of how rules are applied to evaluate messages, see How DLP rules are applied to evaluate messages.

Manage DLP policies

Integrating sensitive information rules with transport rules

What's new for transport rules

Data loss prevention

DLP policy templates supplied in Exchange

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-04*

In Microsoft Exchange Server 2013 and Exchange Online, you can use data loss prevention (DLP) policy templates as a starting point for building DLP policies that help you meet your specific regulatory and business policy needs. You can modify the templates to meet the specific needs of your organization.

Caution:
You should enable your DLP policies in test mode before running them in your production environment. During such tests, it is recommended that you configure sample user mailboxes and send test messages that invoke your test policies in order to confirm the results. Use of these policies does not ensure compliance with any regulation. After your testing is complete, make the necessary configuration changes in Exchange so the transmission of information complies with your organization's policies. For example, you might need to configure TLS with known business partners or add more restrictive transport rule actions, such as adding rights protection to messages that contain a certain type of data.

Templates available for DLP

The following table lists the DLP policy templates in Exchange. To learn more about customizing these templates to create DLP policies, see Manage DLP policies.

Template	Description
Australia Financial Data	Helps detect the presence of information commonly considered to be financial data in Australia, including credit cards, and SWIFT codes.

Australia Health Records Act (HRIP Act)	Helps detect the presence of information commonly considered to be subject to the Health Records and Information Privacy (HRIP) act in Australia, like medical account number and tax file number.
Australia Personally Identifiable Information (PII) Data	Helps detect the presence of information commonly considered to be personally identifiable information (PII) in Australia, like tax file number and driver's license.
Australia Privacy Act	Helps detect the presence of information commonly considered to be subject to the privacy act in Australia, like driver's license and passport number.
Canada Financial Data	Helps detect the presence of information commonly considered to be financial data in Canada, including bank account numbers and credit cards.
Canada Health Information Act (HIA)	Helps detect the presence of information subject to Canada Health Information Act (HIA) for Alberta, including data like passport numbers and health information.
Canada Personal Health Act (PHIPA) - Ontario	Helps detect the presence of information subject to Canada Personal Health Information Protection Act (PHIPA) for Ontario, including data like passport numbers and health information.
Canada Personal Health Information Act (PHIA) - Manitoba	Helps detect the presence of information subject to Canada Personal Health Information Act (PHIA) for Manitoba, including data like health information.

Canada Personal Information Protection Act (PIPA)	Helps detect the presence of information subject to Canada Personal Information Protection Act (PIPA) for British Columbia, including data like passport numbers and health information.
Canada Personal Information Protection Act (PIPEDA)	Helps detect the presence of information subject to Canada Personal Information Protection and Electronic Documents Act (PIPEDA), including data like passport numbers and health information.
Canada Personally Identifiable Information (PII) Data	Helps detect the presence of information commonly considered to be personally identifiable information (PII) in Canada, like health ID number and social insurance number.
France Data Protection Act	Helps detect the presence of information commonly considered to be subject to the Data Protection Act in France, like the health insurance card number.
France Financial Data	Helps detect the presence of information commonly considered to be financial information in France, including information like credit card, account information, and debit card numbers.
France Personally Identifiable Information (PII) Data	Helps detect the presence of information commonly considered to be personally identifiable information (PII) in France, including information like passport numbers.
Germany Financial Data	Helps detect the presence of information commonly considered to be financial data in Germany like EU debit card numbers.

Germany Personally Identifiable Information (PII) Data	Helps detect the presence of information commonly considered to be personally identifiable information (PII) in Germany, including information like driver's license and passport numbers.
Israel Financial Data	Helps detect the presence of information commonly considered to be financial data in Israel, including bank account numbers and SWIFT codes.
Israel Personally Identifiable Information (PII) Data	Helps detect the presence of information commonly considered to be personally identifiable information (PII) in Israel, like national ID number.
Israel Protection of Privacy	Helps detect the presence of information commonly considered to be subject to the Protection of Privacy in Israel, including information like bank account numbers or national ID.
Japan Financial Data	Helps detect the presence of information commonly considered to be financial information in Japan, including information like credit card, account information, and debit card numbers.
Japan Personally Identifiable Information (PII) Data	Helps detect the presence of information commonly considered to be personally identifiable information (PII) in Japan, including information like driver's license and passport numbers.
Japan Protection of Personal Information	Helps detect the presence of information subject to Japan Protection of Personal

	Information, including data like resident registration numbers.
PCI Data Security Standard (PCI DSS)	Helps detect the presence of information subject to PCI Data Security Standard (PCI DSS), including information like credit card or debit card numbers.
Saudi Arabia - Anti-Cyber Crime Law	Helps detect the presence of information commonly considered to be subject to the Anti-Cyber Crime Law in Saudi Arabia, including international bank account numbers and SWIFT codes.
Saudi Arabia Financial Data	Helps detect the presence of information commonly considered to be financial data in Saudi Arabia, including international bank account numbers and SWIFT codes.
Saudi Arabia Personally Identifiable Information (PII) Data	Helps detect the presence of information commonly considered to be personally identifiable information (PII) in Saudi Arabia, like national ID number.
U.K. Access to Medical Reports Act	Helps detect the presence of information subject to United Kingdom Access to Medical Reports Act, including data like National Health Service numbers.
U.K. Data Protection Act	Helps detect the presence of information subject to United Kingdom Data Protection Act, including data like national insurance numbers.
U.K. Financial Data	Helps detect the presence of information commonly considered to be financial information in United Kingdom, including

	information like credit card, account information, and debit card numbers.
U.K. Personal Information Online Code of Practice (PIOCP)	Helps detect the presence of information subject to United Kingdom Personal Information Online Code of Practice, including data like health information.
U.K. Personally Identifiable Information (PII) Data	Helps detect the presence of information commonly considered to be personally identifiable information (PII) in United Kingdom, including information like driver's license and passport numbers.
U.K. Privacy and Electronic Communications Regulations	Helps detect the presence of information subject to United Kingdom Privacy and Electronic Communications Regulations, including data like financial information.
U.S. Federal Trade Commission (FTC) Consumer Rules	Helps detect the presence of information subject to U.S. Federal Trade Commission (FTC) Consumer Rules, including data like credit card numbers.
U.S. Financial Data	Helps detect the presence of information commonly considered to be financial information in United States, including information like credit card, account information, and debit card numbers.
U.S. Gramm-Leach-Bliley Act (GLBA)	Helps detect the presence of information subject to Gramm-Leach-Bliley Act (GLBA), including information like social security numbers or credit card numbers.
U.S. Health Insurance Act (HIPAA)	Helps detect the presence of information

	subject to United States Health Insurance Portability and Accountability Act (HIPAA),including data like social security numbers and health information.
U.S. Patriot Act	Helps detect the presence of information commonly subject to U.S. Patriot Act, including information like credit card numbers or tax identification numbers.
U.S. Personally Identifiable Information (PII) Data	Helps detect the presence of information commonly considered to be personally identifiable information (PII) in the United States, including information like social security numbers or driver's license numbers.
U.S. State Breach Notification Laws	Helps detect the presence of information subject to U.S. State Breach Notification Laws, including data like social security and credit card numbers.
U.S. State Social Security Number Confidentiality Laws	Helps detect the presence of information subject to U.S. State Social Security Number Confidentiality Laws, including data like social security numbers.

Data loss prevention

Create a DLP policy from a template

Sensitive information types inventory

Manage DLP policies

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-03*

You can view, change, or remove existing data loss prevention (DLP) policies in Microsoft Exchange Server 2013, using the Exchange Administration Center (EAC) or the Exchange Management Shell.

For additional management tasks related to DLP, see DLP procedures.

For more information about The Exchange Management Shell, see Exchange Management Shell.

What do you need to know before you begin?

- Estimated time to complete each procedure: 15-60 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Data loss prevention (DLP)" entry in the Messaging policy and compliance permissions topic.
- For any DLP policy, you can select one of three modes:
-
- **Enforce** Rules within the policy are evaluated for all messages and supported file types. Mail flow can be disrupted if data is detected that meets the conditions of the policy. All actions described within the policy are taken.
-
- **Test DLP policy with Policy Tips** Rules within the policy are evaluated for all messages and supported file types. Mail flow will not be disrupted if data is detected that meets the conditions of the policy. That is, messages are not blocked. If Policy Tips are configured, they are shown to users.
-
- **Test DLP policy without Policy Tips** Rules within the policy are evaluated for all messages and supported file types. Mail flow will not be disrupted if data is detected that meets the conditions of the policy. That is, messages are not blocked. If Policy Tips are configured, they are not shown to users.
- An individual rule within a DLP policy can have its own mode settings. When the mode of a policy is different than the mode of a rule within that policy, the rule setting has priority and will be evaluated according to its mode.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

View the details of an existing DLP policy

You may need to view the rules and actions of an existing DLP policy that you have already established for your organization. This can be useful if you experience unexpected mail flow issues or if your organization changes the way sensitive information needs to be monitored.

Use the EAC to view the details within an existing DLP policy

1. In the EAC, navigate to **Compliance management** > **Data loss prevention**.
2. Double-click one of the policies that appear in your list of policies, or highlight one item and click **Edit** ✎.
3. On the **Edit DLP policy** page, click **Rules**.

Tip:
You can create a DLP policy and leave it in a non-activated or disabled mode. In this mode, a policy is not enforced and you can change any predicates, actions, or values associated with its rules before you test or begin enforcing it.

Use the Shell to view the details within an existing DLP policy

This example returns information about the fictitious DLP policy named Employee Numbers. The command is piped to the **Format-List** cmdlet to display the detailed configuration of the specified DLP policy.

```
Get-DlpPolicy "Employee Numbers" | Format-List
```

For syntax and parameter information, see Get-DlpPolicy.

Change a DLP policy

You can change an existing DLP policy by modifying either the name of the policy or the rules that govern the effects of the policy. An example rule change might include adding custom disclaimer text to a message body and RMS protection for messages sent within a specific domain and that are detected to have sensitive information. If you are using DLP policy templates, keep in mind that these are only one of the features in Exchange 2013 that can help you design and apply a robust policy and compliance system for your messaging environment.

Use the EAC to change an existing DLP policy

1. In the EAC, navigate to **Compliance management** > **Data loss prevention**.
2. Double-click one of the template-based policies that appear in your list of policies or highlight one item and click **Edit** ✎.
3. On the **Edit DLP policy** page, click **Rules**.
4. To change an existing rule, highlight the rule and click **Edit** ✎.
5. To add a new blank rule that you can fully customize, click **New** +.
6. To add a rule about sender notification, blocking messages, or allowing overrides, click the arrow

next to the **New +** icon.

7. To remove a rule, highlight the rule and click **Delete** 🗑.
8. Click **Save** to finish modifying the policy and save your changes.

Use the Shell to change an existing DLP policy

You can specify the action and notification level of a policy using the Exchange Management Shell. This example sets the mode for a fictitious DLP policy named Employee Numbers so that the actions are not enforced and notification messages are not displayed.

```
Set-DlpPolicy "Employee Numbers" -Mode Audit
```

For syntax and parameter information, see Set-DlpPolicy.

Delete a DLP policy

You can permanently remove a DLP policy using the EAC. Once you've deleted a policy, it will no longer be enforced and none of the rules and actions will be saved.

Alternatively, you can set the operational state or mode of a policy to **Test DLP policy without Policy Tips**. This stops it from being enforced in your message environment, but preserves the detailed configuration settings of the policy itself. This can be useful if there is a possibility that you will need to enforce the policy again in the future.

Use the EAC to delete an existing DLP policy

1. In the EAC, navigate to **Compliance management** > **Data loss prevention**.
2. Select the policy you want to remove in your list of policies, and then click **Delete** 🗑.

Use the Shell to delete an existing DLP policy

This example removes the fictitious DLP policy named Employee Numbers.

```
Remove-DlpPolicy "Employee Numbers"
```

For syntax and parameter information, see Remove-DlpPolicy.

Data loss prevention

Policy Tips

Create a DLP policy from a template

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-07-31*

In Microsoft Exchange Server 2013, you can use data loss prevention (DLP) policy templates to help meet the messaging policy and compliance needs of your organization. These templates contain pre-built sets of rules that can help you manage message data that is associated with several common legal and regulatory requirements. To see a list of all the templates supplied by Microsoft, see DLP policy templates supplied in Exchange. Example DLP templates that are supplied can help you manage:

- Gramm-Leach-Bliley Act (GLBA) data
- Payment Card Industry Data Security Standard (PCI-DSS)
- United States Personally Identifiable Information (U.S. PII)

You can customize any of these DLP templates or use them as-is. DLP policy templates are built on top of transport rules that include new conditions or predicates and actions. DLP policies support the full range of traditional transport rules, and you can add the additional rules after a DLP policy has been established. For more information about policy templates, see DLP policy templates. To learn more about transport rule capabilities, see Transport rules. Once you have started enforcing a policy, you can learn about how to observe the results by reviewing the following topics:

Exchange 2013: DLP policy detection reports

Exchange Online: **Summary data reports for DLP policies**

Caution:

You should enable your DLP policies in test mode before running them in your production environment. During such tests, it is recommended that you configure sample user mailboxes and send test messages that invoke your test policies in order to confirm the results.

For additional management tasks related to creating a DLP policy from a template, see DLP procedures.

What do you need to know before you begin?

- Estimated time to complete: 30 minutes
- Ensure that Exchange 2013 is setup as described in Planning and deployment.
- Configure both administrator and user accounts within your organization and validate basic mail flow.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the “Data loss prevention (DLP)” entry in the Messaging policy and compliance permissions topic
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the EAC to configure a DLP policy from a template

1. In the EAC, navigate to **Compliance management** > **Data loss prevention**, and then click **Add +**
   .

Note:
You can also select this action if you click the arrow next to the **Add +** icon and select **New DLP policy from template** from the drop down menu.

2. On the **Create a new DLP policy from a template** page, complete the following fields:
   a. **Name** Add a name that will distinguish this policy from others.
   b. **Description** Add an optional description that summarizes this policy.
   c. **Choose a template** Select the appropriate template to begin creating a new policy.
   d. **More options** Select the mode or state. The new policy is not fully enabled until you specify that it should be. The default mode for a policy is test without notifications.
   e. Click **Save** to finish creating the policy.

Note:
In addition to the rules within a specific template, your organization may have additional expectations or company policies that apply to regulated data within your messaging environment. Exchange 2013 makes it easy for you to change the basic template in order to add actions so that your Exchange messaging environment complies with your own requirements.

You can modify policies by editing the rules within them once the policy has been saved in your Exchange 2013 environment. An example rule change might include making specific people exempt from a policy or sending a notice and blocking message delivery if a message is found to have sensitive content. For more information about editing policies and rules, see Manage DLP policies.

You have to navigate to the specific policy's rule set on the **Edit DLP policy** page and use the tools available on that page in order to change a DLP policy you have already created in Exchange 2013.

Some policies allow the addition of rules that invoke RMS for messages. You must have RMS configured on the Exchange server before adding the actions to make use of these types of rules.

For any of the DLP policies, you can change the rules, actions, exceptions, enforcement time period or whether other rules within the policy are enforced and you can add your own custom conditions for each.

For more information

Data loss prevention

Create a custom DLP policy

Messaging policy and compliance > Data loss prevention > DLP policy templates >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-09-26*

A custom data loss prevention (DLP) policy allows you to establish conditions, rules, and actions that can help meet the specific needs of your organization, and which may not be covered in one of the pre-existing DLP templates.

The rule conditions that are available to you in a single policy include all the traditional transport rules in addition to the sensitive information types presented in Sensitive information types inventory. For more information about transport rules in Exchange 2013, see Transport rules.

Caution:

You should enable your DLP policies in test mode before running them in your production environment. During such tests, it is recommended that you configure sample user mailboxes and send test messages that invoke your test policies in order to confirm the results.

For additional management tasks related to creating a custom DLP policy, see DLP procedures.

What do you need to know before you begin?

- Estimated time to complete: 60 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Data loss prevention (DLP)" entry in the Messaging policy and compliance permissions topic.
- In order to create a new custom DLP policy, you must follow the installation instructions for Exchange 2013. For more information about deployment, see Planning and deployment.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the EAC to create a custom DLP policy without any existing rules

1. In the EAC, navigate to **Compliance management** > **Data loss prevention**. Any existing policies

that you have configured are shown in a list.

2. Click the arrow that is beside the **Add +** icon, and select **New custom policy**.

Important:
If you click **Add +** icon instead of the arrow, you will create a new policy based on a template. For more information about using templates, see Create a DLP policy from a template.

3. On the **New custom policy** page, complete the following fields:
   a. **Name** Add a name that will distinguish this policy from others.
   b. **Description** Add an optional description that summarizes this policy.
   c. **Choose a state** Select the mode or state for this policy. The new policy is not fully enabled until you specify that it should be. The default mode for a policy is test without notifications.
4. Click **Save** to finish creating the new policy reference information. The policy is added to the list of all policies that you have configured, although there are not yet any rules or actions associated with this new custom policy.
5. Double-click the policy that you just created or select it and click **Edit** .
6. On the **Edit DLP policy** page, click **Rules**.

Click **Add +** to add a new blank rule. You can establish conditions using all the traditional transport rules in addition to the sensitive information types.

In order to avoid confusion, supply a unique name for each part of your policy or rule when you have the option to provide your own character string. There are several options additional options available to you:

   a. Click the arrow that is beside the **Add +** icon to add a rule about sender notification or allowing overrides.
   b. To remove a rule, highlight the rule and click **Delete** .
   c. Click **More options** ••• to add additional conditions and actions for this rule including time-bound limits of enforcement or effects on other rules in this policy.
7. Click **Save** to finish modifying the policy and save your changes.

DLP policy templates are one type of feature Microsoft Exchange that can help you design and apply a robust policy and compliance system for your messaging environment. For more information about compliance features, see Messaging policy and compliance.

Transport rules

Integrating sensitive information rules with transport rules

Define your own DLP templates and

information types

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-05-23*

You can develop data loss prevention (DLP) policy templates as XML files independent of Microsoft Exchange Server 2013 and then import them using the Exchange Administration Center or the Exchange management shell. This section describes the process and details of authoring and tuning DLP XML files for use within a DLP solution. You are not required to develop your own DLP XML files because the Exchange Administration Center provides a way for you to get started quickly with existing DLP policy templates and transport rules in order to scan messages.

Looking for management tasks related to DLP policy templates? See DLP procedures.

Note:

Exchange 2013: DLP is a premium feature that requires an Exchange Enterprise Client Access License (CAL). For more information about CALs and server licensing, see Exchange Server Licensing.
Exchange Online: DLP is a premium feature that requires an Exchange Online Plan 2 subscription. For more information, see Exchange Online Licensing.

Important:

It's beyond the scope of this documentation to recommend a business model or information about file packaging or deployment guidelines for the sensitive information rules or to discuss how such rules would be distributed. Furthermore, this documentation does not discuss protection mechanisms, such as encryption, for custom developed rules, nor does it discuss how such mechanism would be employed.

Extend the information types to meet your needs

The following sections describe concepts and the XML schema definition that you must understand in order to begin creating your own XML files for both DLP policy templates and sensitive information rule packages that can be imported into Exchange 2013 and used as DLP policies.

DLP in Microsoft Exchange helps you to apply organizational-specific policy to sensitive information. A key factor in the strength of a DLP solution is the ability to correctly identify confidential or sensitive information that may be unique to the organization, regulatory needs, geography, or other aspects of business. Although Microsoft has provided policy templates and sensitive information types within the product for you to get started, your unique business needs can require a custom data loss prevention solution. For this reason, Microsoft provides a way for you to create and import your own DLP policy templates or your own sensitive information definitions within classification rule packages. An accurate DLP solution relies on configuring the correct set of rules for the sensitive information detection engine that provide high degree of

protection while minimizing false positives and negatives.

Develop your own DLP policy templates

You can write your own DLP policy template XML file and import it. This approach to extending the DLP solution provided in Exchange will allow you to build DLP policies that closely match your DLP requirements.

Managing custom templates and their related policies is similar to managing the DLP policies that you create based on Microsoft-supplied templates. In a typical DLP policy lifecycle, you would do the following:

1. Create your own DLP policy template, a custom XML file. To learn more, see Developing DLP policy template files.
2. Import your custom template. To learn more, see Import a DLP policy from a file.
3. Create a DLP Policy based on your custom template. To learn more, see Create a DLP policy from a template.
4. Update your custom template by repeating steps 1 and 2.
5. Remove your custom template. To learn more, see Remove-DlpPolicyTemplate.

For more information about the XML schema definition and concepts related to developing your own templates, see Developing DLP policy template files.

Develop your own sensitive information types and matching logic in classification rule packages

You can write your own sensitive information definitions in a classification rule package, which is an XML file, and import it as part of your DLP solution. The sensitive information detection engine provides the deep content analysis capabilities for identifying sensitive information like credit card numbers, social security numbers, and company intellectual property. The engine is controlled by a configurable set of instructions, or rules, for scanning and analyzing the content. The rules are combined together into a classification rule package, an XML document that adheres to a standardized rules package XML schema definition. Here's how you can develop your own.

1. Create your own sensitive information types, a custom XML file. To learn more, see Developing sensitive information rule packages.
2. Import your sensitive information type. To learn more, see New-ClassificationRuleCollection.
3. Create custom template based on your information types. To learn more, see Developing sensitive information rule packages
4. Update your custom template by repeating steps 1 and 2.
5. Remove your custom template. To learn more, see Remove-ClassificationRuleCollection

For more information about the rule packages, see Developing sensitive information rule packages and Matching methods and techniques for rule packages.

Understanding rule types in rule packages

The rules within a rule package configure the process for detecting well-defined content characteristics; for example, rules for finding a driver's license number. Two main rule types are available: Entity and Affinity.

Entity rules are targeted toward well-defined (and oftentimes regulated) identifiers such as U.S. social security numbers. An Entity is represented by a collection of countable patterns. A pattern defines a collection of matches with an explicit primary match identifier. An example Entity is a driver's license.

Affinity rules are targeted toward a certain type of document such as a corporate financial statement. An Affinity is represented as a collection of independent evidences. Evidence is an aggregation of required matches within certain proximity. An example of an Affinity is the U.S. Sarbanes-Oxley Act.

Developing DLP policy template files

Data loss prevention > DLP policy templates > Define your own DLP templates and information types >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-07-16*

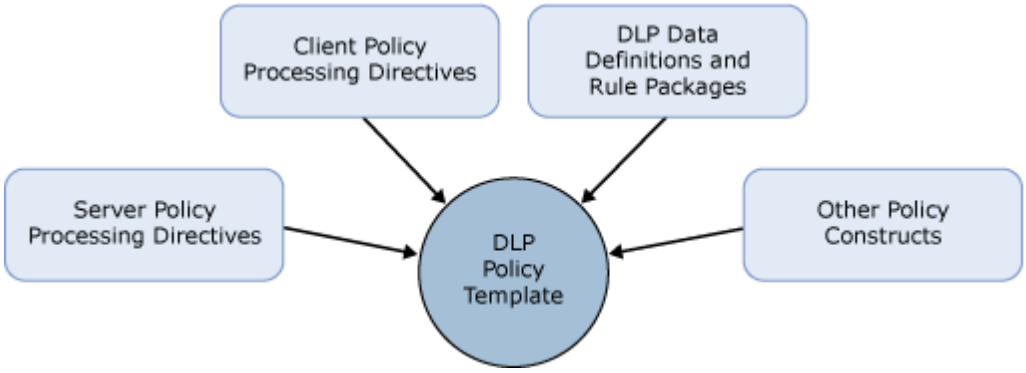
This overview explains the components of an XML schema definition for data loss prevention (DLP) policy template files and also provides an XML-format example policy file. It will be helpful to understand the overall DLP architecture and rule-development process before you begin. For more information, see Data loss prevention and Define your own DLP templates and information types.

In order to make data loss prevention solutions easy to adopt and manage, a conceptual model known as DLP policies and policy templates is introduced in Microsoft Exchange Server 2013. DLP policy templates provide a preliminary design for your intended DLP policy. In order to be valuable,

a DLP policy template must encapsulate all the directives and data objects that are required to meet a specific policy objective, such as a regulation or business need. The template is not environment-specific. It is simply a definition or model of a policy that can be provided as part of the product configuration or supplied by independent software vendors and partners. DLP policies on the other hand, are run-time instantiations of the templates that are specific to the deployment environment. Your existing messaging policy framework can incorporate DLP policies through the use of transport rules. Transport rules provide great flexibility in adapting and expressing the richness of your DLP solutions.

Policy template sources and structure

DLP policy templates are typically influenced from multiple sources such as server-based processing directives, client computer policies, or other policy constructs as shown in the following image:



Simple management operations are available for DLP policy templates though both the Exchange Management Shell and Internet-based interfaces, such as the Exchange Administration Center, which include Import, Export, Deletion and Query capabilities. A DLP policy is created by referencing a DLP policy template as part of the creation process. These referenced DLP policy templates may be references to ones installed in the system, which are stored in active directory domain services, or be provided as input directly from externally supplied policies.

DLP policy templates are represented as XML documents. A single XML schema is used for policies provided within Exchange and externally also. The conceptual structure of the XML document is represented in the table below, which shows the major elements. The set of policy component definitions help you achieve a specific policy objective such as a regulation or business need.

Structural Element	Meaning or Example
Publisher	Microsoft or Partner
Version	15.0.1.0
Policy Name	PCI-DSS
Description	The PCI-DSS DLP policy helps detect the presence

	of information subject to PCI Data Security Standard (PCI DSS), including information like credit card or debit card numbers. Use of this policy does not ensure compliance with any regulation. After your testing is complete, make the necessary configuration changes in Exchange so the transmission of information complies with your organization's policies. Examples include configuring TLS with known business partners or adding more restrictive transport rule actions, such as adding rights protection to messages that contain this type of data.
Metadata	Tags to describe the local regulation, country or region, keywords and more.
Set of policy constructs	1. Transport rule definitions, such as conditions and actions. 2. Email client behavior definitions that control client experience through interactive notifications. 3. Optionally, configuration references that need to be coordinated with client environment-specific settings.
Set of data classifications	1. Specifies classification entities or affinities. 2. Entities have count and confidence; affinities only have a confidence. 3. Comes with its own set of properties and classification schema.

Policy template format definition

DLP Policy templates are expressed as XML documents which adhere to the following schema. Note that the XML is case-sensitive. For instance, `dlpPolicyTemplates` will work, but `DlpPolicyTemplates` won't work.

```
<?xml version="1.0" encoding="UTF-8"?>
<dlpPolicyTemplates>
  <dlpPolicyTemplate id="F7C29AEC-A52D-4502-9670-
141424A83FAB" mode="Audit" state="Enabled"
version="15.0.2.0">
    <contentVersion>4</contentVersion>
    <publisherName>Microsoft</publisherName>
    <name>
      <localizedString lang="en">PCI-DSS</localizedString>
    </name>
    <description>
      <localizedString lang="en">Detects the presence of
information subject to Payment Card Industry Data Security
Standard (PCI-DSS) compliance requirements.</
localizedString>
    </description>
    <keywords></keywords>
    <ruleParameters></ruleParameters>
    <ruleParameters/>
    <policyCommands>
      <!-- The contents below are applied/executed as rules
directly in PS - -->
      <commandBlock>
        <![CDATA[ new-transportRule "PCI-DSS: Monitor
Payment Card Information Sent To Outside" -DlpPolicy "%%
DlpPolicyName%%" -SentToScope NotInOrganization -
SetAuditSeverity High -MessageContainsDataClassifications
@{Name="Credit Card Number"; MinCount="1" } -Comments
"Monitors payment card information sent to outside the
organization as part of the PCI-DSS DLP Policy."]]>
      </commandBlock>
      <commandBlock>
        <![CDATA[ new-transportRule "PCI-DSS: Monitor
Payment Card Information Sent To Within" -DlpPolicy "%%
DlpPolicyName%%" -Comments "Monitors payment card
information sent inside the organization as part of the
PCI-DSS DLP Policy." -SentToScope InOrganization -
SetAuditSeverity Low -MessageContainsDataClassifications
@{Name="Credit Card Number"; MinCount="1" } ]]>
```

```
        </commandBlock>
      </policyCommands>
      <policyCommandsResources></policyCommandsResources>
    </dlpPolicyTemplate>
</dlpPolicyTemplates>
```

If a parameter you include in your XML file for any element includes a space, the parameter has to be surrounded by double quotes or it will not work properly. In the example below, the parameter that follows `-SentToScope` is acceptable and does not include double quotes because it is one continuous string of characters without a space. However, the parameter provided for `–Comments` will not appear in the Exchange Administration Center because there are no double quotes and it includes spaces.

```
<CommandBlock><![CDATA[ new-transportRule "PCI-DSS: Monitor Payment Card Information Sent To Within" -DlpPolicy "PCI-DSS" -Comments Monitors payment card information sent inside the organization -SentToScope InOrganization -SetAuditSeverity Low -MessageContainsDataClassifications @{Name="Credit Card Number"; MinCount="1" } ]]> </CommandBlock>
```

localizedString Element

The template format offers the capability to localize strings in the template which may be presented to the end-user, for example as part of selecting which DLP policy templates are installed. The localizedString element can be used to supply multiple definitions for the Name and Description fields.

ruleParameters Node

This is an optional set of parameters that need to be supplied during the template instantiation phase when creating a DLP policy to map to deployment specific objects. For example an actual distribution group that is available in the deployment.

dlpPolicyTemplate Element

This is the root element for the DLP policy template and is required for every template. Available attributes are shown in the following table:

Attribute Name	Required?	Description
Version	Yes	The version number used in

		this DLP policy template document.
State	No	Optional default configuration for the state of the policy.
Mode	No	Optional default configuration for the mode of the policy.
Id	No	A GUID to uniquely identify this DLP policy template definition in the following format:"A29C69BF-4F98-47F1-9A99-5771DFD2C27F".

Child elements include the following sequence of elements.

Child Element	(minimum, maximum)	Description
PublisherName	(1, 1)	Meta data for the template's publisher
Name	(1, 1)	Localizable name for this template.
Description	(1, 1)	Localizable description for this template.
Keywords	(1, 1)	List of keywords that applies to this template. A template may have an empty list of keywords.
RuleParameters	(0, 1)	List of template parameters that are used in the policy definition.
PolicyCommands	(0, 1)	List of Transport rule definitions for this policy. This is an optional element.

DLP Policy Template: PolicyCommands

This part of the policy template contains the list of the Exchange Management Shell commands that are used to instantiate the policy definition. The import process will execute each of the commands as part of the instantiation process. Sample policy commands are provided here.

```
<PolicyCommands>
    <!-- The contents below are applied/executed as rules
directly in PS - -->
      <CommandBlock> <![CDATA[ new-transportRule "PCI-DSS:
Monitor Payment Card Information Sent To Outside" -
DlpPolicy "PCI-DSS" -SentToScope NotInOrganization -
SetAuditSeverity High -MessageContainsDataClassifications
@{Name="Credit Card Number"; MinCount="1" } -Comments
"Monitors payment card information sent to outside the
organization as part of the PCI-DSS DLP policy."]]></
CommandBlock>
      <CommandBlock><![CDATA[ new-transportRule "PCI-DSS:
Monitor Payment Card Information Sent To Within" -DlpPolicy
"PCI-DSS" -Comments "Monitors payment card information sent
inside the organization as part of the PCI-DSS DLP policy."
-SentToScope InOrganization -SetAuditSeverity Low -
MessageContainsDataClassifications @{Name="Credit Card
Number"; MinCount="1" } ]]> </CommandBlock>
  </PolicyCommands>
```

The format of the cmdlets is the standard Exchange Management Shell cmdlet syntax for the cmdlets used. The commands are executed in sequence. It is possible for each of the command nodes to contain a script block which would be composed of multiple commands. Below is example that illustrates how to embed classification rule pack inside of a dlp policy template, and installing the rule pack as part of the policy creation process. The classification rule pack is embedded in the policy template, and then passed as a parameter to the cmdlet in the template:

```
<CommandBlock>
  <![CDATA[
$rulePack = [system.Text.Encoding]::Unicode.GetBytes('<?xml
version="1.0" encoding="utf-16"?>
<rulePackage xmlns="http://schemas.microsoft.com/
office/2011/mce">
  <RulePack id="c3f021a3-c265-4dc2-b3a7-41a1800bf518">
```

```
    <Version major="1" minor="0" build="0" revision="0"/>
    <Publisher id="e17451d3-9648-4117-a0b1-493a6d5c73ad"/>
    <Details defaultLangCode="en-us">
      <LocalizedDetails langcode="en-us">
        <PublisherName>Contoso</PublisherName>

Developing sensitive information rule packages

Data loss prevention > DLP policy templates > Define your own DLP templates and information types >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-04-19*

The XML schema and guidance in this topic will help you get started creating your own basic data loss prevention (DLP) XML files that define your own sensitive information types in a classification rule package. After you have created a well-formed XML file, you can import it by using either the Exchange Administration Center or the Exchange management shell in order to help create a Microsoft Exchange Server 2013 DLP solution. An XML file that is a custom DLP policy template can contain the XML that is your classification rule package. For an overview about defining your own DLP templates as XML files, see Define your own DLP templates and information types.

Contents

Overview of the rule authoring process

The rule authoring process is made up of the following general steps.

1. Prepare a set of test documents representative of their target environment. Key characteristics to consider for the set of test documents include: A subset of the documents contain the entity or affinity for which the rule is being authored, and a subset of the documents do not contain the entity or affinity for which the rule is being authored.
2. Identify the rules that meet acceptance requirements (precision and recall) to identify qualifying content. This may require the development of multiple conditions within a rule, bound with Boolean logic, which together satisfy the minimum match requirements to identify target documents.
3. Establish the recommended confidence level for the rules based on the acceptance requirements (precision and recall). The recommended confidence element can be thought of as the default confidence level for the rule.
4. Validate the rules by instantiating a policy with them and monitoring the sample test content. Based on the results, adjust the rules, or the confidence level to maximize the detected content while minimizing false positives and negatives. Continue the cycle of validation and rule adjustments until a satisfactory level of content detection is reached for both positive and negative samples.

For information about the XML schema definition for policy template files, see Developing DLP policy template files.

Rule description

Two main Rule types can be authored for the DLP sensitive information detection engine: Entity and Affinity. The Rule type chosen is based on the type of processing logic that should be applied to the processing of the content as described in the previous sections. The rule definitions are configured in an XML document in the format described by the standardized Rules XSD. The rules describe both the type of content to match and the confidence level that the described match represents the target content. Confidence level specifies the probability for the Entity to be present if a Pattern is found in the content or the probability for the Affinity to be present if Evidence is found in the content.

Basic rule structure

The Rule definition is constructed from three main components:

1. **Entity** defines the matching and counting logic for that rule
2. **Affinity** defines the matching logic for the rule
3. **Localized Strings** localization for rule names and their descriptions

Three additional supporting elements are used that define the details of the processing and referenced within the main components: Keyword, Regex, and Function. By using references, a single definition of the supporting elements, like a social security number, can be used to in multiple Entity or Affinity rules. The basic rule structure in XML format can be seen as follows.

```
<?xml version="1.0" encoding="utf-16"?>

      </Resource>
    </LocalizedStrings>
  </Rules>
</RulePackage>
```

Entity rules

Entity Rules are targeted towards well defined identifiers, such as Social Security Number, and are represented by a collection of countable patterns. Entity Rules returns a count and the confidence level of a match, where Count is the total number of instances of the entity that were found and the Confidence Level is the probability that the given entity exists in the given document. Entity contains the "id" attribute as its unique identifier. The identifier is used for localization, versioning, and querying. The Entity id must be a GUID and should not be duplicated in other entities or affinities. It is referenced in the localized strings section.

Entity rules contains optional patternsProximity attribute (default = 300) which is used when applying Boolean logic to specify the adjacency of multiple patterns required to satisfy the match condition. Entity element contains 1 or more child Pattern elements, where each pattern is a distinct representation of the Entity like Credit Card Entity or Driver's License Entity. The Pattern element has a required attribute of confidenceLevel which represents the pattern's precision based on sample dataset. Pattern element can have three child elements:

1. IdMatch - This is required.
2. Match
3. Any

If any of the Pattern elements return "true," the Pattern is satisfied. The count for the Entity element equals the sum of all detected Pattern counts.

$$\text{Entity Count} = \sum_{n=1}^{k} (Pattern\ n = true)$$

where k is the number of Pattern elements for the Entity.

A Pattern element must have exactly one IdMatch element. IdMatch represents the identifier that the Pattern is to match, for example a credit card number or ITIN number. The Count for a pattern is the number of IdMatches matched with the Pattern element. IdMatch element anchors the proximity window for the Match elements.

Another optional sub-element of the Pattern element is the Match element which represents corroborative evidence that is required to be matched to support finding the IdMatch element. For example, the higher confidence rule may require that, in addition to finding a credit card number, additional artifacts exist in the document, within a proximity window of the credit card, like address and name. These additional artifacts would be represented through the Match element or Any element (these are described in detail in Matching Methods and Techniques section). Multiple Match elements can be included in a Pattern definition which can be included directly in the Pattern element or combined using the Any element to define matching semantics. It returns true if a match is found in the proximity window anchored around the IdMatch content. An optional attribute of minOccurs can be used to specify the minimum number of occurrences that need to be satisfied for a successful match.

Both the IdMatch and Match elements do not define the details of what content needs to be matched but instead reference it through the idRef attribute. This promotes reusability of definitions in multiple Pattern constructs.

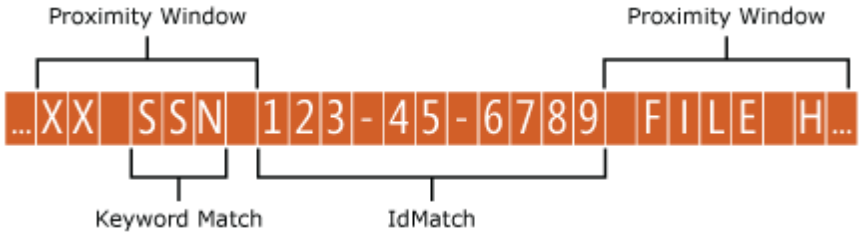
```
<Entity id="..." patternsProximity="300" >
    <Pattern confidenceLevel="85">
        <IdMatch idRef="FormattedSSN" />
        <Any minMatches="1">
            <Match idRef="SSNKeyword" />
            <Match idRef="USDate" />
            <Match idRef="USAddress" />
            <Match idRef="Name" />
        </Any>
    </Pattern>
    <Pattern confidenceLevel="65">
        <IdMatch idRef="UnformattedSSN" />
        <Match idRef="SSNKeyword" />
        <Any minMatches="1">
            <Match idRef="USDate" />
            <Match idRef="USAddress" />
            <Match idRef="Name" />
        </Any>
    </Pattern>
```

```
</Entity>
```

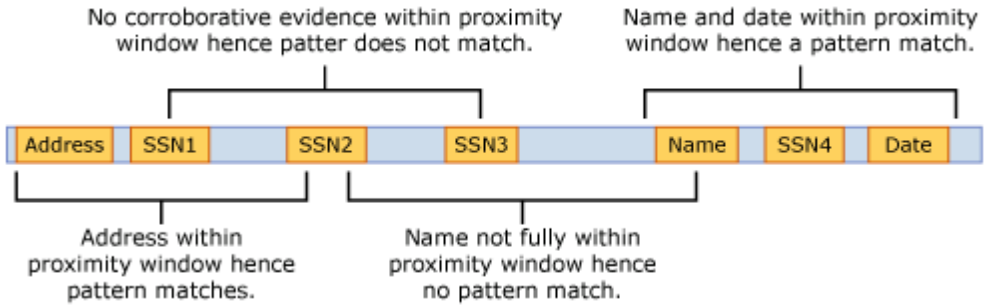
The Entity id element, represented in the previous XML by "…" should be a GUID and it is referenced in the Localized Strings section.

Entity pattern proximity window

Entity holds optional patternsProximity attribute value (integer, default = 300) used to find the Patterns. For each pattern the attribute value defines the distance (in Unicode characters) from the IdMatch location for all other Matches specified for that Pattern. The proximity window is anchored by the IdMatch location, with the window extending to the left and right of the IdMatch.



The example below illustrates how the proximity window affects the matching algorithm where the SSN IdMatch element requires at least 1 of address, name or date corroborating matches. Only SSN1 and SSN4 match because for SSN2 and SSN3, either no or only partial corroborating evidence is found within the proximity window.



Entity confidence level

Entity element's confidence level is the combination of all the satisfied Pattern's confidence levels. They are combined using the following equation:

$$Entity\ Confidence\ Level = 1 - \prod_{i=1}^{k}(1 - Confidence\ Level\ (Pattern\ i))$$

where k is the number of Pattern elements for the Entity and a Pattern that does not match returns a confidence level of 0.

Referring back to the example entity element structure code sample, if both patterns are matched, the entity's confidence level is 94.75% based on the following calculation:

$CL_{Entity} = 1-[(1-CL_{Pattern1}) \times (1-CL_{Pattern1})]$

$= 1-[(1-0.85) \times (1-0.65)]$

$= 1-(0.15 \times 0.35)$

$= 94.75\%$

Similarly, if only the second pattern matches, the Entity's confidence level is 65% based on the following calculation:

$CL_{Entity} = 1 - [(1 - CL_{Pattern1}) \text{ X } (1 - CL_{Pattern1})]$

$= 1 - [(1 - 0) \text{ X } (1 - 0.65)]$

$= 1 - (1 \text{ X } 0.35)$

$= 65\%$

These confidence values are assigned in the rules for individual patterns based on the set of test documents validated as part of the rule authoring process.

Affinity rules

Affinity rules are targeted towards content without well-defined identifiers, for example Sarbanes-Oxley or corporate financial content. For this content no single consistent identifier can be found and instead the analysis requires determining if a collection of evidence is present. Affinity rules do not return a count, instead they return if found and the associated confidence level. Affinity content is represented as a collection of independent evidences. Evidence is an aggregation of required matches within certain proximity. For Affinity rule, the proximity is defined by the evidencesProximity attribute (default is 600) and the minimum confidence level by the thresholdConfidenceLevel attribute.

Affinity rules contains the id attribute for its unique identifier that is used for localization, versioning and querying. Unlike Entity rules, because Affinity rules do not rely on well-defined identifiers, they do not contain the IdMatch element.

Each Affinity rule contains one or more child Evidence elements which define the evidence that is to be found and the level of confidence contributing to the Affinity rule. The affinity is not considered found if the resulting confidence level is below the threshold level. Each Evidence logically represents corroborative evidence for this "type" of document and the confidenceLevel attribute is the precision for that Evidence on the test dataset.

Evidence elements have one or more of Match or Any child elements. If all child Match and Any elements match, the Evidence is found and the confidence level is contributed to the rules confidence level calculation. The same description applies to the Match or Any elements for Affinity rules as for Entity rules.

```
<Affinity id="..."
          evidencesProximity="1000"
          thresholdConfidenceLevel="65">
    <Evidence confidenceLevel="40">
```

```
            <Any>
                <Match idRef="AssetsTerms" />
                <Match idRef="BalanceSheetTerms" />
                <Match idRef="ProfitAndLossTerms" />
            </Any>
        </Evidence>
        <Evidence confidenceLevel="40">
            <Any minMatches="2">
                <Match idRef="TaxTerms" />
                <Match idRef="DollarAmountTerms" />
                <Match idRef="SECTerms" />
                <Match idRef="SECFilingFormTerms" />
                <Match idRef="DollarTotalRegex" />
            </Any>
        </Evidence>
</Affinity>
```

Affinity proximity window

The proximity window for Affinity is calculated differently than for Entity patterns. Affinity proximity follows a sliding window model. The affinity proximity algorithm attempts to find the maximum number of matching evidences in the given window. Evidences in the proximity window must have a confidence level greater than the threshold defined for the Affinity rule to be found.

Affinity confidence level

Confidence level for the Affinity equals the combination of found Evidences within the proximity window for the Affinity rule. While similar to the confidence level of Entity rule, the key difference is the application of proximity window. Similar to the Entity rules, Affinity element's confidence level is the combination of all the satisfied Evidence confidence levels, but for Affinity rule it only represents the highest combination of Evidence elements found within the proximity window. The Evidence confidence levels are combined using the following equation:

$$Affinity\ Confidence\ Level = 1 - \prod_{i=1}^{k} (1 - Confidence\ Level\ (Evidence\ i))$$

where k is the number of Evidence elements for the Affinity matched within the proximity window.

Referring back to Figure 4 Example Affinity rule structure, if all three evidences are matched within the proximity sliding window, the affinity confidence level is 85.6% based on the calculation below.

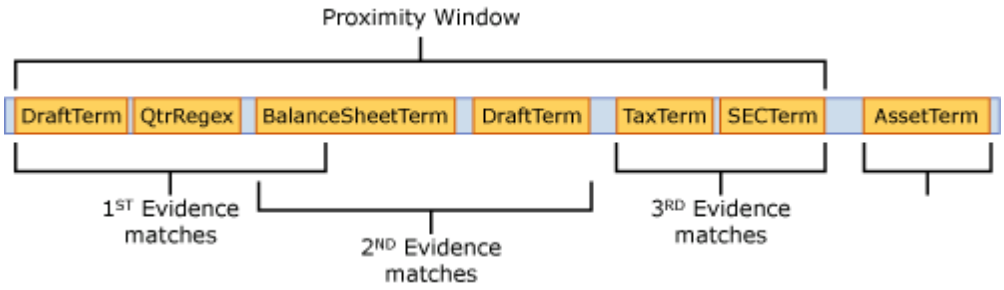
This exceeds the Affinity rule threshold of 65 which results in the rule matching.

$CL_{Affinity} = 1 - [(1 - CL_{Evidence\ 1}) X (1 - CL_{Evidence\ 2}) X (1 - CL_{Evidence\ 2})]$

$= 1 - [(1 - 0.6) X (1 - 0.4) X (1 - 0.4)]$

$= 1 - (0.4 X 0.6 X 0.6)$

$= 85.6\%$



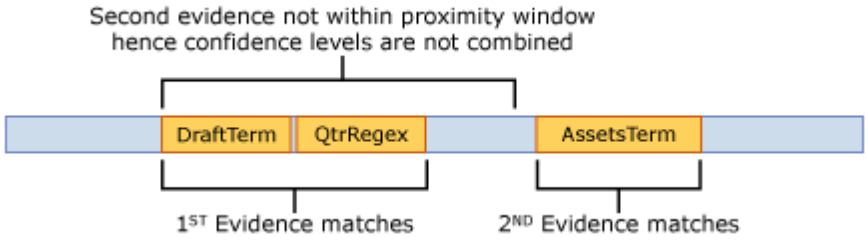
Using the same example rule definition, if only the first evidence matches because the second Evidence is outside of the proximity window, the highest Affinity confidence level is 60% based on the calculation below and the Affinity rule does not match since the threshold of 65 was not met.

$CL_{Affinity} = 1 - [(1 - CL_{Evidence\ 1}) X (1 - CL_{Evidence\ 2}) X (1 - CL_{Evidence\ 2})]$

$= 1 - [(1 - 0.6) X (1 - 0) X (1 - 0)]$

$= 1 - (0.4 X 1 X 1)$

$= 60\%$



Tuning confidence levels

One of the key aspects of the rule authoring process is the tuning of confidence levels for both Entity and Affinity rules. After creating the rule definitions, run the rule against the representative content and collect the accuracy data. Compare the returned results for each pattern or evidence against the expected results for the test documents.

Test Content	P_1 or E_1	P_2 or E_2	P_n or E_n	Returned Result	Expected Result
Content 1	+	-	-	+	+
Content 2	-	-	+	+	-
Content n	-	-	-	-	+

If the rules meet acceptance requirements, that is, the Pattern or Evidence has a confidence rate above an established threshold (e.g. 75%)—the match expression is complete and it can be moved to the next step.

If the Pattern or Evidence do not meet the confidence level, then re-author it (e.g. add more corroborative evidence; remove or add additional Patterns/Evidences; etc.) and repeat this step.

Next, tune the confidence level for each Pattern or Evidence in your rules based on the results from the previous step. For each Pattern or Evidence, aggregate the number of True Positives (TP), subset of the documents that contain the entity or affinity for which the rule is being authored and that resulted in a match and the number of False Positives (FP), a subset of documents that do not contain the entity or affinity for which the rule is being authored and that also returned a match. Set confidence level for each Pattern/Evidence using the following calculation:

Confidence Level = True Positives / (True Positives + False Positives)

Pattern or Evidence	True Positives	False Positives	Confidence Level
P_1or E_1	4	1	80%
P_2or E_2	2	2	50%
$P_n$or E_n	9	10	47%

Using local languages in your XML file

The rule schema supports storing of localized name and description for each of Entity and Affinity elements. Each Entity and Affinity element must contain a corresponding element in the LocalizedStrings section. To localize each element, include a Resource element as a child of the LocalizedStrings element to store name and descriptions for multiple locales for each element. The Resource element includes a required idRef attribute which matches the corresponding idRef attribute for each element that is being localized. The Locale child elements of the Resource element contains the localized name and descriptions for each specified locale.

```
<LocalizedStrings>
    <Resource idRef="guid">
```

```
        <Locale langcode="en-US" default="true">
            <Name>affinity name en-us</Name>
            <Description>
                affinity description en-us
            </Description>
        </Locale>
        <Locale langcode="de">
            <Name>affinity name de</Name>
            <Description>
                affinity description de
            </Description>
        </Locale>
    </Resource>
</LocalizedStrings>
```

Data loss prevention

Matching methods and techniques for rule packages

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-03-21*

This topic describes techniques for matching pattern and evidence elements within a data loss prevention (DLP) XML file that is designed to contain your own custom sensitive information type rule package. After you have created a well-formed XML file, you can import the file by using the Exchange admin center (EAC) or Exchange Management Shell in order to help create your Microsoft Exchange Server 2013 DLP solution. Before you can make use of the matching methods described here, you should already have a DLP XML file started. For more information about defining your own DLP templates and XML files, see Define your own DLP templates and information types.

The Match element

The `Match` element is used within the `Pattern` and `Evidence` elements to represents the underlying keyword, regex or function that is to be matched. The definition of the match itself is stored outside of the `Rule` element and is referenced through the `idRef` required attribute. Multiple `Match` elements can be included in a Pattern definition which can be included directly in the `Pattern` element or combined using the `Any` element to define matching semantics.

An optional attribute of `minoccurs` can be used to specify the minimum number of occurrences that need to be satisfied for a successful match of each of the `Match` elements.

```
<?xml version="1.0" encoding="utf-8"?>
<Rules packageId="...">
        ...
<Entity id="...">
  <Pattern confidenceLevel="85">
            <IdMatch idRef="FormattedSSN" />
            <Match idRef="USDate" minOccurs="2"/>
            <Match idRef="USAddress" />
```

```
  </Pattern>
</Entity>
        ...
         <Keyword id="FormattedSSN "> ... </Keyword>
         <Regex id=" USDate "> ... </Regex>
         <Regex id="USAddress"> ... </Regex>
        ...
</Rules>
```

Defining keyword-based matches

A common Rule requirement is to match based on well-known keyword string expressions. This is accomplished by using the `Keyword` element. The Keyword element has an "id" attribute that is used as a reference in the corresponding Entity or Affinity rules. A single Keyword element can be referenced in multiple Entity and Affinity rules.

The matching can be performed using either an exact match or word match based algorithms. Exact match uses a case-sensitive algorithm that searches for the text in the specified language. Word match applies a matching algorithm based on word boundaries. The terms to be matched can be included inline in the Keyword definition by using the Term sub-element or in an external dictionary file by specifying the Dictionary sub-element. This is configured by Term and Dictionary sub-elements.

Tip:

Use the constant based match style over regex for better efficiency and performance. Use regex matching only in cases where constant based matches are not sufficient and flexibility of regular expressions is required.

```
<Keyword id="Word_Example">
    <Group matchStyle="word">
        <Term>card verification</Term>
        <Term>cvn</Term>
        <Term>cid</Term>
        <Term>cvc2</Term>
        <Term>cvv2</Term>
        <Term>pin block</Term>
        <Term>security code</Term>
    </Group>
</Keyword>
...
<Keyword id="String_Example">
```

```
    <Group matchStyle="string">
        <Term>card</Term>
        <Term>pin</Term>
        <Term>security</Term>
    </Group>
</Keyword>
```

Defining regular expression based matches

Another common method of matching is based on regular expressions. The flexibility of regular expression matching makes this a common choice for implementing matches for data such as driver's license numbers, addresses. Common regular expression syntax is used to define the regex patterns. The table here provides examples of some of the most common regular expression tokens available.

Tip:
Use the constant based match style over regex for better efficiency and performance. Use regex matching only in cases where constant based matches are not sufficient and flexibility of regular expressions is required.

Symbol	Meaning
c	Match the literal character c once, unless it is one of the special characters.
^	Match the beginning of a line.
.	Match any character that isn't a new line.
$	Match the end of a line.
|	Logical OR between expressions.
()	Group sub-expressions.
[]	Define a character class.
*	Match the preceding expression zero or more times.
+	Match the preceding expression one or more times.

?	Match the preceding expression zero or one time.
{*n*}	Match the preceding expression *n* times.
{*n*,}	Match the preceding expression at least *n* times.
{*n*, *m*}	Match the preceding expression at least *n* times and at most *m* times.
\d	Match a digit.
\D	Match a character that is not a digit.
\w	Match an alpha character, including the underscore.
\W	Match a character that is not an alpha character.
\s	Match a whitespace character (any of \t, \n, \r, or \f).
\S	Match a non-whitespace character.
\t	Tab.
\n	New line.
\r	Carriage return.
\f	Form feed.
m	Escape *m*, where *m* is one of the meta characters described above: ^, ., $, |, (), [], *, +, ?, \, or /.

The Regex element has an "id" attribute that is used as a reference in the corresponding Entity or Affinity rules. A single Regex element can be referenced in multiple Entity and Affinity rules. The Regex expression is defined as the value of the Regex element.

```
<Regex id="CCRegex">
     \bcc\#\s|\bcc\#\:\s
</Regex>
...
<Regex id="ItinFormatted">
    (?:^|[\s\,\:])(?:9\d{2})[- ](?:[78]\d[-
     ]\d{4})(?:$|[\s\,]|\.\s)
</Regex>
...
<Regex id="NorthCarolinaDriversLicenseNumber">
    (^|\s|\:)(\d{1,8})($|\s|\.\s)
</Regex>
```

Combining multiple match elements

A common technique to increase the matching confidence is to define semantics between multiple Match elements, for example that one or more of the matches need to occur. The Any element allows the definition of the logic based between multiple matches. The Any element can be used as sub-element in the Pattern element. It contains one or more Match children elements and defines the logic of matches between them. See below for XML code examples for the Any elements with all matches, “not” logic, and exact match count.

Optional minMatches attribute can be used (default = 1) to define the minimum number of Match elements that must be met to satisfy a match. Similarly, optional maxMatches attribute can be used (default = number of children Match elements) to define the maximum number of Match elements that must be met to satisfy a match. These conditions are combined using logical operators based on the usage of the minMatches and maxMatches attributes, allowing following semantics:

- Matching all children Match elements

Not matching any children Match elements

Matching an exact subset of any children Match elements

```
<Any minMatches="3" maxMatches="3">
    <Match idRef="USDate" />
    <Match idRef="USAddress" />
    <Match idRef="Name" />
</Any>

<Any maxMatches="0">
    <Match idRef="USDate" />
    <Match idRef="USAddress" />
```

```
    <Match idRef="Name" />
</Any>

<Any minMatches="1" maxMatches="1">
    <Match idRef="USDate" />
    <Match idRef="USAddress" />
    <Match idRef="Name" />
</Any>
```

Increasing confidence level with more evidence

For entity base rules, another option of increasing confidence is to define multiple Pattern elements, each with increasing number of corroborative evidence. This is achieved by using minMatches and maxMatches for Any element to create independent patterns with increasing confidence level based on increasing number of corroborative evidence. For example:

- if one piece of corroborative evidence is found: confidence level is 65%
- if two pieces: confidence level is 75%
- if three pieces: confidence level is 85%

```
<Entity id="..." patternsProximity="300" >
    <Pattern confidenceLevel="65">
        <IdMatch idRef="UnformattedSSN" />
        <Any maxMatches="1">
            <Match idRef="USDate" />
            <Match idRef="USAddress" />
            <Match idRef="Name" />
        </Any>
    </Pattern>
    <Pattern confidenceLevel="75">
        <IdMatch idRef="UnformattedSSN" />
        <Any minMatches="2" maxMatches="2">
            <Match idRef="USDate" />
            <Match idRef="USAddress" />
            <Match idRef="Name" />
        </Any>
    </Pattern>
    <Pattern confidenceLevel="85">
        <IdMatch idRef="UnformattedSSN" />
        <Any minMatches="3">
            <Match idRef="USDate" />
```

```
            <Match idRef="USAddress" />
            <Match idRef="Name" />
        </Any>
    </Pattern>
</Entity>
```

Example: US Social Security rule

This section includes an introduction description for authoring of a rule matching a US Social Security number. First, start with a description of how we identify content that contains social security number. A Social Security Number is found if:

1. Regex matches a formatted SSN (and it's in the valid SSN range)
2. Corroborative Evidence one of the following must occur nearby:
   a. Keyword match {Social Security, Soc Sec, SSN, SSNS, SSN#, SS#, SSID}
   b. Text representing a US address
   c. Text representing a date
   d. Text representing a name

Next, translate the description into the Rule schema representation:

```
<Entity id="a44669fe-0d48-453d-a9b1-2cc83f2cba77"
         patternsProximity="300"
RecommendedConfidence="85">
    <Pattern confidenceLevel="85">
      <IdMatch idRef="FormattedSSN" />
      <Any minMatches="1">
          <Match idRef="SSNKeywords" />
          <Match idRef="USDate" />
          <Match idRef="USAddress" />
          <Match idRef="Name" />
      </Any>
    </Pattern>
</Entity>
```

Data loss prevention

Define your own DLP templates and information types

Import a DLP policy from a file

Export a DLP policy from Exchange 2013

Messaging policy and compliance > Data loss prevention > DLP policy templates >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-08-10*

You can view or change the details within your DLP policies without using the Exchange admin center (EAC) or Exchange Management Shell cmdlets by exporting the policies, saving them as an XML file, and modifying that XML file. Typically you would then import the XML file back into Exchange. In this way, policies can be edited independent of Exchange. However, they must meet specific format requirements, also referred to as XML schema, in order to work correctly.

Caution:

When you export DLP policies by using the procedure described here, those policies are no longer available to Exchange and will not help you scan messages. There is no ability to copy the policy information while leaving it in-place within Exchange.

For additional management tasks related to DLP, see Manage DLP policies.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Data loss prevention (DLP)" entry in the Messaging policy and compliance permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

The EAC doesn't provide a way to export DLP policies or templates to an external file. Use the Exchange Management Shell to perform this task.

Use the Shell to export a DLP policy

exCollapse

This example exports all DLP policies and associated transport rules along with their attributes to an XML file in the path C:\My Documents\exportedRules.xml. Exporting a DLP policy collection removes all existing DLP policies that are defined in your organization. This isn't the same as copying your polices into a file, which implies that they will still be active and filtering messages. After you export the DLP data using the cmdlet provided here, the DLP policies are no longer available to Exchange and will not help you scan messages. Make sure that you have a backup of your current DLP policy collection before you export and modify your current DLP policies. One way to achieve this is to export and then immediately import the same XML file.

1. Open the Exchange Management Shell.
2. Type `Get-ClassificationRuleCollection`, and your organization's rules should display on screen. If you haven't created any rules of your own, you'll see the default, out-of-box rules, labeled "Microsoft Rule Package."
3. Store that in a variable by typing `$ruleCollections = Get-ClassificationRuleCollection`.
4. Now make a formatted XML file with all that data by typing `Set-Content -path "C:\My Documents\exportedRules.xml" -Encoding Byte -Value $ruleCollections.SerializedClassificationRuleCollection`.

You can now edit the XML file to adjust the policies as needed. For details on importing policies back into Exchange, see Import a DLP policy from a file.

How do you know this worked?

exCollapse

To verify that you have successfully exported your DLP policies, do the following:

1. In the EAC, go to **Compliance** > **Data Loss Prevention** and observe the listed DLP policies in the center window.
2. You have successfully exported your DLP policies if there are no items listed in the policy summary view in the center window.

Import a DLP policy from a file

Import a DLP policy from a file

Messaging policy and compliance > Data loss prevention > DLP policy templates >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-03*

You can manage sensitive information through DLP policies by importing a file that contains policy

information settings. Policies can be developed independent of Exchange as XML files. However, they must meet specific format requirements in order to work correctly. Alternatively, policies that are exported from a previous version of Exchange can be imported into Microsoft Exchange Server 2013.

Caution:

You should enable your DLP policies in test mode before running them in your production environment. During such tests, it is recommended that you configure sample user mailboxes and send test messages that invoke your test policies in order to confirm the results.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Data loss prevention (DLP)" entry in the Messaging policy and compliance permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to import a DLP policy from a file

Use the following procedure to import a DLP policy from a file. In order to avoid confusion, supply a unique name for each part of your policy or rule when you have the option to provide your own name.

1. In the EAC, navigate to **Compliance management** > **Data loss prevention**.
2. Click the arrow that is next to the **Add +** icon, then click **Import policy**.
3. On the **Import policy** page, complete the following fields:
   a. **Select the file to import** Add the name of the policy file you want to install.
   b. **Name** Add a name that will distinguish this policy from others.
   c. **Description** Optionally, add a description that summarizes this policy.
   d. **More options** Select the mode or state for this policy. The new policy is not fully enabled until you specify that it should be. The default mode for a policy is test without notifications.
   e. Click **Next** to validate and import the policy.

Use the Shell to import a DLP policy from a file

This example imports a DLP policy file in the file C:\My Documents\DLP Backup.xml. Importing a

DLP policy collection from an XML file removes or overwrites all pre-existing DLP policies that were defined in your organization. Make sure that you have a backup of your current DLP policy collection before you import and overwrite your current DLP policies.

```
Import-DlpPolicyCollection -FileData ([Byte[]]$(Get-Content
-Path " C:\My Documents\DLP Backup.xml " -Encoding Byte -
ReadCount 0))
```

Data loss prevention

Policy templates from Microsoft partners

Messaging policy and compliance > Data loss prevention > DLP policy templates >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-01-31*

The data loss prevention (DLP) features can help you identify and monitor many categories of sensitive information. As you configure your DLP polices, you have the option to import a file from a source outside Microsoft Exchange to use as a DLP policy template. Microsoft partner companies can develop and distribute these types of templates. This topic will be updated with a link to help you find these companies once they are available.

DLP policy template files that can be imported are XML documents that contain instructions for scanning and analyzing message data. These templates can contain new sensitive information definitions in classification rule packages, or they can utilize rule packages that exist within Exchange already. The XML documents must adhere to a Microsoft-defined XML schema definition. For more information about the schema definition, see Define your own DLP templates and information types.

Policy Tips

Exchange Server 2013 > Messaging policy and compliance > Data loss prevention >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-02-21*

You can help to prevent your organization's Microsoft Outlook, Outlook Web App (OWA), and OWA for Devices email users from inappropriately sending sensitive information by creating data loss prevention (DLP) policies that include *Policy Tip* notification messages. Similar to MailTips that were introduced in Microsoft Exchange Server 2010, Policy Tip notification messages are displayed to users in Outlook while they are composing an email message. Policy Tip notification messages only show up if something about the sender's email message seems to violate a DLP policy that you have in place and that policy includes a rule to notify the sender when the conditions that you establish are met. For more general information about data loss prevention, see Data loss prevention.

In order to show Policy Tips to your email senders, your rules must include the **Notify the sender with a Policy Tip** action. You can add this in the rules editor from the Exchange Administration Center. For more information, see Manage policy tips.

The transport rule agent that enforces DLP policies does not differentiate between email message attachments, body text, or subject lines while evaluating messages and the conditions within your policies. For example, if a user creates an email message that includes a credit card number in the body of the message and then attempts to address the message to a recipient outside your organization, then a Policy Tip notification message can be shown to that user in Outlook or Outlook Web App reminding them of your enterprise's expectations for such information. However, this type of notification will only show up if you have configured a DLP policy that restricts the example actions described; in this case adding an external email alias to the header of a message with credit card data. There is a great variety of conditions, actions, and exceptions you can choose from while creating DLP policies. This variety allows you to tailor your data loss prevention efforts in a way that meets your specific organization's needs.

Any time you use either the notify sender action or an override action within a rule, we recommend that you also include the condition that the message was sent from within your organization. You can do this by using the policy rules editor to add the following condition: **The sender is located...** > **inside the organization**. Learn more about changing existing DLP policies at Manage DLP policies. This is a best practice recommendation because the notify sender action is applied as part of your company's message creation experience. The senders referred to by the action are the authors of messages within your company. The user interaction presented by Policy Tips cannot be acted upon by your users for incoming messages and will be ignored when the sender is located outside your organization. You can apply DLP policies to scan incoming messages and take a variety of actions, but when you do this, don't add the notify sender action.

If email senders in your organization who are in the act of composing a message are made aware of your organizational expectations and standards in real time through Policy Tip notifications, then they are less likely to violate standards that your organization wants to enforce.

Note:

- **Exchange Online:** DLP is a premium feature that requires an Exchange Online Plan 2 subscription. For more information, see Exchange Online Licensing.
- **Exchange 2013:** DLP is a premium feature that requires an Exchange Enterprise Client Access License (CAL). For more information about CALs and server licensing, see Exchange Server Licensing.
- If your organization is using Exchange 2013 SP1 or Exchange Online, Policy Tips are available to people sending mail from Outlook 2013, Outlook Web App, or OWA for Devices. However, if your organization is currently using Exchange 2013, Policy Tips are only available to people sending email from Outlook 2013.

Default text for Policy Tips and rule options

You have a range of possible options when you add sender notification rules to DLP policies. When you add a rule to notify the sender by using the **Notify the sender with a Policy Tip** action within a DLP policy, you can choose how restrictive to be. The notification options in the following table are available. For general information about editing policies, see Manage DLP policies. For specific information about creating Policy Tips, see Manage policy tips.

Notification rule	Meaning	Default Policy Tip notification message that Outlook users will see
Notify only	Similar to MailTips, this causes an informative Policy Tip notification message about a policy violation. A sender can prevent this type of tip from showing up by using a Policy Tip options dialog box that can be accessed in Outlook.	This message may contain sensitive content. All recipients must be authorized to receive this content.
Reject message	The message will not be delivered until the condition is no longer present. The sender	This message may contain sensitive content. Your organization won't allow this

	is provided with an option to indicate that their email message does not contain sensitive content. This is also known as a false-positive override. If the sender indicates this, then Outlook will allow the message to leave the outbox so that the user's report may be audited, but Exchange will block the message from being sent.	message to be sent until that content is removed.
Reject unless false positive override	The result with this notification rule is similar to the **Reject message** notification rule. However, if you select this then Exchange will allow the message to be sent to the intended recipient, instead of blocking the message.	**Before the sender selects an option to override:** This message may contain sensitive content. Your organization won't allow this message to be sent until that content is removed. **After the sender selects an option override:** Your feedback will be submitted to your administrator when the message is sent.
Reject unless silent override	The message will not be delivered until the condition is no longer present or the sender indicates an override. The sender is provided with an option to indicate that they wish to override the policy.	**Before the sender selects an option to override:** This message may contain sensitive content. Your organization won't allow this message to be sent until that content is removed.

		After the sender selects an option override: You have overridden your organization's policy for sensitive content in this message. Your action will be audited by your organization.
Reject unless explicit override	The result with this notification rule is similar to the **Reject unless silent override** notification rule, except that in this case when the sender attempts to override the policy, they are required to provide a justification for overriding the policy.	**Before the sender selects an option to override:** This message may contain sensitive content. Your organization won't allow this message to be sent until that content is removed. **After the sender selects an option override:** You have overridden your organization's policy for sensitive content in this message. Your action will be audited by your organization.

Create your own Policy Tip notification messages

You can customize the text of a Policy Tip notification that email senders see in their email program. If you do this, keep in mind that your custom Policy Tip notification text will not appear unless you also configure a DLP policy with a rule that will cause the customized text to appear. For procedures that explain how to create your own Policy Tips, see Manage policy tips. The custom text that you create can replace the default text shown in the column of the table above that is labeled "Default Policy Tip notification message".

When you work in the Policy Tip setting editor—not the rules editor—the following four actions can be configured with custom text. As stated previously in this topic, in order for any of your custom text to appear, a DLP policy rule must include the **Notify the sender with a Policy Tip** action. Add the action to a rule by using the DLP rules editor.

Policy Tip Notification Action	Meaning

Notify the sender	Your text only appears when a **Notify the sender, but allow them to send** action is initiated. This type of action can be configured in the DLP rules editor.
Allow the sender to override	Your text only appears when the following actions are initiated: **Block the message unless it's a false positive**, **Block the message, but allow the sender to override and send**. These types of actions can be configured in the DLP rules editor.
Block the message	Your text only appears when a **Block the message** action is initiated. This type of action can be configured in the DLP rules editor.
Link to compliance URL	Your text only appears when a **Block the message, but allow the sender to override with a business justification and send** action is initiated. This type of action can be configured in the DLP rules editor.

Manage policy tips

Manage policy tips

Messaging policy and compliance > Data loss prevention > Policy Tips >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-02-21*

Policy Tips are informative notices that are displayed to email senders while they're composing a

message. The purpose of the Policy Tip is to educate users that they might be violating the business practices or policies that you are enforcing with the data loss prevention (DLP) policies that you have established. The following procedures will help you begin using Policy Tips. For an overview about working with Policy Tips, see Policy Tips.

What do you need to know before you begin?

- Estimated time to complete each procedure: 30 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Data loss prevention (DLP)" entry in the Messaging policy and compliance permissions topic.
- Policy Tips will only show up for email senders when the following conditions are met:
  1. Sender's message client program is Microsoft Outlook 2013. If your organization has deployed Exchange 2013 SP1 or is using Exchange Online, Policy Tips also show up in Outlook Web App and OWA for Devices.
  2. A transport rule exists that invokes Policy Tip notifications. You can create such a transport rule by configuring a DLP policy that includes the action **Notify the sender with a Policy Tip**.
  3. The content of a message header, message body, or message attachment that is scanned by your transport agent meets the conditions established within the DLP policies or rules that also include Policy Tip notification rules. Put another way, the Policy Tip only shows up for end-users if they do something that causes the associated rule to take action.
- The default Policy Tip notification text that is built into the system will be shown if you don't use the Policy Tip settings feature to customize your Policy Tip text. To learn more about the default text, see Policy Tips.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Create or modify a notify-only Policy Tip

This procedure results in an informational Policy Tip being shown to an email sender when the conditions of a specific rule are met. In Microsoft Outlook, the sender can prevent this tip from showing up by using a Policy Tip options dialog box. To configure custom Policy Tip text, see Create custom Policy Tip notification text.

Use the EAC to configure notify-only Policy Tips

1. In the EAC, go to **Compliance management** > **Data loss prevention**.
2. Double-click one of the policies that appear in your list of policies or highlight one item and

select **Edit** ✎.

3. On the **Edit DLP policy** page, select **Rules**.
4. To add Policy Tips to an existing rule, highlight the rule and select **Edit** ✎.

To add a new blank rule that you can fully customize, select **Add +** and then select **Create a new rule** .

5. In **Apply this rule if**, select, **The message contains sensitive information**. This condition is required.
6. Select **+**, select the sensitive information types, select **Add**, select **OK**, and then select **OK**.
7. In the **Do the following** box, select **Notify the sender with a Policy Tip**, and select an option in the **Choose whether the message is blocked or can be sent** drop-down list, and then select **OK**.
8. If you want to add additional conditions or actions, at the bottom of the window, select **More options**.

Note:

Only the following conditions can be used:

- **The recipient is**
- **The recipient is located**
- **The sender is**
- **The sender is a member of**
- **The sender is located**

The following actions can't be used:

- **Reject the message and include an explanation**
- **Reject the message with the enhanced status code of**
- **Delete the message without notifying anyone**

1. In the **Choose a mode for this rule** list, select whether you want the rule to be enforced. We recommend testing the rule first.
2. Select **Save** to finish modifying the rule and save your changes.

How do you know this worked?

To verify that you have successfully created a Policy Tip that will only notify a sender, do the following:

1. In the EAC, go to **Compliance management** > **Data loss prevention**.
2. Select the policy that you expect to contain a notification message.
3. Select **Edit** ✎ and then select **Rules**.
4. Select the specific rule that you expect to contain a notification message.
5. Confirm that your **Notify the sender** action appears in the lower portion of the rule summary.

Create or modify a block-message Policy Tip

This procedure results in a Policy Tip being shown to an email sender that indicates a message is rejected and it will not be delivered until the problematic condition is no longer present. The sender is provided with an option to indicate that their email message does not contain the

problematic condition. This is also known as a false-positive override. If the sender indicates this, then the message can leave the outbox and the user's report may be audited. However, Exchange will block the message from being sent. To configure custom Policy Tip text, see Create custom Policy Tip notification text.

Use the EAC to configure block-message Policy Tips

1. In the EAC, go to **Compliance management** > **Data loss prevention**.
2. Double-click one of the policies that appear in your list of policies or highlight one item and select **Edit** ✎.
3. On the **Edit DLP policy** page, select **Rules**.
4. To add Policy Tips to an existing rule, highlight the rule and select **Edit** ✎.
5. To add a new blank rule that you can fully customize, select **Add +**.
6. To add an action that will reveal a Policy Tip, select **More options...** and then select the **Add action** button.
7. From the drop down list, select **Notify the sender with a Policy Tip** and then select **Block the message**.
8. Select **OK**, then select **Save** to finish modifying the rule and save your changes.

How do you know this worked?

To verify that you have successfully created a reject message Policy Tip, do the following:

1. In the EAC, go to **Compliance management** > **Data loss prevention**.
2. Select one time to highlight the policy that you expect to contain a notification message.
3. Select **Edit** ✎ and then select **Rules**.
4. Select one time to highlight the specific rule that you expect to contain a notification message.
5. Confirm that your **Notify the sender that the message can't be sent** action appears in the lower portion of the rule summary.

Create or modify a block-unless-override Policy Tip

There are four options for Policy Tips that can reject messages or prevent messages from leaving the sender's outbox. To learn more about these options, see Policy Tips.

Use the EAC to configure block-unless override Policy Tips

1. In the EAC, go to **Compliance management** > **Data loss prevention**.
2. Double-select one of the policies that appear in your list of policies or highlight one item and select **Edit** ✎.
3. On the **edit DLP policy** page, select **Rules**.
4. To add Policy Tips to an existing rule, highlight the rule and select **Edit** ✎.

To add a new blank rule that you can fully customize, select **Add +** and then select **More options...**

.

5. To add the action that will reveal a Policy Tip, Select the **Add action** button.
6. From the drop down list, select **Notify the sender with a Policy Tip** and then select **Block the message, but allow the sender to override and send**.

7. Select **OK**, then select **Save** to finish modifying the rule and save your changes.

How do you know this worked?

To verify that you have successfully created a reject unless override Policy Tip, do the following:

1. In the EAC, go to **Compliance management** > **Data loss prevention**.
2. Select one time to highlight the policy that you expect to contain a notification message.
3. Select **Edit** and then select **Rules**.
4. Select one time to highlight the specific rule that you expect to contain a notification message.
5. Confirm that your **Block the message, but allow the sender to override and send** action appears in the lower portion of the rule summary.

Create custom Policy Tip notification text

This optional procedure will help you to customize the Policy Tip notification text that email senders see in their email program. If you do this, your custom Policy Tip notification text will not appear unless you also configure a DLP policy rule with an action that will cause the notification to appear. Keep in mind that there are default system Policy Tip notifications that can be shown if you do not customize your Policy Tip notification text. To learn more about the default text, see Policy Tips.

Use the EAC to create and manage custom Policy Tip notification text

1. In the EAC, go to **Compliance management** > **Data loss prevention**.
2. Select **Policy Tip settings**.
3. To add a new Policy Tip with your own customized message, select **Add +**. For more information about the action choices available, see Policy Tips.

To modify an existing Policy Tip, highlight the tip and select **Edit**.

To delete an existing Policy Tip, highlight it and select **Delete** and then confirm your action.

4. Select **Save** to finish modifying the Policy Tip and save your changes.
5. Select **Close** to finish managing your Policy Tips and save your changes.

Use the Shell to create custom Policy Tip notification text

The following example creates a new English-language Policy Tip that will block a message from being sent. The text of this custom Policy Tip is changed to the following value: "This message appears to contain restricted content and will not be delivered."

```
New-PolicyTipConfig -Name en\Reject -Value "This message appears to contain restricted content and will not be delivered."
```

For more information about DLP cmdlets, see Policy and compliance cmdlets.

Use the Shell to modify custom Policy Tip notification text

The following example modifies an existing English-language, notify-only Policy Tip. The text of

this custom Policy Tip is changed to "Sending bank account numbers in email is not recommended."

```
Set-PolicyTipConfig en\NotifyOnly "Sending bank account numbers in email is not recommended."
```

For more information about DLP cmdlets, see Policy and compliance cmdlets.

How do you know this worked?

To verify that you have successfully created custom Policy Tip text, do the following:
1. In the EAC, go to **Compliance management** > **Data loss prevention**.
2. Select **Policy Tip settings** .
3. Select **Refresh** .
4. Confirm that your action, locale and text for that locale appear in the list.

Document Fingerprinting

Exchange Server 2013 > Messaging policy and compliance > Data loss prevention >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-02-22*

Information workers in your organization handle many kinds of sensitive information during a typical day. *Document Fingerprinting* makes it easier for you to protect this information by identifying standard forms that are used throughout your organization. This topic describes the concepts behind Document Fingerprinting. If you'd like to learn how to create a document fingerprint, see Protect form data with document fingerprinting.

Basic scenario for Document Fingerprinting

Document Fingerprinting is a Data Loss Prevention (DLP) feature that converts a standard form into a sensitive information type, which you can use to define transport rules and DLP policies. For example, you can create a document fingerprint based on a blank patent template and then create

a DLP policy that detects and blocks all outgoing patent templates with sensitive content filled in. Optionally, you can set up Policy Tips to notify senders that they might be sending sensitive information, and the sender should verify that the recipients are qualified to receive the patents. This process works with any text-based forms used in your organization. Additional examples of forms that you can upload include:

- Government forms
- Health Insurance Portability and Accountability Act (HIPAA) compliance forms
- Employee information forms for Human Resources departments
- Custom forms created specifically for your organization

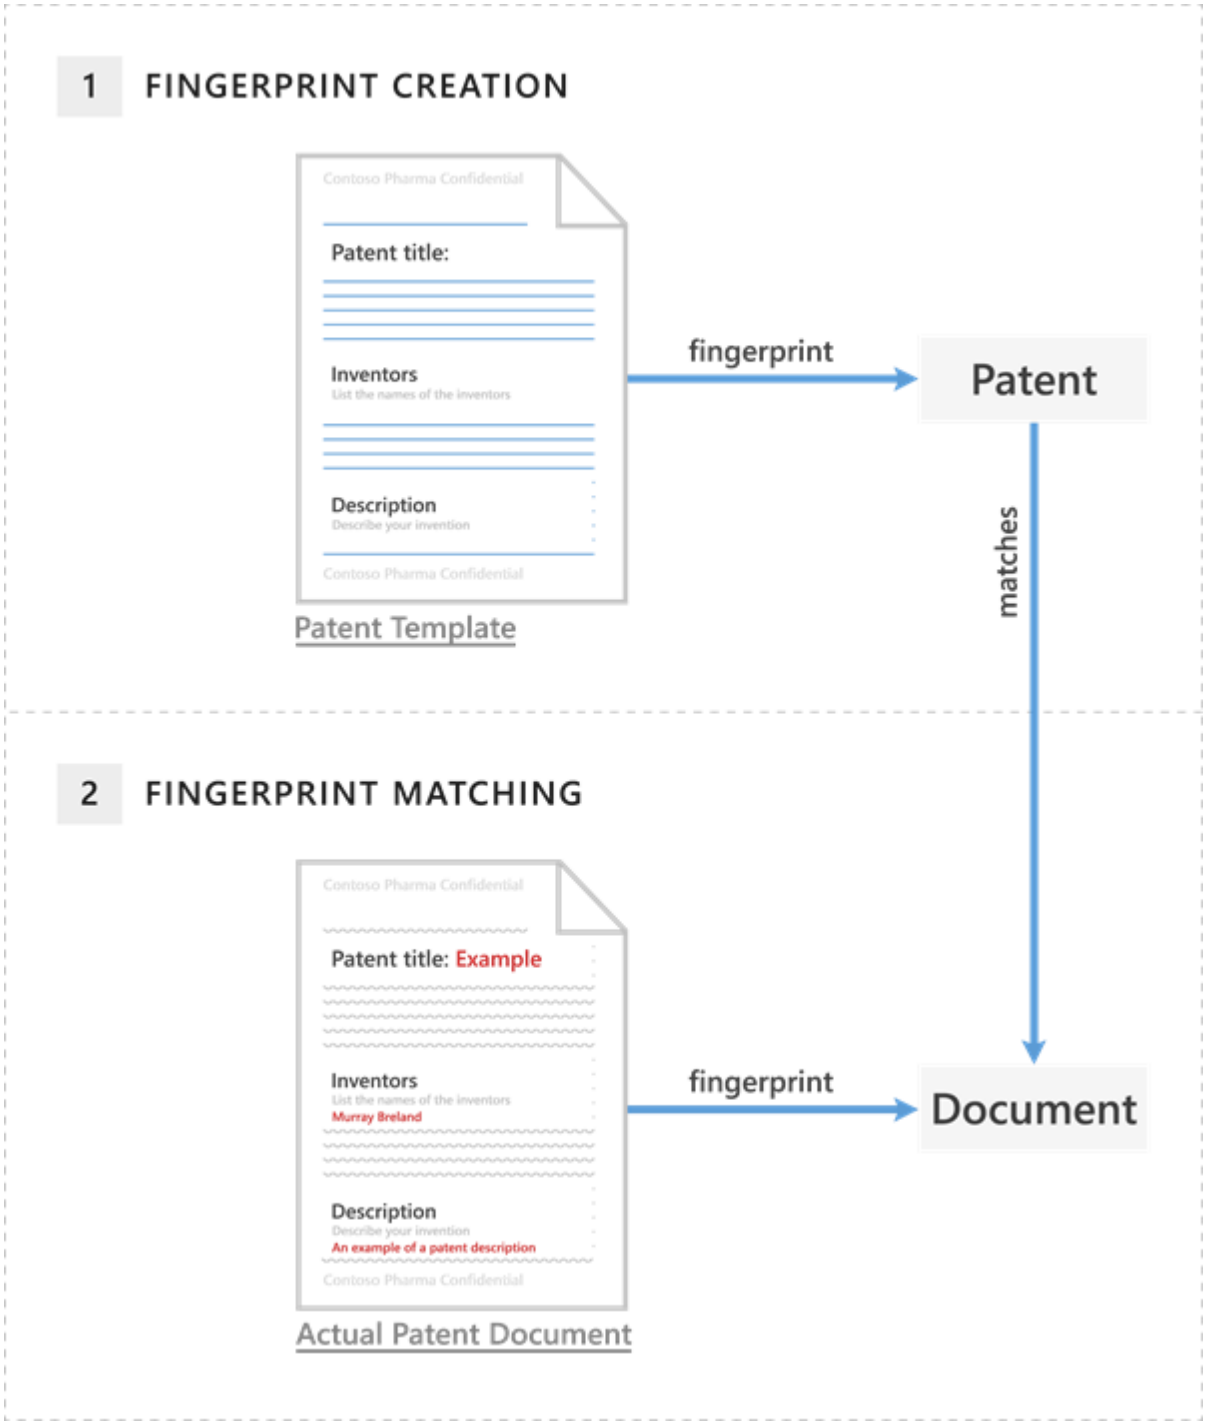
Ideally, your organization already has an established business practice of using certain forms to transmit sensitive information. After you upload an empty form to be converted to a document fingerprint and set up a corresponding policy, the DLP agent will detect any documents in outbound mail that match that fingerprint.

How Document Fingerprinting works

You've probably already guessed that documents don't have actual fingerprints, but the name helps explain the feature. In the same way that a person's fingerprints have unique patterns, documents have unique word patterns. When you upload a file, the DLP agent identifies the unique word pattern in the document, creates a document fingerprint based on that pattern, and uses that document fingerprint to detect outbound documents containing the same pattern. That's why uploading a form or template creates the most effective type of document fingerprint. Everyone who fills out a form uses the same original set of words and then adds his or her own words to the document. As long as the outbound document isn't password protected and contains all the text from the original form, the DLP agent can determine if the document matches the document fingerprint.

The following example shows what happens if you create a document fingerprint based on a patent template, but you can use any form as a basis for creating a document fingerprint.

Example of a patent document matching a document fingerprint of a patent template



The patent template contains the blank fields “Patent title,” “Inventors,” and “Description” and descriptions for each of those fields—that’s the word pattern. When you upload the original patent template, it’s in one of the supported file types and in plain text. The DLP agent uses an algorithm to convert this word pattern into a document fingerprint, which is a small Unicode XML file containing a unique hash value representing the original text, and the fingerprint is saved as a data classification in Active Directory. (As a security measure, the original document itself isn’t stored on the service; only the hash value is stored, and the original document can’t be reconstructed from the hash value.) The patent fingerprint then becomes a sensitive information type that you can associate with a DLP policy. After you associate the fingerprint with a DLP policy, the DLP agent detects any outbound emails containing documents that match the patent fingerprint and deals with them according to your organization’s policy. For example, you might want to set up a DLP policy that prevents regular employees from sending outgoing messages containing patents. The

DLP agent will use the patent fingerprint to detect patents and block those emails. Alternatively, you might want to let your legal department to be able to send patents to other organizations because it has a business need for doing so. You can allow specific departments to send sensitive information by creating exceptions for those departments in your DLP policy, or you can allow them to override a policy tip with a business justification. For more detailed information about creating DLP policy rules and exceptions, see **DLP procedures**, and to learn more about setting up policy tips that users can override, see Manage policy tips.

Supported file types

Document Fingerprinting supports the same **Using transport rules to inspect message attachments**. One quick note about file types: neither transport rules nor Document Fingerprinting supports the .dotx file type, which can be confusing because that's a template file in Word. When you see the word "template" in this and other Document Fingerprinting topics, it refers to a document that you have established as a standard form, not the template file type.

Limitations of document fingerprinting

The Document Fingerprinting DLP agent won't detect sensitive information in the following cases:

- Password protected files
- Files that contain only images
- Documents that don't contain all the text from the original form used to create the document fingerprint

Protect form data with document fingerprinting

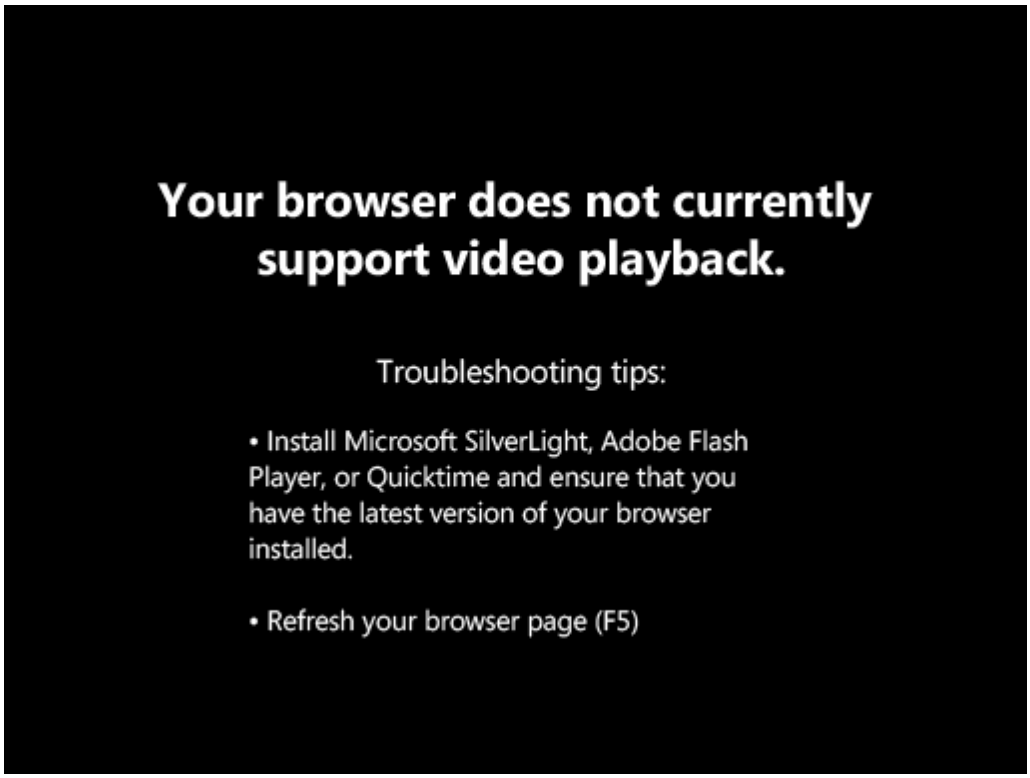
Messaging policy and compliance > Data loss prevention > Document Fingerprinting >

Applies to: *Exchange Server 2013, Exchange Online*

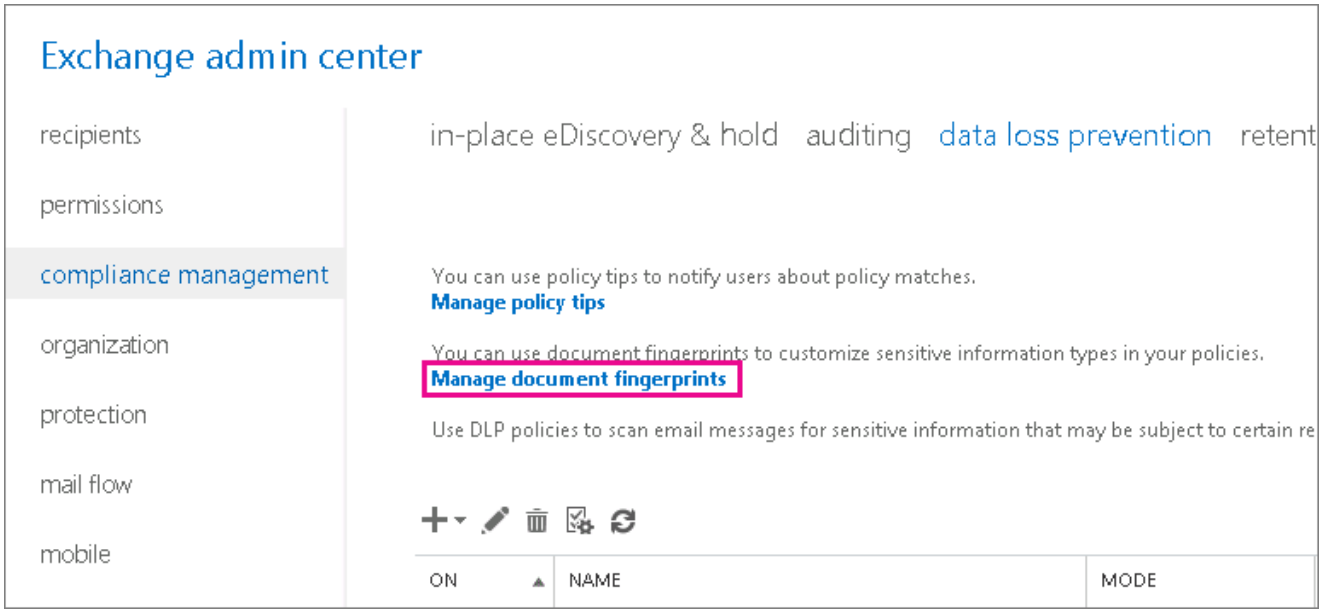
Topic Last Modified: *2014-09-01*

If your organization uses forms to collect sensitive information, users might try emailing those

forms to outside contacts, which creates a security risk. Data loss prevention (DLP) in Exchange helps you protect that information by detecting it with Document Fingerprinting. To use document fingerprinting, simply upload a blank form, such as an intellectual property document, government form, or other standard form used in your organization. Then, add the resulting document fingerprint to a DLP policy or transport rule. Here's how.



Use the EAC to create a document fingerprint



1. In the Exchange Administration Center EAC, go to **compliance management** > **data loss prevention**.
2. Click **Manage document fingerprints**.
3. On the document fingerprints page, click **New +** to create a new document fingerprint.
4. Give the document fingerprint a **Name** and **Description**. (The name you choose will appear in

the sensitive information types list.)

5. To upload a form, click **Add +**.
6. Choose a form, and click **Open**. (Make sure that the file you upload contains text, isn't password protected, and is in one of the **Using transport rules to inspect message attachments**. Otherwise, you'll get an error when you try creating the fingerprint.) Repeat for any additional files you want to add to the document list for this document fingerprint. You can also add or remove files from this document fingerprint later if you want.
7. Click **Save**.

The document fingerprint is now part of your sensitive information types, and you can add it to a DLP policy or add it to a transport rule via the **If the message contains…Sensitive Information** condition.

For more information about adding rules to a DLP policy, see the "Change a DLP policy" section of Manage DLP policies, and for more information about modifying transport rules, see Integrating sensitive information rules with transport rules. If you want to create a new policy, see Create a DLP policy from a template.

Use the Shell to create a classification rule package based on document fingerprinting

Tip:
Even though you can create and modify classification rule packages in the Shell, you might find that creating document fingerprints is a little simpler in the EAC. We recommend you try it there before trying this procedure in the Shell.

DLP uses classification rule packages to detect sensitive content in messages. To create a classification rule package based on a document fingerprint, use the **New-Fingerprint** and **New-DataClassification** cmdlets. Because the results of **New-Fingerprint** aren't stored outside the data classification rule, you always run **New-Fingerprint** and **New-DataClassification** or **Set-DataClassification** in the same PowerShell session. The following example creates a new document fingerprint based on the file C:\My Documents\Contoso Employee Template.docx. You store the new fingerprint as a variable so you can use it with the **New-DataClassification** cmdlet in the same PowerShell session.

```
$Employee_Template = Get-Content "C:\My Documents\Contoso
Employee Template.docx" -Encoding byte
$Employee_Fingerprint = New-Fingerprint -FileData
$Employee_Template -Description "Contoso Employee Template"
```

Now, let's create a new data classification rule named "Contoso Employee Confidential" that uses the document fingerprint of the file C:\My Documents\Contoso Customer Information Form.docx.

```
$Employee_Template = Get-Content "C:\My Documents\Contoso
Customer Information Form.docx" -Encoding byte
$Customer_Fingerprint = New-Fingerprint -FileData
$Customer_Form -Description "Contoso Customer Information
Form"
New-DataClassification -Name "Contoso Customer
Confidential" -Fingerprints $Customer_Fingerprint -
Description "Message contains Contoso customer
information."
```

You can now use the **Get-DataClassification** cmdlet to find all DLP data classification rule packages, and in this example, "Contoso Customer Confidential" is part of the data classification rule packages list.

Finally, add the "Contoso Customer Confidential" data classification rule package to a DLP policy.

```
New-TransportRule -Name "Notify :External Recipient Contoso
confidential" -NotifySender NotifyOnly -Mode Enforce -
SentToScope NotInOrganization -
MessageContainsDataClassification @{Name=" Contoso Customer
Confidential"}
```

The DLP agent now detects documents that match the Contoso Customer Form.docx document fingerprint.

For syntax and parameter information, see New-Fingerprint, New-DataClassification, Set-DataClassification, and Get-DataClassification.

Manage DLP policies

Integrating sensitive information rules with transport rules

DLP policy detection reports

Exchange Server 2013 > Messaging policy and compliance > Data loss prevention >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-02-25*

Data loss prevention (DLP) policy detection management broadly defines the activities that an organization performs in order to identify, investigate, and resolve DLP policy violations. In order to manage incidents, you need access to information that identifies what was detected by your DLP policies. This detection information is integrated with existing Microsoft Exchange Server 2013 data and log formats so that you can leverage an existing rich system of data to manage your mail flow incidents. Detection information is also presented in Microsoft Exchange Online through the **Reports** section, which is accessible from both the Office 365 admin center and the Exchange Admin Center. Learn more about this in Exchange Online at **Summary data reports for DLP policies**.

For information about creating an incident report along with a single policy detection event, see Create incident reports for DLP policy detections. For more information about message logs, see Track messages with delivery reports.

Note:

Exchange Online: DLP is a premium feature that requires an Exchange Online Plan 2 subscription. For more information, see Exchange Online Licensing.
Exchange 2013: DLP is a premium feature that requires an Exchange Enterprise Client Access License (CAL). For more information about CALs and server licensing, see Exchange Server Licensing.

Audit information

Data related to DLP detection management in Exchange is integrated into the message tracking logs, also known as delivery reports. The capabilities reuse much of the existing logging framework available in the system. For more information about the DLP reports in Exchange Online, see **Summary data reports for DLP policies**. For general information, including understanding the structure of the message tracking log files, please review existing content in Managing Message Tracking in the TechNet Library or Track messages with delivery reports.

The delivery report is a detailed log of all message activity as messages are transferred to and from a computer that is running the Transport service on a Mailbox server. For Exchange 2013, but not Exchange Online the message tracking log can be accessed through the Exchange Management Shell by using the **Get-MessageTrackingLog** cmdlet. DLP data is integrated into the delivery report following existing data formats and conventions.

Data logging format

Message tracking logs contain data from the agents involved in processing the mail flow content. For DLP, the transport rule agent (TRA) is used to invoke deep message content scanning and to apply the policies defined as part of the ETRs. The existing AgentInfo Event is used to add DLP related entries in the message tracking log.

The agent name will be **TRA** or **Transport Rule Agent** in the AgentInfo event. A single AgentInfo event will be logged per message describing the DLP processing applied to the message. The **CustomData** field of the message tracking log entry field is where the DLP data logged by the transport rule agent will appear. This field may contain multiple entries: one data classification and client information line for each data classification found in the message, one rule line for each rule that applies to the message, and one health monitoring line for each rule that exceeds the load or execution time threshold.

An example of the DLP log entry is displayed here. The output has been formatted to display strings in separate lines with new lines between.

The Transport Rule Agent requires grouping of the rule ID, DLP Policy ID (optional), last modified date, action, severity, mode, detected data classification (optional), and sender override (optional) based on rule ID (indicated by “TRA=ETR” in the log line). It also requires the data classification ID, count, and confidence level of classifications to be grouped by classification name (indicated by “TRA=DC” in the log line).

Additional groupings include data classification ID, sender override (optional), and override justification (optional) based on data classification ID for all classifications that were detected on the client (indicated by “TRA=CI” in the log line). The Transport Rule Agent also requires the rule ID,

load Wall clock (optional), load CPU clock (optional), execution Wall clock (optional), and execution CPU clock (optional) be grouped by rule ID for all rules that exceed the load or execution Wall or CPU clock thresholds (indicated by "TRA=ETRP" in the log line).

The following is a complete list of the data fields. All data in the MTL is type string. Format column describes how to recognize each field in the Message Tracking Log. Optional Field column specifies what fields might not be logged when a rule matches. DLP Specific column shows what fields are specific to the DLP feature.

Field name	Description	Format	Optional field	DLP specific
TRA	Transport Rule Agent; type AgentName	TRA=DC, ETR, CI, or ETRP	Mandatory	No
DC	Data Classification; type groupName	TRA=DC	Optional	Yes
ETR	Exchange Transport Rule; type groupName	TRA=ETR	Mandatory	No
CI	Client Information, type groupName	TRA=CI	Optional	Yes
ETRP	Exchange Transport Rule Performance; type groupName	TRA=ETRP	Optional	No
dcid	ID of the Data Classification	dcid=GUID	Optional	Yes
count	Count of the Data Classification	count=Integer	Optional	Yes
conf	Confidence level of the Data Classification	conf=Integer (Percent)	Optional	Yes

sndOverride	Sender override; the field is optional. In the TRA=CI line, when field is set to "or" signifies the data classification was overridden. If the field is set to "fp" signifies the data classification was reported as a false positive. In the TRA=ETR line, when the field is set to "or" signifies the rule or part of the rule was overridden. If the field is set to "fp" signifies the rule or part of the rule was reported as a false positive.	sndOverride=or or fp Where "or" represents override and "fp" means false positive. The sndOverride field is present when an end-user had reported either an override or false positive for a rule.	Optional	Yes
just	Justification; the field is optional and only available when the sender override field is equal to "or" in the TRA=CI line. Justification text	just=IW input justification string Justification field is only logged when end user reports an override.	Optional	Yes

	provided by the end user as the reason the data classification should be overridden.			
ruleId	ID for a rule	ruleId=GUID	Mandatory	No
dlpId	ID for a DLP Policy. The field is optional; if there is no dlpId then the rule doesn't belong to a DLP Policy.	dlpId=GUID	Optional	Yes
st	Last Modified Date of a rule	st=UTC date-time	Mandatory	No
action	Action taken by a rule; could have multiple actions per rule	action=single action If there are multiple actions applied for a rule, there will be multiple action fields.	Mandatory	No
sev	Audit severity of the rule	sev=1, 2, or 3 Where 1 represents low, 2 is medium, and 3 means high.	Optional	No

mode	State of the rule when it was hit (enforcement, audit, or auditandnotify).	mode=audit, auditandnotify, or enforcement	Mandatory	No
loadW	Load Wall Clock; the field is optional	loadW=time in ms	Optional	No
loadC	Load CPU Clock; the field is optional	loadC=time in ms	Optional	No
execW	Execute Wall Clock; the field is optional	execW=time in ms	Optional	No
execC	Execute CPU Clock; the field is optional	execC=time in ms	Optional	No
message-id	ID of the message	message-id=ID of message	Mandatory	No
date-time	Date and time the message was sent in universal time	date-time=UTC date-time	Mandatory	No
sender-address	Email address specified in the sender field	sender-address=Email address	Mandatory	No
recipient-address	Email address(es) of the message's recipient(s)	recipient-address=Email address	Mandatory	No

message-subject	Data found in the subject field of the message	message-subject=end-user input subject string	Mandatory	No

Create incident reports for DLP policy detections

Messaging policy and compliance > Data loss prevention > DLP policy detection reports >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-08-07*

In Microsoft Exchange, you can establish an action to create an incident report within a DLP policy rule set. Additionally, you can indicate to whom the report should be sent and what to do with the original message. The incident report can contain any of the following information.

Content of an incident management report

The **Generate Incident Report** action enables users to send incident reports to an incident management mailbox. A single incident report will be generated for each message only if the **Generate Incident Report** action is applied within a policy.

The following is a complete list of the line names in the incident report template. The format column describes how to recognize each field in the report. The optional field column specifies what fields might not be in the Report for each rule match. The DLP specific column shows what fields exist as a result of the DLP feature.

Line name	Description	Format	Optional field	DLP specific
Message-Id	ID of the original	Message-Id: ID of	Mandatory	No

	sent message	message		
Sender	True sender of the original message	Sender: Email address of sender	Mandatory	No
Subject	Subject of the original message	Subject: end-user input subject string	Mandatory	No
To	Recipient or recipients of the original message Each To line will only contain a single recipient, and there can be up to 10 recipients displayed in the Incident Report. If there are additional recipients, the next To line will display the remaining number of recipients.	To: Email address of recipient	Mandatory	No
CC	CC email address of the original message; the line is optional Each CC line will only contain a single CC email	CC: Email address of CC recipient	Optional	No

	address, and there can only be up to 10 CC email addresses that are displayed in the Incident Report. If there are additional CC addresses, the next CC line will display the remaining number of CC email addresses.			
BCC	BCC email address of the original message; the line is optional Each BCC line will only contain a single BCC email address, and there can only be up to 10 BCC addresses that are displayed in the Incident Report. If there are additional BCC email addresses, the following BCC line will display the remaining	BCC: Email address of BCC recipient	Optional	No

	number of BCC email addresses.			
Severity	Audit severity of the rule hit; displays the highest severity if multiple rules were hit.	Severity: Low, Medium, or High	Optional	No
Override	Displays if an override was reported for the message, and the justification of the override if provided.	Override: Yes, Justification: IW input justification string	Optional	Yes
False Positive	Displays if a false positive was reported for the message.	False Positive: Yes	Optional	Yes
Data Classification	Detected data classifications found in the original message; the line is optional. Each data classification line will only contain a single detected classification along with its count, confidence,	Data Classification: sensitive information type, Count: instances of the sensitive information found in the message, Confidence: percent value, Recommended Minimum Confidence:	Optional	Yes

	and recommended minimum confidence level. Up to 5 detected classifications will be displayed in the Incident Report. If the detected classification was an affinity, the count value does not apply and will not be shown.	percent value		
Rule Hit	Displays all the rules that hit the original message. Includes the name of the rule that was hit, the DLP Policy (optional) that the rule resides in, action(s) that were taken on the message because of the rule, data classification(s) in the rule that caused the rule to hit, and the definition of the	Rule Hit: rule name, DLP Policy: DLP Policy name if applicable, Action: single action, Data Classification: sensitive information type, Definition: rule definition if applicable	Mandatory	No

	rule.			
ID Match	Displays the matched data classification, the exact matched content from the message, and the primary evidence of the data classification match; the line is optional.	ID Match: sensitive information type, Value: actual value of the sensitive data, Context: text around the sensitive data in the message	Optional	Yes

DLP procedures

Exchange Server 2013 > Messaging policy and compliance > Data loss prevention >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-02*

You can begin using a data loss prevention (DLP) solution in your messaging environment by using the following procedures. To learn about concepts and objectives for DLP, see Data loss prevention.

Create a DLP policy from a template Information to help you configure a Microsoft-supplied, pre-built set of policy rules. Policy templates are an easy way to get started with managing message data that is associated with several common legal and regulatory requirements.

Create a custom DLP policy Information to help you configure policy rules to meet the specific needs of your organization which may not be covered in one of the pre-existing DLP templates. The rule conditions that are available to you in a single policy include all the traditional transport rules in addition to the new sensitive information types.

Import a DLP policy from a file Information to help you import a file that contains policy

information settings. Policies that are created independent of Exchange as XML files must meet specific format requirements in order to work correctly.

Manage DLP policies Information to help you view, change, or remove existing data loss prevention policies.

Note:
Data Loss Prevention is a premium feature that requires an Enterprise Client Access License (CAL).

Integrating sensitive information rules with transport rules

Exchange Server 2013 > Messaging policy and compliance > Data loss prevention >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-16*

In Microsoft Exchange Server 2013, you can create DLP policies that contain rules for not only traditional message classifications and existing transport rules but also combine these with rules for sensitive information found within messages. The existing transport rules framework offers rich capabilities to define messaging policies, covering the entire spectrum of soft to hard controls. Examples include:

- Limiting the interaction between recipients and senders, including interactions between departmental groups inside an organization.
- Applying separate policies for communications within and outside of an organization.
- Preventing inappropriate content from entering or leaving an organization.
- Filtering confidential information.
- Tracking or archiving messages that are sent to or received from specific individuals.
- Redirecting inbound and outbound messages for inspection before delivery.
- Applying disclaimers to messages as they pass through the organization.

Transport rules allow you to apply messaging policies to email messages that flow through the transport pipeline in the Transport service on Mailbox servers and on Edge Transport servers. These rules allow system administrators to enforce messaging policies, help keep messages more secure,

help to protect messaging systems, and help prevent accidental information loss. For more information about transport rules, see Transport rules.

Sensitive information rules within the transport rule framework

Sensitive information rules are integrated with the transport rules framework by introduction of a condition that you can customize: **If the message contains…Sensitive Information**. This condition can be configured with one or more sensitive information types that are contained within the messages. When multiple DLP policies or rules within a policy are configured with this condition, the policy or rule is satisfied when any of the conditions match. Exchange 2013 policy rules examine the subject, body and any attachments of a message. If the rule matches any of these message components, the rule actions will be applied.

The sensitive information condition may be combined with any of the already existing transport rules to define messaging policies. If combined, the condition works in conjunction with other rules and provides the AND semantics. For example, two different conditions are added together with an AND statement such that both need to match for the action to be applied. Any of the transport rule actions can be configured as result of rules containing the sensitive information type matching. Many different file types can be scanned by the transport rules agent, which scans messages to enforce transport rules. To learn more about the supported file types, see Using transport rules to inspect message attachments.

The rules can also be used in the exception part of a rule definition. Their use in the exception definition is independent of their use as a condition within the rule. This provides the flexibility to define rules that have the condition specifying multiple information types to be applied as part of the condition and also differing information types in the condition. This would allow policies such as matching specific traditional message-classification rules, but not matching other sensitive information types before performing actions that you define within a policy.

Information Rights Management

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-11-01*

Every day, information workers use e-mail to exchange sensitive information such as financial reports and data, legal contracts, confidential product information, sales reports and projections, competitive analysis, research and patent information, and customer and employee information. Because people can now access their e-mail from just about anywhere, mailboxes have transformed into repositories containing large amounts of potentially sensitive information. As a result, information leakage can be a serious threat to organizations. To help prevent information leakage, Microsoft Exchange Server 2013 includes Information Rights Management (IRM) features, which provide persistent online and offline protection of e-mail messages and attachments.

Contents

What is information leakage?

Leakage of potentially sensitive information can be costly for an organization and have wide-ranging impact on the organization and its business, employees, customers, and partners. Local and industry regulations increasingly govern how certain types of information are stored, transmitted, and secured. To avoid violating applicable regulations, organizations must protect themselves against intentional, inadvertent, or accidental information leakage.

The following are some consequences resulting from information leakage:

- **Financial damage** Depending on the size, industry, and local regulations, information leakage may result in financial impact due to loss of business or due to fines and punitive damages imposed by courts or regulatory authorities. Public companies may also risk losing market capitalization due to adverse media coverage.

- **Damage to image and credibility** Information leakage can damage an organization's image and credibility with customers. Moreover, depending on the nature of communication, leaked e-mail messages can potentially be a source of embarrassment for the sender and the organization.
- **Loss of competitive advantage** One of the most serious threats from information leakage is the loss of competitive advantage in business. Disclosure of strategic plans or disclosure of merger and acquisition information can potentially lead to loss of revenue or market capitalization. Other threats include loss of research information, analytical data, and other intellectual property.

Return to top

Traditional solutions to information leakage

Although traditional solutions to information leakage may protect initial access to data, they often don't provide constant protection. The following table lists some traditional solutions and their limitations.

Traditional solutions

Solution	Description	Limitations
Transport Layer Security (TLS)	TLS is an Internet standard protocol used to secure communications over a network by means of encryption. In a messaging environment, TLS is used to secure server/server and client/server communications. By default, Exchange 2010 uses TLS for all internal message transfers. Opportunistic TLS is also enabled by default for sessions with external hosts. Exchange first attempts to use TLS encryption for the session, but if a TLS connection can't be established with the destination server, Exchange uses SMTP. You can also	TLS only protects the SMTP session between two SMTP hosts. In other words, TLS protects information in motion, and it doesn't provide protection at the message-level or for information at rest. Unless the messages are encrypted using another method, messages in the sender's and recipients' mailboxes remain unprotected. For e-mail sent outside the organization, you can require TLS only for the first hop. After a remote SMTP host outside your organization receives the message, it can relay it to another SMTP host over an

	configure domain security to enforce mutual TLS with external organizations.	unencrypted session. Because TLS is a transport layer technology, it can't provide control over what the recipient does with the message.
E-mail encryption	Users can use technologies such as S/MIME to encrypt messages.	Users decide whether a message gets encrypted. There are additional costs of a public key infrastructure (PKI) deployment, with the accompanying overhead of certificate management for users and protection of private keys. After a message is decrypted, there's no control over what the recipient can do with the information. Decrypted information can be copied, printed, or forwarded. By default, saved attachments aren't protected. Messages encrypted using technologies such as S/MIME can't be accessed by your organization. The organization can't inspect message content, and therefore can't enforce messaging policies, scan messages for viruses or malicious content, or take any other action that requires accessing the content.

Finally, traditional solutions often lack enforcement tools that apply uniform messaging policies to prevent information leakage. For example, a user sends a message containing sensitive information and marks it as **Company Confidential** and **Do Not Forward**. After the message is delivered to the recipient, the sender or the organization no longer has control over the information. The recipient can willfully or inadvertently forward the message (using features such as automatic forwarding rules) to external e-mail accounts, subjecting your organization to substantial information leakage risks.

Return to top

IRM in Exchange 2013

In Exchange 2013, you can use IRM features to apply persistent protection to messages and attachments. IRM uses Active Directory Rights Management Services (AD RMS), an information protection technology in Windows Server 2008 and later. With the IRM features in Exchange 2013, your organization and your users can control the rights recipients have for e-mail. IRM also helps allow or restrict recipient actions such as forwarding a message to other recipients, printing a message or attachment, or extracting message or attachment content by copying and pasting. IRM protection can be applied by users in Microsoft Outlook or Microsoft Office Outlook Web App, or it can be based on your organization's messaging policies and applied using transport protection rules or Outlook protection rules. Unlike other e-mail encryption solutions, IRM also allows your organization to decrypt protected content to enforce policy compliance.

AD RMS uses extensible rights markup language (XrML)-based certificates and licenses to certify computers and users, and to protect content. When content such as a document or a message is protected using AD RMS, an XrML license containing the rights that authorized users have to the content is attached. To access IRM-protected content, AD RMS-enabled applications must procure a use license for the authorized user from the AD RMS cluster.

Note:

In Exchange 2013, the Prelicensing agent attaches a use license to messages protected using the AD RMS cluster in your organization. For more details, see Prelicensing later in this topic.

Applications used to create content must be RMS-enabled to apply persistent protection to content using AD RMS. Microsoft Office applications, such as Word, Excel, PowerPoint and Outlook are RMS-enabled and can be used to create and consume protected content.

IRM helps you do the following:

- Prevent an authorized recipient of IRM-protected content from forwarding, modifying, printing, faxing, saving, or cutting and pasting the content.
- Protect supported attachment file formats with the same level of protection as the message.
- Support expiration of IRM-protected messages and attachments so they can no longer be viewed after the specified period.
- Prevent IRM-protected content from being copied using the Snipping Tool in Microsoft Windows.

However, IRM can't prevent information from being copied using the following methods:

- Third-party screen capture programs
- Use of imaging devices such as cameras to photograph IRM-protected content displayed on the screen
- Users remembering or manually transcribing the information

To learn more about AD RMS, see Active Directory Rights Management Services.

AD RMS rights policy templates

AD RMS uses XrML-based rights policy templates to allow compatible IRM-enabled applications to apply consistent protection policies. In Windows Server 2008 and later, the AD RMS server exposes a Web service that can be used to enumerate and acquire templates. Exchange 2013 ships with the Do Not Forward template. When the Do Not Forward template is applied to a message, only the recipients addressed in the message can decrypt the message. The recipients can't forward the message, copy content from the message, or print the message. You can create additional RMS templates on the AD RMS server in your organization to meet your IRM protection requirements.

IRM protection is applied by applying an AD RMS rights policy template. Using policy templates, you can control permissions that recipients have on a message. Actions such as replying, replying to all, forwarding, extracting information from a message, saving a message, or printing a message can be controlled by applying the appropriate rights policy template to the message.

For more information about rights policy templates, see AD RMS Policy Template Considerations.

For more information about creating AD RMS rights policy templates, see AD RMS Rights Policy Templates Deployment Step-by-Step Guide.

Return to top

Applying IRM protection to messages

In Exchange 2010, IRM protection can be applied to messages using the following methods:

- **Manually by Outlook users** Your Outlook users can IRM-protect messages with the AD RMS rights policy templates available to them. This process uses the IRM functionality in Outlook, and not Exchange. However, you can use Exchange to access messages, and you can take actions (such as applying transport rules) to enforce your organization's messaging policy. For more information about using IRM in Outlook, see Introduction to using IRM for e-mail messages.
- **Manually by Outlook Web App users** When you enable IRM in Outlook Web App, users can IRM-protect messages they send, and view IRM-protected messages they receive. In Exchange 2013 Cumulative Update 1 (CU1), Outlook Web App users can also view IRM-protected attachments using Web-Ready Document Viewing. For more information about IRM in Outlook Web App, see Information Rights Management in Outlook Web App.
- **Manually by Windows Mobile and Exchange ActiveSync device users** In the release to manufacturing (RTM) version of Exchange 2010, users of Windows Mobile devices can view and create IRM-protected messages. This requires users to connect their supported Windows Mobile

devices to a computer and activate them for IRM. In Exchange 2010 SP1, you can enable IRM in Microsoft Exchange ActiveSync to allow users of Exchange ActiveSync devices (including Windows Mobile devices) to view, reply to, forward, and create IRM-protected messages. For more information about IRM in Exchange ActiveSync, see Information Rights Management in Exchange ActiveSync.

- **Automatically in Outlook 2010 and later** You can create Outlook protection rules to automatically IRM-protect messages in Outlook 2010 and later. Outlook protection rules are deployed automatically to Outlook 2010 clients, and IRM-protection is applied by Outlook 2010 when the user is composing a message. For more information about Outlook protection rules, see Outlook protection rules.
- **Automatically on Mailbox servers** You can create transport protection rules to automatically IRM-protect messages on Exchange 2013 Mailbox servers. For more information about transport protection rules, see Transport protection rules.

Note:
IRM protection isn't applied again to messages that are already IRM-protected. For example, if a user IRM-protects a message in Outlook or Outlook Web App, IRM protection isn't applied to the message using a transport protection rule.

Return to top

Scenarios for IRM protection

Scenarios for IRM protection are described in the following table.

Scenarios for IRM protection

Sending IRM-protected messages	Supported	Requirements
Within the same on-premises Exchange 2013 deployment	Yes	For requirements, see IRM Requirements later in this topic.
Between different forests in an on-premises deployment	Yes	For requirements, see Configuring AD RMS to Integrate with Exchange Server 2010 Across Multiple Forests.
Between an on-premises Exchange 2013 deployment and a cloud-based Exchange organization	Yes	• Use an on-premises AD RMS server. • Export the trusted publishing domain from your on-premises AD RMS server.

		• Import the trusted publishing domain in your cloud-based organization.
To external recipients	No	Exchange 2010 doesn't include a solution for sending IRM-protected messages to external recipients in a non-federated organization. AD RMS offers solutions using trust policies. You can configure a trust policy between your AD RMS cluster and Microsoft account (formerly known as Windows Live ID). For messages sent between two organizations, you can create a federated trust between the two Active Directory forests using Active Directory Federation Services (AD FS). To learn more, see Understanding AD RMS Trust Policies.

Return to top

Decrypting IRM-protected messages to enforce messaging policies

To enforce messaging policies and for regulatory compliance, you must be able to access encrypted message content. To meet eDiscovery requirements due to litigation, regulatory audits, or internal investigations, you must also be able to search encrypted messages. To help with these tasks, Exchange 2013 includes the following IRM features:

- **Transport decryption** To apply messaging policies, transport agents such as the Transport Rules agent should have access to message content. Transport decryption allows transport agents installed on Exchange 2013 servers to access message content. For more information, see Transport decryption.

- **Journal report decryption** To meet compliance or business requirements, organizations can use journaling to preserve messaging content. The Journaling agent creates a journal report for messages subject to journaling and includes metadata about the message in the report. The original message is attached to the journal report. If the message in a journal report is IRM-protected, journal report decryption attaches a cleartext copy of the message to the journal report. For more information, see Journal report decryption.
- **IRM decryption for Exchange Search** With IRM decryption for Exchange Search, Exchange Search can index content in IRM-protected messages. When a discovery manager performs an In-Place eDiscovery search, IRM-protected messages that have been indexed are returned in search results. For more information, see In-Place eDiscovery.

Note:

In Exchange 2010 SP1 and later, members of the Discovery Management role group can access IRM-protected messages returned by a discovery search and residing in a discovery mailbox. To enable this functionality, use the *EDiscoverySuperUserEnabled* parameter with Set-IRMConfiguration cmdlet. For more information, see Configure IRM for Exchange Search and In-Place eDiscovery.

To enable these decryption features, Exchange servers must have access to the message. This is accomplished by adding the Federation mailbox, a system mailbox created by Exchange Setup, to the super users group on the AD RMS server. For details, see Add the Federation Mailbox to the AD RMS Super Users Group.

Return to top

Prelicensing

To view IRM-protected messages and attachments, Exchange 2013 automatically attaches a prelicense to protected messages. This prevents the client from having to make repeated trips to the AD RMS server to retrieve a use license, and enables offline viewing of IRM-protected messages and attachments. Prelicensing also allows IRM-protected messages to be viewed in Outlook Web App. When you enable IRM features, prelicensing is enabled by default.

Return to top

IRM agents

In Exchange 2013, IRM functionality is enabled using transport agents in the Transport service on Mailbox servers. IRM agents are installed by Exchange Setup on a Mailbox server. You can't control IRM agents using the management tasks for transport agents.

Note:

In Exchange 2013, IRM agents are built-in agents. Built-in agents aren't included in the list of agents returned by the **Get-TransportAgent** cmdlet. For more information, see Transport agents.

The following table lists the IRM agents implemented in the Transport service on Mailbox servers.

IRM agents in the Transport service on Mailbox servers

Agent	Event	Function
RMS Decryption agent	OnEndOfData (SMTP) and OnSubmittedMessage	Decrypts messages to allow access to transport agents.
Transport Rules agent	OnRoutedMessage	Flags messages that match rule conditions in a transport protection rule to be IRM-protected by the RMS Encryption agent.
RMS Encryption agent	OnRoutedMessage	Applies IRM protection to messages flagged by the Transport Rules agent and re-encrypts transport decrypted messages.
Prelicensing agent	OnRoutedMessage	Attaches a prelicense to IRM-protected messages.
Journal Report Decryption agent	OnCategorizedMessage	Decrypts IRM-protected messages attached to journal reports and embeds cleartext versions along with the original encrypted messages.

For more information about transport agents, see Transport agents.

Return to top

IRM requirements

To implement IRM in your Exchange 2013 organization, your deployment must meet the requirements described in the following table.

IRM requirements

Server	Requirements

AD RMS cluster	• **Operating system** Windows Server 2012, Windows Server 2008 R2 or Windows Server 2008 SP2 with the hotfix Active Directory Rights Management Services role in Windows Server 2008 is required. • **Service connection point** Exchange 2010 and AD RMS-aware applications use the service connection point registered in Active Directory to discover an AD RMS cluster and URLs. AD RMS allows you to register the service connection point from within AD RMS Setup. If the account used to set up AD RMS isn't a member of the Enterprise Admins security group, service connection point registration can be performed after setup is complete. There is only one service connection point for AD RMS in an Active Directory forest. • **Permissions** Read and Execute permissions to the AD RMS server certification pipeline (`ServerCertification.asmx` file on AD RMS servers) must be assigned to the following: ○ Exchange Servers group or individual Exchange servers ○ AD RMS Service group on AD RMS servers By default, the ServerCertification.asmx file is located in the `\inetpub\wwwroot\_wmcs\certification\` folder on AD RMS servers. For details, see Set Permissions on the AD RMS Server Certification Pipeline. • **AD RMS super users** To enable transport decryption, journal report decryption, IRM in Outlook Web App, and IRM for Exchange Search, you must add the Federation mailbox, a system mailbox created by Exchange 2013

	Setup, to the super users group on the AD RMS cluster. For details, see Add the Federation Mailbox to the AD RMS Super Users Group.
Exchange	• Exchange 2010 or later is required. • The hotfix FIX: ArgumentNullException exception error message when a .NET Framework 2.0 SP2-based application tries to process a response with zero-length content to an asynchronous ASP.NET Web service request: "Value cannot be null" is recommended for Microsoft .NET Framework 2.0 SP2.
Outlook	• Users can IRM-protect messages in Outlook. Beginning with Outlook 2003, AD RMS templates for IRM-protecting messages is supported. • Outlook protection rules are an Exchange 2010 and Outlook 2010 feature. Previous versions of Outlook don't support this feature.
Exchange ActiveSync	• Devices supporting Exchange ActiveSync protocol version 14.1, including Windows Mobile devices, can support IRM in Exchange ActiveSync. The mobile e-mail application on a device must support the **RightsManagementInformation** tag defined in Exchange ActiveSync protocol version 14.1. In Exchange 2013, IRM in Exchange ActiveSync allows users with supported devices to view, reply to, forward, and create IRM-protected messages without requiring the user to connect the device to a computer and activate it for IRM. For details, see Information Rights Management in Exchange ActiveSync.

Note:

AD RMS cluster is the term used for an AD RMS deployment in an organization, including a

single server deployment. AD RMS is a Web service. It doesn't require that you set up a Windows Server failover cluster. For high availability and load-balancing, you can deploy multiple AD RMS servers in the cluster and use Network Load Balancing.

Important:
In a production environment, installing AD RMS and Exchange on the same server isn't supported.

Exchange 2013 IRM features support Microsoft Office file formats. You can extend IRM protection to other file formats by deploying custom protectors. For more information about custom protectors, see Information Protection and Control Partners in Independent Software Vendors.

Return to top

Configuring and testing IRM

You must use the Exchange Management Shell to configure IRM features in Exchange 2013. To configure individual IRM features, use the Set-IRMConfiguration cmdlet. You can enable or disable IRM for internal messages, transport decryption, journal report decryption, Exchange Search, and Outlook Web App. For more information about configuring IRM features, see Information Rights Management procedures.

After you set up an Exchange 2013 server, you can use the Test-IRMConfiguration cmdlet to perform end-to-end tests of your IRM deployment. These tests are useful to verify IRM functionality immediately after initial IRM configuration and on an ongoing basis. The cmdlet performs the following tests:

- Inspects IRM configuration for your Exchange 2013 organization.
- Checks the AD RMS server for version and hotfix information.
- Verifies whether an Exchange server can be activated for RMS by retrieving a Rights Account Certificate (RAC) and client licensor certificate.
- Acquires AD RMS rights policy templates from the AD RMS server.
- Verifies that the specified sender can send IRM-protected messages.
- Retrieves a super user use license for the specified recipient.
- Acquires a prelicense for the specified recipient.

Return to top

Extend Rights Management with the Rights Management connector

The Microsoft Rights Management connector (RMS connector) is an optional application that enhances data protection for your Exchange 2013 server by employing cloud-based Microsoft Rights Management services. Once you install the RMS connector, it provides continuous data

protection during the lifespan of the information and because these services are customizable, you can define the level of protection you need. For example, you can limit email message access to specific users or set view-only rights for certain messages.

To learn more about the RMS connector and how to install it, see Rights Management connector.

Transport protection rules

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-13*

Email messages and attachments increasingly contain business critical information such as product specifications, business strategy documents, and financial data, or personally identifiable information (PII) such as contact details, social security numbers, credit card numbers, and employee records. There are a number of industry-specific and local regulations in many parts of the world that govern the collection, storage, and disclosure of PII.

To help protect sensitive information, organizations create messaging policies that provide guidelines about how to handle this information. In Microsoft Exchange Server 2013, you can use transport protection rules to implement these messaging policies by inspecting message content, encrypting sensitive email content, and using rights management to control access to the content.

For management tasks related to managing IRM, see Information Rights Management procedures.

Transport protection rules and AD RMS

Transport protection rules allow you to use transport rules to IRM-protect messages by applying an Active Directory Rights Management Services (AD RMS) rights policy template.

Note:
AD RMS is an information protection technology that works with Rights Management Service (RMS)-enabled applications and clients to protect sensitive information online and offline. To use IRM protection in an on-premise Exchange deployment, Exchange 2013 requires an on-premises deployment of AD RMS running on Windows Server 2008 or later.

AD RMS uses XML-based policy templates to allow compatible IRM-enabled applications to apply consistent protection policies. In Windows Server 2008 and later, the AD RMS server exposes a Web service that can be used to enumerate and acquire templates. Exchange 2013 ships with the Do Not Forward template.

When the Do Not Forward template is applied to a message, only the recipients addressed in the message can decrypt the message. The recipients can't forward the message to anyone else, copy

content from the message, or print the message.

Additional RMS templates can be created in the on-premises AD RMS deployment to meet rights protection requirements in your organization.

Important:
If a rights policy template is removed from the AD RMS server, you must modify any transport protection rules that use the removed template. If a transport protection rule continues to use a rights policy template that's been removed, the AD RMS server will fail to license the content to any of the recipients, and a non-delivery report (NDR) will be delivered to the sender. In Windows Server 2008 and later, rights policy templates can be archived instead of deleted. Archived templates can still be used to license content, but when you create or modify a transport protection rule, archived templates aren't included in the list of templates.

For more information about creating AD RMS templates, see AD RMS Rights Policy Templates Deployment Step-by-Step Guide.

Automatic protection using transport protection rules

Messages containing business critical information or PII can be identified by using a combination of transport rule conditions, including regular expressions to identify text patterns such as social security numbers. Organizations require different levels of protection for sensitive information. Some information may be restricted to employees, contractors, or partners; while other information may be restricted only to full-time employees. The desired level of protection can be applied to messages by applying an appropriate rights policy template. For example, users may mark messages or email attachments as Company Confidential. As illustrated in the following figure, you can create a transport protection rule to inspect message content for the words "Company Confidential", and automatically IRM-protect the message.

For more information about creating transport rules to enforce rights protection, see Create a Transport Protection Rule.

Persistent protection of email attachments

Users send business critical information and PII in email attachments using common Microsoft Office file formats such as Microsoft Office Word, Excel, and PowerPoint. All of these file formats support persistent protection via IRM, and you can make sure that the business critical information and PII in these documents are properly protected. Transport protection rules apply the same protection to email messages and attachments in supported file formats.

Transport rules agent and encryption agent

When you use transport protection rules to IRM-protect messages based on rule conditions, the Transport Rules agent on the Transport service inspects messages. If they meet all the conditions and none of the exceptions, it flags the message to be IRM-protected. The Encryption agent, a

built-in transport agent that fires on the **OnRoutedMessage** event, actually applies IRM protection to the message. The Encryption agent acts on messages only if IRM is enabled for internal messages. For more information about enabling IRM, see Enable or Disable IRM for Internal Messages.

When the transport service is restarted, and it processes the first message that requires IRM encryption, the Encryption agent must be able to reach an AD RMS server in the organization. For subsequent messages, the agent doesn't need to contact the AD RMS server. Upon failure to encrypt a message due to transient conditions, Exchange retries the message three times at 10-minute intervals. After three retries, if the message can't be encrypted, it isn't delivered to recipients. An NDR is sent to the sender. We recommend that you plan your AD RMS deployment for high availability to make sure message flow isn't impacted.

When planning to use transport protection rules, you must consider the type of information you want to protect and plan on creating rules accordingly. In Exchange 2013, transport rules have a large number of predicates that allow you to inspect message content, including supported attachments, message headers, sender and recipient addresses, their Active Directory attributes such as department, distribution group membership, and management relationships of the sender with recipients. For more details about transport rule predicates available in Exchange 2013, see Transport rule conditions (predicates).

You must also consider the messaging traffic in your organization, and the number of messages that will be protected using transport protection rules. Applying IRM protection to a large number of messages requires more resources on the Mailbox server. Additionally, protecting a large number of messages or all messages also impacts the client experience, particularly for Microsoft Outlook users.

Outlook protection rules

Exchange Server 2013 > Messaging policy and compliance > Information Rights Management >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-13*

Every day, information workers exchange sensitive information by email, including financial reports and data, customer and employee information, and confidential product information and specifications. In Microsoft Exchange Server 2013, Microsoft Outlook, and Microsoft Office Outlook Web App, users can apply Information Rights Management (IRM) protection to messages by applying an Active Directory Rights Management Services (AD RMS) rights policy template. This requires an AD RMS deployment in the organization. For more information about AD RMS, see Active Directory Rights Management Services.

However, when left to the discretion of users, messages may be sent in clear text without IRM protection. In organizations that use email as a hosted service, there's a risk of information leakage as a message leaves the client and is routed and stored outside the boundaries of an organization. Although email hosting companies may have well-defined procedures and checks to help mitigate the risk of information leakage, after a message leaves the boundary of an organization, the organization loses control of the information. Outlook protection rules can help protect against this type of information leakage.

For management tasks related to managing IRM, see Information Rights Management procedures.

Automatic IRM protection in Outlook

In Exchange 2013, Outlook protection rules help your organization protect against the risk of information leakage by automatically applying IRM-protection to messages in Exchange 2013. Messages are IRM-protected before they leave the Outlook client. This protection is also applied to any attachments using supported file formats.

When you create Outlook protection rules on an Exchange 2013 server, the rules are automatically distributed to Outlook 2010 by using Exchange Web Services. For Outlook 2010 to apply the rule, the AD RMS rights policy template you specify must be available on users' computers.

Important:

If a rights policy template is removed from the AD RMS server, you must modify any Outlook protection rules that use the removed template. If an Outlook protection rule continues to use a rights policy template that's been removed, and transport decryption is enabled in the organization, the Decryption agent will fail to decrypt the message protected with a template that's no longer available. If transport decryption is configured as mandatory, the Transport service will reject the message and send a non-delivery report (NDR) to the sender. For more details about transport decryption, see Transport decryption. For more details about AD RMS rights policy templates, see AD RMS Policy Template Considerations.
In Windows Server 2008 and later, rights policy templates can be archived instead of deleted. Archived templates can still be used to license content, but when you create or modify an Outlook protection rule, archived templates aren't included in the list of templates.

Outlook protection rules are similar to transport protection rules. Both are applied based on message conditions, and both protect messages by applying an AD RMS rights protection template. However, transport protection rules are applied in the Transport service on the Mailbox server by the Transport Rules agent. Outlook protection rules are applied in Outlook 2010, before the message leaves the user's computer. Messages protected by an Outlook protection rule enter the transport pipeline with IRM protection already applied. Additionally, messages protected with an Outlook protection rule are also saved in an encrypted format in the Sent Items folder of the sender's mailbox.

Note:

If transport decryption is enabled in your Exchange organization, messages that are IRM-protected by an Outlook protection rule using the AD RMS server in your organization can be

decrypted by the Decryption agent on Transport service. Message content can be inspected by the Transport Rules agent and other transport agents installed on the Transport service. For more details about transport decryption, see Transport decryption.

When you use transport protection rules, users have no indication of whether a message is going to be automatically protected on the Transport service. When an Outlook protection rule is applied to a message in Outlook 2010, users know if a message will be IRM-protected. If required, users can also select a different rights policy template.

Creating Outlook protection rules

To create Outlook protection rules, you must use the New-OutlookProtectionRule cmdlet in the Exchange Management Shell. For detailed instructions, see Create an Outlook Protection Rule.

When creating a rule, you can specify whether the user can override it, either by removing IRM-protection or by applying a different AD RMS rights policy template than the one specified in the rule. If a user overrides the IRM protection applied by an Outlook protection rule, Outlook 2010 inserts the `X-MS-Outlook-Client-Rule-Overridden` header in the message, which allows you to determine that the rule was overridden by the user.

Predicates in Outlook protection rules

Outlook protection rules allow you to use three predicates to automatically apply IRM protection in Outlook 2010:

- **FromDepartment** The *FromDepartment* predicate looks up the sender's department attribute in Active Directory and automatically IRM-protects the message if the sender's department matches the department specified in the rule. For example, you can create an Outlook protection rule to automatically protect all messages sent by the Research department.
- **SentTo** Your organization may need to protect messages sent to certain sensitive recipients, such as the All Company or Finance distribution groups. Using the *SentTo* predicate, you can create an Outlook protection rule to automatically IRM-protect messages sent to specified recipients.
- **SentToScope** The *SentToScope* predicate allows you to create an Outlook protection rule to automatically IRM-protect messages sent inside or outside the organization. For example, you can use the *SentToScope* predicate with the *FromDepartment* predicate to IRM-protect messages sent by a particular department to internal users.

Transport decryption

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-13*

In Microsoft Exchange Server 2013, Microsoft Outlook 2010 and later, and Microsoft Office Outlook Web App, users can use Information Rights Management (IRM) to protect their messages. You can create Outlook protection rules to automatically apply IRM protection to messages before they're sent from an Outlook 2010 client. You can also create transport protection rules to apply IRM protection to messages in transit that match the rule conditions. Transport decryption allows access to IRM-protected messaging content to enforce messaging policies.

For management tasks related to managing IRM, see Information Rights Management procedures.

Limitations of other encryption solutions

If it's critical that your organization protects sensitive information, including high business impact (HBI) information and personally identifiable information (PII), consider encrypting e-mail messages and attachments. E-mail encryption solutions such as S/MIME have been available for a long time. These encryption solutions have seen varying degrees of adoption in organizations of different types. However, such solutions present the following challenges:

- **Inability to apply messaging policies** Organizations also face compliance requirements that require inspection of messaging content to make sure it adheres to messaging policies. However, messages encrypted with most client-based encryption solutions, including S/MIME, prevent content inspection on the server. Without content inspection, an organization can't validate that all messages sent or received by its users comply with messaging policies. For example, to comply with a legal regulation, you've configured a transport rule to detect PII, such as a social security number, and automatically apply a disclaimer to the message. If the message is encrypted, the Transport Rules agent on the Transport service can't access message content, and therefore won't apply the disclaimer. This results in a violation of the policy.
- **Decreased security** Antivirus software is unable to scan encrypted message content, further exposing an organization to risk from malicious content such as viruses and worms. Encrypted messages are generally considered to be trusted by most users, thereby increasing the likelihood of a virus spreading throughout your organization. For example, you've configured an Outlook protection rule to automatically apply IRM protection to all messages sent to the All Employees distribution list with the Company Confidential rights management service (RMS) template. A user's workstation is infected with a virus that propagates by automatically using Reply All to reply to messages. If the message carrying the virus is encrypted, the antivirus scanner can't scan the message.
- **Impact to custom transport agents** Many organizations develop custom transport agents for different purposes, such as meeting additional processing requirements for compliance, security, or custom message routing. Custom transport agents developed by an organization to inspect or modify messages are unable to process encrypted messages. If the custom transport agents developed by your organization can't access message content, message encryption may prevent your organization from meeting the goals for which the custom transport agents are developed.

Using transport decryption for encrypted content

In Exchange 2013, IRM features address these challenges. If messages are IRM-protected, transport decryption allows you to decrypt them in transit. IRM-protected messages are decrypted by the Decryption agent, a compliance-focused transport agent.

Note:

In Exchange 2013, the Decryption agent is a built-in agent. Built-in agents aren't included in the list of agents returned by the **Get-TransportAgent** cmdlet. For more details, see Transport agents.

The Decryption agent decrypts the following types of IRM-protected messages:

- Messages IRM-protected by the user in Outlook Web App.
- Messages IRM-protected by the user in Outlook 2010.
- Messages IRM-protected automatically by Outlook protection rules in Exchange 2013 and Outlook 2010.

Important:

Only messages IRM-protected by the AD RMS server in your organization are decrypted by the Decryption agent.

Note:

Messages protected in-transit using transport protection rules aren't required to be decrypted by the Decryption agent. The Decryption agent fires on the **OnEndOfData** and **OnSubmit** transport events. Transport protection rules are applied by the Transport Rules agent, which fires on the **OnRoutedMessage** event, and IRM-protection is applied by the Encryption agent on the **OnRoutedMessage** event. For more information about transport agents and a list of SMTP events on which they can be registered, see Transport agents.

Transport decryption is performed on the first Exchange 2013 Transport service that handles a message in an Active Directory forest. If a message is transferred to a Transport service in another Active Directory forest, the message is decrypted again. After decryption, unencrypted content is available to other transport agents on that server. For example, the Transport Rules agent on a Transport service can inspect message content and apply transport rules. Any actions specified in the rule, such as applying a disclaimer or modifying the message in any other way, can be taken on the unencrypted message. Third-party transport agents, such as antivirus scanners, can scan the message for viruses and malware. After other transport agents have inspected the message and possibly made modifications to it, it's encrypted again with the same user rights that it had before being decrypted by the Decryption agent. The same message isn't decrypted again by other the Transport service on other Mailbox servers in the organization.

Messages decrypted by the Decryption agent don't leave the Transport service without being encrypted again. If a transient error is returned when decrypting or encrypting the message, the Transport service retries the operation twice. After the third failure, the error is treated as a permanent error. If any permanent errors occur, including when transient errors are treated as permanent errors after retries, the Transport service treats them as follows:

- If the permanent error occurs during decryption, a non-delivery report (NDR) is sent only if transport decryption is set to `Mandatory`, and the encrypted message is sent with the NDR. For more details about the configuration options available for transport decryption, see Configuring Transport Decryption later in this topic.
- If the permanent error occurs during re-encryption, an NDR is always sent without the decrypted message.

Important:

Any custom or third-party agents installed on a Transport service have access to the decrypted message. You must consider the behavior of such transport agents. We recommend that you test all custom and third-party transport agents thoroughly before you deploy them in a production environment.
After a message is decrypted by the Decryption agent, if a transport agent creates a new message and embeds (attaches) the original message to the new one, only the new message is protected. The original message, which becomes an attachment to the new message, doesn't get re-encrypted. A recipient receiving such a message can open the attached message and take actions such as forwarding or replying, which would bypass rights enforcement.

Configuring transport decryption

Transport decryption is configured by using the Set-IRMConfiguration cmdlet in the Exchange Management Shell. However, before you configure transport decryption, you must provide Exchange 2013 servers the right to decrypt content protected by your AD RMS server. This is done by adding the Federation mailbox to the super users group configured on the AD RMS cluster in your organization.

Important:

In cross-forest AD RMS deployments where you have an AD RMS cluster deployed in each forest, you must add the Federation mailbox to the super users group on the AD RMS cluster in each forest to allow the Transport service on an Exchange 2013 Mailbox server or an Exchange 2010 Hub Transport server to decrypt the messages protected against each AD RMS cluster.

For details, see Add the Federation Mailbox to the AD RMS Super Users Group.

Exchange 2013 allows two different settings when enabling transport decryption:

- **Mandatory** When transport decryption is set to `Mandatory`, the Decryption agent rejects the message and returns an NDR to the sender if a permanent error is returned when decrypting a message. If your organization doesn't want a message to be delivered if it can't be successfully decrypted and actions such as antivirus scanning and transport rules are applied, you must choose this setting.
- **Optional** When transport decryption is set to Optional, the Decryption agent uses a best-effort approach. Messages that can be decrypted are decrypted, but messages with a permanent error on decryption are also delivered. If your organization prioritizes message delivery over messaging policy, you must use this setting.

For more information about configuring transport decryption, see Enable or Disable Transport

Decryption.

Journal report decryption

Exchange Server 2013 > Messaging policy and compliance > Information Rights Management >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-16*

In Microsoft Exchange Server 2013, Information Rights Management (IRM) allows Microsoft Outlook 2010 and later and Microsoft Office Outlook Web App users to protect their messages. You can create Outlook protection rules to automatically apply IRM-protection to messages before they're sent from an Outlook 2010 client. You can also create transport protection rules to apply IRM protection to messages in transit that match the rule conditions.

To learn about Outlook protection rules, see Outlook protection rules.

Limitations of standard encryption solutions

If your organization encrypts messages by using traditional solutions such as S/MIME, your records managers won't be able to inspect or search the encrypted content. Archiving encrypted messages that contain inaccessible and unsearchable content may not meet business, regulatory, or compliance requirements. When faced with an electronic discovery (eDiscovery) request, an inability to decrypt, search, and present content from encrypted messages can be a challenge, and failure to do so may expose your organization to legal and financial risks.

Also, your organization's messaging policies may require journaled messages to be decrypted so the content can be accessible to eDiscovery tools, automated processes, or records managers who access a journaling mailbox. Journal report decryption in Exchange 2010 can help you meet these requirements.

To learn more about journaling, see Journaling.

Journal report decryption

Journal report decryption allows you to save a clear-text copy of IRM-protected messages in journal reports, along with the original, IRM-protected message. If the IRM-protected message contains any supported attachments that were protected by the Active Directory Rights Management Services (AD RMS) cluster in your organization, the attachments are also decrypted.

Important:
To use journal report decryption, you must have an Exchange Enterprise client access license

(CAL). Journal report decryption only supports premium journaling.

Decryption is performed by the Journal Report Decryption agent, a compliance-focused transport agent. The Journal Report Decryption agent fires on the **OnCategorizedMessage** event. Messages protected in-transit using transport protection rules are already encrypted by the Encryption agent, which fires on the **OnRoutedMessage** event, before they get to the Journal Report Decryption agent. The Journal Report Decryption agent decrypts these messages.

Note:

In Exchange 2013, the Journal Report Decryption agent is a built-in agent. Built-in agents aren't included in the list of agents returned by the **Get-TransportAgent** cmdlet. For more details, see Transport agents.

The agent decrypts the following types of IRM-protected messages:

- Messages that were IRM-protected by the user in Outlook Web App.
- Messages that were IRM-protected by the user in Outlook 2010.
- Messages that were IRM-protected automatically in Outlook 2010 by using Outlook protection rules.
- Messages that were IRM-protected automatically in transit by using transport protection rules.

Important:

Only messages that were IRM-protected by the AD RMS server in your organization are decrypted by the Journal Report Decryption agent. The agent doesn't decrypt an attachment if it isn't protected at the same time as the message (and therefore doesn't have the same use license), or if an IRM-protected file is attached to an unprotected message.

Configuring journal report decryption

Journal report decryption is configuredb using the Set-IRMConfiguration cmdlet in the Exchange Management Shell. However, before you configure journal report decryption, you must assign Exchange 2013 servers the permissions to decrypt content that's IRM-protected by your AD RMS server. To do this, you add the Federation mailbox to the super users group configured on your organization's AD RMS cluster. For details, see Add the Federation Mailbox to the AD RMS Super Users Group.

Important:

In cross-forest AD RMS deployments where you have an AD RMS cluster deployed in each forest, you must add the Federation mailbox to the super users group on the AD RMS cluster in each forest to allow Exchange 2013 Transport service to decrypt the messages protected against each AD RMS cluster.

For details about how to configure journal report decryption, see Enable or Disable Journal Report Decryption.

After you enable journal report decryption, the journaling mailbox may contain journal reports with sensitive information in an unencrypted form. As a best practice, we recommend that access to the journaling mailbox be monitored closely and restricted only to authorized individuals. This is a

best-practice even if you're not using IRM protection for e-mail.

Information Rights Management in Outlook Web App

Applies to: *Exchange Server 2013*

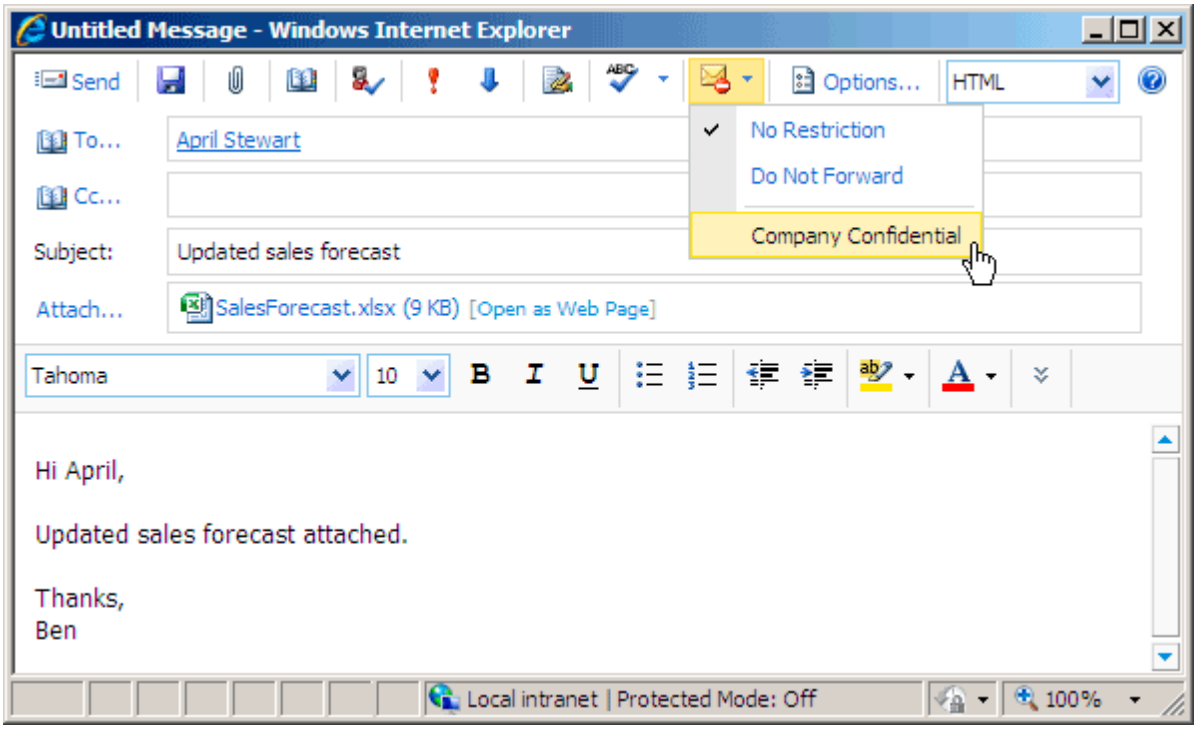
Topic Last Modified: *2012-10-16*

Information workers increasingly use e-mail to exchange sensitive information. To help secure this information, organizations can use Information Rights Management (IRM) to apply persistent protection to messaging content. Prior to Microsoft Exchange Server 2010, effective use of IRM protection was limited to Outlook clients. In Exchange Server 2007, Microsoft Outlook Web Access users were required to download the Rights Management add-in for Microsoft Internet Explorer so they could access IRM-protected content.

In Exchange 2013, IRM in Outlook Web App allows your users to access the rich IRM functionality offered by Exchange to apply persistent IRM-protection to messaging content.

The following IRM functionality is available in Outlook Web App:

- **Send IRM-protected messages** As shown in the following figure, Outlook Web App users can use the permissions drop-down list and select a rights policy template to apply to the message. This allows users to send IRM-protected messages from within Outlook Web App. Messages are IRM-protected by Client Access servers.



- **IRM-protected attachments** When users send an IRM-protected message from Outlook Web App, any files attached to the message also receive the same IRM protection and are protected by using the same rights policy template as the message. In Exchange 2013, IRM protection is applied to files associated with Microsoft Office Word, Excel, and PowerPoint, as well as .xps files and e-mail messages. IRM protection is applied to an attachment only if it's not already IRM-protected. To learn more about Active Directory Rights Management Services (AD RMS) rights policy templates, see Information Rights Management.

Note:
IRM in Outlook Web App protects only the supported file attachments mentioned in this section. Attachments that use unsupported file formats aren't protected. When Outlook Web App users protect a message and attach a file of an unsupported type, a notification is displayed informing the users that only supported file types are protected.

Important:
IRM protection can't be applied to a message that's already signed or encrypted by using S/MIME. To apply IRM protection, S/MIME signature and encryption must be removed from the message. The same applies for IRM-protected messages; users can't sign or encrypt them by using S/MIME.

- **Read IRM-protected messages** Messages protected by senders using your organization's AD RMS cluster are rendered in the preview pane in Outlook Web App. No add-ins need to be installed, and the computer doesn't need to be enrolled in the AD RMS deployment. When a user opens a message or views it in the preview pane, the message is decrypted by using the use license added by the Pre-licensing agent. After decryption, the message is displayed in the preview pane. If a pre-license isn't available, Outlook Web App requests one from the AD RMS server and then renders the message. When reading IRM-protected attachments in Outlook Web App, Web-Ready Document Viewing isn't available.

Note:
IRM in Outlook Web App can't prevent users from taking screen captures by using Print Screen functionality in the way Outlook and other Office applications do. This impacts the EXTRACT right, which prevents message content from being copied, if specified in the AD RMS rights policy template.

- **Cross-browser, multiple platform IRM support** IRM in Outlook Web App offers cross-browser, multiple platform IRM support. IRM in Outlook Web App is supported in all browsers supported by Exchange 2013, including on Apple Macintosh and Linux operating systems. To learn more about supported browsers and operating systems, see Outlook Web App Supported Browsers.
- **WebReady Document Viewing** In Exchange 2013, users can view supported IRM-protected attachments by using WebReady Document Viewing. This allows users to view supported attachments without having to download the attachment use the associated application.

Looking for management tasks related to managing IRM? See Information Rights Management procedures.

Enabling IRM in Outlook Web App

To enable IRM in Outlook Web App, you must add the Federation mailbox, a system mailbox created by Exchange 2013 Setup, to the super users group in AD RMS. For details, see Add the Federation Mailbox to the AD RMS Super Users Group. This allows Exchange 2013 servers to access IRM-protected messages.

You must also enable IRM in Outlook Web App by using the Set-IRMConfiguration cmdlet in the Exchange Management Shell. This enables IRM in Outlook Web App for your Exchange 2013 organization. You can disable or enable IRM in Outlook Web App for an Outlook Web App virtual directory. You can also control IRM in Outlook Web App at the following levels of granularity:

- **Per-Outlook Web App virtual directory** To enable or disable IRM in Outlook Web App for an Outlook Web App virtual directory, use the **Set-OWAVirtualDirectory** cmdlet and set the *IRMEnabled* parameter to `$false` or `$true` (default). This allows you to disable IRM in Outlook Web App for one virtual directory on an Exchange 2013 Client Access server, while keeping it enabled on another virtual directory on a different Client Access server.
- **Per-Outlook Web App mailbox policy** To enable or disable IRM in Outlook Web App for an Outlook Web App mailbox policy, use the **Set-OWAMailboxPolicy** cmdlet and set the *IRMEnabled* parameter to `$false` or `$true` (default). This allows you to enable IRM in Outlook Web App for one set of users and disable it for another set of users by assigning them a different Outlook Web App mailbox policy.

For more information, see Enable or Disable Information Rights Management on Client Access Servers.

Information Rights Management in Exchange ActiveSync

Exchange Server 2013 > Messaging policy and compliance > Information Rights Management >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-13*

Information workers often use e-mail to exchange sensitive information. To help secure this information, organizations can use Information Rights Management (IRM) to apply persistent protection to messaging content. Because mobile devices are increasingly being used to access e-mail, it's important that your mobile device users be able to create and consume IRM-protected content.

Contents

Security

Enabling IRM in Exchange ActiveSync

Looking for management tasks related to IRM? See Information Rights Management procedures.

Mobile IRM protection in Exchange 2013

In Exchange 2013, IRM in Microsoft Exchange ActiveSync allows your users to access rich IRM functionality on any supported Exchange ActiveSync device without having to configure AD RMS permissions or connect the device to a computer and activate it for IRM. Also, the mobile device doesn't need to be running Windows. Exchange ActiveSync is licensed by Microsoft to mobile device manufacturers, original equipment manufacturers (OEMs), and others. For a list of current Exchange ActiveSync licensees, see Exchange ActiveSync Protocol.

Using IRM in Exchange ActiveSync, mobile device users can:

- Create IRM-protected messages.
- Read IRM-protected messages.
- Reply to and forward IRM-protected messages.

Return to top

Requirements

The following requirements apply:

- The Client Access servers in your organization must be running Exchange 2010 SP1 or later.
- An AD RMS server must be deployed in your organization.
- IRM must be enabled for internal messages. This is a prerequisite for all IRM features in Exchange 2010. For details, see Enable or Disable IRM for Internal Messages.
- IRM must be enabled in the Exchange ActiveSync mailbox policy. You can enable or disable IRM for different sets of users using different Exchange ActiveSync mailbox policies.
- Devices that support Exchange ActiveSync protocol version 14.1, including Windows phones, can support IRM in Exchange ActiveSync. The device's mobile e-mail application must support the RightsManagementInformation tag defined in Exchange ActiveSync version 14.1.

Return to top

Security

When you enable IRM in Exchange ActiveSync, the Client Access server decrypts IRM-protected messages before providing the messages for access by the supported mobile device. Upon synchronization, IRM-protected messages reside on the mobile device in an unencrypted format. IRM protection is enforced by the IRM-capable e-mail client application on the mobile device.

IRM in Exchange ActiveSync doesn't decrypt IRM-protected attachments on the Client Access server.

Access to IRM-protected files is enforced by the application used to create or view the file. For example, on a Windows phone, IRM protection for Microsoft Office files is enforced by Microsoft Office Mobile. To access IRM-protected Office files, users must connect the device to a computer and activate Office Mobile with the RMS server.

When enabling IRM in Exchange ActiveSync, we recommend using the Exchange ActiveSync policy settings shown in the following table to help secure mobile devices.

Exchange ActiveSync policy settings

Setting	Configure using the New Exchange ActiveSync Mailbox Policy wizard	Configure using the New-ActiveSyncMailboxPolicy cmdlet
Require that the user enter a password to access information on their mobile device.	Select the **Require password** check box.	Set the *DevicePasswordEnabled* parameter to `$true`.
Enable encryption for the mobile device.	Select the **Require password** check box, and then select the **Require encryption on device** check box.	Set the *RequireDeviceEncryption* parameter to `$true`. **Important:** When you set the *RequireDeviceEncryption* parameter to `$true`, mobile devices that don't support device encryption will be unable to connect.
Don't allow non-provisionable mobile devices to synchronize with the Exchange server.	Clear the **Allow non-provisionable devices** check box.	Set the *AllowNonProvisionableDevices* parameter to `$false`.

To learn more, see Mobile device mailbox policies.

Return to top

Enabling IRM in Exchange ActiveSync

To enable IRM in Exchange ActiveSync, perform the following tasks:

1. Add the Federation mailbox (a system mailbox created by Exchange 2013 and Exchange 2010 Setup) to the super users group in AD RMS. This allows Exchange 2013 and Exchange 2010 servers to access IRM-protected messages. For details, see Add the Federation Mailbox to the AD

RMS Super Users Group.

2. Use the Set-IRMConfiguration cmdlet in the Exchange Management Shell to enable IRM on the Client Access server. This enables IRM in Exchange ActiveSync and IRM in Microsoft Office Outlook Web App for your organization. For details, see Enable or Disable Information Rights Management on Client Access Servers.

Return to top

Information Rights Management logging

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-13*

In Microsoft Exchange Server 2013, Information Rights Management (IRM) operations are logged in IRM logs. IRM logs help you monitor and troubleshoot interactions between the Rights Management Services (RMS) client on an Exchange 2013 server and the Active Directory Rights Management Services (AD RMS) cluster in your organization.

To learn about IRM, see Information Rights Management.

Contents

Looking for management tasks related to IRM? See Information Rights Management procedures.

Structure of IRM logs

By default, IRM logs are located in C:\Program Files\Microsoft\Exchange Server\V14\Logging\IRMLogs.

The naming convention for IRM log files is <*Process*>_<*Process identifier* or *IIS AppPool identifier*>_IRMLOG*yyyymmdd-nnnn*.log, where:

- <*Process*> = process that creates the log file. For example, on Transport service, this will be EdgeTransport.

- *<Process identifier* or *IIS AppPool identifier>* = numerical ID of the process.
- *yyyymmdd* = Coordinated Universal Time (UTC) date when the log file was created.
- *nnnn* = instance number, which starts at 1 for each day.

An example IRM log file name is EdgeTransport_1056_IRMLOG20101201-1.log.

The following table shows the logs generated on different server roles.

Logs on server roles

Server role	IRM log file name	Description
Transport service	EdgeTransport_<*Process identifier*>_IRMLOG*yyyymmdd*-*nnnn*.log	This log is used to record all RMS transactions made by the transport pipeline on Transport service (for example, transport protection rules and journal report decryption). The process identifier (PID) of the edgetransport.exe process is used to generate the log file name.
Mailbox	msftefd_<*Process identifier*>_IRMLOG*yyyymmdd*-*nnnn*.log	This log is used to record all RMS transactions that occur during search and index requests. Exchange 2013 Mailbox servers use the msftefd.exe process for content indexing. The PID of the msftefd.exe process is used to generate the log file name.
Client Access	w3wp_MSExchangeOWAAppOol_IRMLOG*yyyymmdd*-*nnnn*.log	This log is used to record all transactions for IRM in Microsoft Office Outlook Web App.
All Exchange 2013 server roles	w3wp_MSExchangePowerShellAppPool_IRMLOG*yyyymmdd*-	This log is used to record all IRM RMS transactions issued

	nnnn.log	from Windows PowerShell, for example, when issuing the **Test-IRMConfiguration** cmdlet.

Return to top

Logging process

Information is written to the log file until the file size reaches its maximum specified value. When the maximum size is reached, a log file that has an incremental instance number is created. This process is repeated throughout the day. Circular logging deletes the oldest log files when the IRM log directory reaches its maximum specified size or when a log file reaches the maximum age specified in the IRM logging configuration on each server.

Return to top

Information written to IRM logs

IRM log files are text files that contain data in comma-separated value (CSV) format. Each IRM log has a header that contains the following information:

- **#Software** Name of the software that created the IRM log file. Typically, the value is `Microsoft Exchange Server`.
- **#Version** Version number of the software that created the IRM log file.
- **#Log-type** Log type value, which is `Rms Client Manager Log`.
- **#Date** The UTC date and time when the log file was created. The UTC date and time is represented in the ISO 8601 date-time format: *yyyy-mm-dd*T*hh:mm:ss.fff*Z, where:
  - yyyy = year
  - *mm* = month
  - *dd* = day
  - T = time designator used to show the start of the time component
  - *hh* = hour
  - *mm* = minute
  - *ss* = second
  - *fff* = fractions of a second
  - Z = Zulu, which is another way to denote UTC
- **#Fields** Comma-delimited field names used in IRM log files.

The IRM log stores each RMS transaction event on a single line, organized in comma-separated fields. The following table lists the fields in IRM logs for all server roles that have IRM features enabled.

Fields used in IRM logs

Field	Description
Date-time	Lists the UTC timestamp.
Feature	Lists the RMS client feature used. Valid values include: ○ `RacClc` ○ `Template` ○ `Prelicense` ○ `UseLicense` ○ Signature verification ○ `ServerInfo`
Event-Type	Lists the event type. Valid values include: ○ `Acquire` An RMS license or template is requested. ○ `Success` An RMS license or template is acquired successfully. ○ `Exception` An error has occurred. ○ `Queued` A request is pending.
Tenant-Id	Reserved for internal Microsoft use.
Server-url	Lists the RMS server URL accessed during the operation.
Context	Used by the calling process to tie multiple RMS transactions together. Valid values include: ○ `MessageID: <Actual message ID>` ○ `MailboxGuid: <Mailbox GUID>` ○ `AttachmentFileName: <File name>`
Transaction-id	Identifies a unique transaction. All events that occur during one transaction have the same transaction ID.

Return to top

Managing IRM logs

On each server role that has IRM features enabled, IRM logging is enabled by default. For each server role, you can modify the following IRM log configuration by using the server role's corresponding **Set** cmdlet. For example, to configure IRM logging on a Mailbox server, you use the **Set-MailboxServer** cmdlet.

Configuration parameters for IRM logs

Parameter	Description
IrmLogEnabled	Enables logging of IRM transactions. IRM logging is enabled by default. To disable IRM logging for a server role, set the parameter to `$false`.
IrmLogMaxAge	Specifies the maximum age for an IRM log file. Files older than the specified age are deleted. The default value is `30.00:00:00` (30 days).
IrmLogMaxDirectorySize	Specifies the maximum size of all IRM logs in the connectivity log directory. When a directory reaches its maximum file size, the server deletes the oldest log files first. The default value is `250 MB`.
IrmLogMaxFileSize	Specifies the maximum file size for a single log file. When a file reaches the specified size, a log file is created, and the instance number is incremented. The default value is `10 MB`.
IrmLogPath	Specifies the IRM log location. The default path is %ExchangeInstallPath%Logging\IRMLogs.

For detailed syntax and parameter information, see the following topics:

- Set-MailboxServer
- Set-ClientAccessServer
- Set-TransportService

Information Rights Management procedures

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-11-01*

Enable or Disable IRM for Internal Messages

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-12*

In Microsoft Exchange Server 2013, Information Rights Management (IRM) is enabled by default for internal messages. This allows you to create transport protection rules and Microsoft Outlook protection rules to IRM-protect messages in transport and on Microsoft Outlook 2010 and later clients. Enabling IRM for internal messages is a prerequisite for all other IRM features in Exchange Server 2013, such as transport decryption, journal rule decryption, IRM in Microsoft Office Outlook Web App, and IRM in Microsoft Exchange ActiveSync.

Caution:

Disabling IRM for internal messages disables all IRM features in the Exchange organization. The client-side IRM features in Outlook (for example, the ability to read, reply to, forward, and create IRM-protected messages using an Active Directory Rights Management Services (AD RMS) server) aren't affected.

For additional management tasks related to IRM, see Information Rights Management procedures.

What do you need to know before you begin?

- Estimated time to complete: 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Rights protection" entry in the Messaging policy and compliance permissions topic.
- You can't use the Exchange Administration Center (EAC) to enable or disable IRM for internal messages. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to enable IRM for internal messages

This example enables IRM for internal messages for the Exchange organization.

```
Set-IRMConfiguration -InternalLicensingEnabled $true
```

For detailed syntax and parameter information, see Set-IRMConfiguration.

Use the Shell to disable IRM for internal messages

This example disables IRM for internal messages for the Exchange organization.

```
Set-IRMConfiguration -InternalLicensingEnabled $false
```

For detailed syntax and parameter information, see Set-IRMConfiguration.

How do you know this worked?

To verify that you've enabled or disabled IRM for internal messages, use the Get-IRMConfiguration cmdlet to check the configuration.

Create a Transport Protection Rule

Messaging policy and compliance > Information Rights Management > Information Rights Management procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-12-04*

You can use transport protection rules to apply persistent rights protection to messages based on properties such as sender, recipient, message subject, and content.

Caution:

Before you create transport rules in your production environment, we recommend creating them in a test environment and testing them thoroughly. The transport rules created in this topic are examples. You can create transport rules by using the appropriate transport rule predicates and values based on your requirements.

For additional management tasks related to Information Rights Management (IRM), see Information Rights Management procedures.

What do you need to know before you begin?

- Estimated time to completion: 2-5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport rules" entry in the Messaging policy and compliance permissions topic.
- A server running Active Directory Rights Management Services (AD RMS) must be available in your organization and contain existing RMS templates.
- If you configure transport protection rules to protect messages using IRM, and you also use journaling, consider enabling journal report decryption to allow the Journaling agent to save an unencrypted copy of the message in the journal report. To learn more, see Journal report decryption.
- After you create a transport protection rule, if the rule can't be applied to messages because an AD RMS server is unavailable, messages will be queued by the Transport service on Mailbox servers. Depending on the volume of these messages, additional disk space may be consumed on Mailbox servers. Exchange will attempt to IRM-protect the message three times. After these attempts, if the AD RMS server is unreachable or the message can't be IRM-protected, a non-delivery report (NDR) is sent to the sender.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to create a transport protection rule

1. Navigate to **Mail flow** > **Rules**.
2. In the list view, click **New +**.
3. In **New Rule**, first click **More options**, and then complete the following fields:
   - **Name** Type a name for the transport rule.
   - **Apply this rule if** Select a condition and enter any required values for the condition. To add more conditions, click **Add condition**.

Important:

If you don't select any conditions when creating a transport protection rule, all messages handled by Exchange 2013 servers with the Transport service in your organization are IRM-protected. IRM-protecting all messages requires more resources. Therefore, we recommend that you plan your Mailbox server and AD RMS deployment accordingly.

   - **Do the following** Select **Apply rights protection to the message with** and then use the **Select RMS template** dialog box to select a template.
   - **Except if** (Optional) Click **Add exception** to specify an exception to the rule.
4. Click **Save** to create the transport rule.

Use the Shell to create a transport protection rule

- To create a transport protection rule, you must have existing RMS templates in your AD RMS deployment. This example retrieves the available templates from your AD RMS cluster.

```
Get-RMSTemplate | format-list
```

For detailed syntax and parameter information, see Get-RMSTemplate.

- This example creates the transport protection rule Protect-BusinessCriticalProject. The rule IRM-protects messages that contain the phrase "Business Critical" in the Subject field with the **Do Not Forward** template.

Note:

The `SubjectContainsWords` predicate is used in this example. You can use any combination of transport rule predicates to form the conditions and exceptions for the rule. For information about the available predicates, see Transport rule conditions (predicates).

```
New-TransportRule -Name "Protect-BusinessCriticalProject" -
SubjectContainsWords "Business Critical" -
ApplyRightsProtectionTemplate "Do Not Forward"
```

For detailed syntax and parameter information, see New-TransportRule.

How do you know this worked?

To verify that you have successfully created a transport protection rule, do one of the following:

- Use the EAC to verify that the rule has been created, and then click **Edit** to view the rule's properties.

- Use the Get-TransportRule cmdlet to retrieve the rule. For an example of how to retrieve a rule, see Examples in **Get-TransportRule**.
- Using Outlook, Outlook Web App, or a mobile device, send a test message that meets the rule conditions and check whether the message received by the recipient is IRM-protected.

Create an Outlook Protection Rule

Messaging policy and compliance > Information Rights Management > Information Rights Management procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-12-04*

Using Microsoft Outlook protection rules, you can protect messages with Information Rights Management (IRM) by applying an Active Directory Rights Management Services (AD RMS) template in Outlook 2010 before the messages are sent.

For additional management tasks related to IRM, see Information Rights Management procedures.

What do you need to know before you begin?

- Estimated time to completion: 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Rights protection" entry in the Messaging policy and compliance permissions topic.
- You must have an AD RMS server deployed in the same Active Directory forest as your server running Microsoft Exchange Server 2013.
- If you configure Outlook protection rules to IRM-protect messages, consider enabling transport decryption to allow transport agents, including the Transport Rules agent, to decrypt and access the message. If you use journaling, you should also consider enabling journal report decryption to allow the Journaling agent to save an unencrypted copy of the message in the journal report. For more information, see Journal report decryption.
- You can't use the Exchange Administration Center (EAC) to create Outlook protection rules. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to create an Outlook protection rule

This example creates the Outlook protection rule Project Contoso. The rule protects messages sent to the ContosoPMs distribution group with the AD RMS template Business Critical.

```
New-OutlookProtectionRule -Name "Project Contoso" -SentTo
"DL-ContosoPMs@contoso.com" -ApplyRightsProtectionTemplate
"Business Critical"
```

Note:

When you use the `SentTo` predicate for an Outlook protection rule and specify a distribution group, only messages addressed to the distribution group in the To, Cc, or Bcc fields are IRM-protected. IRM protection isn't applied to messages addressed to individual members of the distribution group.

You can also use the `FromDepartment` and `SentToScope` predicates to apply IRM protection to messages sent from users in the specified department or messages sent to the specified scope (`InOrganization` for internal messages, `All` for all recipients).

For detailed syntax and parameter information, see New-OutlookProtectionRule.

How do you know this worked?

To verify that you have successfully created an Outlook protection rule, do the following:

- Run the Get-OutlookProtectionRule cmdlet to make sure that the rule has been created and to view the rule's properties. For an example of how to retrieve an Outlook protection rule, see Examples in **Get-OutlookProtectionRule**.
- Use Outlook 2010 to create a test message that meets the rule's condition and make sure the rule is triggered on the client.

Note:

It may take some time for an Outlook protection rule to be available in Outlook.

Remove an Outlook Protection Rule

Messaging policy and compliance > Information Rights Management > Information Rights Management procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-12-04*

Using Microsoft Outlook protection rules, you can protect messages with Information Rights Management (IRM) by applying an Active Directory Rights Management Services (AD RMS) template in Outlook 2010 before the messages are sent. To prevent an Outlook protection rule from being applied, you can disable the rule. Removing an Outlook protection rule removes the

rule definition from Active Directory.

For additional management tasks related to IRM, see Information Rights Management procedures.

What do you need to know before you begin?

- Estimated time to completion: 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Rights protection" entry in the Messaging policy and compliance permissions topic.
- You can't use the Exchange Administration Center (EAC) to remove Outlook protection rules. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to remove an Outlook protection rule

This example removes the Outlook protection rule OPR-DG-Finance.

```
Remove-OutlookProtectionRule -Identity "OPR-DG-Finance"
```

For detailed syntax and parameter information, see Remove-OutlookProtectionRule.

Use the Shell to remove all Outlook protection rules

This example removes all Outlook protection rules in the Exchange organization.

```
Get-OutlookProtectionRule | Remove-OutlookProtectionRule
```

For detailed syntax and parameter information, see Get-OutlookProtectionRule and Remove-OutlookProtectionRule.

How do you know this worked?

To verify that you have successfully removed an Outlook protection rule, use the Get-OutlookProtectionRule cmdlet to retrieve Outlook protection rules. For an example of how to retrieve Outlook protection rules, see Examples in **Get-OutlookProtectionRule**.

Add the Federation Mailbox to the AD RMS Super Users Group

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-12-10*

For the following Microsoft Exchange Server 2013 Information Rights Management (IRM) features to be enabled, you must add the Federation mailbox (a system mailbox created by Exchange 2013 Setup) to the super users group on your organization's Active Directory Rights Management Services (AD RMS) cluster:

- IRM in Microsoft Office Outlook Web App
- IRM in Exchange ActiveSync
- Journal report decryption
- Transport decryption

You can configure a mail-enabled distribution group as a super users group in AD RMS. Members of the distribution group are granted an owner use license when they request a license from the AD RMS cluster. This allows them to decrypt all RMS-protected content published by that cluster. Whether you use an existing distribution group or create a distribution group and configure it as the super users group in AD RMS, we recommend that you dedicate the distribution group for this purpose and configure the appropriate settings to approve, audit, and monitor membership changes.

Caution:

Configuring a super users group in AD RMS allows group members to decrypt IRM-protected content. We recommend that you take adequate measures to control and monitor group membership and enable auditing to track membership changes. You can also limit unwanted changes to group membership by configuring the group as a restricted group using Group Policy. For details, see Restricted Groups Policy Settings.

For additional management tasks related to IRM, see Information Rights Management procedures.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Distribution groups" entry in the Recipients Permissions topic.
- An AD RMS cluster must be deployed in the Active Directory forest.
- If a super users group is already configured on an AD RMS cluster, any modifications to the

distribution group membership can take up to 24 hours to be refreshed by the AD RMS cluster. This is a result of caching the group membership on the cluster.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

How do you do this?

Step 1: Use the Shell to add the Federation mailbox to a distribution group

If a distribution group has been created and configured as a super users group in the AD RMS cluster, you can add the Exchange 2013 Federation mailbox as a member of that group. If a super users group isn't configured, you must create a distribution group and add the Federation mailbox as a member.

1. Create a distribution group dedicated for use as an AD RMS super users group. For details, see Manage Distribution Groups.
2. Add the user **FederatedEmail.4c1f4d8b-8179-4148-93bf-00a95fa1e042** to the new distribution group. The Federation mailbox is a system mailbox, and therefore not visible in the EAC. To add it to a distribution group, you must use the Add-DistributionGroupMember cmdlet from the Shell.

This example adds the Federation mailbox to the ADRMSSuperUsers distribution group.

```
Add-DistributionGroupMember ADRMSSuperUsers -Member
FederatedEmail.4c1f4d8b-8179-4148-93bf-00a95fa1e042
```

For detailed syntax and parameter information, see Add-DistributionGroupMember.

Step 2: Use AD RMS to set up a super users group

Perform the following procedure on an AD RMS cluster. The account used to perform this procedure must be a member of the AD RMS Enterprise Administrators local group on the AD RMS server.

1. Open the Active Directory Rights Management Services console and expand the AD RMS cluster.
2. In the console tree, expand **Security Policies**, and then click **Super Users**.
3. In the action pane, click **Enable Super Users**.
4. In the result pane, click **Change Super User Group** to open the **Super Users** property sheet.
5. In the **Super user group** box, type the email address of the distribution group you created in the

previous procedure, or click **Browse** to select a distribution group.

How do you know this worked?

After you have added the Federation mailbox to a new or existing distribution group, use the Get-DistributionGroupMember cmdlet to check the membership of the group.

For an example of how to check distribution group membership, see Example 1 in **Get-DistributionGroupMember**.

After you have used AD RMS to set up a super users group, you can use the following methods to verify that the super users group has been configured correctly. Additionally, you can use Test-IRMConfiguration cmdlet to verify IRM functionality.

- Use the AD RMS console to verify that the correct group has been configured as the super users group.
- Run the following PowerShell command on an AD RMS server to retrieve the super users group.

Important:
The ADRMSAdmin PowerShell module is available in Windows Server 2008 R2 and later.

```
Import-Module ADRMSAdmin
New-PSDrive -Name MyRmsAdmin -PsProvider AdRmsAdmin -Root https://localhost
Get-ItemProperty -Path MyRmsAdmin:\SecurityPolicy\SuperUser
```

Enable or Disable Transport Decryption

Messaging policy and compliance > Information Rights Management > Information Rights Management procedures >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-07-22*

Enabling transport decryption allows the Transport Rules agent on Microsoft Exchange Server 2013 Mailbox servers to access content in messages protected by Information Rights Management (IRM). As a result, other transport agents can access message content and possibly make changes to it. For example, the Transport Rules agent may need to inspect message content and apply transport rules (such as rules that apply a disclaimer to the message). To successfully decrypt IRM-protected messages, you must add the Federated Delivery mailbox to the super users group configured on your Active Directory Rights Management Services (AD RMS) server.

Important:
Members of the super users group are granted an owner use license when they request a

license from the AD RMS cluster. This allows them to decrypt all RMS-protected content created by that AD RMS cluster.

When enabling transport decryption, you can specify the following settings:

- **Mandatory** Rejects messages that can't be decrypted and returns a non-delivery report (NDR) to the sender.
- **Optional** Uses a best-effort approach to decryption. If possible, messages are decrypted, but they're delivered even if decryption fails. This is the default setting.

To learn more about transport decryption, see Transport decryption.

For additional management tasks related to IRM, see Information Rights Management procedures.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Rights protection" entry in the Messaging policy and compliance permissions topic.
- An AD RMS server exists in the Active Directory forest and is accessible.
- The Federated Delivery mailbox has been added to the AD RMS super users group. For details, see Add the Federation Mailbox to the AD RMS Super Users Group.
- You can't use the Exchange Administration Center (EAC) to enable transport decryption. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to enable transport decryption

This example enables transport decryption for the Exchange 2013 organization. Messages that can't be decrypted are rejected and an NDR is returned to the sender.

```
Set-IRMConfiguration -TransportDecryptionSetting Mandatory
```

For detailed syntax and parameter information, see Set-IRMConfiguration.

Use the Shell to disable transport decryption

This example disables transport decryption for the Exchange 2013 organization.

```
Set-IRMConfiguration -TransportDecryptionSetting Disabled
```

For detailed syntax and parameter information, see Set-IRMConfiguration.

How do I know this worked?

To verify that you have enabled or disabled transport decryption, use the **Get-IRMConfiguration** cmdlet and check the value of the *JournalDecryptionEnabled* property.

For an example of how to check the IRM configuration, see Examples in **Get-IRMConfiguration**.

Configure IRM for Exchange Search and In-Place eDiscovery

Messaging policy and compliance > Information Rights Management > Information Rights Management procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-11-16*

In Microsoft Exchange Server 2013, you can configure Information Rights Management (IRM) so that Exchange Search can index IRM-protected messages.

When members of the Discovery Management role group perform an In-Place eDiscovery search, IRM-protected messages are returned in the search results and copied to the Discovery mailbox specified in the search. Furthermore, members of the Discovery Management role group can use Outlook Web App to access the IRM-protected messages that were copied to the Discovery mailbox as a result of the discovery search.

Note:
Members of the Discovery Management role group can't access IRM-protected messages exported from a Discovery mailbox to another mailbox or to a .pst file. IRM-protected messages in a Discovery mailbox can be accessed only by using Outlook Web App.

For additional management tasks related to IRM, see Information Rights Management procedures.

What do you need to know before you begin?

- Estimated time to completion: 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Rights protection" entry in the Messaging policy and compliance permissions topic.

- IRM must be configured in your Exchange 2013 organization. To learn more, see Enable or Disable IRM for Internal Messages.
- The Federation mailbox must be added to the Active Directory Rights Management Services (AD RMS) super users group. To learn more, see Add the Federation Mailbox to the AD RMS Super Users Group.
- You can't use the Exchange Administration Center (EAC) to configure IRM for Exchange Search and In-Place eDiscovery. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to configure IRM for Exchange Search

This example configures IRM to allow Exchange Search to index IRM-protected messages.

Note:

By default, the *SearchEnabled* parameter is set to `$true`. To disable indexing of IRM-protected messages, set it to `$false`. Disabling indexing of IRM-protected messages prevents them from being returned in search results when users search their mailbox or when discovery managers use In-Place eDiscovery.

```
Set-IRMConfiguration -SearchEnabled $true
```

For detailed syntax and parameter information, see Set-IRMConfiguration.

Use the Shell to configure IRM for In-Place eDiscovery

This example enables members of the Discovery Management role group to access IRM-protected messages that reside in the Discovery mailbox.

Note:

By default, the *EDiscoverySuperUserEnabled* parameter is set to `$true`. To disable access to IRM-protected messages for members of the Discovery Management role group, set it to `$false`.

```
Set-IRMConfiguration -EDiscoverySuperUserEnabled $true
```

For detailed syntax and parameter information, see Set-IRMConfiguration.

How do you know this worked?

To verify that you have successfully configured IRM for Exchange Search and In-Place eDiscovery, use the **Get-IRMConfigurtaion** cmdlet to retrieve the IRM configuration information. For an example of how to retrieve the IRM configuration, see Examples in **Get-IRMConfiguration**.

Enable or Disable Journal Report Decryption

Messaging policy and compliance > Information Rights Management > Information Rights Management procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-12-04*

Enabling journal report decryption allows the Journaling agent to attach a decrypted copy of a rights-protected message to the journal report. Before you enable journal report decryption, you must add the Federated Delivery mailbox to the super users group configured on your Active Directory Rights Management Services (AD RMS) server.

For additional management tasks related to Information Rights Management (IRM), see Information Rights Management procedures.

What do you need to know before you begin?

- Estimated time to complete: 1 minute
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Rights protection" entry in the Messaging policy and compliance permissions topic.
- Members of the super users group are granted an owner use license when they request a license from the AD RMS cluster. This allows them to decrypt all RMS-protected content created by that AD RMS cluster.
- An AD RMS cluster must be installed in the Active Directory forest.
- The Federated Delivery mailbox has been added to an AD RMS super users group. For details, see Add the Federation Mailbox to the AD RMS Super Users Group.
- You can't use the Exchange Administration Center (EAC) to enable journal report decryption. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to enable journal report decryption

This example enables journal report decryption for the Exchange organization.

```
Set-IRMConfiguration -JournalReportDecryptionEnabled $true
```

For detailed syntax and parameter information, see Set-IRMConfiguration.

Use the Shell to disable journal report decryption

This example disables journal report decryption for the Exchange organization.

```
Set-IRMConfiguration -JournalReportDecryptionEnabled $false
```

For detailed syntax and parameter information, see Set-IRMConfiguration.

How do you know this worked?

To verify that you have enabled or disabled journal report decryption, run the **Get-IRMConfiguration** cmdlet and check the value of the *JournalDecryptionEnabled* property.

For an example of how to check the IRM configuration, see Examples in **Get-IRMConfiguration**.

Enable or Disable Information Rights Management on Client Access Servers

Messaging policy and compliance > Information Rights Management > Information Rights Management procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-12-04*

Enabling Information Rights Management (IRM) on Client Access servers enables the following features:

- Microsoft Office Outlook Web App
- IRM in Microsoft Exchange ActiveSync

When IRM is enabled on Client Access servers, Outlook Web App users can IRM-protect messages by applying an Active Directory Rights Management Services (AD RMS) template created on your AD RMS cluster. Outlook Web App users can also view IRM-protected messages and supported attachments. Before you enable IRM on Client Access servers, you must add the Federation mailbox to the super users group on the AD RMS cluster.

Important:
Members of the super users group are granted an owner use license when they request a license from the AD RMS cluster. This allows them to decrypt all RMS-protected content by that cluster.

For additional management tasks related to IRM, see Information Rights Management procedures.

What do you need to know before you begin?

- Estimated time to completion: 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Information Rights Management (IRM) configuration" entry in the Messaging policy and compliance permissions topic.
- An AD RMS cluster must be installed in the Active Directory forest.
- The Federation mailbox has been added to the AD RMS super users group. For detailed instructions, see Add the Federation Mailbox to the AD RMS Super Users Group.
- IRM features must be enabled for the organization. For detailed instructions, see Enable or Disable IRM for Internal Messages.
- You can use the **Set-IRMConfiguration** cmdlet to enable or disable IRM in Outlook Web App and IRM in Exchange ActiveSync for the entire Exchange organization or at specific levels.

You can control IRM in Outlook Web App at the following levels:

  - **Per-Outlook Web App virtual directory** To enable or disable IRM in Outlook Web App for an Outlook Web App virtual directory, use the **Set-OWAVirtualDirectory** cmdlet and set the *IRMEnabled* parameter to `$false` or `$true` (default). This allows you to disable IRM in Outlook Web App for one virtual directory on an Exchange 2013 Client Access server, while keeping it enabled on another virtual directory on a different Client Access server.
  - **Per-Outlook Web App mailbox policy** To enable or disable IRM in Outlook Web App for an Outlook Web App mailbox policy, use the **Set-OWAMailboxPolicy** cmdlet and set the *IRMEnabled* parameter to `$false` or `$true` (default). This allows you to enable IRM in Outlook Web App for one set of users and disable it for another set of users by assigning them a different Outlook Web App mailbox policy.

You can control IRM in Exchange ActiveSync per Exchange ActiveSync mailbox policy. To disable or enable IRM in Exchange ActiveSync for an Exchange ActiveSync mailbox policy, use the **Set-ActiveSyncMailboxPolicy** cmdlet and set the *IRMEnabled* parameter to `$false` or `$true` (default). This allows you to enable IRM in Exchange ActiveSync for one set of users and disable it for another

set of users by assigning them a different Exchange ActiveSync mailbox policy.

- You can't use the Exchange Administration Center (EAC) to enable or disable IRM on Client Access servers. You must use the Shell.

What do you want to do?

Use the Shell to enable IRM on Client Access servers

This example enables IRM on a Client Access server for an Exchange organization.

```
Set-IRMConfiguration -ClientAccessServerEnabled $true
```

For detailed syntax and parameter information, see Set-IRMConfiguration.

Use the Shell to disable IRM on Client Access servers

This example disables IRM on a Client Access server for an Exchange organization.

```
Set-IRMConfiguration -ClientAccessServerEnabled $false
```

For detailed syntax and parameter information, see Set-IRMConfiguration.

How do you know this worked?

To verify that you have successfully enabled or disabled IRM on Client Access servers, do the following:

- Run the **Get-IRMConfiguration** cmdlet and check the value of the *ClientAccessServerEnabled* property.

For an example of how to retrieve the IRM configuration, see Examples in **Get-IRMConfiguration**.

- Use Outlook Web App to create or read an IRM-protected message.

Enable or Disable Information Rights Management Logging

Messaging policy and compliance > Information Rights Management > Information Rights Management procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-12*

In Exchange Server 2013, you can use Information Rights Management (IRM) logs to monitor and troubleshoot IRM operations. IRM logging is enabled by default.

IRM logs use the following common set of parameters:

- *IrmLogEnabled* Enables or disables IRM logging. Default: `$true`.
- *IrmLogMaxAge* Specifies the maximum age of IRM log files. Files older than the specified age are deleted. Default: 30 days.
- *IrmLogMaxDirectorySize* Specifies the maximum size of the directory that contains IRM logs. When a directory reaches its maximum file size, the server deletes the oldest log files first. Default: 250 MB.
- *IrmLogMaxFileSize* Specifies the maximum size of each IRM log file. When a log file reaches the specified size, a new log file is created. Default: 10 MB.
- *IrmLogPath* Specifies the location of the IRM log directory. Default: `%ExchangeInstallPath%Logging\IRMLogs`.

For additional management tasks related to IRM, see Information Rights Management procedures.

What do you need to know before you begin?

- Estimated time to complete each procedure: 2-5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Configure IRM logging" entry in the Messaging policy and compliance permissions topic.
- You can't use the Exchange Administration Center (EAC) to enable or disable IRM logging on a server. You must use the Shell
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to enable IRM logging on a server

This example enables IRM log on a Mailbox server.

```
Set-TransportService -Identity EXCH01 -IRMLogEnabled $true
```

For detailed syntax and parameter information, see Set-TransportService.

Use the Shell to disable IRM logging on a server

This example disables IRM logging on a Mailbox server.

```
Set-TransportService -Identity EXCH01 -IRMLogEnabled $false
```

For detailed syntax and parameter information, see Set-TransportService.

How do you know this worked?

To verify that you have successfully enabled or disbled IRM logging on a server, run the Get-TransportService cmdlet to retrieve IRM settings.

This example retrieves all IRM logging properties on the server EXCH01.

```
Get-TransportService -Identity EXCH01 | Format-List IRMLog*
```

S/MIME for message signing and encryption

Exchange Server 2013 > Messaging policy and compliance >

Applies to: *Exchange Online*

Topic Last Modified: *2014-03-23*

S/MIME (Secure/Multipurpose Internet Mail Extensions) is a widely accepted method, or more precisely a protocol, for sending digitally signed and encrypted messages. S/MIME allows you to encrypt emails and digitally sign them. When you use S/MIME with an email message, it helps the people who receive that message to be certain that what they see in their inbox is the exact message that started with the sender. It will also help people who receive messages to be certain that the message came from the specific sender and not from someone pretending to be the sender. To do this, S/MIME provides for cryptographic security services such as authentication, message integrity, and non-repudiation of origin (using digital signatures). It also helps enhance privacy and data security (using encryption) for electronic messaging. For a more complete background about the history and architecture of S/MIME in the context of email, see Understanding S/MIME.

As an administrator, you can enable S/MIME-based security for your organization if you have mailboxes in either Exchange 2013 SP1 or Exchange Online, a part of Office 365. Use the guidance in the topics linked here along with the Exchange Management Shell to set up S/MIME. To use S/MIME in supported versions of Outlook or ActiveSync, with either Exchange 2013 SP1 or Exchange Online, the users in your organization must have certificates issued for signing and encryption purposes and data published to your on-premises Active Directory Domain Service (AD DS). Your AD DS must be located on computers at a physical location that you control and not at a remote facility or cloud-based service somewhere on the internet. For more information about AD DS, see

Active Directory Domain Services.

Supported scenarios and technical considerations

If your organization uses either Exchange 2013 SP1 or Exchange Online, you can set up S/MIME to work with any of the following end points:

- Outlook 2010
- Outlook 2013
- Outlook Web App
- Exchange ActiveSync (EAS)

The steps that you follow to set up S/MIME with each of these end points is slightly different depending on which you choose. Generally, you will need to accomplish the following:

- Set up your certificate authority and public key infrastructure to issue S/MIME certificates for users.
- Publish the user certificate in an on-premises AD DS account in the UserSMIMECertificate and/or UserCertificate attributes.
- For Exchange Online organizations, synchronize the user certificates from AD DS to Azure Active Directory by using an appropriate version of DirSync. These certificates will then get synchronized from Azure Active Directory to Exchange Online directory and will be used when encrypting a message to a recipient.
- Set up a virtual certificate collection in order to validate S/MIME. This information is used by OWA when validating the signature of an email and ensuring that it was signed by a trusted certificate.
- Set up the Outlook or EAS end point to use S/MIME.

Setup S/MIME with Outlook Web App

Setting up S/MIME for Exchange 2013 SP1 or Exchange Online with Outlook Web App involves the following key steps:

1. Configure S/MIME settings for Outlook Web App
2. Set up virtual certificate collection to validate S/MIME
3. **Sync user certificates to Office 365 for S/MIME** This step applies to Exchange Online only.

Related message encryption technologies

As message security becomes more important, administrators need to understand the principles and concepts of secure messaging. This understanding is especially important because of the growing variety of protection-related technologies, such as S/MIME, that have become available. To understand more about S/MIME and how it works in context of email, see Understanding S/MIME. A variety of encryption technologies work together to provide protection for messages at rest and in-transit. S/MIME can work simultaneously with the following technologies but is not dependent on them:

Transport Layer Security (TLS) encrypts the tunnel or the route between email servers in order to help prevent snooping and eavesdropping.

Secure Sockets Layer (SSL) encrypts the connection between email clients and Office 365 servers.

BitLocker encrypts the data on a hard drive in a datacenter so that if someone gets unauthorized access, they can't read it.

S/MIME compared with Office 365 Message Encryption

S/MIME requires a certificate and publishing infrastructure that is often used in business-to-business and business-to-consumer situations. The user controls the cryptographic keys in S/MIME and can choose whether to use them for each message they send. Email programs such as Outlook search a trusted root certificate authority location to perform digital signing and verification of the signature. Office 365 Message Encryption is a policy-based encryption service that can be configured by an administrator, and not an individual user, to encrypt mail sent to anyone inside or outside of the organization. It's an online service that's built on Windows Azure Rights Management and does not rely on a public key infrastructure. Office 365 Message Encryption also provides additional capabilities, such as the capability to customize the mail with organization's brand. For more information about Office 365 Message Encryption, see Office 365 Message Encryption.

Secure Mail (2000)

Configure S/MIME settings for Outlook Web App

Exchange Server 2013 > Messaging policy and compliance > S/MIME for message signing and encryption >

Applies to: *Exchange Online*

Topic Last Modified: *2014-02-23*

As an organization administrator for both Exchange 2013 and Exchange Online, you can set up Outlook Web App to allow sending and receiving S/MIME-protected messages. Use the `SMIMEConfig` cmdlet to manage this feature through the Exchange Management Shell interface.

For more information such as a detailed description of parameters and examples for `get-SMIMEConfig` and `set-SMIMEConfig`, see the Get-SmimeConfig and Set-SmimeConfig documentation.

You can only use the Shell to perform this procedure. To learn how to open the Shell in your on-premises Exchange organization, see Open the Shell. To learn how to use Windows PowerShell to connect to Exchange Online, see **Connect to Exchange Online using remote PowerShell**.

For more information

S/MIME for message signing and encryption

Set up virtual certificate collection to validate S/MIME

Exchange Server 2013 > Messaging policy and compliance > S/MIME for message signing and encryption >

Applies to: *Exchange Online*

Topic Last Modified: *2014-02-23*

As a tenant administrator you will need to configure a virtual certificate collection that will be used to validate S/MIME certificates. This virtual certificate collection is set up as a certificate store file type with an SST filename extension. The SST file contains all the root and intermediate certificates that are used when validating an S/MIME certificate.

Create and save an SST

You can only use the Shell to perform this procedure. To learn how to open the Shell in your on-premises Exchange organization, see Open the Shell. To learn how to use Windows PowerShell to connect to Exchange Online, see **Connect to Exchange Online using remote PowerShell**.

As an administrator, you can create this SST file by exporting the certificates from a trusted machine using the `Export-Certificate` cmdlet and specifying the type as SST. For more information the `Export-Certificate` cmdlet, see the Export-Certificate reference topic.

Once the SST file is generated, use the `Set-Smimeconfig` cmdlet to save it in the virtual certificate store by using the *-SMIMECertificateIssuingCA* parameter. For example: `Set-SmimeConfig -SMIMECertificateIssuingCA (Get-Content filename.sst -Encoding Byte)`

Ensuring a certificate is valid

Exchange 2013 SP1 first checks for the SST file and validates the certificate. If the validation fails, it will look at the local machine certificate store to validate the certificate. This behavior is new for Exchange 2013 SP1 and different from prior versions of Exchange. In Exchange Online only the SST will be used for validation.

S/MIME for message signing and encryption

Mailbox audit logging

Exchange Server 2013 > Messaging policy and compliance >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-12-12*

Because mailboxes can contain sensitive, high business impact (HBI) information and personally identifiable information (PII), it's important that you track who logs on to the mailboxes in your

organization and what actions are taken. It's especially important to track access to mailboxes by users other than the mailbox owner. These users are referred to as *delegate users*.

By using *mailbox audit logging*, you can log mailbox access by mailbox owners, delegates (including administrators with full access permissions to mailboxes), and administrators.

When you enable audit logging for a mailbox, you can specify which user actions (for example, accessing, moving, or deleting a message) will be logged for a logon type (administrator, delegate user, or owner). Audit log entries also include important information such as the client IP address, host name, and process or client used to access the mailbox. For items that are moved, the entry includes the name of the destination folder.

Mailbox audit logs

Mailbox audit logs are generated for each mailbox that has mailbox audit logging enabled. Log entries are stored in the Recoverable Items folder in the audited mailbox, in the Audits subfolder. This ensures that all audit log entries are available from a single location, regardless of which client access method was used to access the mailbox or which server or workstation an administrator used to access the mailbox audit log. If you move a mailbox to another Mailbox server, the mailbox audit logs for that mailbox are also moved because they're located in the mailbox.

By default, mailbox audit log entries are retained in the mailbox for 90 days and then deleted. You can modify this retention period by using the *AuditLogAgeLimit* parameter with the Set-Mailbox cmdlet. If a mailbox is on In-Place Hold or Litigation Hold, audit log entries are only retained until the audit log retention period for the mailbox is reached. To retain audit log entries longer, you have to increase the retention period by changing the value for the *AuditLogAgeLimit* parameter. You can also export audit log entries before the retention period is reached. For more information, see:

- Export mailbox audit logs
- Create a mailbox audit log search

Enabling mailbox audit logging

Mailbox audit logging is enabled per mailbox. Use the **Set-Mailbox** cmdlet to enable or disable mailbox audit logging. For details, see Enable or disable mailbox audit logging for a mailbox.

When you enable mailbox audit logging for a mailbox, access to the mailbox and certain administrator and delegate actions are logged by default. To log actions taken by the mailbox owner, you must specify which owner actions should be audited.

Mailbox actions logged by mailbox audit logging

The following table lists the actions logged by mailbox audit logging, including the logon types for which the action can be logged.

Action	Description	Administrator	Delegate	Owner
Copy	An item is copied to another folder.	Yes	Yes	No
Create	An item is created in the mailbox. (For example, a message is sent or received.) Note that folder creation isn't audited.	Yes*	Yes*	Yes
FolderBind	A mailbox folder is accessed.	Yes*	Yes**	No
HardDelete	An item is deleted permanently from the Recoverable Items folder.	Yes*	Yes*	Yes
MessageBind	An item is accessed in the reading pane or opened.	Yes	No	No
Move	An item is moved to another folder.	Yes*	Yes	Yes
MoveToDeletedItems	An item is moved to the Deleted Items folder.	Yes*	Yes	Yes
SendAs	A message is sent using Send As permissions.	Yes*	Yes*	Not applicable

SendOnBehalf	A message is sent using Send on Behalf permissions.	Yes*	Yes	Not applicable
SoftDelete	An item is deleted from the Deleted Items folder.	Yes*	Yes*	Yes
Update	An item's properties are updated.	Yes*	Yes*	Yes

* Audited by default if auditing is enabled for a mailbox.

** Entries for folder bind actions performed by delegates are consolidated. One log entry is generated for individual folder access within a time span of three hours.

If you no longer require certain types of mailbox actions to be audited, you should modify the mailbox's audit logging configuration to disable those actions. Existing log entries aren't purged until the age limit for audit log entries is reached.

Searching mailbox audit log entries

You can use the following methods to search mailbox audit log entries:

- **Synchronously search a single mailbox** You can use the Search-MailboxAuditLog cmdlet to synchronously search mailbox audit log entries for a single mailbox. The cmdlet displays search results in the Exchange Management Shell window. For details, see Search the mailbox audit log for a mailbox.
- **Asynchronously search one or more mailboxes** You can create a mailbox audit log search to asynchronously search mailbox audit logs for one or more mailboxes, and then have the search results sent to a specified email address. The search results are sent as an XML attachment. To create the search, use the New-MailboxAuditLogSearch cmdlet. For details, see Create a mailbox audit log search.
- **Use auditing reports in the Exchange Admin Center (EAC)** You can use the **Auditing** tab in the EAC to run a non-owner mailbox access report or export entries from the mailbox audit log. For details, see:
  - Run a non-owner mailbox access report
  - Export mailbox audit logs

Mailbox audit log entries

The following table describes the fields logged in a mailbox audit log entry.

Field	Populated with
Operation	One of the following actions: • Copy • Create • FolderBind • HardDelete • MessageBind • Move • MoveToDeletedItems • SendAs • SendOnBehalf • SoftDelete • Update
OperationResult	One of the following results: • Failed • PartiallySucceeded • Succeeded
LogonType	Logon type of the user who performed the operation. Logon types include: • Owner • Delegate • Admin
DestFolderId	Destination folder GUID for move operations.
DestFolderPathName	Destination folder path for move operations.
FolderId	Folder GUID.
FolderPathName	Folder path.
ClientInfoString	Details that identify which client or Exchange component performed the operation.
ClientIPAddress	Client computer IP address.

ClientMachineName	Client computer name.
ClientProcessName	Name of the client application process.
ClientVersion	Client application version.
InternalLogonType	Logon type of the user who performed the operation. Logon types include: • Owner • Delegate • Admin
MailboxOwnerUPN	Mailbox owner user principal name (UPN).
MailboxOwnerSid	Mailbox owner security identifier (SID).
DestMailboxOwnerUPN	Destination mailbox owner UPN, logged for cross-mailbox operations.
DestMailboxOwnerSid	Destination mailbox owner SID, logged for cross-mailbox operations.
DestMailboxOwnerGuid	Destination mailbox owner GUID.
CrossMailboxOperation	Information about whether the operation logged is a cross-mailbox operation (for example, copying or moving messages between mailboxes).
LogonUserDisplayName	Display name of user who is logged on.
DelegateUserDisplayName	Delegate user display name.
LogonUserSid	SID of user who is logged on.
SourceItems	ItemID of mailbox items on which the logged action is performed (for example, move or delete). For operations performed on a number of items, this field is returned as a collection of

	items.
SourceFolders	Source folder GUID.
ItemId	Item ID.
ItemSubject	Item subject.
MailboxGuid	Mailbox GUID.
MailboxResolvedOwnerName	Mailbox user resolved name in the format *DOMAIN\SamAccountName*.
LastAccessed	Time when the operation was performed.
Identity	Audit log entry ID.

More information

- **Administrator access to mailboxes** Mailboxes are considered to be accessed by an administrator only in the following scenarios:
  - In-Place eDiscovery is used to search a mailbox.
  - The New-MailboxExportRequest cmdlet is used to export a mailbox.
  - Microsoft Exchange Server MAPI Editor is used to access the mailbox.
- **Bypassing mailbox auditing logging** Mailbox access by authorized automated processes such as accounts used by third-party tools or accounts used for lawful monitoring can create a large number of mailbox audit log entries and may not be of interest to your organization. You can configure such accounts to bypass mailbox audit logging. For details, see Bypass a user account from mailbox audit logging.
- **Logging mailbox owner actions** For mailboxes such as the Discovery Search Mailbox, which may contain more sensitive information, consider enabling mailbox audit logging for mailbox owner actions such as message deletion.

Mailbox audit logging procedures

Applies to: *Exchange Server 2013*

Topic Last Modified: *2010-07-16*

Enable or disable mailbox audit logging for a mailbox

Bypass a user account from mailbox audit logging

Search the mailbox audit log for a mailbox

Create a mailbox audit log search

Enable or disable mailbox audit logging for a mailbox

Messaging policy and compliance > Mailbox audit logging > Mailbox audit logging procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-14*

With mailbox audit logging, you can track logons to a mailbox as well as what actions are taken while the user is logged on. When you enable mailbox audit logging for a mailbox, some actions performed by administrators and delegates are logged by default. None of the actions performed by the mailbox owner are logged. To learn more about mailbox audit logging, see Mailbox audit logging.

Caution:

Auditing of mailbox owner actions can generate a large number of mailbox audit log entries and is therefore disabled by default. We recommend that you only enable auditing of specific owner actions needed to meet business or security requirements.

For additional tasks related to mailbox audit logging, see Mailbox audit logging procedures.

What do you need to know before you begin?

- Estimated time to complete: 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mailbox audit logging" entry in the Messaging policy and compliance permissions topic.
- You can't use the Exchange Administration Center (EAC) to enable or disable mailbox audit logging. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to enable or disable mailbox audit logging

You can use the Shell to enable or disable mailbox audit logging for a mailbox. This enables or disables logging of all operations specified for administrator, delegates, and the mailbox owner.

This example enables mailbox audit logging for Ben Smith's mailbox.

```
Set-Mailbox -Identity "Ben Smith" -AuditEnabled $true
```

This example disables mailbox audit logging for Ben Smith's mailbox.

```
Set-Mailbox -Identity "Ben Smith" -AuditEnabled $false
```

For detailed syntax and parameter information, see Set-Mailbox.

Use the Shell to configure mailbox audit logging settings for administrator, delegate, and owner access

When mailbox audit logging is enabled for a mailbox, only the administrator, delegate, and owner actions specified in the audit logging configuration for the mailbox are logged.

This example specifies that the `SendAs` or `SendOnBehalf` actions performed by delegate users will be logged for Ben Smith's mailbox.

```
Set-Mailbox -Identity "Ben Smith" -AuditDelegate
SendAs,SendOnBehalf -AuditEnabled $true
```

This example specifies that the `MessageBind` and `FolderBind` actions performed by administrators will be logged for Ben Smith's mailbox.

```
Set-Mailbox -Identity "Ben Smith" -AuditAdmin
MessageBind,FolderBind -AuditEnabled $true
```

This example specifies that the `HardDelete` action performed by the mailbox owner will be logged for Ben Smith's mailbox.

```
Set-Mailbox -Identity "Ben Smith" -AuditOwner HardDelete -
AuditEnabled $true
```

For detailed syntax and parameter information, see Set-Mailbox.

How do you know this worked?

To verify that you have successfully enabled mailbox audit logging for a mailbox and specified the correct logging settings for administrator, delegate, or owner access, use the Get-Mailbox cmdlet to retrieve the mailbox audit logging settings for that mailbox.

This example retrieves Ben Smith's mailbox settings and pipes the specified audit settings, including the audit log age limit, to the **Format-List** cmdlet.

```
Get-Mailbox "Ben Smith" | Format-List *audit*
```

Bypass a user account from mailbox audit logging

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-05-21*

When you enable mailbox audit logging for a mailbox, specified mailbox access events (for example, accessing a folder or a message, or permanently deleting a message) are logged. However, access by some authorized accounts, such as accounts used by third-party tools or accounts used for lawful monitoring, can create a large number of mailbox audit log entries and may not be of interest to your organization.

You can configure a user or computer account to bypass mailbox audit logging, so actions taken by that user or account for any mailbox aren't logged. By bypassing trusted user or computer accounts that need frequent access to mailboxes, you can reduce the noise in mailbox audit logs.

Caution:

If you use mailbox audit logging to audit mailbox access and actions, you must monitor mailbox audit bypass associations at regular intervals. If a mailbox audit bypass association is added for an account, the account can access any mailbox in the organization to which it has been assigned permissions, without any mailbox audit logging entries being generated for such access or any actions taken (such as message deletions).

For additional management tasks related to mailbox audit logging, see Mailbox audit logging procedures.

What do you need to know before you begin?

- Estimated time to complete: 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mailbox audit logging" entry in the Messaging policy and compliance permissions topic.
- When an account is configured to bypass mailbox audit logging, access to any mailbox by that account won't be logged. You can't configure an account to bypass the logging of access to a specific mailbox.
- You can't use the Exchange Administration Center (EAC) to enable or disable mailbox audit logging bypass for an account. You must use the Shell.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to enable or disable mailbox audit logging bypass for an account

For an example of how to enable mailbox audit logging bypass for an account, see Example 1 in Set-MailboxAuditBypassAssociation.

For an example of how to disable mailbox audit logging bypass for an account, see Example 2 in Set-MailboxAuditBypassAssociation.

How do you know this worked?

After you have bypassed a user account from mailbox audit logging, you can check the bypass settings by running the Get-MailboxAuditBypassAssociation cmdlet.

For examples of how to check mailbox audit bypass associations, see Examples in Get-MailboxAuditBypassAssociation.

Search the mailbox audit log for a mailbox

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

You can synchronously search mailbox audit log entries for a mailbox and have the search results displayed in the Shell.

If you want to search mailbox audit logs for multiple mailboxes and have the results emailed to a specified address, you must create a mailbox audit log search instead. For details, see Create a mailbox audit log search.

For additional management tasks related to mailbox audit logging, see Mailbox audit logging procedures.

What do you need to know before you begin?

- Estimated time to complete: 1 minute.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mailbox audit logging" entry in the Messaging policy and compliance permissions topic.
- By default, mailbox audit logging is disabled for all mailboxes. For each mailbox you want to audit, you must enable audit logging and specify the mailbox owner, delegate, or administrator actions you want to audit. For details, see Enable or disable mailbox audit logging for a mailbox.
- You can't use the EAC to search the mailbox audit log for a mailbox. However, you can use the EAC to run or search for and export a non-owner mailbox access report.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to search the mailbox audit log for a mailbox

For examples of how to use the Shell to search the mailbox audit log for a mailbox, see Examples in Search-MailboxAuditLog.

Create a mailbox audit log search

Messaging policy and compliance > Mailbox audit logging > Mailbox audit logging procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-11*

You can create a mailbox audit log search to asynchronously search one or more mailboxes and have the search results sent by email as an XML file to specified addresses.

To search mailbox audit logs for a single mailbox and have the results displayed in the Shell, see Search the mailbox audit log for a mailbox.

For additional management tasks related to mailbox audit logging, see Mailbox audit logging procedures.

What do you need to know before you begin?

- Estimated time to complete: 2 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mailbox audit logging" entry in the Messaging policy and compliance permissions topic.
- By default, mailbox audit logging is disabled for all mailboxes. For each mailbox you want to audit, you must enable audit logging and specify the mailbox owner, delegate, or administrator actions you want to audit. For more details, see Enable or disable mailbox audit logging for a mailbox.
- You can't use the EAC to search mailbox audit logs for owner access. The auditing section in EAC includes reports for non-owner mailbox access and also allows you to search for and export non-owner access events.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to create a mailbox audit log search

1. Navigate to **Compliance management** > **Auditing**.
2. In the list view, select **Export mailbox audit logs**.
3. In **Export Mailbox Audit Logs**, complete the following fields, and then click **Export**:
   - **Start date**
   - **End date**
   - **Search these mailboxes or leave blank to find all mailboxes accessed by non-owners**

Caution:
Depending on the number of mailboxes in your organization and the amount of mailbox audit

log data in each mailbox, searching all mailboxes may take a long time.

- **Search for access by**

Select from the following types of access events you want to search:

  - **All non-owners**
  - **External users**
  - **Administrators and delegated users**
  - **Administrators**

- **Send the auditing report to**

Use the Shell to create a mailbox audit log search

For an example of how to use the Shell to create a mailbox audit log search, see Example 1 in **New-MailboxAuditLogSearch**.

Administrator audit logging

Exchange Server 2013 > Messaging policy and compliance >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-08*

You can use administrator audit logging in Microsoft Exchange Server 2013 to log when a user or administrator makes a change in your organization. By keeping a log of the changes, you can trace changes to the person who made the change, augment your change logs with detailed records of the change as it was implemented, comply with regulatory requirements and requests for discovery, and more.

By default, audit logging is enabled in new installations of Exchange 2013.

Contents

What gets audited

Cmdlets that are run directly in the Exchange Management Shell are audited. In addition, operations performed using the Exchange admin center (EAC) are also logged because those operations run cmdlets in the background.

Cmdlets, regardless of where they're run, are audited if a cmdlet is on the cmdlet auditing list and one or more parameters on that cmdlet are on the parameter auditing list. **Get-** and **Search-** cmdlets aren't logged. Audit logging is intended to show what actions have been taken to modify objects in an Exchange organization rather than what objects have been viewed.

Important:
A cmdlet might not be logged if an error occurs before the cmdlet calls the Admin Audit Log cmdlet extension agent. If an error occurs after the Admin Audit Log agent is called, the cmdlet is logged along with the associated error. For more information, see the Admin Audit Log Agent section later in this topic. Changes made using Microsoft Exchange Server 2010 management tools are logged; however, changes using Microsoft Exchange Server 2007 management tools aren't logged. Changes to the audit log configuration are refreshed every 60 minutes on computers that have the Shell open at the time a configuration change is made. If you want to apply the changes immediately, close and then open the Shell again on each computer. A command may take up to 15 minutes after it's run to appear in audit log search results. This is because audit log entries must be indexed before they can be searched. If a command doesn't appear in the administrator audit log, wait a few minutes and run the search again.

Audit logging configuration

By default, if audit logging is enabled, a log entry is created every time any cmdlet, other than a **Get-** or **Search-** cmdlet, is run. If you don't want to audit every cmdlet that's run, you can configure audit logging to audit only the cmdlets and parameters you're interested in. You configure audit logging with the **Set-AdminAuditLogConfig** cmdlet. The parameters referenced in the following sections are used with this cmdlet.

Important:
Changes to the administrator audit log configuration are always logged, regardless of whether the **Set-AdministratorAuditLog** cmdlet is included in the list of cmdlets being audited and whether audit logging is enabled or disabled.

When a command is run, Exchange inspects the cmdlet that was used. If the cmdlet that was run matches any of the cmdlets provided with the *AdminAuditLogConfigCmdlets* parameter, Exchange then checks the parameters specified in the *AdminAuditLogConfigParameters* parameter. If at least one or more parameters from the parameters list are matched, Exchange logs the cmdlet that was run in the mailbox specified using the *AdminAuditLogMailbox* parameter. The following sections contain more information about each aspect of the audit logging configuration.

For more information about managing audit logging configuration, see Manage administrator audit logging.

Return to top

Cmdlets

You can control which cmdlets are audited by providing a list of cmdlets, and their parameters, that you want to log. When you configure audit logging, you can specify to audit every cmdlet, or you can specify the cmdlets you want to audit by using the *AdminAuditLogConfigCmdlets* parameter. You can specify full cmdlet names, such as **New-Mailbox**, or you can specify partial cmdlet names and enclose those names in wildcard characters, such as an asterisk (*). For example, if you want to log when any cmdlet that contains the string `Transport` runs, you can specify a value of `*Transport*`. You can use a mix of full cmdlet names and partial cmdlet names at the same time to tailor the audit logging configuration to your needs.

Parameters

In addition to specifying which cmdlets you want to log, you can also indicate that cmdlets should only be logged if certain parameters on those cmdlets are used. Use the *AdminAuditLogConfigParameters* parameter to specify which parameters should be logged. As with cmdlets, you can specify full parameter names, such as `Database`, or partial parameter names enclosed in wildcard characters (*), such as `*Address*`, or a combination of both.

Audit log age limit

By default, audit logging is configured to store audit log entries for 90 days. After 90 days, the audit log entry is deleted. You can change the audit log age limit using the *AdminAuditLogAgeLimit* parameter. You can specify the number of days, hours, minutes, and seconds that audit log entries should be kept. To specify a value, use the format `dd.hh:mm:ss` where the following applies:

- **dd** The number of days to keep the audit log entry.
- **hh** The number of hours to keep the audit log entry.
- **mm** The number of minutes to keep the audit log entry.
- **ss** The number of seconds to keep the audit log entry.

You must specify multiple years using the `dd` field. For example, 365 days equals one year; 730 days equals two years; 913 days equals two years and six months. For example, to set the audit log age limit to two years and six months, use the syntax `913.00:00:00`.

Caution:

You can set the audit log age limit to a value that's less than the current age limit. If you do this, any audit log entry whose age exceeds the new age limit is deleted.
If you set the age limit to 0, Exchange deletes all the entries in the audit log.
We recommend that you grant permissions to configure the audit log age limit only to highly trusted users.

Verbose logging

By default, the administrator audit log records only the cmdlet name, cmdlet parameters (and values specified), the object that was modified, who ran the cmdlet, when the cmdlet was run, and on what server the cmdlet was run. The administrator audit log doesn't log what properties were modified on the object. If you want the audit log to also include the properties of the object that were modified, you can enable verbose logging by setting the *LogLevel* parameter to `verbose`. When you enable verbose logging, in addition to the information logged by default, the properties modified on an object, including their old and new values, are included in the audit log.

Test cmdlets

Cmdlets that begin with the verb **Test** aren't logged by default. You can indicate that **Test** cmdlets should be logged by setting the *TestCmdletLoggingEnabled* parameter to `$true`. Although you can enable logging of test cmdlets, we recommend that you do this only for short periods of time because test cmdlets can produce a large amount of information.

Audit logs

Each time a cmdlet is logged, an audit log entry is created. Audit logs are stored in a hidden, dedicated arbitration mailbox that can only be accessed using the EAC or the **Search-AdminAuditLog** or **New-AdminAuditLogSearch** cmdlet. It can't be opened using Microsoft Outlook Web App or Microsoft Outlook. The following sections provide information about the following:

- What's included in the logs
- Reports available on the EAC **auditing** page
- Audit log search cmdlets

Audit log contents

Each audit log entry contains the information described in the following table. The audit log contains one or more audit log entries. The number of audit log entries is controlled by the audit log age limit specified using the **Set-AdminAuditLogConfig** cmdlet. Any audit log entry that exceeds the age limit is deleted.

Audit log entry fields

Field	Description
`RunspaceId`	This field is used internally by Exchange.
`ObjectModified`	This field contains the object that was modified by the cmdlet specified in the `CmdletName` field.
`CmdletName`	This field contains the name of the cmdlet that

	was run by the user in the `Caller` field.
`CmdletParameters`	This field contains the parameters that were specified when the cmdlet in the `CmdletName` field was run. Also stored in this field, but not visible in the default output, is the value specified with the parameter, if any. For more information about how to access the additional information in this field, see Search the role group changes or administrator audit logs.
`ModifiedProperties`	This field contains the properties that were modified on the object in the `ObjectModified` field. Also stored in this field, but not visible in the default output, are the old value of the property and the new value that was stored. For more information about how to access the additional information in this field, see Search the role group changes or administrator audit logs. **Important:** This field is only populated if the *LogLevel* parameter on the **Set-AdminAuditLogConfig** cmdlet is set to `Verbose`.
`Caller`	This field contains the user account of the user who ran the cmdlet in the `CmdletName` field.
`Succeeded`	This field specifies whether the cmdlet in the `CmdletName` field ran successfully. The value is either `True` or `False`.
`Error`	This field contains the error message generated if the cmdlet in the `CmdletName` field failed to complete successfully.
`RunDate`	This field contains the date and time when the

	cmdlet in the `CmdletName` field was run. The date and time are stored in Coordinated Universal Time (UTC) format.
`OriginatingServer`	This field indicates the server on which the cmdlet specified in the `CmdletName` field was run.
`Identity`	This field is used internally by Exchange.
`IsValid`	This field is used internally by Exchange.
`ObjectState`	This field is used internally by Exchange.

Return to top

EAC auditing reports

The **auditing** page in the EAC has several reports that provide information about various types of compliance and administrative configuration changes. The following reports provide information about configuration changes in your organization:

- **Administrator role group report** This report enables you to search for changes to management role groups that you specify within a specified timeframe. The results that are returned include the role groups that have been changed, who changed them and when, and what changes were made. A maximum of 3,000 entries can be returned. If your search might return more than 3,000 entries, use the **Administrator audit log** report or the **Search-AdminAuditLog** cmdlet.
- **Administrator audit log** This report enables you to export the audit log entries recorded within a specified timeframe to a XML file and then send the file via email to a recipient you specify. For more information about the contents of the XML file, see Administrator audit log structure.

For information about how to use these reports, see Search the role group changes or administrator audit logs.

For information about the other reports included on the **auditing** page see Exchange auditing reports.

Search-AdminAuditLog cmdlet

When you run the **Search-AdminAuditLog** cmdlet, all the audit log entries that match the search criteria you specify are returned. You can specify the following search criteria:

- **Cmdlets** Specifies the cmdlets you want to search for in the administrator audit log.
- **Parameters** Specifies the parameters, separated by commas, you want to search for in the

administrator audit log. You can only search for parameters if you specify a cmdlet to search for.

- **End date** Scopes the administrator audit log results to log entries that occurred on or before the specified date.
- **Start date** Scopes the administrator audit log results to log entries that occurred on or after the specified date.
- **Object IDs** Specifies that only administrator audit log entries that contain the specified changed objects should be returned
- **User IDs** Specifies that only the administrator audit log entries that contain the specified IDs of the user who ran the cmdlet should be returned.
- **Successful completion** Specifies whether only administrator audit log entries that indicated a success or failure should be returned.

Each audit log entry returned contains the information described in the table in Audit Log Contents. By default, only the first 1,000 log entries that match the criteria you specify are returned. However, you can override this default and return more or fewer entries using the *ResultSize* parameter. You can specify a value of `Unlimited` with the *ResultSize* parameter to return all log entries that match the specified criteria.

For information about how to use the **Search-AdminAuditLog** cmdlet, see Search the role group changes or administrator audit logs.

New-AdminAuditLogSearch cmdlet

The **New-AdminAuditLogSearch** cmdlet searches the audit log just like the **Search-AdminAuditLog** cmdlet. However, instead of displaying the results of the audit log search in the Shell, the **New-AdminAuditLogSearch** cmdlet performs the search and then sends the results of the search to a recipient you specify via an email message. The results are included as an XML attachment to the email message.

You can use the same search criteria with the **New-AdminAuditLogSearch** cmdlet that's used on the **Search-AdminAuditLog** cmdlet. For a list of the search criteria, see Search-AdminAuditLog Cmdlet.

After you run the **New-AdminAuditLogSearch** cmdlet, Exchange may take up to 15 minutes to deliver the report to the specified recipient. The XML file attached report can be a maximum of 10 megabytes (MB). The XML file contains the same information described in the table in Audit Log Contents. For more information about the structure of the XML file, see Administrator audit log structure.

Note:

Outlook Web App doesn't allow you to open XML attachments by default. You can either configure Exchange to allow XML attachments to be viewed using Outlook Web App, or you can use another email client, such as Microsoft Outlook, to view the attachment. For information about how to configure Outlook Web App to allow you to view an XML attachment, see View or configure Outlook Web App virtual directories.

For information about how to use the **New-AdminAuditLogSearch** cmdlet, see Search the role group changes or administrator audit logs.

Return to top

Manual audit log entries

In addition to logging Exchange cmdlets when they're run, Exchange 2013 enables you to manually write log entries to the audit log. Exchange 2013 supports this using the **Write-AdminAuditLog** cmdlet. Situations where you might want to add a manual log entry include the following:

- Custom script entry and exit
- Change control information
- Maintenance start and end times

With the **Write-AdminAuditLog** cmdlet, you specify a string of text to include in the audit log using the *Comment* parameter. The *Comment* parameter accepts an alphanumeric string up to 500 characters. Included in the manual audit log entry along with the comment string is all of the same information captured when an Exchange cmdlet is logged. For a description of each field included in the audit log, see the table in Audit Log Contents.

You can retrieve manual audit log entries the same way as any other log entry, using the EAC **auditing** page or using the **Search-AdminAuditLog** or **New-AdminAuditLogSearch** cmdlets.

To view the contents of the *Comment* parameter on the **Write-AdminAuditLog** cmdlet in a manual audit log entry, see Search the role group changes or administrator audit logs.

Active Directory replication

Administrator audit logging relies on Active Directory replication to replicate the configuration settings you specify to the domain controllers in your organization. Depending on your replication settings, the changes you make may not be immediately applied to all servers running Exchange 2013 or Exchange 2010 in your organization.

Admin Audit Log agent

The Admin Audit Log built-in cmdlet extension agent performs administrator audit logging of cmdlet operations in Exchange 2013. This agent reads the audit log configuration and then performs an evaluation of each cmdlet run in your organization. If the criteria you've specified in the audit log configuration matches the cmdlet that's being run, the agent generates an audit log.

The Admin Audit Log agent is enabled by default, which is required for audit logging to function. It can't be disabled, and its priority can't be changed. For more information about cmdlet extension agents, see Cmdlet extension agents.

Administrator audit log structure

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-11-19*

Administrator audit logs contain a record of all the cmdlets and parameters that have been run in the Exchange Management Shell and by the Exchange Administration Center (EAC). They're created on-demand when you run the Administrator audit log report in the EAC, or when you run the **New-AdminAuditLogSearch** cmdlet in the Shell. For more information about audit logs, see Administrator audit logging.

The audit logs are XML files and can contain multiple audit log entries. The following table describes each XML tag and its associated attributes.

Looking for management tasks related to Administrator audit logs? See Manage administrator audit logging.

Audit log XML tags and attributes

Element	Attribute	Description
`<?xml version="1.0" encoding="utf-8"?>`	`N/A`	This is the XML document declaration tag. It's included in every audit log XML file and contains the XML version number and the character encoding value.
`SearchResults`	`N/A`	This tag contains all the audit log entries in the XML file. The `Event` tag is a child of this tag. There is only one `SearchResults` tag per XML file.
`Event`		This tag contains the audit log entry for an individual cmdlet. This tag contains the `Caller`, `Cmdlet`, `ObjectModified`, `RunDate`, `Succeeded`, `Error`, and

		`OriginatingServer` attributes. The `CmdletParameters` and `ModifiedProperties` tags are children of this tag. There is one `Event` tag per audit log entry.
	`Caller`	This attribute contains the user account of the user who ran the cmdlet in the `Cmdlet` attribute.
	`Cmdlet`	This attribute contains the name of the cmdlet that was run by the user in the `Caller` attribute.
	`ObjectModified`	This attribute contains the object that was modified by the cmdlet specified in the `Cmdlet` attribute. The `ModifiedProperties` tag shows which properties were modified on this object.
	`RunDate`	This attribute contains the date and time when the cmdlet in the `Cmdlet` attribute was run.
	`Succeeded`	This attribute specifies whether the cmdlet in the `Cmdlet` attribute ran successfully. The value is either `True` or `False`.
	`Error`	This attribute contains the error message generated if the cmdlet in the `Cmdlet` attribute failed to complete successfully.

		If no error was encountered, the value is set to `None`.
	`OriginatingServer`	This attribute contains the server on which the cmdlet specified in the `Cmdlet` attribute was run.
`CmdletParameters`	`N/A`	This tag contains all of the parameters specified when the cmdlet was run. The `Parameter` tag is a child of this tag. There is one `CmdletParameters` tag per `Event` tag.
`Parameter`		This tag contains an individual parameter that was specified when the cmdlet was run. This tag contains the `Name` and `Value` attributes. There can be multiple `Parameter` tags per `CmdletParameters` tag.
	`Name`	This attribute contains the name of the parameter that was specified on the cmdlet that was run.
	`Value`	This attribute contains the value that was provided on the parameter specified in the `Name` attribute.
`ModifiedProperties`	`N/A`	This tag contains all of the properties that were modified

		by the cmdlet that was run. The `Property` tag is a child of this tag. There is one `ModifiedProperties` tag per `Event` tag. **Important:** This tag is only populated if the *LogLevel* parameter on the **Set-AdminAuditLogConfig** cmdlet is set to `Verbose`.
`Property`		This tag contains an individual property that was specified when the cmdlet was run. This tag contains the `Name`, `OldValue`, and `NewValue` attributes. There can be multiple `Property` tags per `ModifiedProperties` tag.
	`Name`	This attribute contains the name of the property that was modified when the cmdlet was run.
	`OldValue`	This attribute contains the value that was contained in the property specified in the `Name` attribute before it was changed.
	`NewValue`	This attribute contains the value that the property in the `Name` attribute was changed to.

Example audit log entry

The following is an example of a typical audit log entry. Based on the information in log entry, we know the following occurred:

- On 10/18/2012 at 3:48 P.M. Pacific Daylight Time (UTC-7), the user `Administrator` ran the cmdlet **Set-Mailbox**.
- The two following parameters were provided when the **Set-Mailbox** cmdlet was run:
  - *Identity* with a value of `david`
  - *ProhibitSendReceiveQuota* with a value of `10GB`
- The two following properties on the object `david` were modified:

Note:

The modified properties are saved to the audit log because the *LogLevel* parameter on the `Set-AdminAuditLogConfig` cmdlet was set to `Verbose` in this example.

  - *ProhibitSendReceiveQuota* with a new value of `10GB`, which replaced the old value of `35GB`
- The operation completed successfully without any errors.

```
<?xml version="1.0" encoding="utf-8"?>
<SearchResults>
  <Event Caller="corp.e15a.contoso.com/Users/Administrator"
Cmdlet="Set-Mailbox" ObjectModified="corp.e15a.contoso.com/
Users/david" RunDate="2012-10-18T15:48:15-07:00"
Succeeded="true" Error="None" OriginatingServer="WIN8MBX
(15.00.0516.032)">
    <CmdletParameters>
      <Parameter Name="Identity" Value="david" />
      <Parameter Name="ProhibitSendReceiveQuota" Value="10
GB (10,737,418,240 bytes)" />
    </CmdletParameters>
    <ModifiedProperties>
      <Property Name="ProhibitSendReceiveQuota"
OldValue="35 GB (37,580,963,840 bytes)" NewValue="10 GB
(10,737,418,240 bytes)" />
    </ModifiedProperties>
  </Event>
</SearchResults>
```

Manage administrator audit logging

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-05-17*

Administrator audit logging in Microsoft Exchange Server 2013 enables you to create a log entry each time a specified cmdlet is run. Log entries provide you with information about what cmdlet was run, which parameters were used, who ran the cmdlet, and what objects were affected. For more information about administrator audit logging, see Administrator audit logging.

What do you need to know before you begin?

- Estimated time to complete each procedure: less than 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Administrator audit logging" entry in the Exchange and Shell infrastructure permissions topic.
- Administrator audit logging relies on Active Directory replication to replicate the configuration settings you specify to the domain controllers in your organization. Depending on your replication settings, the changes you make may not be immediately applied to all Exchange 2013 servers in your organization.
- Changes to the audit log configuration are refreshed every 60 minutes on computers that have the Shell open at the time a configuration change is made. If you want to apply the changes immediately, close and then open the Shell again on each computer.
- A command may take up to 15 minutes after it's run to appear in audit log search results. This is because audit log entries must be indexed before they can be searched. If a command doesn't appear in the administrator audit log, wait a few minutes and run the search again.
- You must use the Shell to perform these procedures.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Specify the cmdlets to be audited

By default, audit logging creates a log entry for every cmdlet that's run. If you're enabling audit logging for the first time and want this behavior, you don't have to change the cmdlet audit list. If you've previously specified cmdlets to audit and now want to audit all cmdlets, you can audit all cmdlets by specifying the asterisk (*) wildcard character with the *AdminAuditLogCmdlets* parameter on the **Set-AdminAuditLogConfig** cmdlet, as shown in the following command.

```
Set-AdminAuditLogConfig -AdminAuditLogCmdlets *
```

You can specify which cmdlets to audit by providing a list of cmdlets using the *AdminAuditLogCmdlets* parameter. When you provide the list of cmdlets to audit, you can provide single cmdlets, cmdlets with the asterisk (*) wildcard characters, or a mix of both. Each entry in the list is separated by commas. The following values are all valid:

- `New-Mailbox`
- `*TransportRule`
- `*Management*`
- `Set-Transport*`

This example audits the cmdlets specified in the preceding list.

```
Set-AdminAuditLogConfig -AdminAuditLogCmdlets New-Mailbox,
*TransportRule, *Management*, Set-Transport*
```

For detailed syntax and parameter information, see Set-AdminAuditLogConfig.

Specify the parameters to be audited

By default, audit logging creates a log entry for every cmdlet that's run, regardless of the parameters specified. If you're enabling audit logging for the first time and want this behavior, you don't have to change the parameter audit list. If you've previously specified parameters to audit and now want to audit all parameters, you can do so by specifying the asterisk (*) wildcard character with the *AdminAuditLogParameters* parameter on the **Set-AdminAuditLogConfig** cmdlet, as shown in the following command.

```
Set-AdminAuditLogConfig -AdminAuditLogParameters *
```

You can specify which parameters you want to audit by using the *AdminAuditLogParameters* parameter. When you provide the list of parameters to audit, you can provide single parameters, parameters with the asterisk (*) wildcard characters, or a mix of both. Each entry in the list is separated by commas. The following values are all valid:

- `Database`
- `*Address*`
- `Custom*`
- `*Region`

Note:

For an audit log entry to be created when a command is run, the command must include at least one or more parameters that exist on at least one or more cmdlets specified with the *AdminAuditLogCmdlets* parameter.

This example audits the parameters specified in the preceding list.

```
Set-AdminAuditLogConfig -AdminAuditLogParameters Database,
*Address*, Custom*, *Region
```

For detailed syntax and parameter information, see Set-AdminAuditLogConfig.

Specify the audit log age limit

The audit log age limit determines how long audit log entries will be retained. When a log entry exceeds the age limit, it's deleted. The default is 90 days.

You can specify the number of days, hours, minutes, and seconds that audit log entries should be kept. To specify a value, use the format dd.hh.mm:ss where the following applies:

- **dd** Number of days to keep the audit log entry
- **hh** Number of hours to keep the audit log entry
- **mm** Number of minutes to keep the audit log entry
- **ss** Number of seconds to keep the audit log entry

Caution:

You can set the audit log age limit to a value that's less than the current age limit. If you do this, any audit log entry whose age exceeds the new age limit will be deleted.
If you set the age limit to 0, Exchange deletes all the entries in the audit log.
We recommend that you grant permissions to configure the audit log age limit only to highly trusted users.

This example specifies an age limit of two years and six months.

```
Set-AdminAuditLogConfig -AdminAuditLogAgeLimit 913.00:00:00
```

For detailed syntax and parameter information, see Set-AdminAuditLogConfig.

Enable or disable logging of Test cmdlets

Cmdlets that start with the verb **Test** aren't logged by default. This is because **Test** cmdlets can generate a significant amount of data in a short time. Only enable the logging of **Test** cmdlets for short periods of time.

This command enables the logging of **Test** cmdlets.

```
Set-AdminAuditLogConfig -TestCmdletLoggingEnabled $True
```

This command disables the logging of **Test** cmdlets.

```
Set-AdminAuditLogConfig -TestCmdletLoggingEnabled $False
```

For detailed syntax and parameter information, see Set-AdminAuditLogConfig.

Disable administrator audit logging

To disable administrator audit logging, use the following command.

```
Set-AdminAuditLogConfig -AdminAuditLogEnabled $False
```

Enable administrator audit logging

To enable administrator audit logging, use the following command.

```
Set-AdminAuditLogConfig -AdminAuditLogEnabled $True
```

View administrator audit logging settings

To view the administrator audit logging settings that you've configured for your organization, use the following command.

```
Get-AdminAuditLogConfig
```

Exchange auditing reports

Exchange Server 2013 > Messaging policy and compliance >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-08-26*

Use audit logging to troubleshoot configuration issues by tracking specific changes made by administrators and to help you meet regulatory, compliance, and litigation requirements. Microsoft Exchange provides two types of audit logging:

- *Administrator audit logging* records any action, based on an Exchange Management Shell cmdlet, performed by an administrator. This can help you troubleshoot configuration issues or identify the cause of security-related or compliance-related problems. In Exchange Online, actions performed by Microsoft administrators and delegated administrators, are also recorded.
- *Mailbox audit logging* records whenever a mailbox is accessed by someone other than the person who owns the mailbox. This can help you determine who has accessed a mailbox and what they've done.

This topic explains the following:

- Export audit logs
- Run auditing reports
- Configure audit logging

- Enable mailbox audit logging
- Give users access to auditing reports
- Configure Outlook Web App to allow XML attachments

Export audit logs

On the **Compliance Management** > **Auditing** page in the Exchange admin center (EAC), you can search for and export entries from the administrator audit log and the mailbox audit log.

- **Export the administrator audit log** Any action performed by an administrator that's based on a Shell cmdlet and doesn't begin with the verbs **Get**, **Search**, or **Test** is logged in the administrator audit log. Audit log entries include the cmdlet that was run, the parameter and values used with the cmdlet, and when the operation was successful. You can search for and export entries from the administrator audit log. When you export your search results, Microsoft Exchange saves them in an XML file and attaches it to an email message. For more information, see:
  - Search the role group changes or administrator audit logs
  - **View and export the external admin audit log**
- **Export mailbox audit logs** When mailbox audit logging is enabled for a mailbox, Microsoft Exchange stores a record of actions performed on mailbox data by non-owners in the mailbox audit log, which is stored in a hidden folder in the mailbox being audited. Entries in this log indicate if the mailbox was accessed by someone other than the owner, who accessed the mailbox and when, the actions performed by the non-owner, and whether the action was successful. When you search for entries in the mailbox audit log and export them, Microsoft Exchange saves the search results in an XML file and attaches it to an email message. For more information, see Export mailbox audit logs.

Note:

By default, audit log entries are kept for 90 days. When an entry is older than 90 days, it's deleted. This setting can't be changed in a cloud-based organization. However, it can be changed in an on-premises Exchange organization by using the **Set-AdminAuditLog** cmdlet.

Run auditing reports

When you run any of the following reports on the **Auditing** page in the EAC, the results are displayed in the details pane of the report.

- **Run a non-owner mailbox access report** Use this report to find mailboxes that have been accessed by someone other than the person who owns the mailbox. For more information, see Run a non-owner mailbox access report.
- **Run an administrator role group report** Use this report to search for changes made to administrator role groups. For more information, see Search the role group changes or administrator audit logs.
- **Run an in-place discovery and hold report** Use this report to find mailboxes that have been put on, or removed from, In-Place Hold. For more information, see:
  - In-Place Hold

    - In-Place eDiscovery
- **Run a per-mailbox litigation hold report** Use this report to find mailboxes that were put on, or removed from, litigation hold. For more information, see.
    - Run a per-mailbox litigation hold report
    - Place a mailbox on Litigation Hold
- **Run the admin audit log report** Use this report to view entries from the administrator audit log. Instead of exporting the administrator audit log, which can take up to 24 hours to receive in an email message, you can run this report in the EAC. This report records configuration changes made by administrators in your organization. Up to 5000 entries will be displayed on multiple pages. To narrow the search, you can specify a date range. For more information, see:
    - View the administrator audit log
    - Administrator audit logging
- **Run the external admin audit log report** This report is only available in Exchange Online and Exchange Online Protection. Actions performed by Microsoft administrators or delegated administrators are logged in the administrator audit log. Use the external admin audit log report to search for and view the actions that administrators outside your organization performed on the configuration of your Exchange Online organization. For more information, see **View and export the external admin audit log**.

Configure audit logging

Before you can run auditing reports and export audit logs, you have to configure audit logging for your organization.

Enable mailbox audit logging

You have to enable mailbox audit logging for each mailbox that you want to run a non-owner mailbox access report for. If mailbox audit logging isn't enabled for a mailbox, you won't get any results when you run a report for it or export the mailbox audit log.

To enable mailbox audit logging for a single mailbox, run the following command in the Shell.

```
Set-Mailbox <Identity> -AuditEnabled $true
```

To enable mailbox auditing for all user mailboxes in your organization, run the following commands.

```
$UserMailboxes = Get-mailbox -Filter {(RecipientTypeDetails
-eq 'UserMailbox')}
$UserMailboxes | ForEach {Set-Mailbox $_.Identity -
AuditEnabled $true}
```

Give users access to Auditing reports

By default, administrators can access and run any of the reports on the Auditing page in the EAC. However, other users, such as a records manager or legal staff, have to be assigned the necessary permissions.

The easiest way to give users access is to add them to the Records Management role group. You can also use the Shell to give a user access to the **Auditing** page in the EAC by assigning the Audit Logs role to the user.

Add a user to the Records Management role group

1. Go to **Permissions** > **Admin Roles**.
2. In the list of role groups, click **Records Management**, and then click **Edit** .
3. Under **Members**, click **Add +**.
4. In the **Select Members** dialog box, select the user. You can search for a user by typing all or part of a display name, and then clicking **Search** . You can also sort the list by clicking the **Name** or **Display Name** column headings.
5. Click **Add +** and then click **OK** to return to the role group page.
6. Click **Save** to save the change to the role group.

In the details pane, the user is listed under **Members** and can access the Auditing page in the EAC, run auditing reports, and export audit logs.

Assign the Audit Logs role to a user

Run the following command to assign the Audit Logs role to a user.

```
New-ManagementRoleAssignment -Role "Audit Logs" -User
<Identity>
```

This enables the user to select **Compliance Management** > **Auditing** in the EAC to run any of the reports. The user can also export the mailbox audit log, and export and view the administrator audit log.

Note:

To allow a user to run auditing reports but not to export audit logs, use the preceding command to assign the View-Only Audit Logs role.

Configure Outlook Web App to allow XML attachments

When you export the mailbox audit log or administrator audit log, Microsoft Exchange attaches the audit log, which is an XML file, to an email message. However, Outlook Web App blocks XML attachments by default. If you want to use Outlook Web App to access these audit logs, you have to configure Outlook Web App to allow XML attachments.

Run the following command to allow XML attachments in Outlook Web App.

```
Set-OwaMailboxPolicy -Identity Default -AllowedFileTypes
'.rpmsg','.xlsx','.xlsm','.xlsb','.tiff','.pptx','.pptm','.
ppsx','.ppsm','.docx','.docm','.zip','.xls','.wmv','.wma','
.wav','.vsd','.txt','.tif','.rtf','.pub','.ppt','.png','.pd
f','.one','.mp3','.jpg','.gif','.doc','.bmp','.avi','.xml'
```

Export mailbox audit logs

Exchange Server 2013 > Messaging policy and compliance > Exchange auditing reports >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-11-13*

When mailbox auditing is enabled for a mailbox, Microsoft Exchange logs information in the *mailbox audit log* whenever a user other than the owner accesses the mailbox. Each log entry includes information about who accessed the mailbox and when, the actions performed by the non-owner, and whether the action was successful. Entries in the mailbox audit log are retained for 90 days by default. You can use the mailbox audit log to determine if a user other than the owner has accessed a mailbox.

When you export entries from mailbox audit logs, Microsoft Exchange saves the entries in an XML file and attaches it to an email message sent to the specified recipients.

What do you need to know before you begin?

- Estimated time to complete each procedure: Times are variable. In Exchange Online, the mailbox audit log is sent within a few days after you export it.
- Procedures in this topic require specific permissions. See each procedure for its permissions information.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Configure mailbox audit logging

You have to enable mailbox audit logging on each mailbox that you want to audit before you can

export and view mailbox audit logs. You also have to configure Microsoft Outlook Web App to allow XML attachments to use Outlook Web App to access the audit log.

Step 1: Enable mailbox audit logging

You have to enable mailbox audit logging for each mailbox that you want to run a non-owner mailbox access report for. If mailbox audit logging isn't enabled for a mailbox, you won't get any results for that mailbox when you export the mailbox audit log.

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mailbox audit logging" entry in the Messaging policy and compliance permissions topic.

To enable mailbox audit logging for a single mailbox, run the command in the Shell.

```
Set-Mailbox <Identity> -AuditEnabled $true
```

To enable mailbox audit logging for all user mailboxes in your organization, run the following commands.

```
$UserMailboxes = Get-mailbox -Filter {(RecipientTypeDetails
-eq 'UserMailbox')}

$UserMailboxes | ForEach {Set-Mailbox $_.Identity -
AuditEnabled $true}
```

Step 2: Configure Outlook Web App to allow XML attachments

When you export the mailbox audit log, Microsoft Exchange attaches the audit log, which is an XML file, to an email message. However, Outlook Web App blocks XML attachments by default. To access the exported audit log, you have to use Microsoft Outlook or configure Outlook Web App to allow XML attachments.

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Outlook Web App mailbox policies" entry in the Clients and mobile devices permissions topic.

Run the following command to allow XML attachments in Outlook Web App.

```
Set-OwaMailboxPolicy -Identity Default -AllowedFileTypes
'.rpmsg','.xlsx','.xlsm','.xlsb','.tiff','.pptx','.pptm','.
ppsx','.ppsm','.docx','.docm','.zip','.xls','.wmv','.wma','
.wav','.vsd','.txt','.tif','.rtf','.pub','.ppt','.png','.pd
f','.one','.mp3','.jpg','.gif','.doc','.bmp','.avi','.xml'
```

Note:

In Exchange Online, use the value `OwaMailboxPolicy-Default` for the *Identity* parameter.

How do you know this worked?

To verify that you've successfully configured mailbox audit logging, do the following:

1. Run the following command to verify that audit logging is configured for mailboxes.

```
Get-Mailbox | FL Name,AuditEnabled
```

A value of `True` for the *AuditEnabled* property verifies that audit logging is enabled.

2. Run the following command to verify that XML attachments are allowed in Outlook Web App for your organization.

```
Get-OwaMailboxPolicy | Select-Object -ExpandProperty AllowedFileTypes
```

Verify that `.xml` is included in the list of allowed file types.

Export the mailbox audit log

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "View-only administrator audit logging" entry in the Exchange and Shell infrastructure permissions topic.

1. In the Exchange Administration Center (EAC), navigate to **Compliance Management** > **Auditing**.
2. Click **Export mailbox audit logs**.
3. Configure the following search criteria for exporting the entries from the mailbox audit log:
   - **Start and end dates** Select the date range for the entries to include in the exported file.
   - **Mailboxes to search audit log for** Select the mailboxes to retrieve audit log entries for.
   - **Type of non-owner access** Select one of the following options to define the type of non-owner access to retrieve entries for:
     - **All non-owners** Search for access by administrators and delegated users inside your organization, and by Microsoft datacenter administrators in Exchange Online.
     - **External users** Search for access by Microsoft datacenter administrators.
     - **Administrators and delegated users** Search for access by administrators and delegated users inside your organization.
     - **Administrators** Search for access by administrators in your organization.
   - **Recipients** Select the users to send the mailbox audit log to.
4. Click **Export**.

Microsoft Exchange retrieves entries in the mailbox audit log that meet your search criteria, saves them to a file named SearchResult.xml, and then attaches the XML file to an email message sent to the recipients that you specified.

How do you know this worked?

Sign in to the mailbox where the mailbox audit log was sent. If you've successfully exported the audit log, you'll receive a message sent from Exchange. The audit log will be attached to this

message. As previously stated, in Exchange Online, it may take a few days to receive this message.

View the mailbox audit log

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "View-only administrator audit logging" entry in the Exchange and Shell infrastructure permissions topic.

To open or save the SearchResult.xml file:

1. Sign in to the mailbox where the mailbox audit log was sent.
2. In the Inbox, open the message with the XML file attachment sent by Microsoft Exchange. Notice that the body of the email message contains the search criteria.
3. Click the attachment and select to open or save the XML file.

Entries in the mailbox audit log

The following example shows an entry from the mailbox audit log contained in the SearchResult.xml file. Each entry is preceded by the **<Event>** XML tag and ends with the **</Event>** XML tag. This entry shows that the administrator purged the message with the subject, "**Notification of litigation hold**" from the Recoverable Items folder in David's mailbox on April 30, 2010.

```
<Event MailboxGuid="6d4fbdae-e3ae-4530-8d0b-f62a14687939"

```

Useful fields in the mailbox audit log

Watch for these fields. They can help you identify specific information about each instance of non-owner access of a mailbox.

Field	Description
Owner	The owner of the mailbox that was accessed by a non-owner.
LastAccessed	The date and time when the mailbox was accessed.
Operation	The action that was performed by the non-owner. For more information, see the "What gets logged in the mailbox audit log?" section in Learn more about running a non-owner mailbox access report.
OperationResult	Whether the action performed by the non-owner succeeded or failed.
LogonType	The type of non-owner access. These include administrator, delegate, and external.
FolderPathName	The name of the folder that contained the message that was affected by the non-owner.
ClientInfoString	Information about the mail client used by the non-owner to access the mailbox.
ClientIPAddress	The IP address of the computer used by the non-owner to access the mailbox.

InternalLogonType	The logon type of the account used by the non-owner to access this mailbox.
MailboxOwnerUPN	The email address of the mailbox owner.
LogonUserDN	The display name of the non-owner.
Subject	The subject line of the email message that was affected by the non-owner.

How do you know this worked?

If you can view the XML file that's attached to the message sent by Exchange and the file contains audit log entries, then you've successfully configured, exported, and viewed a mailbox audit log.

Run a non-owner mailbox access report

Exchange Server 2013 > Messaging policy and compliance > Exchange auditing reports >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-08-25*

The Non-Owner Mailbox Access Report in the Exchange Administration Center (EAC) lists the mailboxes that have been accessed by someone other than the person who owns the mailbox. When a mailbox is accessed by a non-owner, Microsoft Exchange logs information about this action in a mailbox audit log that's stored as an email message in a hidden folder in the mailbox being audited. Entries from this log are displayed as search results and include a list of mailboxes accessed by a non-owner, who accessed the mailbox and when, the actions performed by the non-owner, and whether the action was successful. By default, entries in the mailbox audit log are retained for 90 days.

When you enable mailbox audit logging for a mailbox, Microsoft Exchange logs specific actions by non-owners, including both administrators and users, called *delegated users*, who have been assigned permissions to a mailbox. You can also narrow the search to users inside or outside your organization.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mailbox audit logging" entry in the Messaging policy

and compliance permissions topic.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Enable mailbox audit logging

You have to enable mailbox audit logging for each mailbox that you want to run a non-owner mailbox access report for. If mailbox audit logging isn't enabled, you won't get any results when you run a report.

To enable mailbox audit logging for a single mailbox, run the following Shell command.

```
Set-Mailbox <Identity> -AuditEnabled $true
```

For example, to enable mailbox auditing for a user named Florence Flipo, run the following command.

```
Set-Mailbox "Florence Flipo" -AuditEnabled $true
```

To enable mailbox auditing for all user mailboxes in your organization, run the following commands.

```
$UserMailboxes = Get-mailbox -Filter {(RecipientTypeDetails
-eq 'UserMailbox')}

$UserMailboxes | ForEach {Set-Mailbox $_.Identity -
AuditEnabled $true}
```

How do you know this worked?

Run the following command to verify that you've successfully configured mailbox audit logging.

```
Get-Mailbox | FL Name,AuditEnabled
```

A value of `True` for the *AuditEnabled* property verifies that audit logging is enabled.

Run a non-owner mailbox access report

1. In the EAC, navigate to **Compliance Management** > **Auditing**.

2. Click **Run a non-owner mailbox access report**.

By default, Microsoft Exchange runs the report for non-owner access to any mailboxes in the organization over the past two weeks. The mailboxes listed in the search results have been enabled for mailbox audit logging.

3. To view non-owner access for a specific mailbox, select the mailbox from the list of mailboxes. View the search results in the details pane.

Tip:
Want to narrow the search results? Select the start date, end date, or both, and select specific mailboxes to search. Click **Search** to re-run the report.

Search for specific types of non-owner access

You can also specify the type of non-owner access, also called the logon type, to search for. Here are your options:

- **All non-owners** Search for access by administrators and delegated users inside your organization. Also includes access user outside of your organization.
- **External users** Search for access by users outside of your organization.
- **Administrators and delegated users** Search for access by administrators and delegated users inside your organization.
- **Administrators** Search for access by administrators in your organization.

What gets logged in the mailbox audit log?

When you run a non-owner mailbox access report, entries from the mailbox audit log are displayed in the search results in the EAC. Each report entry contains this information:

- Who accessed the mailbox and when
- The actions performed by the non-owner
- The affected message and its folder location
- Whether the action was successful

The following table describes the types of actions logged, and whether these actions are logged by default for access by administrators and for access by delegated users. If you want to track actions that aren't logged by default, you have to use the Shell to enable logging of those actions.

Action	Description	Administrators	Delegated users
Update	A message was changed.	Yes	Yes
Copy	A message was copied to another folder.	No	No
Move	A message was moved to another folder.	Yes	No

Move To Deleted Items	A message was moved to the Deleted Items folder.	Yes	No
Soft-delete	A message was deleted from the Deleted Items folder.	Yes	Yes
Hard-delete	A message was purged from the Recoverable Items folder.	Yes	Yes
FolderBind	A mailbox folder was accessed.	Yes	No
Send as	A message was sent using SendAs permission. This means another user sent the message as though it came from the mailbox owner.	Yes	Yes
Send on behalf of	A message was sent using SendOnBehalf permission. This means another user sent the message on behalf of the mailbox owner. The message will indicate to the recipient who the message was sent on behalf of and who actually sent the message.	Yes	No

MessageBind	A message was viewed in the preview pane or opened.	No	No

How do you know this worked?

To verify that you've successfully run a non-owner mailbox access report, check the search results pane. Mailboxes that you ran the report for are displayed in this pane. If there are no results for a specific mailbox, it's possible there hasn't been access by a non-owner or that non-owner access hasn't taken place within the specified date range. As previously described, be sure to verify that audit logging has been enabled for the mailboxes you want to search for access by non-owners.

Run a per-mailbox litigation hold report

Exchange Server 2013 > Messaging policy and compliance > Exchange auditing reports >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-13*

If your organization is involved in a legal action, you may have to take steps to preserve relevant data, such as email messages, that may be used as evidence. In situations like this, you can use litigation hold to retain all email sent and received by specific people or retain all email sent and received in your organization for a specific time period. For more information about what happens when a mailbox is on litigation hold and how to enable and disable it, see the "Mailbox Features" section in Manage user mailboxes.

Use the litigation hold report to keep track of the following types of changes made to a mailbox in a given time period:

- Litigation hold was enabled.
- Litigation hold was disabled.

For each of these change types, the report includes the user who made the change and the time and date the change was made.

What do you need to know before you begin?

- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "View-only administrator audit logging" entry in the Exchange and Shell infrastructure permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

Use the EAC to run a litigation hold report

1. In the EAC, navigate to **Compliance Management** > **Auditing**.
2. Click **Run a per-mailbox litigation hold report**.

Microsoft Exchange runs the report for litigation hold changes made to any mailbox in the past two weeks.

3. To view the changes for a specific mailbox, in the search results pane, select the mailbox. View the search results in the details pane.

Tip:

Want to narrow the search results? Select the start date, end date, or both, and select specific mailboxes to search. Click **Search** to re-run the report.

How do you know this worked?

To verify that you've successfully run a litigation hold report, mailboxes that had litigation hold changes within the date range are displayed in the search results pane. If there are no results, then no changes to litigation hold have taken place within the date range or recent changes haven't taken effect yet.

Note:

When a mailbox is put on litigation hold, it can take up to 60 minutes for the hold to take effect.

Search the role group changes or administrator audit logs

Exchange Server 2013 > Messaging policy and compliance > Exchange auditing reports >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2013-12-02*

You can search the administrator audit logs to discover who made changes to organization, server, and recipient configuration. This can be helpful when you're trying to track the cause of unexpected behavior, to identify a malicious administrator, or to verify that compliance requirements are being met. For more information about administrator audit logging, see Administrator audit logging.

If you want to search the mailbox audit log, see Mailbox audit logging.

Tip:
In Exchange Online, you can use the EAC to view entries in the administrator audit log. For more information, see View the administrator audit log.

What do you need to know before you begin?

- Estimated time to complete each procedure: less than 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "View-only administrator audit logging" entry in the Exchange and Shell infrastructure permissions topic.
- Administrator audit logging is enabled by default. To verify that it's enabled, run the following command:

```
Get-AdminAuditLogConfig | FL AdminAuditLogEnabled
```

A value of `True` indicates that administrator audit logging is enabled. A value of `False` indicates that it's disabled. If you need to enable administrator audit logging for an on-premises Exchange organization, run the following command:

```
Set-AdminAuditLogConfig -AdminAuditLogEnabled $true
```

Note:
The **Set-AdminAuditLogConfig** cmdlet isn't available in Exchange Online.

For more information, see Manage administrator audit logging.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to run the management role group changes report

If you want to know what changes to management role group membership have been made to role groups in your organization, you can use the Administrator Role Group report in the Exchange Administration Center (EAC). Using the Administrator Role Group report, you can view a list of role groups that have changed during a specified date range. You can also select the specific role groups you want to view changes for.

1. In the EAC, select **Compliance management** > **Auditing**, and then click **Run an administrator**

role group report.

2. Select a date range using the **Start date** and **End date** fields.
3. Click **Select role groups**, and then select the role groups you want to show changes for or leave this field blank to search for changes in all role groups.
4. Click **Search**.

If any changes are found using the criteria you specified, a list of changes will be displayed in the results pane. Clicking a role group displays the changes to the role group in the details pane.

Use the EAC to export the administrator audit log

If you want to create an XML file that contains changes made to your organization, you can use the Export Administrator Audit Log report in the EAC. Using the Export Administrator Audit Log report, you can specify a date range to search for audit log entries that contain changes made by users you specify. The XML file is then sent to a recipient as an email attachment. The maximum size of the XML file is 10 megabytes (MB).

Note:
Outlook Web App doesn't allow you to open XML attachments by default. You can either configure Exchange to allow XML attachments to be viewed using Outlook Web App, or you can use another email client, such as Microsoft Outlook, to view the attachment. For information about how to configure Outlook Web App to allow you to view an XML attachment, see View or configure Outlook Web App virtual directories.

1. In the EAC, select **Compliance management** > **Auditing**, and then click **Export the administrator audit log**.
2. Select a date range using the **Start date** and **End date** fields.
3. In the **Send the auditing report to** field, click **Select users** and then select the recipient you want to send the report to.
4. Click **Export**.

If any log entries are found using the criteria you specified, an XML file will be created and sent as an email attachment to the recipient you specified.

Use the Shell to search for audit log entries

You can use the Shell to search for audit log entries that meet the criteria you specify. For a list of search criteria, see Administrator audit logging. This procedure uses the **Search-AdminAuditLog** cmdlet and displays search results in the Shell. You can use this cmdlet when you need to return a set of results that exceeds the limits defined on the **New-AdminAuditLogSearch** cmdlet or in the EAC Audit Reporting reports.

If you want to send audit log search results in an email attachment to a recipient, see Use the Shell to search for audit log entries and send results to a recipient later in this topic.

To search the audit log for criteria you specify, use the following syntax.

```
Search-AdminAuditLog - Cmdlets <cmdlet 1, cmdlet 2, ...> -
Parameters <parameter 1, parameter 2, ...> -StartDate
<start date> -EndDate <end date> -UserIds <user IDs> -
ObjectIds <object IDs> -IsSuccess <$True | $False >
```

Note:

The **Search-AdminAuditLog** cmdlet returns a maximum of 1,000 log entries by default. Use the *ResultSize* parameter to specify up to 250,000 log entries. Or, use the value `Unlimited` to return all entries.

This example performs a search for all audit log entries with the following criteria:

- **Start date** 08/04/2012
- **End date** 10/03/2012
- **User IDs** davids, chrisd, kima
- **Cmdlets** **Set-Mailbox**
- **Parameters** *ProhibitSendQuota*, *ProhibitSendReceiveQuota*, *IssueWarningQuota*, *MaxSendSize*, *MaxReceiveSize*

```
Search-AdminAuditLog -Cmdlets Set-Mailbox -Parameters
ProhibitSendQuota, ProhibitSendReceiveQuota,
IssueWarningQuota, MaxSendSize, MaxReceiveSize -StartDate
08/04/2012 -EndDate 10/03/2012 -UserIds davids, chrisd,
kima
```

This example searches for changes made to a specific mailbox. This is useful if you're troubleshooting or you need to provide information for an investigation. The following criteria are used:

- **Start date** 05/01/2012
- **End date** 10/03/2012
- **Object ID** contoso.com/Users/DavidS

```
Search-AdminAuditLog -StartDate 05/01/2012 -EndDate
10/03/2012 -ObjectID contoso.com/Users/DavidS
```

If your searches return many log entries, we recommend that you use the procedure provided in Use the Shell to search for audit log entries and send results to a recipient later in this topic. The procedure in that section sends an XML file as an email attachment to the recipients you specify, enabling you to more easily extract the data you're interested in.

For detailed syntax and parameter information, see Search-AdminAuditLog.

View details of audit log entries

The **Search-AdminAuditLog** cmdlet returns the fields described in the "Audit log contents section of Administrator audit logging. Of the fields returned by the cmdlet, two fields, **CmdletParameters**

and **ModifiedProperties**, contain additional information that isn't viewable by default.

To view the contents of the **CmdletParameters** and **ModifiedProperties** fields, use the following steps. Or, you can use the procedure in Use the Shell to search for audit log entries and send results to a recipient later in this topic to create an XML file.

This procedure uses the following concepts:

- Arrays
- User-defined variables

1. Decide the criteria you want to search for, run the **Search-AdminAuditLog** cmdlet, and store the results in a variable using the following command.

```
$Results = Search-AdminAuditLog <search criteria>
```

2. Each audit log entry is stored as an array element in the variable `$Results`. You can select an array element by specifying its array element index. Array element indexes start at zero (0) for the first array element. For example, to retrieve the 5th array element, which has an index of 4, use the following command.

```
$Results[4]
```

3. The previous command returns the log entry stored in array element 4. To see the contents of the **CmdletParameters** and **ModifiedProperties** fields for this log entry, use the following commands.

```
$Results[4].CmdletParameters
$Results[4].ModifiedProperties
```

4. To view the contents of the **CmdletParameters** or **ModifiedParameters** fields in another log entry, change the array element index.

Use the Shell to search for audit log entries and send results to a recipient

You can use the Shell to search for audit log entries that meet the criteria you specify, and then send those results to a recipient you specify as an XML file attachment. The results are sent to the recipient within 15 minutes. For a list of search criteria, see Administrator audit logging.

Note:
Outlook Web App doesn't allow you to open XML attachments by default. You can either configure Exchange to allow XML attachments to be viewed using Outlook Web App, or you can use another email client, such as Microsoft Outlook, to view the attachment. For information about how to configure Outlook Web App to allow you to view an XML attachment, see View or configure Outlook Web App virtual directories.

To search the audit log for criteria you specify, use the following syntax.

```
New-AdminAuditLogSearch -Cmdlets <cmdlet 1, cmdlet 2, ...>
-Parameters <parameter 1, parameter 2, ...> -StartDate
<start date> -EndDate <end date> -UserIds <user IDs> -
ObjectIds <object IDs> -IsSuccess <$True | $False > -
StatusMailRecipients <recipient 1, recipient 2, ...> -Name
<string to include in subject>
```

This example performs a search for all audit log entries with the following criteria:

- **Start date** 08/04/2012
- **End date** 10/03/2012
- **User IDs** davids, chrisd, kima
- **Cmdlets** **Set-Mailbox**
- **Parameters** *ProhibitSendQuota*, *ProhibitSendReceiveQuota*, *IssueWarningQuota*, *MaxSendSize*, *MaxReceiveSize*

The command sends the results to the davids@contoso.com SMTP address with "Mailbox limit changes" included in the subject line of the message.

```
New-AdminAuditLogSearch -Cmdlets Set-Mailbox -Parameters
ProhibitSendQuota, ProhibitSendReceiveQuota,
IssueWarningQuota, MaxSendSize, MaxReceiveSize -StartDate
08/04/2012 -EndDate 10/03/2012 -UserIds davids, chrisd,
kima -StatusMailRecipients davids@contoso.com -Name
"Mailbox limit changes"
```

Note:

The report that the **New-AdminAuditLogSearch** cmdlet generates can be a maximum of 10 MB in size. If the search you perform returns a report larger than 10 MB, change the search criteria you specified. For example, reduce the size of the date range and run multiple reports, each with a portion of the original date range.

For more information about the format of the XML file, see Administrator audit log structure.

For detailed syntax and parameter information, see New-AdminAuditLogSearch.

View the administrator audit log

Exchange Server 2013 > Messaging policy and compliance > Exchange auditing reports >

Applies to: *Exchange Server 2013, Exchange Online Protection, Exchange Online*

Topic Last Modified: *2014-08-07*

In Microsoft Exchange Online Protection (EOP), Microsoft Exchange Online, and Microsoft Exchange 2013, you can use the Exchange admin center (EAC) to search for and view entries in the *administrator audit log*. The administrator audit log records specific actions, based on Exchange Management Shell cmdlet, performed by administrators and users who have been assigned administrative privileges. Entries in the administrator audit log provide you with information about what cmdlet was run, which parameters were used, who ran the cmdlet, and what objects were affected.

Note:

- The administrator audit log doesn't record any action that is based on an Exchange Management Shell cmdlet that begins with the verbs **Get**, **Search**, or **Test**.
- Audit log entries are kept for 90 days. When an entry is older than 90 days, it's deleted.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "View reports" entry in the **Feature permissions in EOP** topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the EAC to view the administrator audit log

1. In the EAC, navigate to **Compliance management** > **Auditing**, and choose **View the administrator audit log**.
2. Choose a **Start date** and **End date**, and then choose **Search**. All configuration changes made during the specified time period are displayed, and can be sorted, using the following information:
   - **Date** The date and time that the configuration change was made. The date and time are stored in Coordinated Universal Time (UTC) format.
   - **Cmdlet** The name of the cmdlet that was used to make the configuration change.
   - **User** The name of the user account of the user who made the configuration change.

Up to 5000 entries will be displayed on multiple pages. Specify a smaller date range if you need to narrow your results. If you select an individual search result, the following information is displayed in the details pane:

- **Object modified** The object that was modified by the cmdlet.
- **Parameters (Parameter:Value)** The cmdlet parameters that were used, and any value specified with the parameter.

3. If you want to print a specific audit log entry, choose the **Print** button in the details pane.

How do you know this worked?

If you've successfully run an administrator audit log report, configuration changes made within the date range you specify are displayed in the search results pane. If there are no results, change the date range and then run the report again.

Note:

When a change is made in your organization, it may take up to 15 minutes to appear in audit log search results. If a change doesn't appear in the administrator audit log, wait a few minutes and run the search again.

Anti-spam and anti-malware protection

Exchange Server 2013 >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-13*

Microsoft Exchange Server 2013 customers are automatically provided with anti-spam and anti-malware protection. The following topics (and their associated subtopics) provide overview information and configuration steps for customizing the built-in spam filtering and malware filtering settings so that they best meet the needs of your organization:

Anti-spam protection Describes the basic built-in anti-spam protection features as well as other anti-spam protection options such as using a cloud-hosted anti-spam solution and managing quarantined messages.

Anti-malware protection Describes the basic built-in anti-malware protection features as well as other anti-malware protection options. Among the information included are an Anti-Malware FAQ and details about how to configure anti-malware settings using the Exchange Administration Center or the Exchange Management Shell.

You can also use anti-malware programs in the Windows operating system on Exchange servers to help further enhance the security and health of your Exchange organization. However, there are important considerations for how to best implement file-level scanning with Exchange 2013. For more information, see Anti-Virus Software in the Operating System on Exchange Servers.

Tip:

You can also create transport rules to enforce company specific regulations and policies; for more information see Transport rules. Exchange 2013 customers who have purchased the data loss prevention (DLP) feature can also create DLP policies to help protect sensitive data; for more information, see Data loss prevention.

Anti-spam protection

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-01-23*

Spammers, or malicious senders, use a variety of techniques to send spam into your organization. No single tool or process can eliminate all spam. However, Microsoft Exchange Server 2013 provides a layered, multipronged, and multifaceted approach to reducing spam. Exchange uses transport agents to provide anti-spam filtering, and the built-in anti-spam agents that are available in Exchange 2013 are relatively unchanged from Microsoft Exchange Server 2010.

For more anti-spam features and easier management, you can elect to purchase the Forefront Online Protection for Exchange (FOPE) hosted email filtering service or the next version of this service, Microsoft Exchange Online Protection (EOP). For a comparison of EOP and Exchange 2013 features, see Benefits of anti-spam features in Exchange Online Protection over Exchange Server 2013.

For information about the built-in anti-malware capabilities in Exchange 2013, see Anti-malware protection.

Contents

Anti-spam agents on Mailbox servers

Typically, you would enable the anti-spam agents on a mailbox server if your organization doesn't have an Edge Transport server, or doesn't do any prior anti-spam filtering before accepting incoming messages. For more information, see Enable anti-spam functionality on Mailbox servers.

Like all transport agents, each anti-spam agent is assigned a priority value. A lower value indicates a higher priority, so typically, an anti-spam agent with priority 1 will act on a message before an anti-spam agent with priority 9. However, the SMTP event where the anti-spam agent is registered is also very important in determining the order that anti-spam agents act on messages. A low priority anti-spam agent that's registered on an SMTP event early in the transport pipeline will act on a message before a high priority anti-spam agent that's registered on an SMTP event later in the transport pipeline.

Based on the default priority value of the anti-spam agent, and the SMTP event in the transport pipeline where the anti-spam agent is registered, the following list describes the agents and the default order in which they are applied to messages on a Mailbox server:

1. **Sender Filter agent** Sender filtering compares the sender on the MAIL FROM: SMTP command to an administrator-defined list of senders or sender domains who are prohibited from sending messages to the organization to determine what action, if any, to take on an inbound message. For more information, see Sender filtering.
2. **Sender ID agent** Sender ID relies on the IP address of the sending server and the Purported Responsible Address (PRA) of the sender to determine whether the sender is spoofed or not. For more information, see Sender ID.
3. **Content Filter agent** Content filtering assesses the contents of a message. For more information, see Content filtering.

Spam quarantine is a feature of the Content Filter agent that reduces the risk of losing legitimate messages that are incorrectly classified as spam. Spam quarantine provides a temporary storage location for messages that are identified as spam and that shouldn't be delivered to a user mailbox inside the organization. For more information, see Spam quarantine.

Content filtering also acts on the safelist aggregation feature. Safelist aggregation collects data from the anti-spam safe lists that Microsoft Outlook and Outlook Web App users configure and makes this data available to the Content Filter agent. For more information, see Safelist Aggregation.

4. **Protocol Analysis agent** The Protocol Analysis agent is the underlying agent that implements the sender reputation functionality. Sender reputation relies on persisted data about the IP address of the sending server to determine what action, if any, to take on an inbound message. A sender reputation level (SRL) is calculated from several sender characteristics that are derived from message analysis and external tests. For more information, see Sender reputation and the Protocol Analysis agent.

Return to top

Anti-spam agents on Edge Transport servers

If your organization has an Edge Transport server installed in the perimeter network, all of the anti-spam agents that are available on a Mailbox server are installed and enabled by default on the Edge Transport server. However, the following anti-spam agents are only available on an Edge Transport server:

- **Connection Filtering agent** Connection filtering inspects the IP address of the remote server that's trying to send messages to determine what action, if any, to take on an inbound message. Connection filtering uses an IP Block list, IP Allow list, IP Block List provider services and IP Allow List provider services to determine whether the connection IP should be blocked or allowed. For more information, see Connection Filtering on Edge Transport Servers.
- **Recipient Filter agent** Recipient filtering compares the message recipients on the RCPT TO: SMTP command to an administrator-defined Recipient Block list. If a match is found, the message

isn't permitted to enter the organization. The recipient filter also compares recipients on inbound messages to the local recipient directory to determine whether the message is addressed to valid recipients. When a message isn't addressed to valid recipients, the message is rejected. For more information, see Recipient filtering on Edge Transport servers.

Note:

Although the Recipient Filter agent is available on Mailbox servers, you shouldn't configure it. When recipient filtering on a Mailbox server detects one invalid or blocked recipient in a message that contains other valid recipients, the message is rejected. If you install the anti-spam agents on a Mailbox server, the Recipient Filter agent is enabled by default. However, it isn't configured to block any recipients.

- **Attachment Filtering agent** Attachment filtering blocks messages based on attachment file name, file name extension, or file MIME content type. You can configure attachment filtering to block a message and its attachment, to strip the attachment and allow the message to pass through, or to silently delete the message and its attachment. For more information, see Attachment filtering on Edge Transport servers.

Based on the default priority value of the anti-spam agent, and the SMTP event in the transport pipeline where the anti-spam agent is registered, this is the default order in which the anti-spam agents are applied on an Edge Transport server:

1. Connection Filtering agent
2. Sender Filter agent
3. Recipient Filter agent
4. Sender ID agent
5. Content Filter agent
6. Protocol Analysis agent for sender reputation
7. Attachment Filtering agent

Return to top

Anti-spam stamps

Anti-spam stamps help you diagnose spam-related problems by applying diagnostic metadata, or stamps, such as sender-specific information, puzzle validation results, and content filtering results, to messages as they pass through the anti-spam features that filter inbound messages from the Internet. For more information, see Anti-spam stamps.

Return to top

Strategy for anti-spam approach

Your strategy for how to configure the anti-spam features and establish the aggressiveness of your anti-spam agent settings requires that you plan and calculate carefully. If you set all anti-spam filters to their most aggressive levels and configure all anti-spam features to reject all suspicious messages, you're more likely to reject messages that aren't spam. On the other hand, if you don't set

the anti-spam filters at a sufficiently aggressive level and don't set the spam confidence level (SCL) threshold low enough, you probably won't see a reduction in the spam that enters your organization.

It's a best practice to reject a message when Exchange detects a bad message through the Connection Filtering agent, Recipient Filter agent, or Sender Filter agent. This approach is better than quarantining such messages or assigning metadata, such as anti-spam stamps, to such messages. The Connection Filtering agent and Recipient Filter agent automatically block messages that are identified by the respective filters. The Sender Filter agent is configurable.

This best practice is recommended because the SCL that underlies connection filtering, recipient filtering, or sender filtering is relatively high. For example, with sender filtering, where the administrator has configured specific senders to block, there's no reason to assign the sender filtering data to such messages and to continue to process them. In most organizations, blocked messages should be rejected. (If you didn't want the messages rejected, you wouldn't have put them on the Blocked Senders List.)

The same logic applies to real-time block list services and recipient filtering, although the underlying confidence isn't as high as the IP Block list. You should be aware that the further along the mail flow path a message travels, the greater the probability of false positives, because the anti-spam features are evaluating more variables. Therefore, you may find that if you configure the first several anti-spam features in the anti-spam chain more aggressively, you can reduce the bulk of your spam. As a result, you'll save processing, bandwidth, and disk resources so that you can process more ambiguous messages.

Ultimately, you must plan to monitor the overall effectiveness of the anti-spam features. If you monitor carefully, you can continue to adjust the anti-spam features to work well together for your environment. With this approach, you should plan on a fairly non-aggressive configuration of the anti-spam features when you start. This approach lets you minimize the number of false positives. As you monitor and adjust the anti-spam features, you can become more aggressive about the type of spam and spam attacks that your organization experiences.

Return to top

Benefits of anti-spam features in Exchange Online Protection over Exchange Server 2013

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-04-14*

Note:
Exchange Online Protection (EOP) is the next version of Forefront Online Protection for Exchange (FOPE). EOP anti-spam protection features are included in Exchange Online.

The following are benefits of using Exchange anti-spam protection in the cloud (Microsoft Exchange Online or Microsoft Exchange Online Protection) as opposed to Microsoft Exchange Server 2013, which has most of the same built-in anti-spam capabilities as Microsoft Exchange Server 2010:

- **More control and easier configuration** Administrators can use the Exchange Administration Center (EAC) web-based management console in order to customize spam filtering settings so that they best meet the needs of your organization. There is no anti-spam user interface in Exchange Server 2013.
- **Stronger connection filtering** In Exchange 2013, connection filtering IP Allow lists and IP Block lists are available only if you install an Edge Transport server in your perimeter network. For more information, see Edge Transport servers. In the cloud, you can choose to skip spam filtering on email messages sent from trusted senders (gathered from various third-party sources), ensuring that these messages are not mistakenly marked as spam. Also, the hosted filtering service uses Microsoft's own block lists and lists aggregated from vendors to provide greater IP-level filtering.
- **Stronger content filtering** You can easily configure your content filter policy to:
  - Filter messages written in specific languages.
  - Filter messages sent from specific countries or regions.
  - Mark bulk email messages (such as advertisements and marketing emails) as spam.
  - Search for attributes in a message and act upon the message if it matches a specific advanced spam option attribute. If you are concerned about phishing, some of these options offer a combination of Sender ID and SPF technologies to authenticate and verify that messages are not spoofed.

In addition to the above content filter options that you can configure in the EAC, the hosted filtering service uses additional URL lists to block suspicious messages that contain specific URLs within their message body.

- **Quicker updates** Spam updates are propagated more quickly across the network. In Exchange Server 2013 updates occur two times per month, whereas the service is updated multiple times per hour.
- **Outbound filtering** Outbound spam filtering is always enabled if you use the hosted service for sending outbound email, thereby protecting organizations using the service and their intended recipients.

Enable anti-spam functionality on Mailbox servers

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-01-23*

In Microsoft Exchange Server 2013, the following anti-spam agents are available in the Transport service on Mailbox servers, but they are not installed by default:

- Content Filter agent
- Sender ID agent
- Sender Filter agent
- Protocol Analysis agent for sender reputation

However, you can install these anti-spam agents on a Mailbox server using a script in the Exchange Management Shell. Typically, you would install the anti-spam agents on a Mailbox server only when your organization accepts all incoming mail without any prior anti-spam filtering.

Note:

Although the Recipient Filter agent is available on Mailbox servers, you shouldn't configure it. When recipient filtering on a Mailbox server detects one invalid or blocked recipient in a message that contains other valid recipients, the message is rejected. Although the Recipient Filter agent is enabled by default, it isn't configured to block any recipients. For more information, see Manage recipient filtering on Edge Transport servers.

What happens if you install the available anti-spam agents in the Transport service on a Mailbox server, but you also have other Exchange anti-spam agents operating on the messages before they reach the Mailbox server? For example, what if you have an Edge Transport server in the perimeter network? The anti-spam agents on the Mailbox server recognize the anti-spam X-header values that are added to messages by other Exchange anti-spam agents, and messages that contain these X-headers pass through without being scanned again. However, recipient look-ups performed by the Recipient Filter agent will occur again on the Mailbox server.

What do you need to know before you begin?

- Estimated time to complete this task: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport configuration" entry in the Mail flow permissions topic.
- The Connection Filter agent and the Attachment Filter agent aren't available on Mailbox servers. They're only available on an Edge Transport server. However, the Malware agent is installed and enabled by default on a Mailbox server. For more information, see Anti-malware protection.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

How do you do this?

Step 1: Use the Shell to run the Install-AntispamAgents.ps1 script

Run the following command:

```
& $env:ExchangeInstallPath\Scripts\Install-AntiSpamAgents.ps1
```

How do you know this step worked?

You know this step worked if the script runs without errors, and asks you to restart the Microsoft Exchange Transport service.

Step 2: Use the Shell to restart the Microsoft Exchange Transport service

Run the following command:

```
Restart-Service MSExchangeTransport
```

How do you know this step worked?

You know this step worked if the Microsoft Exchange Transport service restarts without errors.

Step 3: Use the Shell to specify the internal SMTP servers in your organization

You need to specify the IP addresses of any internal SMTP servers that should be ignored by the Sender ID agent. In fact, you need to specify the IP address of at least one internal SMTP server. If the Mailbox server where you're running the anti-spam agents is the only SMTP server in your organization, specify the IP address of that computer.

To add the IP addresses of internal SMTP servers without affecting any existing values, run the following command:

```
Set-TransportConfig -InternalSMTPServers @{Add="<ip address1>","<ip address2>"...}
```

This example adds the internal SMTP server addresses 10.0.1.10 and 10.0.1.11 to the transport configuration of your organization.

```
Set-TransportConfig -InternalSMTPServers
@{Add="10.0.1.10","10.0.1.11"}
```

How do you know this step worked?

To verify that you have successfully specified the IP address of at least one internal SMTP server, do the following:
1. Run the following command:

```
Get-TransportConfig | Format-List InternalSMTPServers
```

2. Verify the IP address of at least one valid internal SMTP server is displayed.

Sender filtering

Exchange Server 2013 > Anti-spam and anti-malware protection > Anti-spam protection >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-12*

Sender filtering relies on the MAIL FROM: SMTP header to determine what action, if any, to take on an inbound email message. Sender filtering is provided by the Sender Filter agent.

The Sender Filter agent acts on messages from specific senders outside the organization. Administrators maintain a list of senders who are blocked from sending messages to the organization. As an administrator, you can block single senders (such as kim@contoso.com), whole domains (contoso.com), or domains and all subdomains (*.contoso.com). You can also configure what action the Sender Filter agent should take when a message that has a blocked sender is found. You can configure the following actions:

- The Sender Filter agent rejects the SMTP request with a `554 5.1.0 Sender Denied` SMTP session error and closes the connection.
- The Sender Filter agent accepts the message and updates the message to indicate that the message came from a blocked sender. Because the message came from a blocked sender and it's marked as such, the Content Filter agent will use this information when it calculates the spam confidence level (SCL).

You can designate blocked senders and define how the Sender Filter agent should act on messages from blocked senders. For more information about how to configure the Sender Filter agent, see Manage sender filtering.

Important:

The MAIL FROM: SMTP headers can be spoofed. Therefore, you shouldn't rely on the Sender Filter agent only. Use the Sender Filter agent and the Sender ID agent together. The Sender ID agent uses the originating IP address of the sending server to verify that the domain in the MAIL FROM: SMTP header matches the domain that's registered. For more information about the Sender ID agent, see Sender ID.

Using the Sender Filter agent to block messages

When the Sender Filter agent is enabled on an Exchange server, sender filtering blocks inbound messages that come from the Internet, but aren't authenticated. These messages are handled as external messages. You can disable the Sender Filter agent in individual computer configurations. For more information, see Manage sender filtering.

When you enable the Sender Filter agent on an Exchange server, the Sender Filter agent filters all messages that come through all Receive connectors on that computer. As noted earlier in this topic, only messages that come from external sources are filtered. *External sources* are defined as non-authenticated sources. These are considered anonymous Internet sources.

As a best practice, you shouldn't filter email messages from trusted partners or from inside your organization. When you run anti-spam filters, there's always a chance that the filters will detect false positives. You should configure anti-spam agents to run only on messages from potentially untrusted and unknown sources. This will reduce the chance that anti-spam filters will mishandle legitimate messages. You can enable and disable the Sender Filter agent to run on messages from any source. For more information, see Manage sender filtering.

You can configure the Sender Filter agent to block inbound messages that don't specify a sender and domain in the MAIL FROM: SMTP header. You can use this feature to prevent non-delivery report (NDR) attacks on the Exchange server. Most legitimate SMTP messages come from SMTP servers that provide a sender and domain in the MAIL FROM: SMTP command.

Specifying the block action

After you've specified blocked senders and domains, you must specify how you want the Sender Filter agent to act on messages from blocked senders and domains. We recommend that you reject the messages. When you use the Sender Filter agent to block email addresses and domains that are specified by an Exchange administrator, the chance of false positives is relatively less than when you use other anti-spam agents. For example, the Content Filter agent is an anti-spam agent that relies on many different variables to determine whether a message is spam.

There are only two scenarios in which legitimate messages may be rejected by the Sender Filter agent:

- If you mistype an email address or domain name, the wrong sender may be blocked.
- If a domain name is reregistered to a legitimate company after you add the domain to your Blocked Senders list, you will unintentionally block legitimate messages.

In either of these cases, it may still make sense to reject the messages.

Manage sender filtering

Anti-spam and anti-malware protection > Anti-spam protection > Sender filtering >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

Sender filtering is provided by the Sender Filter agent. The Sender Filter agent relies on the **MAIL FROM:** SMTP header to determine what action, if any, to take on an inbound email message.

When sender filtering functionality is enabled on an Exchange server, sender filtering functionality filters all messages that come through all Receive connectors on that computer.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Anti-spam features" entry in the Anti-spam and anti-malware permissions topic.
- You can only use the Shell to perform this procedure.
- By default, anti-spam features aren't enabled in the Transport service on a Mailbox server. Typically, you only enable the anti-spam features on a Mailbox server if your Exchange organization doesn't do any prior anti-spam filtering before accepting incoming messages. For more information, see Enable anti-spam functionality on Mailbox servers.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to enable or disable sender filtering

To disable sender filtering, run the following command:

```
Set-SenderFilterConfig -Enabled $false
```

To enable sender filtering, run the following command:

```
Set-SenderFilterConfig -Enabled $true
```

Note:
When you disable sender filtering, the underlying Sender Filter agent is still enabled. To disable the Sender Filter agent, run the command: `Disable-TransportAgent "Sender Filter Agent"`.

How do you know this worked?

To verify that you have successfully enabled or disabled sender filtering, do the following:
1. Run the following command:

```
Get-SenderFilterConfig | Format-List Enabled
```

2. Verify the value displayed is the value you configured.

Use the Shell to configure blocked senders and domains

To replace the existing values, run the following command:

```
Set-SenderFilterConfig -BlockedSenders <sender1,sender2...>
-BlockedDomains <domain1,domain2...> -
BlockedDomainsAndSubdomains <domain1,domain2...>
```

This example configures the Sender Filter agent to block messages from kim@contoso.com and john@contoso.com, messages from the fabrikam.com domain, and messages from northwindtraders.com and all its subdomains.

```
Set-SenderFilterConfig -BlockedSenders
kim@contoso.com,john@contoso.com -BlockedDomains
fabrikam.com -BlockedDomainsAndSubdomains
northwindtraders.com
```

To add or remove entries without modifying any existing values, run the following command:

```
Set-SenderFilterConfig -BlockedSenders
@{Add="<sender1>","<sender2>"...;
Remove="<sender1>","<sender2>"...} -BlockedDomains
@{Add="<domain1>","<domain2>"...;
Remove="<domain1>","<domain2>"...} -
BlockedDomainsAndSubdomains
@{Add="<domain1>","<domain2>"...;
Remove="<domain1>","<domain2>"...}
```

This example configures the Sender Filter agent with the following information:

- Add chris@contoso.com and michelle@contoso.com to the list of existing senders who are blocked.
- Remove tailspintoys.com from the list of existing sender domains that are blocked.
- Add blueyonderairlines.com to the list of existing sender domains and subdomains that are blocked.

```
Set-SenderFilterConfig -BlockedSenders
@{Add="chris@contoso.com","michelle@contoso.com"} -
BlockedDomains @{Remove="tailspintoys.com"} -
BlockedDomainsAndSubdomains @{Add="blueyonderairlines.com"}
```

How do you know this worked?

To verify that you have successfully configured blocked senders, do the following:
1. Run the following command:

```
Get-SenderFilterConfig | Format-List
BlockedSenders,BlockedDomains,BlockedDomainsAndSubdomains
```

2. Verify the values displayed are the values you configured.

Use the Shell to enable or disable blocking messages with blank senders

To enable or disable blocking message with blank senders, run the following command:

```
Set-SenderFilterConfig -BlankSenderBlockingenabled <$true |
$false>
```

This example configures the Sender Filter agent to block messages that don't specify a sender in the MAIL FROM: SMTP command:

```
Set-SenderFilterConfig -BlankSenderBlockingEnabled $true
```

How do you know this worked?

To verify that you have successfully enabled or disabled blocking messages with blank senders, do the following:
1. Run the following command:

```
Get-SenderFilterConfig | Format-List
BlankSenderBlockingEnabled
```

2. Verify the value displayed is the value you configured.

Sender ID

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-16*

The Sender ID agent is an anti-spam agent that's available in Microsoft Exchange Server 2013. The Sender ID agent relies on the RECEIVED SMTP header and a query to the sending system's DNS service to determine what action, if any, to take on an inbound message.

Sender ID is intended to combat the impersonation of a sender and a domain, a practice that's frequently called *spoofing*. A *spoofed mail* is an email message that has a sending address that was modified to appear as if it originates from a sender other than the actual sender of the message.

Spoofed mails typically contain a From: address that purports to be from a certain organization. In the past, it was relatively easy to spoof the From: address, in both the SMTP session, such as the MAIL FROM: header, and in the RFC 2822 message data, such as From: "Masato Kawai" masato@contoso.com, because the headers weren't validated.

Contents

Using Sender ID to combat spoofing

Sender ID makes spoofing more difficult. When you enable Sender ID, each message contains a Sender ID status in the metadata of the message. When an email message is received, the Exchange server queries the sender's DNS server to verify that the IP address from which the message was received is authorized to send messages for the domain that's specified in the message headers. The IP address of the authorized sending server is referred to as the purported responsible address (PRA).

Domain administrators publish sender policy framework (SPF) records on their DNS servers. SPF records identify authorized outbound email servers. If an SPF record is configured on the sender's DNS server, the Exchange server parses the SPF record and determines whether the IP address from which the message was received is authorized to send email on behalf of the domain that's specified in the message. For more information about what an SPF record contains and how to create an SPF record, see Sender ID.

The Exchange server updates the message metadata with the Sender ID status based on the SPF record. After the Exchange server updates the message metadata, message delivery proceeds as it

ordinarily would.

Sender ID status values

The Sender ID evaluation process generates a Sender ID status for the message. The Sender ID status is used to evaluate the spam confidence level (SCL) rating for the message. This status can be set to one of the following values:

- **Pass** Both the IP address and Purported Responsible Address (PRA) passed the Sender ID verification check.
- **Neutral** Published Sender ID data is explicitly inconclusive.
- **Soft fail** The IP address for the PRA may be in the not permitted set.
- **Fail** The IP Address is not permitted; no PRA is found in the incoming mail or the sending domain does not exist.
- **None** No published SPF data exists in the sender's DNS.
- **TempError** A temporary DNS failure occurred, such as an unavailable DNS server.
- **PermError** The DNS record is invalid, such as an error in the record format.

The Sender ID status is added to the message metadata and is later converted to a MAPI property. The junk email filter in Microsoft Outlook uses the MAPI property during the generation of the SCL value.

Outlook neither displays the Sender ID status nor necessarily flags a message as junk at certain Sender ID values. Outlook uses the Sender ID status value only during the calculation of the SCL value.

Besides the seven scenarios that generate the Sender ID statuses, the Sender ID evaluation process may reveal instances where the From: IP address is missing. If the From: IP address is missing, the Sender ID status can't be set. If the Sender ID status can't be set, Exchange continues to process the message without including a Sender ID status on the message. The message isn't discarded or rejected. In this scenario, Sender ID status isn't set, and an application event is logged.

For more information about how the Sender ID status is displayed in messages, see Anti-spam stamps.

Sender ID options for handling spoofed mail and unreachable DNS servers

You can also define how the Exchange server handles messages that are identified as spoofed mail and how the Exchange server handles messages when a DNS server can't be reached. The options for how the Exchange server handles spoofed mail and unreachable DNS servers include the following actions:

- **Stamp the status** This option is the default action. All inbound messages to your organization have the Sender ID status included in the metadata of the message.
- **Reject** This option rejects the message and sends an SMTP error response to the sending server.

The SMTP error response is a 5*xx* level protocol response with text that corresponds to the Sender ID status.

- **Delete** This option deletes the message without informing the sending system of the deletion. In fact, the Exchange server sends a fake OK SMTP command to the sending server and then deletes the message. Because the sending server assumes the message was sent, it doesn't retry sending the message in the same session.

For more information about how to configure the Sender ID agent, see Manage Sender ID.

Return to top

Updating your organization's Internet-facing DNS to support Sender ID

The effectiveness of Sender ID depends on specific DNS data. The more organizations that update their Internet-facing DNS servers by using an SPF record, the more effectively Sender ID identifies spoofed email messages.

To support the Sender ID infrastructure, you must update your Internet-facing DNS data by creating an SPF record and hosting the SPF record on your public DNS servers. For more information about how to create and deploy SPF records, see Sender ID.

Return to top

Specifying recipients and sender domains to exclude from Sender ID filtering

You may want to exclude specific recipients and sender domains from Sender ID filtering. To do this, you specify the recipients and sender domains using the **Set-SenderIdConfig** cmdlet in the Exchange Management Shell. For more information, see Set-SenderIdConfig.

Return to top

Manage Sender ID

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

Sender ID functionality is provided by the Sender ID agent. Sender ID validates the origin of email

messages by verifying the IP address of the sender against the purported owner of the sender domain. Sender ID filtering is performed on inbound messages that come from the Internet but aren't authenticated. These messages are handled as external messages.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Anti-spam features" entry in the Anti-spam and anti-malware permissions topic.
- You can only use the Shell to perform this procedure.
- By default, anti-spam features aren't enabled in the Transport service on a Mailbox server. Typically, you only enable the anti-spam features on a Mailbox server if your Exchange organization doesn't do any prior anti-spam filtering before accepting incoming messages. For more information, see Enable anti-spam functionality on Mailbox servers.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to enable or disable Sender ID

To disable Sender ID, run the following command:

```
Set-SenderIDConfig -Enabled $false
```

To enable Sender ID, run the following command:

```
Set-SenderIDConfig -Enabled $true
```

Note:

When you disable Sender ID, the underlying Sender ID agent is still enabled. To disable the Sender ID agent, run the command: `Disable-TransportAgent "Sender ID Agent"`.

How do you know this worked?

To verify that you have successfully enabled or disabled Sender ID, do the following:
1. Run the following command:

```
Get-SenderIDConfig | Format-List Enabled
```

2. Verify the value displayed is the value you configured.

Use the Shell to configure the Sender ID action for spoofed messages

To configure the Sender ID action for spoofed messages, run the following command:

```
Set-SenderIDConfig -SpoofedDomainAction <StampStatus | Reject | Delete>
```

This example configures the Sender ID agent to reject any messages where the IP address of the sending server isn't listed as an authoritative SMTP sending server in the DNS Sender Policy Framework (SPF) record for the sending domain.

```
Set-SenderIDConfig -SpoofedDomainAction Reject
```

How do you know this worked?

To verify that you have successfully configured the Sender ID action for spoofed messages, do the following:
1. Run the following command:

```
Get-SenderIDConfig | Format-List SpoofedDomainAction
```

2. Verify the value displayed is the value you configured.

Use the Shell to configure the Sender ID action for transient errors

To configure the Sender ID action for transient errors, run the following command:

```
Set-SenderIDConfig -TempErrorAction <StampStatus | Reject | Delete>
```

This example configures the Sender ID agent to stamp the messages when the Sender ID status can't be determined due to a temporary DNS server error. The message will be processed by other anti-spam agents and the Content Filter agent will use the mark when determining the SCL value for the message.

```
Set-SenderIDConfig -TempErrorAction StampStatus
```

Note that `stampstatus` is the default value for the *TempErrorAction* parameter.

How do you know this worked?

To verify that you have successfully configured the Sender ID action for transient errors, do the following:

1. Run the following command:

```
Get-SenderIDConfig | Format-List TempErrorAction
```

2. Verify the value displayed is the value you configured.

Use the Shell to configure recipient and sender domain exceptions

To replace the existing values, run the following command:

```
Set-SenderIDConfig -BypassedRecipients
<recipient1,recipient2...> -BypassedSenderDomains
<domain1,domain2...>
```

This example configures the Sender ID agent to bypass the Sender ID check for messages sent to kim@contoso.com and john@contoso.com, and to bypass the Sender ID check for messages sent from the fabrikam.com domain.

```
Set-SenderIDConfig -BypassedRecipients
kim@contoso.com,john@contoso.com -BypassedSenderDomains
fabrikam.com
```

To add or remove entries without modifying any existing values, run the following command:

```
Set-SenderIDConfig -BypassedRecipients
@{Add="<recipient1>","<recipient2>"...;
Remove="<recipient1>","<recipient2>"...} -
BypassedSenderDomains @{Add="<domain1>","<domain2>"...;
Remove="<domain1>","<domain2>"...}
```

This example configures the Sender ID agent with the following information:

- Add chris@contoso.com and michelle@contoso.com to the list of existing recipients who bypass the Sender ID check.
- Remove tailspintoys.com from the list of existing domains that bypass the Sender ID check.

```
Set-SenderIDConfig -BypassedRecipients
@{Add="chris@contoso.com","michelle@contoso.com"} -
BypassedSenderDomains @{Remove="tailspintoys.com"}
```

How do you know this worked?

To verify that you have successfully configured recipient and sender domain exceptions, do the following:

1. Run the following command:

```
Get-SenderIDConfig | Format-List
BypassedRecipients,BypassedSenderDomains
```

2. Verify the values displayed are the values you configured.

Content filtering

Exchange Server 2013 > Anti-spam and anti-malware protection > Anti-spam protection >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-16*

The Content Filter agent evaluates inbound email messages and assesses the probability that an inbound message is legitimate or spam. Unlike many other filtering technologies, the Content Filter agent uses characteristics from a statistically significant sample of email messages. The inclusion of legitimate messages in this sample reduces the chance of mistakes. Because the Content Filter agent recognizes characteristics of legitimate messages and spam, its accuracy is increased. Updates to the Content Filter agent are available periodically through Microsoft Update.

Contents

Using the Content Filter agent

The Content Filter agent is one of several anti-spam agents in Exchange. When you configure anti-spam agents on an Exchange server, the agents act on messages cumulatively to reduce the amount of spam that enters the organization. For more information about how to plan and deploy anti-spam agents, see Anti-spam protection.

The Content Filter agent assigns a spam confidence level (SCL) rating to each message. The SCL rating is a number between 0 and 9. A higher SCL rating indicates that a message is more likely to be spam.

You can configure the Content Filter agent to take the following actions on messages according to their SCL rating:

- Delete message
- Reject message
- Quarantine message

For example, you may determine that messages that have an SCL rating of 7 or higher must be deleted, messages that have an SCL rating of 6 must be rejected, and messages that have an SCL rating of 5 must be quarantined.

You can adjust the SCL threshold behavior by assigning different SCL ratings to each of these actions. For more information about how to adjust the SCL threshold to suit your organization's requirements and about per-recipient SCL thresholds, see Spam Confidence Level Threshold.

Note:

Messages that are over 11 MB aren't scanned by the Intelligent Message Filter. Instead, they pass through the Content Filter without being scanned.

Allow phrases and Block phrases

You can customize how the Content Filter agent assigns SCL values by configuring custom words. Custom words are individual words or phrases that the Content Filter agent uses to apply appropriate filter processing. You configure approved words or phrases with Allow phrases and unapproved words or phrases with Block phrases. When the Content Filter agent detects a preconfigured Allow phrase in an inbound message, the Content Filter agent automatically assigns an SCL value of 0 to the message. Alternatively, when the Content Filter agent detects a configured Block phrase in an inbound message, the Content Filter agent assigns an SCL rating of 9.

You can enter custom words or phrases in any combination of uppercase and lowercase letters. However, when the Content Filter agent evaluates message content, it ignores case. The maximum number of custom words or phrases that can be created is 800.

Outlook Email Postmark validation

The Content Filter agent also includes Microsoft Office Outlook Email Postmark validation, a computational proof that Outlook applies to outgoing messages to help recipient messaging systems distinguish legitimate email from junk email. This feature helps reduce the chance of false positives. In the context of spam filtering, a *false positive* exists when a spam filter incorrectly identifies a message from a legitimate sender as spam. When Outlook Email Postmark validation is enabled, the Content Filter agent parses the inbound message for a computational postmark header. The presence of a valid, solved computational postmark header in the message indicates that the client computer that generated the message solved the computational postmark.

Computers don't require significant processing time to solve individual computational postmarks. However, processing postmarks for many messages may be prohibitive to a malicious sender. Anyone who sends millions of spam messages is unlikely to invest the processing power that is required to solve computational postmarks for all outbound spam. If a sender's email contains a valid, solved computational postmark, it's unlikely that the sender is a malicious sender. In this case, the Content Filter agent would lower the SCL rating. If the postmark validation feature is enabled and an inbound message either doesn't contain a computational postmark header or the

computational postmark header isn't valid, the Content Filter agent would not change the SCL rating.

Bypassing the recipient, sender, and sender domain

In some organizations, all email to certain aliases must be accepted. This scenario can introduce problems if your organization is in an industry that manages significant volumes of spam.

For example, a company named Woodgrove Bank has an alias named customerloans@woodgrovebank.com that provides email-based support to external loan customers. The Exchange administrators configure the Content Filter agent to set Block phrases that filter out words or phrases that are typically used in spam that is sent by unscrupulous loan agencies. To prevent potentially legitimate messages from being rejected, the administrators set exceptions to content filtering by entering a list of SMTP email recipient addresses in the Content Filter agent configuration.

You can also specify senders and sender domains that you do not want the Content Filter agent to block.

Safelist aggregation

In Exchange 2013, the Content Filter agent uses the Outlook Safe Senders Lists, Blocked Sender List, Safe Recipients Lists, and trusted contacts from Outlook to optimize spam filtering. *Safelist aggregation* is a set of anti-spam functionality that is shared across Outlook and Exchange. As its name suggests, this functionality collects data from the anti-spam safe lists that Outlook users configure and makes this data available to the anti-spam agents on the Exchange server. Email messages that Outlook users receive from contacts that those users have added to their Outlook Safe Recipients List, Safe Senders List, or trusted contacts list are identified by the Content Filter agent as safe. The Sender Filter agent also performs per-recipient sender filtering using the Blocked Senders list that users configure. For more information, see Safelist Aggregation.

Configuring the Content Filter agent

You configure the Content Filter agent by using the Exchange Management Shell.

Important:
Configuration changes that you make to the Content Filter agent in the Exchange Management Shell are only made on the local computer. If you have the Content Filter agent running on multiple Exchange servers in your organization, you must make Content Filter configuration changes to each computer.

The Content Filter agent depends on updates to determine whether a message can be delivered with confidence that it isn't spam. These updates contain data about phishing Web sites, Microsoft SmartScreen spam heuristics, and other Intelligent Message Filter updates. Content filter updates

generally contain about 6 MB of data that's useful for longer periods of time than other anti-spam update data.

Content filter updates are available from Microsoft Update. The content filter update data is updated and available for download every two weeks.

For more information about how to configure content filtering, see Manage content filtering.

Manage content filtering

Anti-spam and anti-malware protection > Anti-spam protection > Content filtering >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-03-04*

Content filtering is provided by the Content Filter agent. The Content Filter agent filters all messages that come through all Receive connectors on the Exchange server. Only messages that come from non-authenticated sources are filtered.

What do you need to know before you begin?

- Estimated time to complete each procedure: 10 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Anti-spam feature" entry in the Anti-spam and anti-malware permissions topic.
- You can only use the Shell to perform this procedure.
- By default, anti-spam features aren't enabled in the Transport service on a Mailbox server. Typically, you only enable the anti-spam features on a Mailbox server if your Exchange organization doesn't do any prior anti-spam filtering before accepting incoming messages. For more information, see Enable anti-spam functionality on Mailbox servers.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to enable or disable content filtering

To disable content filtering, run the following command:

```
Set-ContentFilterConfig -Enabled $false
```

To enable content filtering, run the following command:

```
Set-ContentFilterConfig -Enabled $true
```

Note:
When you disable content filtering, the underlying Content Filter agent is still enabled. To disable the Content Filter agent, run the command: `Disable-TransportAgent "Content Filter Agent"`.

How do you know this worked?

To verify that you have successfully enabled or disabled content filtering, do the following:
1. Run the following command:

```
Get-ContentFilterConfig | Format-List Enabled
```

2. Verify the value of the *Enabled* property that's displayed.

Use the Shell to enable or disable content filtering for external messages

By default, content filtering functionality is enabled for external messages.

To disable content filtering for external messages, run the following command:

```
Set-ContentFilterConfig -ExternalMailEnabled $false
```

To enable content filtering for external messages, run the following command:

```
Set-ContentFilterConfig -ExternalMailEnabled $true
```

How do you know this worked?

To verify that you have successfully enabled or disabled content filtering for external messages, do the following:
1. Run the following command:

```
Get-ContentFilterConfig | Format-List ExternalMailEnabled
```

2. Verify the value of the *ExternalMailEnabled* property that's displayed.

Use the Shell to enable or disable content filtering for internal messages

As a best practice, you should not filter messages from trusted partners or from inside your organization. When you run anti-spam filters, there's always a chance that the filters will detect false positives. To reduce the chance that filters will mishandle legitimate email messages, you should enable anti-spam agents to run only on messages from potentially untrusted and unknown sources.

To enable content filtering for internal messages, run the following command:

```
Set-ContentFilterConfig -InternalMailEnabled $true
```

To disable content filtering for internal messages, run the following command:

```
Set-ContentFilterConfig -InternalMailEnabled $false
```

How do you know this worked?

To verify that you have successfully enabled or disabled content filtering for internal messages, do the following:

1. Run the following command:

```
Get-ContentFilterConfig | Format-List InternalMailEnabled
```

2. Verify the value of the *InternalMailEnabled* property that's displayed.

Use the Shell to configure recipient and sender exceptions

To replace the existing values, run the following command:

```
Set-ContentFilterConfig -BypassedRecipients
<recipient1,recipient2...> -BypassedSenders
<sender1,sender2...> -BypassedSenderDomains
<domain1,domain2...>
```

This example configures the following exceptions in in content filtering:

- The recipients laura@contoso.com and julia@contoso.com aren't checked by content filtering.
- The senders steve@fabrikam.com and cindy@fabrikam.com aren't checked by content filtering.
- All senders in the domain nwtraders.com and all subdomains aren't checked by content filtering.

```
Set-ContentFilterConfig -BypassedRecipients
laura@contoso.com,julia@contoso.com -BypassedSenders
steve@fabrikam.com,cindy@fabrikam.com -
BypassedSenderDomains *.nwtraders.com
```

To add or remove entries without modifying any existing values, run the following command:

```
Set-ContentFilterConfig -BypassedRecipients
```

```
@{Add="<recipient1>","<recipient2>"...;
Remove="<recipient1>","<recipient2>"...} -BypassedSenders
@{Add="<sender1>","<sender2>"...;
Remove="<sender1>","<sender2>"...} -BypassedSenderDomains
@{Add="<domain1>","<domain2>"...;
Remove="<domain1>","<domain2>"...}
```

This example configures the following exceptions in content filtering:

- Add tiffany@contoso.com and chris@contoso.com to the list of existing recipients who aren't checked by content filtering.
- Add joe@fabrikam.com and michelle@fabrikam.com to the list of existing senders who aren't checked by content filtering.
- Add blueyonderairlines.com to the list of existing domains whose senders aren't checked by content filtering.
- Remove the domain woodgrovebank.com and all subdomains from the list of existing domains whose senders aren't checked by content filtering.

```
Set-ContentFilterConfig -BypassedRecipients
@{Add="tiffany@contoso.com","chris@contoso.com"} -
BypassedSenders
@{Add="joe@fabrikam.com","michelle@fabrikam.com"} -
BypassedSenderDomains @{Add="blueyonderairlines.com";
Remove="*.woodgrovebank.com"}
```

How do you know this worked?

To verify that you have successfully configured the recipient and sender exceptions, do the following:

1. Run the following command:

```
Get-ContentFilterConfig | Format-List Bypassed*
```

2. Verify the values displayed match the settings you specified.

Use the Shell to configure allowed and blocked phrases

To add allowed and blocked words and phrases, run the following command:

```
Add-ContentFilterPhrase -Influence GoodWord -Phrase
<Phrase> -Influence BadWord -Phrase <Phrase>
```

This example allows all messages that contain the phrase "customer feedback".

```
Add-ContentFilterPhrase -Influence GoodWord -Phrase
```

```
"customer feedback"
```

This example blocks all messages that contain the phrase "stock tip".

```
Add-ContentFilterPhrase -Influence BadWord -Phrase "stock
tip"
```

To remove allowed or blocked phrases, run the following command:

```
Remove-ContentFilterPhrase -Phrase <Phrase>
```

This example removes the phrase "stock tip":

```
Remove-ContentFilterPhrase -Phrase "stock tip"
```

How do you know this worked?

To verify that you have successfully configured the allowed and block phrases, do the following:
1. Run the following command:

```
Get-ContentFilterPhrase | Format-List Influence,Phrase
```

2. Verify the values displayed match the settings you specified.

Use the Shell to configure SCL thresholds

To configure the spam confidence level (SCL) thresholds and actions, run the following command:

```
Set-ContentFilterConfig -SCLDeleteEnabled <$true | $false>
-SCLDeleteThreshold <Value> -SCLRejectEnabled <$true |
$false> -SCLRejectThreshold <Value> -SCLQuarantineEnabled
<$true | $false> -SCLQuarantineThreshold <Value>
```

Note:
The Delete action takes precedence over the Reject action, and the Reject action takes precedence over the Quarantine action. Therefore, the SCL threshold for the Delete action should be greater than the SCL threshold for the Reject action, which in turn should be greater than the SCL threshold for the Quarantine action. Only the Reject action is enabled by default, and it has the SCL threshold value 7.

This example configures the following values for the SCL thresholds:

- The Delete action is enabled and the corresponding SCL threshold is set to 9.
- The Reject action is enabled and the corresponding SCL threshold is set to 8.
- The Quarantine action is enabled and the corresponding SCL threshold is set to 7.

```
Set-ContentFilterConfig -SCLDeleteEnabled $true -
```

```
SCLDeleteThreshold 9 -SCLRejectEnabled $true -
SCLRejectThreshold 8 -SCLQuarantineEnabled $true -
SCLQuarantineThreshold 7
```

How do you know this worked?

To verify that you have successfully configured the SCL thresholds, do the following:
1. Run the following command:

```
Get-ContentFilterConfig | Format-List SCL*
```

2. Verify the values displayed match the settings you specified.

Use the Shell to configure the rejection response

When the Reject action is enabled, you can customize the rejection response that's sent to the message sender. The rejection response can't exceed 240 characters.

To configure a custom rejection response, run the following command:

```
Set-ContentFilterConfig -RejectionResponse "<Custom Text>"
```

This example configures the Content Filter agent to send a customized rejection response.

```
Set-ContentFilterConfig -RejectionResponse "Your message
was rejected because it appears to be SPAM."
```

How do you know this worked?

To verify that you have successfully configured the rejection response, do the following:
1. Run the following command:

```
Get-ContentFilterConfig | Format-List *Reject*
```

2. Verify the values displayed match the settings you specified.

Use the Shell to enable or disable Outlook Email Postmarking

Outlook Email Postmarking validation is a computational proof that Microsoft Outlook applies to outgoing messages to help recipient messaging systems distinguish legitimate email from junk email. Postmarking is available in Outlook 2007 or newer. Postmarking helps reduce false positives. Outlook Email Postmarking is enabled by default.

To disable Outlook Email Postmarking, run the following command:

```
Set-ContentFilterConfig -
OutlookEmailPostmarkValidationEnabled $false
```

To enable Outlook Email Postmarking, run the following command:

```
Set-ContentFilterConfig -
OutlookEmailPostmarkValidationEnabled $true
```

How do you know this worked?

To verify that you have successfully configured Outlook Email Postmarking, do the following:
1. Run the following command:

```
Get-ContentFilterConfig | Format-List
OutlookEmailPostmarkValidationEnabled
```

2. Verify the value displayed matches the setting you specified.

Safelist Aggregation

Anti-spam and anti-malware protection > Anti-spam protection > Content filtering >

Topic Last Modified: *2013-09-30*

In Microsoft Exchange Server 2013, *safelist aggregation* refers to anti-spam functionality shared across Microsoft Outlook and Exchange. This functionality collects data from the anti-spam Safe Recipients Lists, Safe Senders Lists, Blocked Senders Lists, and contact data that Outlook users configure, and makes this data available to the Exchange anti-spam agents.

When you enable and correctly configure safelist aggregation, the Content Filter agent passes safe email messages to the enterprise mailbox without additional processing. Email messages that Outlook users receive from contacts that those users have added to their Outlook Safe Recipients List or Safe Senders List or have trusted are identified by the Content Filter agent as safe. An Outlook *contact* is a person, inside or outside the user's organization, about whom the user can save several types of information, such as email and street addresses, telephone and fax numbers, and Web page URLs.

In Exchange 2013, the safelist aggregation process also allows the Sender Filtering agent to block incoming messages from the per-recipient Block Senders List.

Safelist aggregation can help reduce the instances of false-positives in anti-spam filtering performed by Exchange. In the context of spam filtering, a *false-positive* occurs when a spam filter incorrectly identifies a legitimate message as spam.

For organizations that filter hundreds of thousands of messages from the Internet every day, even a

small percentage of false-positives means that users might not receive many messages that were incorrectly identified as spam if those messages were quarantined or deleted.

Safelist aggregation is likely the most effective way to reduce false-positives. In Outlook 2010 or newer versions, users can create *Safe Senders Lists*. Safe Senders Lists specify a list of domain names and email addresses from which the Outlook user wants to receive messages. By default, email addresses in Outlook Contacts and in the Exchange global address list are included in this list. By default, Outlook adds all external contacts to which the user sends mail to the Safe Senders List.

Contents

Information stored in the Outlook user's safelist collection

A *safelist collection* is the combined data from the user's Safe Senders List, Safe Recipients List, Blocked Senders List, and external contacts. This data is stored in Outlook and in the Exchange mailbox.

The following types of information are stored in an Outlook user's safelist collection:

- **Safe senders and safe recipients** The From message header indicates a sender. The To field of the email message indicates a recipient. Safe senders and safe recipients are represented by full SMTP addresses, such as masato@contoso.com. Outlook users can add senders and recipients to their safe lists.
- **Blocked senders** Just like safe senders, users can block unwanted senders by adding them to their Blocked Senders Lists.
- **Safe domain** The domain is the part of an SMTP address that follows the @ symbol. For example, contoso.com is the domain in the masato@contoso.com address. Outlook users can add sending domains to their safe lists.

Important:
By default, Exchange doesn't include the domains during safelist aggregation. However, you can configure safelist aggregation to include the safe domain data for the anti-spam agents. For more information, see Configure Content Filtering to Use Safe Domain Data.

- **External contacts** Two types of external contacts can be included in the safelist aggregation. The first type of external contact includes contacts to whom Outlook users have sent mail. This class of contact is added to the Safe Senders List only if an Outlook user selects the corresponding option in the Junk Email settings in Outlook 2007.

The second type of external contact includes the users' Outlook contacts. Users can add or import these contacts into Outlook. This class of contact is added to the Safe Senders List only if an Outlook user selects the corresponding option in the Junk Email Filter settings in Outlook 2010 or

Outlook 2007.

Return to top

How Exchange uses the safelist collection

The safelist collection is stored on the user's Mailbox server. A user can have up to 1,024 unique entries in a safelist collection. Exchange 2013 has a mailbox assistant, called the Junk Email Options mailbox assistant, which monitors changes to the safelist collection for your mailboxes. It then replicates these changes to Active Directory, where the safelist collection is stored on each user object. When the safelist collection is stored on the user object in Active Directory, the safelist collection is aggregated with the anti-spam functionality of Exchange 2013 and is optimized for minimized storage and replication. Exchange uses the safelist collection data during content filtering. If you have a subscribed Edge Transport server in your perimeter network, the Microsoft Exchange EdgeSync service replicates the safelist collection to the Active Directory Lightweight Directory Services (AD LDS) instance on the Edge Transport server.

Important:
Although the safe recipient data is stored in Outlook and can be aggregated into the safelist collection, the content filtering functionality doesn't act on safe recipient data.

Return to top

Hashing of safelist collection entries

Safelist collection entries are hashed (SHA-256) one way before they are stored as array sets across three user object attributes, **msExchSafeSenderHash**, **msExchSafeRecipientHash**, and **msExchBlockedSendersHash**, as a binary large object. When data is hashed, an output of fixed length is produced, and the output is likely to be unique. For hashing of safelist collection entries, a 4-byte hash is produced. When a message is received from the Internet, Exchange hashes the sender address and compares it to the hashes stored on behalf of the Outlook user to whom the message was sent. If the sender matches the safe senders hash, the message bypasses content filtering. If the sender matches the blocked senders hash, the message is blocked.

One-way hashing of safelist collection entries performs the following important functions:

- **Minimizes storage and replication space** Most of the time, hashing reduces the size of the data hashed. Therefore, saving and transmitting a hashed version of a safelist collection entry conserves storage space and replication time. For example, a user who has 200 entries in his or her safelist collection would create about 800 bytes of hashed data stored and replicated in Active Directory.
- **Renders user safelist collections unusable by malicious users** Because one-way hash values are impossible to reverse-engineer into the original SMTP address or domain, the safelist collections don't yield usable email addresses for malicious users who might compromise an Exchange server.

Return to top

Enabling safelist aggregation

Safelist aggregation is enabled by default in Exchange 2013. Unlike in Exchange Server 2007, you don't need to manually run the **Update-SafeList** cmdlet to hash and write the safelist collection data to Active Directory. In Exchange 2013, the safelist collection data is written to Active Directory by the Junk Email Options mailbox assistant.

To make the safelist aggregation data in Active Directory available to Edge Transport servers in the perimeter network, you need to install and configure the Microsoft Exchange EdgeSync service so that the safelist aggregation data is replicated to AD LDS.

You can still manually run safelist aggregation by using the **UpdateSafelist** cmdlet. However, you need to be mindful of the network and replication traffic that may be generated when you run this command. Running **Update-Safelist** on multiple mailboxes where safelists are heavily used may generate a significant amount of traffic. We recommend that if you run the command on multiple mailboxes, you should run the command during off-peak, non-business hours.

The **Update-SafeList** cmdlet reads the safelist collection from the user's mailbox, hashes each entry, sorts the entries for easy search, and then converts the hash to a binary attribute. Finally, the **Update-SafeList** cmdlet compares the binary attribute that was created to any value stored on the attribute. If the two values are identical, the **Update-SafeList** cmdlet doesn't update the user attribute value with the safelist aggregation data. If the two attribute values are different, the **Update-SafeList** cmdlet updates the safelist aggregation value.

Return to top

Manage safelist aggregation

Anti-spam protection > Content filtering > Safelist Aggregation >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-04-10*

Safelist aggregation refers to anti-spam functionality that's shared from Microsoft Outlook to Microsoft Exchange Server 2013. This functionality collects data from the Safe Recipients Lists, Safe Senders Lists, Blocked Senders Lists, and contact data that Outlook users configure, and makes this data available to the Exchange anti-spam agents. Safelist aggregation can help reduce the instances of false-positives in anti-spam filtering performed by the Exchange servers where the anti-spam agents are running.

What do you need to know before you begin?

- Estimated time to complete each procedure: 10 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Recipients Permissions topic, and the "Anti-spam features" section in the Anti-spam and anti-malware permissions topic.
- You can only use the Shell to perform this procedure.
- By default, anti-spam features aren't enabled in the Transport service on a Mailbox server. Typically, you only enable the anti-spam features on a Mailbox server if your Exchange organization doesn't do any prior anti-spam filtering before accepting incoming messages. For more information, see Enable anti-spam functionality on Mailbox servers.
- Be mindful of the network and replication traffic that may be generated when you run the **Update-SafeList** cmdlet. Running the command on multiple mailboxes where safelists are heavily used may generate a significant amount of traffic. We recommend that if you run the command on multiple mailboxes, you should run the command during off-peak, non-business hours.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to configure the mailbox safelist collection limits

You can configure the maximum number of safe senders and blocked senders a user can configure. By default, users can configure up to 5,000 safe senders and 500 blocked senders.

To configure the maximum number of safe senders and blocked senders, run the following command:

```
Set-Mailbox <MailboxIdentity> -MaxSafeSenders <Integer> -
MaxBlockedSenders <Integer>
```

This example configures the mailbox john@contoso.com to have a maximum of 2,000 safe senders and 200 blocked senders.

```
Set-Mailbox john@contoso.com -MaxSafeSenders 2000 -
```

```
MaxBlockedSenders 200
```

How do you know this worked?

To verify that you have successfully configured the mailbox safelist collection limits, do the following:

1. Run the following command:

```
Get-Mailbox <Identity> | Format-List Name,Max*Senders
```

2. Verify the values displayed match the values you configured.

Use the Shell to run the Update-Safelist command

In Exchange 2013, safelist aggregation is done automatically, so you don't need to schedule or manually run the **Update-Safelist** cmdlet. However, you may want to occasionally run this cmdlet to test safelist aggregation.

This example writes the safe senders list for the mailbox john@contoso.com to Active Directory.

```
Update-Safelist john@contoso.com -Type SafeSenders
```

For detailed syntax and parameter information, see Update-SafeList.

How do you know this worked?

To verify that you have successfully configured safelist aggregation, perform the following steps:

Step 1: Use the Shell to verify the Content Filter agent is enabled on the Exchange server

1. Run the following command:

```
Get-ContentFilterConfig | Format-List Enabled
```

2. If the output shows the *Enabled* parameter to be `True`, content filtering is enabled. If it isn't, run the following command to enable content filtering and the Content Filter agent on the Exchange server:

```
Set-ContentFilterConfig -Enabled $true
```

Step 2: (Optional) Use ADSI Edit to verify replication of the safelist aggregation data to Edge Transport servers

This step is only required if you run the Content Filter agent on an Edge Transport server in your perimeter network.

You can view the user objects in the Active Lightweight Directory Services (AD LDS) instance on the Edge Transport server to verify that the safelist collection data is updated for the user objects and that the Microsoft Exchange EdgeSync service has replicated the data to the AD LDS instance.

There are three safelist collection attributes for each user object:

- **msExchSafeRecipientsHash** This attribute stores the hash of the Safe Recipients List collection for the user.
- **msExchSafeSendersHash** This attribute stores the hash of the Safe Senders List collection for the user.
- **msExchBlockedSendersHash** This attribute stores the hash of the Blocked Senders List collection for the user.

If a hexadecimal string, such as `0xac 0xbd 0x03 0xca`, is present on the attribute, the user object was updated. If the attribute has a value of `<Not Set>`, the attribute wasn't updated.

You can search for and view the attributes by using the AD LDS Active Directory Service Interfaces (ADSI) Edit snap-in.

Step 3: Send a test message to verify safelist aggregation is working

To test whether safelist aggregation is functioning, you need to send yourself a message from a safe sender that would otherwise be blocked by content filtering. If safelist aggregation is functioning, the message should arrive in your Inbox.

1. Find an existing external email account to use, or create an email account at a free web-based email provider like Microsoft Hotmail.
2. Add that account to your Safe Senders List in Microsoft Outlook.
3. Use the **Update-SafeList** cmdlet to have the safelist collection from that mailbox copied to Active Directory.
4. Optional: if you are running the Content Filter agent on an Edge Transport server in the perimeter network, run the **Start-EdgeSynchronization** cmdlet to force EdgeSync replication.
5. Add a specific word as a blocked phrase to your content filtering configuration. For detailed steps, see Manage content filtering.
6. From the external email account in step 1, send a message to your Exchange mailbox that includes the blocked phrase you configured in step 5.

If the message is successfully delivered to your Inbox, safelist aggregation is working correctly.

Configure Content Filtering to Use Safe

Domain Data

Topic Last Modified: *2013-09-30*

Safe domain data is an entire domain (for example, @contoso.com) that's stored in a user's Safe Senders List. By default, the Content Filter agent doesn't use safe domain data to identify senders that are allowed to bypass content filtering.

This default setting helps reduce the amount of spam that's delivered into your organization. For example, a user might add the domain of a large email provider to their Safe Senders List. If this domain is frequently used or spoofed by spammers, and if content filtering is configured to use safe domain data to mark the messages as safe, messages from any sender in that domain would be delivered to recipients in your organization.

We recommend that you don't modify the default setting in most cases. However, you can configure users' safe domain data to be stored in Active Directory and used by content filtering to mark messages as safe. To do this, you need to modify the MSExchangeMailboxAssistants.exe.config XML application configuration file that's associated with the Microsoft Exchange Mailbox Assistants service, as detailed later in this topic. When you make this configuration change, the safe domain data is hashed and stored in each user's **msExchSafeSenderHash** user object attribute in Active Directory as part of safelist aggregation. The Content Filter agent can then use the safe domain data to mark messages from senders in those domains as safe. For more information about safelist aggregation, see Safelist Aggregation.

What do you need to know before you begin?

- Estimated time to complete: 10 minutes
- Exchange permissions don't apply to the procedures in this topic. These procedures are performed in the operating system of the Exchange Server.
- Changes you save to the MSExchangeMailboxAssistants.exe.config file are applied after you restart the Microsoft Exchange Mailbox Assistants service.
- Any customized per-server settings you make in Exchange XML application configuration files, for example, web.config files on Client Access servers or the EdgeTransport.exe.config file on Mailbox servers, will be overwritten when you install an Exchange Cumulative Update (CU). Make sure that you save this information so you can easily re-configure your server after the install. You must re-configure these settings after you install an Exchange CU.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use a command prompt to configure content filtering to use safe domain data

1. In the Command Prompt window, open the MSExchangeMailboxAssistants.exe.config file in Notepad by running the following command:

```
Notepad %ExchangeInstallPath%Bin
\MSExchangeMailboxAssistants.exe.config
```

2. Locate the *</appsettings>* key at the end of the file, and paste the following key before the *</appsettings>* key:

```
<add key="IncludeSafeDomains" value="true" />
```

3. When you are finished, save and close the MSExchangeMailboxAssistants.exe.config file.
4. Restart the Microsoft Exchange Mailbox Assistants service by running the following command:

```
net stop MSExchangeMailboxAssistants && net start
MSExchangeMailboxAssistants
```

How do you know this worked?

To verify that you have successfully configured content filtering to use safe domain data, do the following:

1. Verify that adding a domain to a user's Safe Senders List in Outlook updates the user's **msExchSafeSenderHash** attribute in Active Directory. To do this, view the attribute in ADSIEdit.exe or LDP.exe, open the user's mailbox in Outlook, add a domain to the Safe Senders List, run the command `Update-Safelist <username>`, and verify that the original and current values of **msExchSafeSenderHash** are different.
2. After you've verified the safe domain data is stored in Active Directory, send a test message from an external sender in that domain to a user in your organization. Verify the message is marked as safe by examining the anti-spam header fields in the message header.

Spam Confidence Level Threshold

Anti-spam and anti-malware protection > Anti-spam protection > Content filtering >

Topic Last Modified: *2013-10-10*

In Microsoft Exchange Server 2013, you can define specific actions according to spam confidence level (SCL) thresholds. For example, you can define different thresholds for rejecting, deleting, or

quarantining messages on an Exchange server that's running the Content Filter agent.

The combination of this SCL threshold configuration in the Content Filter agent and the SCL Junk Email folder configuration on the user's mailbox helps you implement a more comprehensive and precise anti-spam strategy. This more precise and detailed SCL threshold adjustment functionality in Exchange 2013 can help you reduce the overall cost of deploying and maintaining an anti-spam solution across your Exchange organization.

The Content Filter agent assigns an SCL rating to messages late in the anti-spam cycle, after other anti-spam agents have processed any inbound messages. Many of the other anti-spam agents that process inbound messages before they're processed by the Content Filter agent are deterministic in how they act on a message. For example, on an Edge Transport server the Connection Filter agent rejects any message sent from an IP address on a real-time block list. The Sender Filter agent and Recipient Filter agent process messages in a similarly deterministic manner.

In Exchange 2013, these deterministic anti-spam agents process messages first and therefore greatly reduce the number of messages that must be processed by the Content Filter agent. For more information about the order in which anti-spam agents process messages, see Anti-spam protection.

Because content filtering isn't an exact, deterministic process, the ability to adjust the action that the Content Filter agent performs on different SCL values is important. By carefully adjusting the SCL threshold configuration, you can minimize the following:

- Size of the spam quarantine storage
- Number of legitimate email messages mistakenly quarantined
- Number of legitimate email messages that reach the Microsoft Outlook user's Junk Email folder
- Number of offensive spam email messages that reach the Outlook user's Inbox or Junk Email folder
- Number of spam email messages that reach the Outlook user's Inbox

SCL threshold actions

By adjusting SCL threshold actions, you can escalate the content filtering action taken on messages that have a greater risk of being spam. To understand this functionality, it's helpful to understand the different SCL threshold actions and how they're implemented:

- **SCL delete threshold** When the SCL value for a specific message is equal to or higher than the SCL delete threshold, the Content Filter agent deletes the message. There's no protocol-level communication that tells the sending system or sender that the message was deleted. If the SCL value for a message is lower than the SCL delete threshold value, the Content Filter agent doesn't delete the message. Instead, the Content Filter agent compares the SCL value to the SCL reject threshold.
- **SCL reject threshold** When the SCL value for a specific message is equal to or higher than the SCL reject threshold, the Content Filter agent deletes the message and sends a rejection response to the sending system. You can customize the rejection response. In some cases, a non-delivery report (NDR) is sent to the original sender of the message. If the SCL value for a message is lower

than the SCL delete and SCL reject threshold values, the Content Filter agent doesn't delete or reject the message. Instead, the Content Filter agent compares the SCL value to the SCL quarantine threshold.

- **SCL quarantine threshold** When the SCL value for a specific message is equal to or higher than the SCL quarantine threshold, the Content Filter agent sends the message to a quarantine mailbox. Email administrators must periodically review the quarantine mailbox. If the SCL value for a message is lower than the SCL delete, reject, and quarantine threshold values, the Content Filter agent doesn't delete, reject, or quarantine the message. Instead, the Content Filter agent sends the message to the appropriate Mailbox server, where the per-recipient SCL Junk Email folder threshold value of the message is evaluated.
- **SCL Junk Email folder threshold** If the SCL value for a specific message exceeds the SCL Junk Email folder threshold, the message is delivered to the user's Junk Email folder. If the SCL value for a message is lower than the SCL delete, reject, quarantine, and Junk Email folder threshold values, the message is delivered to the user's Inbox.

The Content Filter agent and the Junk Email folder process the SCL threshold value differently. The Content Filter agent takes action on the SCL threshold value that you configure. The Junk Email folder takes action on the SCL threshold value that you configure plus 1. For example, if you configure the Delete action to an SCL of 8 on the Content Filter agent, all messages with an SCL of 8 or greater are deleted. However, if you configure the Junk Email folder with an SCL threshold of 4, all messages with an SCL of 5 or greater are moved to the Junk Email folder.

For example, if you set the SCL delete threshold to 8, the SCL reject threshold to 7, the SCL quarantine threshold to 6, and the SCL Junk Email folder threshold to 4, all messages with an SCL of 5 or lower are delivered to the user's mailbox. Messages with an SCL value of 5 are put in the user's Junk Email folder. Messages with an SCL value of 4 or lower are put in the user's Inbox.

You can configure the SCL delete, reject, quarantine, and Junk Email folder settings in the following locations:

- **On the Content Filter agent configuration (per-transport server SCL configuration)** You use the **Set-ContentFilterConfig** cmdlet to enable or disable and set the SCL delete, reject, and quarantine thresholds on the Exchange server where you're running the Content Filter agent. Over time, as you analyze the spam functionality and metrics provided by the anti-spam logging and reporting features, you can make additional adjustments to these SCL threshold configurations as needed.

The SCL parameters that are available on the **Set-ContentFilterConfig** cmdlet are described in the following table.

Parameter	Description
SCLDeleteEnabled	This parameter enables or disables deleting a message without a non-delivery report (NDR) when the SCL value of the message is greater than or equal to the value specified by the *SCLDeleteThreshold* parameter. Valid input for

	this parameter is `$true` or `$false`.
SCLDeleteThreshold	Valid input for this parameter is an integer from 0 through 9 inclusive. The value of this parameter should be greater than the other SCL threshold parameters. This parameter is only meaningful if the value of the *SCLDeleteEnabled* parameter is `$true`.
SCLRejectEnabled	This parameter enables or disables rejecting a message with an NDR when the SCL value of the message is greater than or equal to the value specified by the *SCLRejectThreshold* parameter. Valid input for this parameter is `$true` or `$false`.
SCLRejectThreshold	Valid input for this parameter is an integer from 0 through 9 inclusive. The value of this parameter should be less than the *SCLDeleteThreshold* parameter, but greater than the other SCL threshold parameters This parameter is only meaningful if the value of the *SCLRejectEnabled* parameter is `$true`.
SCLQuarantineEnabled	This parameter enables or disables sending a message to the spam quarantine mailbox when the SCL value of the message is greater than or equal to the value specified by the *SCLQuarantineThreshold* parameter. Valid input for this parameter is `$true` or `$false`. For more information about the spam quarantine mailbox, see Spam quarantine.
SCLQuarantineThreshold	Valid input for this parameter is an integer from 0 through 9 inclusive. The value of this parameter should be less than the *SCLRejectThreshold* parameter, but greater than the *SCLJunkThreshold* parameter on the

	Set-OrganizationConfig or **Set-Mailbox** cmdlets. This parameter is only meaningful if the value of the *SCLQuarantineThreshold* parameter is `$true`.

- **On the organization configuration settings (organization-wide SCL configuration)** You use the **Set-OrganizationConfig** cmdlet to set the SCL Junk Email folder threshold for all mailboxes in the organization.

The SCL parameter that's available on the **Set-OrganizationConfig** cmdlet is described in the following table. For an example of using SCLJunkThreshold, see Configure Anti-Spam Settings on Mailboxes.

Parameter	Description
SCLJunkThreshold	This parameter specifies the SCL value that a message must exceed for the message to be moved into the Junk Email folder of the recipient's mailbox. Valid input for this parameter is an integer from 0 through 9 inclusive. The value of this parameter should be less than the other SCL threshold parameters. For example, if you specify the value 4, then messages with an SCL value of 5 or higher are moved into the user's Junk Email folder.

- **On user mailboxes (per-recipient SCL configuration)** You use the **Set-Mailbox** cmdlet to enable or disable and set per-recipient SCL delete, reject, quarantine, and Junk Email folder thresholds on individual mailboxes. You can only use the **Set-Mailbox** cmdlet to enable or disable the SCL Junk Email folder threshold on individual mailboxes. The per-recipient SCL delete, reject, and quarantine thresholds are stored in Active Directory and are replicated to subscribed Edge Transport servers by the Microsoft Exchange EdgeSync service. The per-recipient SCL threshold configurations are used by the Content Filter agent even if you've set per-transport server SCL configurations. Therefore, if you've set per-recipient SCL thresholds, the Content Filter agent uses the per-recipient SCL thresholds for specific users instead of the SCL configuration on the Content Filter agent. For examples, see Configure Anti-Spam Settings on Mailboxes.

Note:
Per-recipient SCL thresholds are not enforced on mail received through distribution groups.

The same SCL parameters are available on the **Set-Mailbox** cmdlet that are available on the **Set-ContentFilterConfig** and **Set-OrganizationConfig** cmdlets:

- *SCLDeleteEnabled*
- *SCLDeleteThreshold*

- *SCLRejectEnabled*
- *SCLRejectThreshold*
- *SCLQuarantineEnabled*
- *SCLQuarantineThreshold*
- *SCLJunkThreshold*

However, all the SCL parameters on the **Set-Mailbox** cmdlet also accept the value `$null`. If an SCL setting on a mailbox is blank (`$null`), the corresponding Content Filter agent setting or organization configuration setting is applied to the mailbox. If an SCL setting on a mailbox has the value of `$true` or `$false`, the setting on the mailbox overrides the corresponding organization-wide setting on the Content Filter agent or the organization configuration.

The SCL parameter that's only available on the **Set-Mailbox** cmdlet is described in the following table.

Parameter	Description
SCLJunkEnabled	This parameter enables or disables delivering a message to the user's Junk Email folder when the SCL value of the message is greater than the value specified by the *SCLQuarantineThreshold* parameter. Valid input for this parameter is `$true`, `$false`, or `$null`. Note that junk email filtering is enabled by default for all user mailboxes in the organization. By default, the *Enabled* parameter is set to the value `$true` on the **Set-MailboxJunkEmailConfiguration** cmdlet for all user mailboxes.

For more information about configuring the SCL thresholds on a mailbox, see Configure Anti-Spam Settings on Mailboxes.

Monitoring the SCL thresholds

You can use several built-in scripts located in the `%ExchangeInstallPath%Scripts` folder, such as **get-AntispamSCLHistogram.ps1**, for gathering filtering result data. If the data indicates that you need to make immediate adjustments, reconfigure the SCL thresholds. Otherwise, collect data and analyze the spam reporting to determine whether adjustments are required.

Configure Anti-Spam Settings on Mailboxes

Topic Last Modified: *2014-02-28*

You can configure specific anti-spam settings on individual mailboxes that are different than the anti-spam settings that are applied to the rest of the mailboxes in your Exchange organization. When you configure an anti-spam setting on a mailbox, that setting overrides the corresponding organization-wide content filtering or organization configuration anti-spam setting.

What do you need to know before you begin?

- Estimated time to complete each procedure: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Anti-spam features" entry in the Anti-spam and anti-malware permissions topic, and the "Anti-spam" entry in the Recipients Permissions topic.
- By default, anti-spam features aren't enabled in the Transport service on a Mailbox server. Typically, you only enable the anti-spam features on a Mailbox server if your Exchange organization doesn't do any prior anti-spam filtering before accepting incoming messages. For more information, see Enable anti-spam functionality on Mailbox servers.
- You can only use the Shell to perform this procedure.
- The Junk Email Folder SCL threshold value behaves differently than the SCL delete, reject, and quarantine values. For more information, see Spam Confidence Level Threshold.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to configure anti-spam features on a single mailbox

To configure the anti-spam settings on a single mailbox, use the following syntax.

```
Set-Mailbox <MailboxIdentity> -AntispamBypassEnabled <$true
| $false> -RequireSenderAuthenticationEnabled <$true |
$false> -SCLDeleteEnabled <$true | $false | $null> -
SCLDeleteThreshold <0-9 | $null> -SCLJunkEnabled <$true |
$false | $null > -SCLJunkThreshold <0-9 | $null> -
SCLQuarantineEnabled <$true | $false | $null > -
SCLQuarantineThreshold <0-9 | $null> -SCLRejectEnabled
<$true | $false | $null > -SCLRejectThreshold <0-9 | $null>
```

This example configures the mailbox of a user named Jeff Phillips to bypass all the anti-spam filters and to have messages that meet or exceed a Junk Email folder SCL threshold of 5 delivered to his Junk Email folder in Microsoft Outlook.

```
Set-Mailbox "Jeff Phillips" -AntispamBypassEnabled $true -
SCLJunkEnabled $true -SCLJunkThreshold 4
```

How do you know this worked?

To verify that you have successfully configured the anti-spam features on a single mailbox, do the following:
1. Run the following command:

```
Get-Mailbox <MailboxIdentity> | Format-List
SCL*,Bypass*,*SenderAuth*
```

2. Verify the value displayed is the value you configured.

Use the Shell to configure anti-spam features on multiple mailboxes

To configure all the anti-spam settings on multiple mailboxes, use the following syntax.

```
Get-Mailbox [<Filter>]| Set-Mailbox <Anti-Spam Settings>
```

This example enables the SCL quarantine threshold with a value of 7 on all mailboxes in the Users container in the Contoso.com domain.

```
Get-Mailbox -OrganizationalUnit Contoso.com/Users | Set-
Mailbox -SCLQuarantineEnabled $true -SCLQuarantineThreshold
7
```

How do you know this worked?

To verify that you have successfully configured the anti-spam features on multiple mailboxes, do

the following:
1. Run the following command:

```
Get-Mailbox [<Filter>] | Format-List Name,SCL*,*SenderAuth*
```

2. Verify the values displayed are the values you configured.

Use the Shell to configure the junk email threshold for all mailboxes in your organization

Run the following command:

```
Set-OrganizationConfig -SCLJunkThreshold <Integer>
```

This example sets the organization's junk email threshold to 5.

```
Set-OrganizationConfig -SCLJunkThreshold 5
```

How do you know this worked?

To verify that you have successfully configured the junk email threshold for all mailboxes in your organization, do the following:
1. Run the following command:

```
Get-OrganizationConfig | Format-List SCLJunkThreshold
```

2. Verify the value displayed is the value you configured.

Sender reputation and the Protocol Analysis agent

Exchange Server 2013 > Anti-spam and anti-malware protection > Anti-spam protection >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-16*

Sender reputation is part of the Exchange anti-spam functionality that blocks messages according to many characteristics of the sender. Sender reputation relies on persisted data about the sender to determine what action, if any, to take on an inbound message. The Protocol Analysis agent is the underlying agent for sender reputation functionality.

When you configure anti-spam agents on an Exchange server, the agents act on messages

cumulatively to reduce the number of unsolicited messages that enter the organization.

Contents

Calculation of the sender reputation level

A sender reputation level (SRL) is calculated from the following statistics:

- **HELO/EHLO analysis** The HELO and EHLO SMTP commands are intended to provide the domain name, such as Contoso.com, or IP address of the sending SMTP server to the receiving SMTP server. Malicious users, or *spammers*, frequently forge the HELO/EHLO statement in various ways. For example, they type an IP address that doesn't match the IP address from which the connection originated. Spammers also put domains that are known to be locally supported at the receiving server in the HELO statement in an attempt to appear as if the domains are in the organization. In other cases, spammers change the domain that's passed in the HELO statement. The typical behavior of a legitimate user may be to use a different, but relatively constant, set of domains in their HELO statements.

Therefore, analysis of the HELO/EHLO statement on a per-sender basis may indicate that the sender is likely to be a spammer. For example, a sender that provides many different unique HELO/EHLO statements in a specific time period is more likely to be a spammer. Senders who consistently provide an IP address in the HELO statement that doesn't match the originating IP address as determined by the Connection Filter agent are also more likely to be spammers. Remote senders who consistently provide a local domain name in the HELO statement that's in the same organization as the Exchange server are also more likely to be spammers.

- **Reverse DNS lookup** Sender reputation also verifies that the originating IP address from which the sender transmitted the message matches the registered domain name that the sender submits in the HELO or EHLO SMTP command.

Sender reputation performs a reverse DNS query by submitting the originating IP address to DNS. The result that's returned by DNS is the domain name that's registered by using the domain naming authority for that IP address. Sender reputation compares the domain name that's returned by DNS to the domain name that the sender submitted in the HELO/EHLO SMTP command. If the domain names don't match, the sender is likely to be a spammer, and the overall SRL rating for the sender is increased.

The Sender ID agent performs a similar task, but the success of the Sender ID agent relies on legitimate senders to update their DNS infrastructure to identify all the email-sending SMTP servers in their organization. By performing a reverse DNS lookup, you can help identify potential spammers.

- **Analysis of SCL ratings on messages from a particular sender** When the Content Filter agent

processes a message, it assigns a spam confidence level (SCL) rating to the message. The SCL rating is a number from 0 through 9. A higher SCL rating indicates that a message is more likely to be spam. Data about each sender and the SCL ratings that their messages yield is persisted for analysis by sender reputation. Sender reputation calculates statistics about a sender according to the ratio between all messages from that sender that had a low SCL rating in the past and all messages from that sender that had a high SCL rating in the past. Additionally, the number of messages that have a high SCL rating that the sender has sent in the last day is applied to the overall SRL.

- **Sender open proxy test** An *open proxy* is a proxy server that accepts connection requests from anyone anywhere and forwards the traffic as if it originated from the local hosts. Proxy servers relay TCP traffic through firewall hosts to provide user applications transparent access across the firewall. Because proxy protocols are lightweight and independent of user application protocols, proxies can be used by many different services. Proxies can also be used to share a single Internet connection by multiple hosts. Proxies are usually set up so that only trusted hosts inside the firewall can cross through the proxies. A legitimate sender may be an open proxy because of an unintentional misconfiguration or malware.

Open proxies provide an ideal way for malicious users to hide their true identities and launch denial of service attacks (DoS) or send spam. As more proxy servers are configured to be open by default, open proxies have become more common. Additionally, malicious users can use multiple open proxies together to hide the sender's originating IP address.

When sender reputation performs an open proxy test, it does so by formatting an SMTP request in an attempt to connect back to the Exchange server from the open proxy. If an SMTP request is received from the proxy, sender reputation verifies that the proxy is an open proxy and updates the open proxy test statistic for that sender.

Sender reputation weighs each of these statistics and calculates an SRL for each sender. The SRL is a number from 0 through 9 that predicts the probability that a specific sender is a spammer or otherwise malicious user. A value of 0 indicates that the sender isn't likely to be a spammer; a value of 9 indicates that the sender is likely to be a spammer.

You can configure a block threshold from 0 through 9 at which sender reputation issues a request to the Sender Filter agent, and, therefore, blocks the sender from sending a message into the organization. When a sender is blocked, the sender is added to the Blocked Senders list for a configurable period. How blocked messages are handled depends on the configuration of the Sender Filter agent. The following actions are the options for handling blocked messages:

- Reject
- Delete and archive
- Accept and mark as a blocked sender

If a sender is included in the IP Block list or Microsoft IP Reputation Service, sender reputation issues an immediate request to the Sender Filter agent to block the sender. To take advantage of this functionality, you must enable and configure the Microsoft Exchange Anti-spam Update Service.

By default, sender reputation sets a rating of 0 for senders that haven't been analyzed. After a

sender has sent 20 or more messages, sender reputation calculates an SRL that's based on the statistics listed earlier in this topic.

Return to top

Use of the SRL

Sender reputation acts on messages during two phases of the SMTP session:

- **At the MAIL FROM: SMTP command** Sender reputation acts on a message only if the message was blocked or otherwise acted on by the Connection Filter agent, Sender Filter agent, Recipient Filter agent, or Sender ID agent. In this case, sender reputation retrieves the sender's current SRL rating from the sender profile that's persisted about that sender on the Exchange server. After this rating is retrieved and evaluated, the Exchange server configuration dictates the behavior that occurs at a particular connection according to the block threshold.
- **After the "end of data" SMTP command** The end of data transfer (**EOD**) SMTP command is given when all the actual message data is sent. At this point in the SMTP session, many of the anti-spam agents have processed the message. As a by-product of anti-spam processing, the statistics that sender reputation relies on are updated. Therefore, sender reputation has the data to calculate or recalculate an SRL rating for the sender.

For more information, see Manage sender reputation.

Return to top

Enabling and configuring the detection of open proxy servers

Sender reputation evaluates several sender characteristics to calculate an SRL. Among the characteristics that sender reputation evaluates are the results of a test for open proxy servers. Frequently, spammers route messages through open proxy servers on the Internet. By routing spam through open proxy servers, spammers can send messages that appear to originate from a different server than their own.

When sender reputation calculates an SRL, sender reputation tries to connect to the sender's originating IP address by using a variety of common proxy protocols, such as SOCKS4, SOCKS5, HTTP, Telnet, Cisco, and Wingate. Sender reputation formats a protocol-specific request in an attempt to connect back to the Edge Transport server from the open proxy server by using an SMTP request. If an SMTP request is received from the proxy server, sender reputation verifies that the proxy server is an open proxy server and adjusts the SRL rating according to this result. By default, detection of open proxy servers is enabled on sender reputation.

For more information about how to enable and configure detection of open proxy servers, see Manage sender reputation.

Return to top

Setting the SRL block threshold

The SRL is a number from 0 through 9 that predicts the probability that a specific sender is a spammer or otherwise malicious user. You must set a threshold for sender blocking by SRL. This SRL block threshold defines the SRL value that must be exceeded for sender reputation to block a sender. By default, the SRL is set at 7. You should monitor the effectiveness of the agent at the default level. You may find that you can adjust the value to meet the needs of your organization. If you set other anti-spam agents aggressively, you may be able to set a higher SRL threshold for sender reputation than you would if the other anti-spam agents weren't set aggressively. For more information about how to adjust anti-spam configurations so that they work together to reduce spam, see Anti-spam protection.

On an Edge Transport server, if the SRL block threshold is exceeded for a particular sender, sender reputation adds the sender to the IP Block list on the Connection Filter agent. Sometimes, spammers send batches of spam from a single sender. In this scenario, if sender reputation calculates an SRL that exceeds the SRL block threshold, the sender is added to the Sender Block List for a configurable duration of time. The default duration is 24 hours. After 24 hours, the sender is removed from the Sender Block List and can send messages again.

When a sender is added to the IP Block list, sender reputation deletes the profile for the sender. Sender reputation deletes the profile because the blocked sender's existing profile indicates that the sender's SRL exceeds the SRL block threshold. This would cause the blocked sender to be added to the IP Block list again as soon as the duration for sender blocking ends.

For more information, see Manage sender reputation.

Return to top

Manage sender reputation

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

Sender reputation is provided by the Protocol Analysis agent. Sender reputation blocks messages according to various characteristics of the sender. Sender reputation relies on persisted data about the sender to determine what action, if any, to take on an inbound message.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Anti-spam features" entry in the Anti-spam and anti-malware permissions topic.
- You can only use the Shell to perform this procedure.
- By default, anti-spam features aren't enabled in the Transport service on a Mailbox server. Typically, you only enable the anti-spam features on a Mailbox server if your Exchange organization doesn't do any prior anti-spam filtering before accepting incoming messages. For more information, see Enable anti-spam functionality on Mailbox servers.
- The Protocol Analysis agent is the underlying agent for sender reputation functionality. When you disable sender reputation, the Protocol Analysis agent is still enabled.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to enable or disable sender reputation

This example disables sender reputation.

```
Set-SenderReputationConfig -Enabled $false
```

This example enables sender reputation.

```
Set-SenderReputationConfig -Enabled $true
```

How do you know this worked?

To verify that you have successfully enabled or disabled sender reputation, do the following:
1. Verify the Protocol Analysis agent is installed and enabled by running the following command:

```
Get-TransportAgent
```

2. Verify the sender reputation values you configured by running the following command:

```
Get-SenderReputationConfig | Format-List
Enabled,*MailEnabled
```

Use the Shell to enable or disable sender reputation for internal or external messages

By default, sender reputation is enabled for external messages, and disabled for internal messages. A message is considered external if it comes from an unauthenticated connection that's external to your Exchange organization. A message is considered internal if it comes from authenticated connection, and the sender's domain is configured as an authoritative domain in your Exchange organization.

To disable sender reputation for external messages, run the following command:

```
Set-SenderReputationConfig -ExternalMailEnabled $false
```

To enable sender reputation for external messages, run the following command:

```
Set-SenderReputationConfig -ExternalMailEnabled $true
```

To disable sender reputation for internal messages, run the following command:

```
Set-SenderReputationConfig -InternalMailEnabled $false
```

To enable sender reputation for internal messages, run the following command:

```
Set-SenderReputationConfig -InternalMailEnabled $true
```

How do you know this worked?

To verify that you have successfully enabled or disabled sender reputation for internal and external messages, do the following:
1. Run the following command:

```
Get-SenderReputationConfig | Format-List
Enabled,*MailEnabled
```

2. Verify the values displayed match the values you configured.

Use the Shell to configure sender reputation properties

To configure the sender reputation properties, run the following command:

```
Set-SenderReputationConfig -SrlBlockThreshold <Value> -
SenderBlockingPeriod <Hours>
```

This example sets the sender reputation level (SRL) block threshold to 6 and configures sender reputation to add offending senders to the IP Block List for 36 hours:

```
Set-SenderReputationConfig -SrlBlockThreshold 6 -
SenderBlockingPeriod 36
```

How do you know this worked?

To verify that you have successfully configured the sender reputation properties, do the following:
1. Run the following command:

```
Get-SenderReputationConfig
```

2. Verify the values displayed match the values you configured.

Use the Shell to configure outbound access for the detection of open proxy servers

You may need to perform additional steps to allow sender reputation to traverse any firewalls that are between the Internet and the Exchange server that's running the Protocol Analysis agent. The following table lists the outbound ports that are required for sender reputation.

Protocols	Ports
SOCKS4, SOCKS5	1081, 1080
Wingate, Telnet, Cisco	23
HTTP CONNECT, HTTP POST	6588, 3128, 80

To configure outbound access for the detection of open proxy servers, run the following command:

```
Set-SenderReputationConfig -ProxyServerName <String> -
ProxyServerPort <Port> -ProxyServerType <String>
```

This example configures sender reputation to use the open proxy server named SERVER01 that uses the HTTP CONNECT protocol on port 80.

```
Set-SenderReputationConfig - ProxyServerName SERVER01 -
ProxyServerPort 80 -ProxyServerType HttpConnect
```

How do you know this worked?

To verify that you have successfully configured outbound access for detection of open proxy servers, do the following:
1. Run the following command:

```
Get-SenderReputationConfig | Format-List ProxyServer*
```

2. Verify the values displayed are the values you configured.

Connection Filtering on Edge Transport Servers

Exchange Server 2013 > Anti-spam and anti-malware protection > Anti-spam protection >

Topic Last Modified: *2014-02-10*

Connection filtering is an anti-spam feature in Microsoft Exchange Server 2013 that allows or blocks email based on the message source. Connection filtering is performed by the Connection Filtering agent that's available only on Edge Transport servers. The Connection Filtering agent relies on the IP address of the connecting mail server to determine what action, if any, to take on an inbound message.

By default, the Connection Filtering agent is the first anti-spam agent to evaluate an inbound message on an Edge Transport server. The source IP address of the SMTP connection is checked against the allowed and blocked IP addresses. If the source IP address is specifically allowed, the message is sent to the recipients in your organization without additional processing by other anti-spam agents. If the source IP address is specifically blocked, the SMTP connection is dropped. If the source IP address isn't specifically allowed or blocked, the message flows through the other anti-spam agents on the Edge Transport server.

Connection filtering compares the IP address of the source mail server to the values in the IP Allow list, the IP Block list, IP Allow list providers, and IP Block list providers. You need to configure at least one of these four IP address data stores for connection filtering to function. If you don't specify any IP address data, you should disable the Connection Filtering agent. For more information, see Manage Connection Filtering on Edge Transport Servers.

Contents

IP Block list

The IP Block list contains the IP addresses of email servers that you want to block. You manually maintain the IP addresses in the IP Block list. You can add individual IP addresses or IP address ranges. You can specify an expiration time that specifies how long the IP address entry will be blocked. When the expiration time is reached, the IP address entry in the IP Block list is disabled.

If the Connection Filtering agent finds the source IP address on the IP Block list, the SMTP connection will be dropped after all the **RCPT TO** headers (envelope recipients) in the message are processed.

IP addresses can also be automatically added to the IP Block list by the Sender Reputation feature of the Protocol Analysis agent. For more information, see Sender reputation and the Protocol Analysis agent.

IP Allow list

The IP Allow list contains the IP addresses of email servers that you want to designate as trustworthy sources of email. Email from mail servers that you specify in the IP Allow list is exempt from processing by other Exchange anti-spam agents.

You manually maintain the IP addresses in the IP Allow list. You can add individual IP addresses or IP address ranges. You can specify an expiration time that specifies how long the IP address entry will be allowed. When the expiration time is reached, the entry in the IP Allow list is disabled.

Return to top

IP Block List providers

IP Block List providers are frequently referred to as *real-time block lists*, or RBLs. IP Block List providers compile lists of mail server IP addresses that send spam. Many IP Block List providers also compile lists of mail server IP addresses that could be used for spam. Examples include mail servers that are configured for open relay, Internet service providers (ISPs) that assign dynamic IP addresses, and ISPs that allow SMTP mail server traffic from dial-up accounts.

When you configure connection filtering to use an IP Block List provider, the Connection Filtering agent compares the IP address of the connecting mail server to the list of IP addresses at the IP Block List provider. If there's a match, the message isn't allowed in your organization. You can configure connection filtering to use multiple IP Block List providers, and you assign different priority values to each provider.

The Connection Filtering agent checks the source IP address at the IP Allow list and the IP Block list. If the IP address doesn't exist on either list, the Connection Filtering agent queries the IP Block List provider according to the priority value that you assigned. If the IP address is defined at an IP Block List provider, the Edge Transport server waits for and processes the **RCPT TO** header, responds to the sending mail server with an `SMTP 550` error, and closes the connection. The connection isn't immediately dropped so that the connection attempt can be logged, and because you can specify recipients that are exempt from having messages blocked by any IP Block list providers.

If the IP address isn't defined at any of the IP Block List providers, the Content Filtering agent hands the message off to the next transport agent on the Edge Transport server.

For each IP Block List provider, you can customize the SMTP 550 error that's returned to the sender when a message is blocked. You should identify the IP Block List provider that identified the message source as spam. If a legitimate source mail server is erroneously identified as a spam source, the administrator can then contact the IP Block List provider and take the steps necessary to remove the mail server from the IP Block List provider.

IP Block List providers can return different codes to identify why an IP address is defined in their lists. Most IP Block List providers return bitmask or absolute value data types. Within these data types, the IP Block List provider can use multiple values to classify the IP address by threat type.

There are issues to consider when using IP Block list providers:

- Outages or delays at the IP Block list provider service can cause delays in the processing of messages on the Edge Transport server. You should always select reliable IP Block list providers.
- Source servers that you know to be legitimate can be erroneously identified as spam sources. For example, the mail server can be unintentionally configured to act as an open relay. You should always select IP Block list providers that provide clear procedures for evaluation and removal from their services.

Return to top

Bitmask and absolute value examples

This section shows an example of the status codes returned by most Block List providers. For details about the status codes that the provider returns, see the documentation from the specific provider.

For bitmask data types, the IP Block List provider service returns a status code of 127.0.0.*x*, where the integer *x* is any one of the values listed in the following table.

Values and status codes for bitmask data types

Value	Status code
1	The IP address is on an IP Block list.
2	The SMTP server is configured to act as an open relay.
4	The IP address supports a dial-up IP address.

For absolute value types, the IP Block List provider returns explicit responses that define why the IP address is defined in their block lists. The following table shows examples of absolute values and the explicit responses.

Values and status codes for absolute value data types

Value	Explicit response
127.0.0.2	The IP address is a direct spam source.
127.0.0.4	The IP address is a bulk mailer.
127.0.0.5	The remote server sending the message is known to support multistage open relays.

Return to top

IP Allow List providers

IP Allow List providers are also known as *safe lists* or *white lists*. IP Allow List providers are configured just like IP Block List providers, but the results are the opposite: they define mail server IP addresses that are definitely not associated with spam activity. If the IP address of the connecting mail server is defined at an IP Allow List provider, the message is exempt from processing by other Exchange anti-spam agents. For this reason, IP Block List providers are used much more frequently than IP Allow List providers. Choose your IP Allow List providers carefully.

Return to top

Test IP Block List providers and IP Allow List providers

After you configure connection filtering to use an IP Block List provider or an IP Allow List provider, you can run tests to verify that the providers are working correctly. Most providers provide test IP addresses that you can use to test their services. When you test a provider, the Connection Filtering agent issues a DNS query that should result in a specific response from the provider. For more information about how to test IP addresses against an IP Block List provider service or an IP Allow List provider service, see Manage Connection Filtering on Edge Transport Servers.

Return to top

Configure connection filtering on Edge Transport servers that aren't directly connected to the Internet

You can use connection filtering on Edge Transport servers that don't directly receive email from the Internet. In this scenario, the Edge Transport server is behind another mail server that receives and processes messages directly from the Internet. For example, your organization might send email traffic through an anti-spam server, service, or appliance before the messages reach the Edge Transport server. In this scenario, the Connection Filtering agent needs to extract the correct source IP address from the message. To do this, the Connection Filtering agent needs to parse the

Received header field values in the message header and compare those values to the known IP addresses of the mail server that sits between the Edge Transport server and the Internet.

Every mail server that accepts and relays an SMTP message along the delivery path adds its own **Received** header field in the message header. The **Received** header typically contains the domain name and IP address of the mail server that processed the message.

If the Edge Transport server doesn't accept messages directly from the Internet, you need to use the *InternalSMTPServers* parameter on the **Set-TransportConfig** cmdlet on an Exchange 2013 Mailbox server to identify the IP address of the mail server that sit between the Edge Transport server and the Internet. The IP address data is replicated to Edge Transport servers by EdgeSync. When messages are received by the Edge Transport server, the Connection Filtering agent assumes an IP address in a **Received** header field that doesn't match a value specified by the *InternalSMTPServers* parameter is the source IP address that needs to be checked. Therefore, you need specify all internal SMTP servers in order for connection filtering to function correctly.

Return to top

Manage Connection Filtering on Edge Transport Servers

Topic Last Modified: *2014-02-10*

Connection filtering is an anti-spam feature that's provided by the Connection Filtering agent, which is available only on Edge Transport servers in Microsoft Exchange 2013. Connection filtering enables the following features:

- IP Block list
- IP Block List providers
- IP Allow list
- IP Allow List providers

Each of these features can be enabled or disabled separately.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Anti-spam features" entry in the Anti-spam and anti-malware permissions topic.
- You can only use the Shell to perform this procedure.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to enable or disable connection filtering

To completely enable or disable connection filtering, you enable or disable the Connection Filtering agent. The change takes effect after you restart the Microsoft Exchange Transport service. When you restart the Microsoft Exchange Transport service on an Edge Transport server, mail flow on the server is temporarily interrupted.

To disable connection filtering, run the following command:

```
Disable-TransportAgent "Connection Filtering Agent"
```

To enable connection filtering, run the following command:

```
Enable-TransportAgent "Connection Filtering Agent"
```

To make the change take effect, restart the Microsoft Exchange Transport service by running the following command:

```
Restart-Service MSExchangeTransport
```

How do you know this worked?

To verify that you successfully enabled or disabled connection filtering, run the following command and verify that the value displayed is the value you configured.

```
Get-TransportAgent "Connection Filtering Agent" | Format-
List Enabled
```

IP Block list procedures

These procedures apply to the IP Block list that you manually configure. They don't apply to IP Block List providers.

Use the **IPBlockListConfig** cmdlets to view and configure how connection filtering uses the IP Block list. Use the **IPBlockListEntry** cmdlets to view and configure the IP addresses in the IP Block list.

Use the Shell to view the configuration of the IP Block list

To view the configuration of the IP Block list, run the following command:

```
Get-IPBlockListConfig | Format-List *Enabled,*Response
```

Use the Shell to enable or disable the IP Block list

To disable the IP Block list, run the following command:

```
Set-IPBlockListConfig -Enabled $false
```

To enable the IP Block list, run the following command:

```
Set-IPBlockListConfig -Enabled $true
```

How do you know this worked?

To verify that you successfully enabled or disabled the IP Block list, run the following command and verify that the value displayed is the value you configured.

```
Get-IPBlockListConfig | Format-List Enabled
```

Use the Shell to configure the IP Block list

To configure the IP Block list, use the following syntax:

```
Set-IPBlockListConfig [-ExternalMailEnabled <$true | $false>] [-InternalMailEnabled <$true | $false> -MachineEntryRejectionResponse "<Custom response text>"] [-StaticEntryRejectionResponse "<Custom response text>"]
```

This example configures the IP Block list with the settings as follows:

- The IP Block list filters incoming connections from internal and external mail servers. By default, connections are filtered from external mail servers only (*ExternalMailEnabled* is set to `$true`, and *InternalMailEnabled* is set to `$false`). Non-authenticated connections and authenticated connections from external partners are considered external.
- The custom response text for connections that were filtered by IP addresses that were automatically added to the IP Block list by the sender reputation feature of the Protocol Analysis agent is set to the value "Connection from IP address {0} was rejected by sender reputation."
- The custom response text for connections that were filtered by IP addresses that were manually added to the IP Block list is set to the value "Connection from IP address {0} was rejected by connection filtering."

```
Set-IPBlockListConfig -InternalMailEnabled $true -MachineEntryRejectionResponse "Connection from IP address {0} was rejected by sender reputation." -
```

```
StaticEntryRejectionResponse "Connection from IP address
{0} was rejected by connection filtering."
```

How do you know this worked?

To verify that you successfully configured the IP Block list, run the following command and verify that the values displayed are the values you configured.

```
Get-IPBlockListConfig | Format-List *MailEnabled,*Response
```

Use the Shell to view IP Block list entries

To view all IP Block list entries, run the following command:

```
Get-IPBlockListEntry
```

Note that each IP Block list entry is identified by an integer value. The identity integer is assigned in ascending order when you add entries to the IP Block list and the IP Allow list.

To view a specific IP Block list entry, use the following syntax:

```
Get-IPBlockListEntry <-Identity IdentityInteger | -
IPAddress IPAddress>
```

For example, to view the IP Block list entry that contains the IP address 192.168.1.13, run the following command:

```
Get-IPBlockListEntry -IPAddress 192.168.1.13
```

Note:

When you use the *IPAddress* parameter, the resulting IP Block list entry can be an individual IP address, an IP address range, or a Classless InterDomain Routing (CIDR) IP. To use the *Identity* parameter, you specify the integer value that's assigned to the IP Block list entry.

Use the Shell to add IP Block list entries

To add IP Block list entries, use the following syntax:

```
Add-IPBlockListEntry <-IPAddress IPAddress | -IPRange IP
range or CIDR IP> [-ExpirationTime <DateTime>] [-comment
"<Descriptive Comment>"]
```

The following example adds the IP Block list entry for the IP address range 192.168.1.10 through 192.168.1.15 and configures the IP Block list entry to expire on July 4, 2014 at 15:00.

```
Add-IPBlockListEntry -IPRange 192.168.1.10-192.168.1.15 -
ExpirationTime "7/4/2014 15:00"
```

How do you know this worked?

To verify that you successfully added an IP Block list entry, run the following command and verify that the new IP Block list entry is displayed.

```
Get-IPBlockListEntry
```

Use the Shell to remove IP Block list entries

To remove IP Block list entries, use the following syntax:

```
Remove-IPBlockListEntry <IdentityInteger>
```

The following example removes the IP Block list entry that has the *Identity* value 3.

```
Remove-IPBlockListEntry 3
```

The following example removes the IP Block list entry that contains the IP address 192.168.1.12 without using the *Identity* integer value. Note that the IP Block list entry can be an individual IP address or an IP address range.

```
Get-IPBlockListEntry -IPAddress 192.168.1.12 | Remove-
IPBlockListEntry
```

How do you know this worked?

To verify that you successfully removed an IP Block list entry, run the following command and verify that the IP Block list entry you removed is gone.

```
Get-IPBlockListEntry
```

IP Block List provider procedures

These procedures apply to IP Block List providers. They don't apply to the IP Block list.

Use the **IPBlockListProvidersConfig** cmdlets to view and configure how connection filtering uses all IP Block List providers. Use the **IPBlockListProvider** cmdlets to view, configure, and test IP Block List providers.

Use the Shell to view the configuration of all IP Block List providers

To view how connection filtering uses all IP Block List providers, run the following command:

```
Get-IPBlockListProvidersConfig | Format-List
*Enabled,Bypassed*
```

Use the Shell to enable or disable all IP Block List providers

To disable all IP Block List providers, run the following command:

```
Set-IPBlockListProvidersConfig -Enabled $false
```

To enable all IP Block List providers, run the following command:

```
Set-IPBlockListProvidersConfig -Enabled $true
```

How do you know this worked?

To verify that you enabled or disabled all IP Block List providers, run the following command an verify that the value displayed is the value you configured.

```
Get-IPBlockListProvidersConfig | Format-List Enabled
```

Use the Shell to configure all IP Block List providers

To configure how connection filtering uses all IP Block List providers, use the following syntax:

```
Set-IPBlockListProvidersConfig [-BypassedRecipients
<recipient1,recipient2...>] [-ExternalMailEnabled <$true |
$false>] [-InternalMailEnabled <$true | $false>]
```

The following example configures all IP Block List providers with the following settings:

- IP Block List providers filter incoming connections from internal and external mail servers. By default, connections are filtered from external mail servers only (*ExternalMailEnabled* is set to `$true`, and *InternalMailEnabled* is set to `$false`). Non-authenticated connections and authenticated connections from external partners are considered external.
- Messages sent to the internal recipients chris@fabrikam.com and michelle@fabrikam.com are excluded from filtering by IP Block List providers. Note that if you want to add recipients to the list without affecting existing recipients, use the syntax, `@{Add="<recipient1>","<recipient2>"...}`.

```
Set-IPBlockListProvidersConfig -BypassedRecipients
chris@fabrikam.com,michelle@fabrikam.com -
InternalMailEnabled $true
```

For more information, see Set-IPBlockListProvidersConfig.

How do you know this worked?

To verify that you successfully configured all IP Block List providers, run the following command and verify that the values displayed are the values you configured.

```
Get-IPBlockListProvidersConfig | Format-List
*MailEnabled,Bypassed*
```

Use the Shell to view IP Block List providers

To view the summary list of all the IP Block List providers, run the following command:

```
Get-IPBlockListProvider
```

To view the details of a specific provider, use the following syntax:

```
Get-IPBlockListProvider <IPBlockListProviderIdentity>
```

The following example show the details of the provider named Contoso IP Block List Provider.

```
Get-IPBlockListProvider "Contoso IP Block List Provider" |
Format-List
Name,Enabled,Priority,LookupDomain,*Match,*Response
```

Use the Shell to add an IP Block List provider

To add an IP Block List provider, use the following syntax:

```
Add-IPBlockListProvider -Name "<Descriptive Name>" -
LookupDomain <FQDN> [-Priority <Integer>] [-Enabled <$true
| $false>] [-AnyMatch <$true | $false>] [-BitmaskMatch
<IPAddress>] [-IPAddressesMatch
<IPAddressStatusCode1,IPAddressStatusCode2...>] [-
RejectionResponse "<Custom Text>"]
```

This example creates an IP Block List provider named "Contoso IP Block List Provider" with the following options:

- **FQDN to use the provider** rbl.contoso.com
- **Bitmask code to use from the provider** 127.0.0.1

```
Add-IPBlockListProvider -Name "Contoso IP Block List
Provider" -LookupDomain rbl.contoso.com -BitmaskMatch
127.0.0.1
```

Note:
When you add a new IP Block List provider, it's enabled by default (the value of *Enabled* is `$true`), and the priority value is incremented (the first entry has the *Priority* value 1).

For more information, see Add-IPBlockListProvider.

How do you know this worked?

To verify that you successfully added an IP Block List provider, run the following command and verify that the new IP Block List provider is displayed.

```
Get-IPBlockListProvider
```

Use the Shell to enable or disable an IP Block List provider

To enable or disable a specific IP Block List provider, use the following syntax:

```
Set-IPBlockListProvider <IPBlockListProviderIdentity> -
Enabled <$true | $false>
```

The following example disables the provider named Contoso IP Block List Provider.

```
Set-IPBlockListProvider "Contoso IP Block List Provider" -
Enabled $false
```

The following example enables the provider named Contoso IP Block List Provider.

```
Set-IPBlockListProvider "Contoso IP Block List Provider" -
Enabled $true
```

How do you know this worked?

To verify that you successfully enabled or disabled an IP Block List provider, run the following command and verify that the value displayed is the value you configured.

```
Get-IPBlockListProvider <IPBlockListProviderIdentity> |
Format-List Enabled
```

Use the Shell to configure an IP Block List provider

The configuration options that are available on the **Set-IPBlockListProvider** cmdlet are identical to those on the **New-IPBlockListProvider** cmdlet.

To configure an existing IP Block List provider, use the following syntax:

```
Set-IPBlockListProvider <IPBlockListProviderIdentity> -Name
"<Descriptive Name>" -LookupDomain <FQDN> [-Priority
<Integer>] [-AnyMatch <$true | $false>] [-BitmaskMatch
<IPAddress>] [-IPAddressesMatch
<IPAddressStatusCode1,IPAddressStatusCode2...>] [-
RejectionResponse "<Custom Text>"]
```

For example, to add the IP address status code 127.0.0.1 to the list of existing status codes for the provider named Contoso IP Block List Provider, run the following command:

```
Set-IPBlockListProvider "Contoso IP Block List Provider" -
```

```
IPAddressesMatch @{Add="127.0.0.1"}
```

For more information, see Set-IPBlockListProvider.

How do you know this worked?

To verify that you successfully configured an IP Block List provider, run the following command and verify that the values displayed are the values you configured.

```
Get-IPBlockListProvider <IPBlockListProviderIdentity> |
Format-List
```

Use the Shell to test an IP Block List provider

To test an IP Block List provider, use the following syntax.

```
Test-IPBlockListProvider <IPBlockListProviderIdentity> -
IPAddress <IPAddressToTest>
```

The following example tests the provider named Contoso IP Block List Provider by looking up the IP address 192.168.1.1.

```
Test-IPBlockListProvider "Contoso IP Block List Provider" -
IPAddress 192.168.1.1
```

Use the Shell to remove an IP Block List provider

To remove an IP Block List provider, use the following syntax:

```
Remove-IPBlockListProvider <IPBlockListProviderIdentity>
```

The following example removes the IP Block List provider named Contoso IP Block List Provider.

```
Remove-IPBlockListProvider "Contoso IP Block list Provider"
```

How do you know this worked?

To verify that you successfully removed an IP Block List provider, run the following command and verify that the IP Block List provider you removed is gone.

```
Get-IPBlockListProvider
```

IP Allow list procedures

These procedures apply to the IP Allow list that you manually configure. They don't apply to IP Allow List providers.

Use the **IPAllowListConfig** cmdlets to view and configure how connection filtering uses the IP Allow list. Use the **IPAllowListEntry** cmdlets to view and configure the IP addresses in the IP Allow list.

Use the Shell to view the configuration of the IP Allow list

To view the configuration of the IP Allow list, run the following command.

```
Get-IPAllowListConfig | Format-List *Enabled
```

Use the Shell to enable or disable the IP Allow list

To disable the IP Allow list, run the following command:

```
Set-IPAllowListConfig -Enabled $false
```

To enable the IP Allow list, run the following command:

```
Set-IPAllowListConfig -Enabled $true
```

How do you know this worked?

To verify that you successfully enabled or disabled the IP Allow list, run the following command and verify that the value displayed is the value you configured.

```
Get-IPAllowListConfig | Format-List Enabled
```

Use the Shell to configure the IP Allow list

To configure the IP Allow list, use the following syntax:

```
Set-IPAllowListConfig [-ExternalMailEnabled <$true |
$false>] [-InternalMailEnabled <$true | $false>
```

This example configures the IP Allow list to filter incoming connections from internal and external mail servers. By default, connections are filtered from external mail servers only (*ExternalMailEnabled* is set to `$true`, and *InternalMailEnabled* is set to `$false`). Non-authenticated connections and authenticated connections from external partners are considered external.

```
Set-IPAllowListConfig -InternalMailEnabled $true
```

How do you know this worked?

To verify that you successfully configured the IP Allow list, run the following command and verify that the values displayed are the values you configured.

```
Get-IPAllowListConfig | Format-List *MailEnabled
```

Use the Shell to view IP Allow list entries

To view all IP Allow list entries, run the following command:

```
Get-IPAllowListEntry
```

Note that each IP Allow list entry is identified by an integer value. The identity integer is assigned in ascending order when you add entries to the IP Block list and the IP Allow list.

To view a specific IP Allow list entry, use the following syntax:

```
Get-IPAllowListEntry <-Identity IdentityInteger | -
IPAddress IPAddress>
```

For example, to view the IP Allow list entry that contains the IP address 192.168.1.13, run the following command:

```
Get-IPAllowListEntry -IPAddress 192.168.1.13
```

Note:

When you use the *IPAddress* parameter, the resulting IP Allow list entry can be an individual IP address, an IP address range, or a Classless InterDomain Routing (CIDR) IP. To use the *Identity* parameter, you specify the integer value that's assigned to the IP Allow list entry.

Use the Shell to add IP Allow list entries

To add IP Allow list entries, use the following syntax:

```
Add-IPAllowListEntry <-IPAddress IPAddress | -IPRange IP
range or CIDR IP> [-ExpirationTime <DateTime>] [-Comment
"<Descriptive Comment>"]
```

This example adds the IP Allow list entry for the IP address range 192.168.1.10 through 192.168.1.15 and configures the IP Allow list entry to expire on July 4, 2014 at 15:00.

```
Add-IPAllowListEntry -IPRange 192.168.1.10-192.168.1.15 -
ExpirationTime "7/4/2014 15:00"
```

How do you know this worked?

To verify that you successfully added an IP Allow list entry, run the following command and verify that the new IP Allow list entry is displayed.

```
Get-IPAllowListEntry
```

Use the Shell to remove IP Allow list entries

To remove IP Allow list entries, use the following syntax:

```
Remove-IPAllowListEntry <IdentityInteger>
```

The following example removes the IP Allow list entry that has the *Identity* value 3.

```
Remove-IPAllowListEntry 3
```

This example removes the IP Allow list entry that contains the IP address 192.168.1.12 without using the *Identity* integer value. Note that the IP Allow list entry can be an individual IP address or an IP address range.

```
Get-IPAllowListEntry -IPAddress 192.168.1.12 | Remove-IPAllowListEntry
```

How do you know this worked?

To verify that you successfully removed an IP Allow list entry, run the following command and verify that the IP Allow list entry you removed is gone.

```
Get-IPAllowListEntry
```

IP Allow List provider procedures

These procedures apply to IP Allow List providers. They don't apply to the IP Allow list.

Use the **IPAllowListProvidersConfig** cmdlets to view and configure how connection filtering uses all IP Allow List providers. Use the **IPAllowListProvider** cmdlets to view, configure, and test IP Allow List providers.

Use the Shell to view the configuration of all IP Allow List providers

To view how connection filtering uses all IP Allow List providers, run the following command:

```
Get-IPAllowListProvidersConfig | Format-List *Enabled
```

Use the Shell to enable or disable all IP Allow List providers

To disable all IP Allow List providers, run the following command:

```
Set-IPAllowListProvidersConfig -Enabled $false
```

To enable all IP Allow List providers, run the following command:

```
Set-IPAllowListProvidersConfig -Enabled $true
```

How do you know this worked?

To verify that you enabled or disabled all IP Allow List providers, run the following command and verify that the value displayed is the value you configured.

```
Get-IPAllowListProvidersConfig | Format-List Enabled
```

Use the Shell to configure all IP Allow List providers

To configure how connection filtering uses all IP Allow List providers, use the following syntax:

```
Set-IPAllowListProvidersConfig [-ExternalMailEnabled <$true
| $false>] [-InternalMailEnabled <$true | $false>]
```

This example configures all IP Allow List providers to filter incoming connections from internal and external mail servers. By default, connections are filtered from external mail servers only (*ExternalMailEnabled* is set to `$true`, and *InternalMailEnabled* is set to `$false`). Non-authenticated connections and authenticated connections from external partners are considered external.

```
Set-IPAllowListProvidersConfig -InternalMailEnabled $true
```

For more information, see Set-IPBlockListProvidersConfig.

How do you know this worked?

To verify that you successfully configured all IP Allow List providers, run the following command and verify that the values displayed are the values you configured.

```
Get-IPAllowListProvidersConfig | Format-List *MailEnabled
```

Use the Shell to view IP Allow List providers

To view the summary list of all the IP Allow List providers, run the following command.

```
Get-IPAllowListProvider
```

To view the details of a specific provider, use the following syntax.

```
Get-IPAllowListProvider <IPAllowListProviderIdentity>
```

This example show the details of the provider named Contoso IP Allow List Provider.

```
Get-IPAllowListProvider "Contoso IP Allow List Provider" |
Format-List Name,Enabled,Priority,LookupDomain,*Match
```

Use the Shell to add an IP Allow List provider

To add an IP Allow List provider, use the following syntax:

```
Add-IPAllowListProvider -Name "<Descriptive Name>" -
LookupDomain <FQDN> [-Priority <Integer>] [-Enabled <$true
| $false>] [-AnyMatch <$true | $false>] [-BitmaskMatch
<IPAddress>] [-IPAddressesMatch
<IPAddressStatusCode1,IPAddressStatusCode2...>]
```

This example creates an IP Allow List provider named "Contoso IP Allow List Provider" with the following options:

- **FQDN to use the provider** allow.contoso.com
- **Bitmask code to use from the provider** 127.0.0.1

```
Add-IPAllowListProvider -Name "Contoso IP Allow List
Provider" -LookupDomain allow.contoso.com -BitmaskMatch
127.0.0.1
```

Note:

When you add a new IP Allow List provider, it's enabled by default (the value of *Enabled* is `$true`), and the priority value is incremented (the first entry has the *Priority* value 1).

For more information, see Add-IPBlockListProvider.

How do you know this worked?

To verify that you successfully added an IP Allow List provider, run the following command and verify that the new IP Allow List provider is displayed.

```
Get-IPAllowListProvider
```

Use the Shell to enable or disable an IP Allow List provider

To enable or disable a specific IP Allow List provider, use the following syntax.

```
Set-IPAllowListProvider <IPAllowListProviderIdentity> -
Enabled <$true | $false>
```

This example disables the provider named Contoso IP Allow List Provider.

```
Set-IPAllowListProvider "Contoso IP Allow List Provider" -
Enabled $false
```

This example enables the provider named Contoso IP Allow List Provider.

```
Set-IPAllowListProvider "Contoso IP Allow List Provider" -
Enabled $true
```

How do you know this worked?

To verify that you successfully enabled or disabled an IP Allow List provider, run the following command and verify that the value displayed is the value you configured.

```
Get-IPAllowListProvider <IPAllowListProviderIdentity> |
Format-List Enabled
```

Use the Shell to configure an IP Allow List provider

The configuration options that are available on the **Set-IPAllowListProvider** cmdlet are identical to those on the **New-IPAllowListProvider** cmdlet.

To configure an existing IP Allow List provider, use the following syntax:

```
Set-IPAllowListProvider <IPAllowListProviderIdentity> -Name
"<Descriptive Name>" -LookupDomain <FQDN> [-Priority
<Integer>] [-AnyMatch <$true | $false>] [-BitmaskMatch
<IPAddress>] [-IPAddressesMatch
<IPAddressStatusCode1,IPAddressStatusCode2...>]
```

For example, to add the IP address status code 127.0.0.1 to the list of existing status codes for the provider named Contoso IP Allow List Provider, run the following command:

```
Set-IPAllowListProvider "Contoso IP Allow List Provider" -
IPAddressesMatch @{Add="127.0.0.1"}
```

For more information, see Set-IPBlockListProvider.

How do you know this worked?

To verify that you successfully configured an IP Allow List provider, run the following command and verify that the values displayed are the values you configured.

```
Get-IPAllowListProvider <IPAllowListProviderIdentity> |
Format-List
```

Use the Shell to test an IP Allow List provider

To test an IP Allow List provider, use the following syntax:

```
Test-IPAllowListProvider <IPAllowListProviderIdentity> -
IPAddress <IPAddressToTest>
```

The following example tests the provider named Contoso IP Allow List Provider by looking up the IP address 192.168.1.1.

```
Test-IPAllowListProvider "Contoso IP Allow List Provider" -
```

```
IPAddress 192.168.1.1
```

Use the Shell to remove an IP Allow List provider

To remove an IP Allow List provider, use the following syntax:

```
Remove-IPAllowListProvider <IPAllowListProviderIdentity>
```

This example removes the IP Allow List provider named Contoso IP Allow List Provider.

```
Remove-IPAllowListProvider "Contoso IP Allow List Provider"
```

How do you know this worked?

To verify that you successfully removed an IP Allow List provider, run the following command and verify that the IP Allow List provider you removed is gone.

```
Get-IPAllowListProvider
```

Recipient filtering on Edge Transport servers

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-05-07*

Recipient filtering is an anti-spam feature in Microsoft Exchange Server 2013 that relies on the RCPT TO SMTP header to determine what action, if any, to take on an inbound message. Recipient filtering is performed by the Recipient Filter agent.

The Recipient Filter agent blocks messages according to the characteristics of the intended recipient in the organization. The Recipient Filter agent can help you prevent the acceptance of messages in the following scenarios:

- **Nonexistent recipients** You can prevent delivery to recipients that aren't in the organization's address book. For example, you may want to stop delivery to frequently misused account names, such as administrator@contoso.com or support@contoso.com.
- **Restricted distribution lists** You can prevent delivery of Internet mail to distribution lists that should be used only by internal users.
- **Mailboxes that should never receive messages from the Internet** You can prevent delivery of Internet mail to a specific mailbox or alias that's typically used inside the organization, such as Helpdesk.

The Recipient Filter agent acts on recipients stored in one or both of the following data sources:

- **Recipient Block list** An administrator-defined list of recipients who should never receive messages from the Internet.
- **Recipient Lookup** Queries Active Directory to verify the recipient exists in the organization. On an Edge Transport server, Recipient Lookup requires access to Active Directory information provided by EdgeSync to the local instance of Active Directory Lightweight Directory Services (AD LDS).

When you enable the Recipient Filter agent, one of the following actions is taken on inbound messages according to the characteristics of the recipients. These recipients are indicated by the RCPT TO header.

- If the inbound message contains a recipient that is on the Recipient Block list, the Exchange server sends a `550 5.1.1 User unknown` SMTP session error to the sending server.
- If the inbound message contains a recipient that doesn't match any recipients in Recipient Lookup, the Exchange server sends a `550 5.1.1 User unknown` SMTP session error to the sending server.
- If the recipient isn't on the Recipient Block list and the recipient is in Recipient Lookup, the Exchange server sends a `250 2.1.5 Recipient OK` SMTP response to the sending server, and the next anti-spam agent in the chain processes the message.

Contents

Configuring recipient lookup

One of the most effective ways to reduce spam is to validate recipients before accepting inbound messages from the Internet. You enable the blocking of messages sent to recipients who don't exist in the Exchange organization, and the blocking of specific recipients using the **Set-RecipientFilterConfig** cmdlet in the Exchange Management Shell. For more information, see Manage recipient filtering on Edge Transport servers.

If you have an Edge Transport server installed in your perimeter network, it's a good idea to configure the AD LDS instance that runs on the Edge Transport server to synchronize with Active Directory. By default, AD LDS is installed and configured on the Edge Transport server. However, you must configure AD LDS to communicate with an Active Directory domain-joined global catalog server by subscribing the Edge Transport server to your organization. For more information, see Use an Exchange 2010 or 2007 Edge Transport server in Exchange 2013.

Return to top

Tarpitting functionality

Recipient Lookup functionality enables the sending server to determine whether an email address is valid or invalid. As mentioned earlier, when the recipient of an inbound message is a known recipient, the Exchange server sends back a `250 2.1.5 Recipient OK` SMTP response to the sending server. This functionality provides an ideal environment for a directory harvest attack.

A *directory harvest attack* is an attempt to collect valid email addresses from a particular organization so that the email addresses can be added to a spam database. Because all spam income relies on trying to make people open email messages, addresses known to be active are a commodity that malicious users, or *spammers*, pay for. Because the SMTP protocol provides feedback for known senders and unknown senders, a spammer can write an automated program that uses common names or dictionary terms to construct email addresses to a specific domain. The program collects all email addresses that return a `250 2.1.5 Recipient OK` SMTP response and discards all email addresses that return a `550 5.1.1 User unknown` SMTP session error. The spammer can then sell the valid email addresses or use them as recipients for unsolicited messages.

To combat directory harvest attacks, Exchange 2013 includes tarpitting functionality. *Tarpitting* is the practice of artificially delaying server responses for specific SMTP communication patterns that indicate high volumes of spam or other unwelcome messages. The intent of tarpitting is to slow down the communication process for such email traffic so that the cost of sending spam increases for the person or organization sending the spam. Tarpitting makes directory harvest attacks too costly to automate efficiently.

If tarpitting isn't configured, the Exchange server immediately returns a `550 5.1.1 User unknown` SMTP session error to the sender when a recipient isn't located in Recipient Lookup. Alternatively, if tarpitting is configured, SMTP waits a specified number of seconds before it returns the `550 5.1.1 User unknown` error. This pause in the SMTP session makes automating a directory harvest attack more difficult and less cost-effective for the spammer. By default, tarpitting is configured for 5 seconds on Receive connectors.

To configure the delay before SMTP returns the `550 5.1.1 User unknown` error, you set the tarpitting interval using the *TarpitInterval* parameter on the **Set-ReceiveConnector** cmdlet. The syntax is:

```
Set-ReceiveConnector <Receive Connector> -TarpitInterval
<00:00:00 to 00:10:00>
```

The default value is `00:00:05` or 5 seconds. The name of the default Receive connector on an Edge Transport server is `Default internal receive connector <server name>`.

Use caution if you decide to change the tarpitting interval. An overly long interval could disrupt ordinary mail flow, whereas an overly brief interval may not be as effective in thwarting a directory harvest attack. If you change the tarpitting interval, do so in small increments and verify the results. For example, if 5 seconds isn't effective, try changing the interval to 10 seconds.

Return to top

Multiple namespaces

The Recipient Filter agent performs recipient lookups only for authoritative domains. If your organization accepts and forwards messages on behalf of another domain that's configured as an internal relay or external relay domain, the Recipient Filter agent doesn't perform a recipient lookup on recipients in those domains. However, if the recipient is specified in the Recipient Block list, the recipient will still be blocked by the Recipient Filter agent.

Note that you can also configure accepted domains locally on an Edge Transport server. If the domain is configured as internal relay or external relay domain, the Recipient Filter agent on the Edge Transport server also doesn't perform a recipient lookup on recipients in those domains.

Return to top

Manage recipient filtering on Edge Transport servers

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-01-23*

Recipient filtering is provided by the Recipient Filter agent. When recipient filtering is enabled on an Exchange server, it filters inbound messages that come from the Internet but aren't authenticated. These messages are handled as external messages.

Note:

Although the Recipient Filter agent is available on Mailbox servers, you shouldn't configure it. When recipient filtering on a Mailbox server detects one invalid or blocked recipient in a message that contains other valid recipients, the message is rejected. If you install the anti-spam agents on a Mailbox server, the Recipient Filter agent is enabled by default. However, it isn't configured to block any recipients. For more information, see Enable anti-spam functionality on Mailbox servers.

What do you need to know before you begin?

- Estimated time to complete each procedure: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Anti-spam features" entry in the Anti-spam and anti-

malware permissions topic.

- You can only use the Shell to perform this procedure.
- By default, anti-spam features aren't enabled in the Transport service on a Mailbox server. Typically, you only enable the anti-spam features on a Mailbox server if your Exchange organization doesn't do any prior anti-spam filtering before accepting incoming messages. For more information, see Enable anti-spam functionality on Mailbox servers.
- The *AddressBookEnabled* parameter on the **Set-AcceptedDomain** cmdlet enables or disables recipient filtering for recipients in an accepted domain. By default, recipient filtering is enabled for authoritative domains, and disabled for internal relay domains and external relay domains. To view the status of the *AddressBookEnabled* parameter for the accepted domains in your organization, run the following command:

```
Get-AcceptedDomain | Format-List Name,AddressBookEnabled
```

- If you disable recipient filtering using the procedure in this topic, recipient filtering functionality will be disabled, but the underlying Recipient Filter agent will remain enabled.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to enable or disable recipient filtering

To disable recipient filtering, run the following command:

```
Set-RecipientFilterConfig -Enabled $false
```

To enable recipient filtering, run the following command:

```
Set-RecipientFilterConfig -Enabled $true
```

Note:

When you disable recipient filtering, the underlying Recipient Filter agent is still enabled. To disable the Recipient Filter agent, run the command: `Disable-TransportAgent "Recipient Filter Agent"`.

How do you know this worked?

To verify that you have successfully enabled or disabled recipient filtering, do the following:

1. Run the following command:

```
Get-RecipientFilterConfig | Format-List Enabled
```

2. Verify the value displayed is the value you configured.

Use the Shell to enable or disable the Recipient Block list

Run the following command:

```
Set-RecipientFilterConfig -BlockListEnabled <$true |
$false>
```

This example enables the Recipient Block list:

```
Set-RecipientFilterConfig -BlockListEnabled $true
```

How do you know this worked?

To verify that you have successfully enabled or disabled the Recipient Block list, do the following:
1. Run the following command:

```
Get-RecipientFilterConfig | Format-List BlockListEnabled
```

2. Verify the value displayed is the value you configured.

Use the Shell to configure the Recipient Block list

To replace the existing values, run the following command:

```
Set-RecipientFilterConfig -BlockedRecipients
<recipient1,recipient2...>
```

This example configures the Recipient Block list with the valuesmark@contoso.com and kim@contoso.com:

```
Set-RecipientFilterConfig -BlockedRecipients
mark@contoso.com,kim@contoso.com
```

To add or remove entries without modifying any existing values, run the following command:

```
Set-RecipientFilterConfig -BlockedRecipients
@{Add="<recipient1>","<recipient2>"...;
Remove="<recipient1>","<recipient2>"...}
```

This example adds chris@contoso.com to the list of recipients, and removes michelle@contoso.com from the list of recipients in the Recipient Block list:

```
Set-RecipientFilterConfig -BlockedRecipients
@{Add="chris@contoso.com"; Remove="michelle@contoso.com"}
```

How do you know this worked?

To verify that you have successfully configured the Recipient Block list, do the following:
1. Run the following command:

```
Get-RecipientFilterConfig | Format-List BlockedRecipients
```

2. Verify the values displayed are the values you configured.

Use the Shell to enable or disable Recipient Lookup

Run the following command:

```
Set-RecipientFilterConfig -RecipientValidationEnabled
<$true | $false>
```

To block messages to recipients that don't exist in your organization, run the following command:

```
Set-RecipientFilterConfig -RecipientValidationEnabled $true
```

How do you know this worked?

To verify that you have successfully enabled or disabled Recipient Lookup, do the following:
1. Run the following command:

```
Get-RecipientFilterConfig | Format-List
RecipientValidationEnabled
```

2. Verify the value displayed is the value you configured.

Attachment filtering on Edge Transport servers

Exchange Server 2013 > Anti-spam and anti-malware protection > Anti-spam protection >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-10*

In Microsoft Exchange Server 2013, you can use attachment filtering on Edge Transport servers to control the attachments that users receive in email messages. Attachment filtering is performed by

the Attachment Filtering agent, which is available only on Edge Transport servers.

Types of attachment filtering

You can use the following types of attachment filtering to control attachments that enter or leave your organization through an Edge Transport server:

- **Filtering based on file name or file name extension** You specify the exact file name or file name extension that you want to filter. An example of a file name filter is `BadFileName.exe`. An example of a file name extension filter is `*.exe`.
- **Filtering based on file MIME content type** You specify the MIME content type value that you want to filter. The MIME content type value indicates what the attachment is—for example, a JPEG image, an executable file, or a Microsoft Excel file. Content types are expressed as `type/subtype`. For example, a JPEG image file is expressed as `image/jpeg`.

To view a complete list of file name extensions and content types that attachment filtering can detect, run the following command on the Edge Transport server:

```
Get-AttachmentFilterEntry | Format-List
```

After you define the files to look for, you can configure the action to take on messages that contain these attachments. You can't specify different actions for different types of attachments. You configure one of the following actions for all the messages that match any of the attachment filters:

- **Reject (block) the message** The message is blocked. The sender receives a non-delivery report (NDR) that explains that the message wasn't delivered because it contained an unacceptable attachment. You can customize the text in the NDR. The default text is: `Message rejected due to unacceptable attachments`.
- **Strip the attachment but allow the message through** The attachment is removed from the message. However, the message itself and any other attachments that don't match the filter are allowed through. If an attachment is stripped, it's replaced with a text file that explains why the attachment was removed. This is the default action.
- **Silently delete the message** The message is deleted. Neither the sender nor the recipient receives notification.

For more information, see Manage attachment filtering on Edge Transport servers.

Note:

You can't retrieve messages that have been blocked or attachments that have been stripped. When you configure attachment filters, carefully examine all possible file name matches and verify that legitimate attachments won't be affected by the filter.
Also, don't remove attachments from digitally signed, encrypted, or rights-protected email messages. If you remove attachments from such messages, you invalidate the digitally signed messages and make encrypted and rights-protected messages unreadable.

Manage attachment filtering on Edge Transport servers

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-10*

Attachment filtering is provided by the Attachment Filter agent that's available only on Edge Transport servers. Attachment filtering can help prevent files that are attached in email messages from entering your organization. You can configure one or more attachment filter entries to filter attachments either by content type or by file name.

What do you need to know before you begin?

- Estimated time to complete each procedure: 10 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Anti-spam features" entry in the Anti-spam and anti-malware permissions and the "Transport agents" entry in the Mail flow permissions topic.
- Configuration changes that you make to attachment filtering on an Edge Transport server are made only to the local computer. If you have multiple Edge Transport servers in your perimeter network, you need to configure attachment filtering on each Edge Transport server separately.
- You can only use the Shell to perform this procedure.
- When you disable attachment filtering and restart the Microsoft Exchange Transport service, all attachment filtering features stop working.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to enable or disable attachment filtering

When you enable or disable the Attachment Filtering agent, the change takes effect after you restart the Microsoft Exchange Transport service. When you restart the Microsoft Exchange Transport service on an Edge Transport server, mail flow on the server is temporarily interrupted.

To disable attachment filtering, run the following command:

```
Disable-TransportAgent "Attachment Filtering Agent"
```

To enable attachment filtering, run the following command:

```
Enable-TransportAgent "Attachment Filtering Agent"
```

After you enable or disable attachment filtering, restart the Microsoft Exchange Transport service by running the following command:

```
Restart-Service MSExchangeTransport
```

How do you know this worked?

To verify that you successfully enabled or disabled attachment filtering, do the following:
1. Run the following command:

```
Get-TransportAgent "Attachment Filtering Agent"
```

2. If the value of **Enabled** is `True`, attachment filtering is enabled. If the value is `False`, attachment filtering is disabled.

Use the Shell to view attachment filtering entries

Attachment filtering entries define the message attachments that you want to keep out of your organization. To view the attachment filtering entries that are used by the Attachment Filtering agent, run the following command:

```
Get-AttachmentFilterEntry | Format-Table
```

To view a specific MIME content type entry, use the following syntax:

```
Get-AttachmentFilteringEntry ContentType:<MIMEContentType>
```

For example, to view the content type entry for JPEG images, run the following command:

```
Get-AttachmentFilteringEntry ContentType:image/jpeg
```

To view a specific file name or file name extension entry, use the following syntax:

```
Get-AttachmentFilteringEntry FileName:<FileName or
FileNameExtension>
```

For example, to view the file name extension entry for JPEG attachments, run the following command:

```
Get-AttachmentFilteringEntry FileName:*.jpg
```

Use the Shell to add attachment filtering entries

To add an attachment filtering entry that filters attachments by MIME content type, use the following syntax:

```
Add-AttachmentFilterEntry -Name <MIMEContentType> -Type
ContentType
```

The following example adds a MIME content type entry that filters JPEG images.

```
Add-AttachmentFilterEntry -Name image/jpeg -Type
ContentType
```

To add an attachment filtering entry that filters attachments by file name or file name extension, use the following syntax:

```
Add-AttachmentFilterEntry -Name <FileName or
FileNameExtension> -Type FileName
```

The following example filters attachments that have the .jpg file name extension.

```
Add-AttachmentFilterEntry -Name *.jpg -Type FileName
```

How do you know this worked?

To verify that you successfully added an attachment filtering entry, do the following:
1. Run the following command to verify that the filtering entry exists.

```
Get-AttachmentFilterEntry | Format-Table
```

2. Send a test message that contains a prohibited attachment from an external mailbox to an internal recipient and verify that the message is rejected, stripped, or deleted.

Use the Shell to remove attachment filtering entries

To remove an attachment filtering entry that filters attachments by MIME content type, use the following syntax:

```
Remove-AttachmentFilterEntry ContentType:<ContentType>
```

The following example removes the MIME content type entry for JPEG images.

```
Remove-AttachmentFilterEntry ContentType:image/jpeg
```

To remove an attachment filtering entry that filters attachments by file name or file name extension, use the following syntax:

```
Remove-AttachmentFilterEntry FileName:<FileName or FileNameExtension>
```

The following example removes the file name entry for the .jpg file name extension.

```
Remove-AttachmentFilterEntry FileName:*.jpg
```

How do you know this worked?

To verify that you successfully removed an attachment filtering entry, do the following:

1. Run the following command to verify that the filtering entry was removed.

```
Get-AttachmentFilterEntry | Format-Table
```

2. Send a test message that contains an allowed attachment from an external mailbox to an internal recipient and verify that the message was successfully delivered with the attachment.

Use the Shell to view the attachment filtering action

To view the attachment filtering action that's used when a prohibited attachment is detected in a message, run the following command:

```
Get-AttachmentFilterListConfig
```

Use the Shell to configure the attachment filtering action

To configure the attachment filtering action that will be used when a prohibited attachment is detected in a message, use the following syntax:

```
Set-AttachmentFilterListConfig [-Action <Reject | Strip | SilentDelete>] [-RejectResponse "<Message text>"] [-AdminMessage "<Replacement file text>"] [-ExceptionConnectors <ConnectorGUID>]
```

This example makes the following changes to the attachment filtering configuration:

- Reject (block) messages that have prohibited attachments.
- Use a custom response for rejected messages.

```
Set-AttachmentFilterListConfig -Action Reject -RejectResponse "This message contains a prohibited attachment. Your message can't be delivered. Please resend
```

```
the message without the attachment."
```

For more information, see Set-AttachmentFilterListConfig.

How do you know this worked?

To verify that you successfully configured the attachment filtering action, send a test message that contains a prohibited attachment from an external mailbox to an internal recipient and verify that the message and the attachment are processed as you expect.

Spam quarantine

Exchange Server 2013 > Anti-spam and anti-malware protection > Anti-spam protection >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-12*

Many organizations are bound by legal or regulatory requirements to preserve or deliver all legitimate email messages. In Microsoft Exchange Server 2013, spam quarantine is a feature of the Content Filter agent that reduces the risk of losing legitimate messages. Spam quarantine provides a temporary storage location for messages identified as spam that shouldn't be delivered to a user mailbox inside the organization.

Messages identified by the Content Filter agent as spam are wrapped in a non-delivery report (NDR) and delivered to a spam quarantine mailbox inside the organization. You can manage messages delivered to the spam quarantine mailbox and take appropriate actions. For example, you can delete messages or let messages flagged as false positives in anti-spam filtering be routed to their intended recipients. In addition, you can configure the spam quarantine mailbox to automatically delete messages after a designated time period.

Contents

Spam confidence level

When an external user sends email messages to a server running Exchange that runs the anti-spam features, the anti-spam features cumulatively evaluate characteristics of the messages and act as follows:

- Those messages suspected to be spam are filtered out.
- A rating is assigned to messages based on the probability that a message is spam. This rating is stored with the message as a message property called the spam confidence level (SCL) rating.

Spam quarantine uses the SCL rating to determine whether mail has a high probability of being spam. The SCL rating is a numeric value from 0 through 9, where 0 is considered less likely to be spam, and 9 is considered most likely to be spam.

You can configure mail that has a certain SCL rating to be deleted, rejected, or quarantined. The rating that triggers any of these actions is referred to as the *SCL quarantine threshold*. Within content filtering, you can configure the Content Filter agent to base its actions on the SCL quarantine threshold. For example, you can set the following conditions:

- SCL delete threshold is set to 8.
- SCL reject threshold is set to 7.
- SCL quarantine threshold is set to 6.
- SCL Junk Email folder threshold is set to 5.

Based on the preceding SCL thresholds, all email with an SCL of 6 will be delivered to the spam quarantine mailbox.

For more information, see Manage content filtering.

Return to top

Spam quarantine

When messages are received by the Exchange server that's running all default anti-spam agents, the content filter is applied as follows:

- If the SCL rating is greater than or equal to the SCL quarantine threshold but less than either the SCL delete threshold or SCL reject threshold, the message goes to the spam quarantine mailbox.
- If the SCL rating is lower than the spam quarantine threshold, it's delivered to the recipient's Inbox.

The message administrator uses Microsoft Outlook to monitor the spam quarantine mailbox for false positives. If a false positive is found, the administrator can send the message to the recipient's mailbox.

The message administrator can review the anti-spam stamps if either of the following conditions is true:

- Too many false positives are filtered into the spam quarantine mailbox.
- Not enough spam is being rejected or deleted.

For more information, see Anti-spam stamps.

You can then adjust the SCL settings to more accurately filter the spam coming into the organization. For more information, see Spam Confidence Level Threshold.

To use spam quarantine, you need to follow these steps:

1. Verify content filtering is enabled.
2. Create a dedicated mailbox for spam quarantine.
3. Specify the spam quarantine mailbox.
4. Configure the SCL quarantine threshold.

5. Manage the spam quarantine mailbox.
6. Adjust the SCL quarantine threshold as needed.

For detailed instructions, see Configure a spam quarantine mailbox.

Return to top

Configure a spam quarantine mailbox

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-19*

Messages determined to be spam by the Content Filter agent can be directed to a spam quarantine mailbox. If the spam confidence level (SCL) quarantine threshold is enabled, all messages that are quarantined are wrapped as non-delivery reports (NDR) and are sent to the SMTP address that you specify as the spam quarantine mailbox. You can review quarantined messages and release them to their intended recipients by using the Send Again feature in Microsoft Outlook.

What do you need to know before you begin?

- Estimated time to complete this task: 45 minutes.
- By default, anti-spam features aren't enabled in the Transport service on a Mailbox server. Typically, you only enable the anti-spam features on a Mailbox server if your Exchange organization doesn't do any prior anti-spam filtering before accepting incoming messages. For more information, see Enable anti-spam functionality on Mailbox servers.
- The person responsible for the spam quarantine mailbox can view potentially private and sensitive messages, and then send mail on behalf of anybody in the Exchange organization.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

How do you do this?

Step 1: Verify content filtering is enabled

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Anti-spam features" entry in the Anti-spam and anti-malware permissions topic.

1. Run the following command to verify the Content Filter agent is installed and enabled on the Exchange server:

```
Get-TransportAgent "Content Filter Agent"
```

2. Run the following command to verify content filtering is enabled:

```
Get-ContentFilterConfig | Format-List Enabled
```

For more information, see Manage content filtering.

Step 2: Create a dedicated mailbox for spam quarantine

To create a dedicated spam quarantine mailbox, follow these steps:

- **Create a dedicated Exchange database** We recommend that you create a dedicated database for the spam quarantine mailbox. The spam quarantine mailbox should have a large database, because if the storage quota limit is reached, messages will be lost. For more information, see Manage mailbox databases in Exchange 2013.
- **Create a dedicated mailbox and user account** We recommend that you create a dedicated mailbox and Active Directory user account for the spam quarantine mailbox. For more information, see Create user mailboxes.

You may apply recipient policies, such as messaging records management, mailbox quotas, and delegation rights, according to your organization's compliance policies and needs. For more information, see Messaging records management.

Note:

If a quarantined message is rejected because of a storage quota, the message will be lost. Exchange doesn't generate NDRs for quarantined messages because the quarantined messages are wrapped as NDRs.

- **Configure Outlook** You need to configure the Outlook delegate access permissions to meet the needs of your organization. In addition, we recommend that you configure the Outlook profile to show the original `Sender[#0x0069001E]`, `Recipient[#0x0E04001E]`, and `Bcc[#0x0E02001E]` fields in the **Message** view. For more information, see Release quarantined messages from the spam quarantine mailbox.

Step 3: Specify the spam quarantine mailbox

You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Anti-spam features" entry in the Anti-spam and anti-malware permissions topic.

Run the following command:

```
Set-ContentFilterConfig -QuarantineMailbox <SmtpAddress>
```

This example sends all messages that exceed the spam quarantine threshold to spamQ@contoso.com.

```
Set-ContentFilterConfig -QuarantineMailbox
spamQ@contoso.com
```

How do you know this step worked?

To verify that you have successfully specified the spam quarantine mailbox, do the following:
1. Run the following command:

```
Get-ContentFilterConfig | Format-List QuarantineMailbox
```

2. Verify the value displayed is the value you configured.

Step 4: Configure the SCL quarantine threshold

The SCL quarantine threshold is the value at which a particular message identified as potential spam is delivered to the spam quarantine mailbox. You can set the SCL quarantine threshold to a value from 0 through 9, where 0 is considered less likely to be spam, and 9 is considered most likely to be spam.

For more information about how to adjust SCL thresholds to suit your organization's requirements and how to adjust per-recipient SCL thresholds, see Manage content filtering.

Step 5: Manage the spam quarantine mailbox

When you manage your spam quarantine mailbox, follow these guidelines:

- Release items that have been sent to the spam quarantine mailbox by using the Send Again feature in Outlook to resend the original message.

For more information, see Release quarantined messages from the spam quarantine mailbox.

- Monitor the spam quarantine mailbox so that the size of the spam quarantine mailbox remains in an acceptable range. The volume of email messages can change because of a larger set of recipients, the natural trend of larger messages, or the threshold on the SCL quarantine action.
- Monitor the spam quarantine mailbox for false positives. If your spam quarantine mailbox includes many false positives, adjust your SCL quarantine threshold. For more information about how to determine why false positives are being delivered to the spam quarantine mailbox, see Anti-spam stamps.
- Use the same Outlook profile to recover quarantined messages from the spam quarantine mailbox. Applying permissions to a different Outlook profile to recover messages isn't supported. You can't use a different Outlook profile to recover or release messages from the spam quarantine mailbox.

Important:

NDRs identified as spam are deleted, even if their SCL rating indicates that they should be quarantined. NDRs aren't delivered to the spam quarantine mailbox. To track such messages, use the agent log or the message tracking log. For more information, see Anti-spam agent logging.

Step 6: Adjust the SCL quarantine threshold

After you configure the SCL quarantine threshold, periodically monitor the settings and adjust them based on your organization's needs. For example, if too many false positives are filtered into the spam quarantine mailbox, raise the SCL quarantine threshold to a larger number. For more information about how to adjust the SCL quarantine threshold, see Spam Confidence Level Threshold.

Configure Outlook to show the original sender in the quarantine mailbox

Anti-spam and anti-malware protection > Anti-spam protection > Spam quarantine >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-07-03*

Spam quarantine is a feature of the Content Filter agent that reduces the risk of losing legitimate messages. Spam quarantine provides a temporary storage location for messages that are identified as spam and that shouldn't be delivered to a user mailbox inside the organization.

When a message meets the spam quarantine threshold, it's wrapped in a non-delivery report (NDR) and delivered to the spam quarantine mailbox. Because the quarantined messages are stored as NDRs in the quarantine mailbox, the postmaster address of your organization will be listed as the From: address for all messages. However, having the original sender address, the original recipient address, and the original spam confidence level (SCL) in the field list would make it easier to locate the message you want to recover.

By default, you can't select these fields in Microsoft Outlook. Before you can add these fields in the message view, you must first create an Outlook form that adds the original sender, original recipient, and original SCL as optional fields you can select. After you create this custom form, you can configure Outlook to display these fields in the message view.

What do you need to know before you begin?

- Estimated time to complete this procedure: 15 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To

see what permissions you need, see the "Mailbox access" entry in the Mail flow permissions topic.

- This procedure requires that you've configured the anti-spam quarantine mailbox. For more information, see Configure a spam quarantine mailbox.
- To access the quarantine mailbox, you need to configure an Outlook profile for that mailbox and then open the mailbox using Outlook. For more information about configuring and using multiple Outlook profiles, see Overview of Outlook e-mail profiles.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Step 1: Use Notepad to create a custom Outlook form

1. Open Notepad, and copy the following code into the document.

```
[Description]
MessageClass=IPM.Note
CLSID={00020D31-0000-0000-C000-000000000046}
DisplayName=Quarantine Extension Form
Category=Standard
Subcategory=Form
Comment=This form allows the Original Sender
(ReceivedRepresentingEmailAddress), Original Recipient
(To), and Original SCL (OriginalScl) values to be viewed as
columns.
LargeIcon=IPML.ico
SmallIcon=IPMS.ico
Version=3.0
Locale=enu
Hidden=1
Owner=Microsoft Corporation
Contact=Your Name
[Platforms]
Platform1=Win16
Platform2=NTx86
Platform9=Win95
[Platform.Win16]
```

```
CPU=ix86
OSVersion=Win3.1
[Platform.NTx86]
CPU=ix86
OSVersion=WinNT3.5
[Platform.Win95]
CPU=ix86
OSVersion=Win95
[Properties]
Property01=ReceivedRepresentingEmailAddress
Property02=DisplayTo
Property03=OriginalScl
[Property.ReceivedRepresentingEmailAddress]
Type=31
NmidInteger=0x0078
DisplayName=ReceivedRepresentingEmailAddress
[Property.DisplayTo]
Type=31
NmidInteger=0x0E04
DisplayName=DisplayTo
[Property.OriginalScl]
Type=3
NmidPropset={41F28F13-83F4-4114-A584-EEDB5A6B0BFF}
NmidString=OriginalScl
DisplayName=OriginalScl
[Verbs]
Verb1=1
[Verb.1]
DisplayName=&Open
Code=0
Flags=0
Attribs=2
[Extensions]
Extensions1=1
[Extension.1]
Type=31

NmidInteger=1
Value=1000000000000000
```

2. Save the file in your Office Forms folder using the following values:
   - **Path** <*Office Install Path*>\<*OfficeVersion*>\Forms\<*LCID*>
     - <*Office Install Path*> For 32-bit versions of Office on 32-bit versions of Microsoft Windows, or 64-bit versions of Office on 64-bit versions of Windows, the default path is `C:\Program Files\Microsoft Office`. For 32-bit versions of Office on 64-bit versions of Windows, the default path is `C:\Program Files (x86)\Microsoft Office`.
     - <*OfficeVersion*> For Outlook 2007, the value is `office12`. For Outlook 2010, the value is `office14`. For Outlook 2013, the value is `office15`.
     - <*LCID*> This is your locale ID (LCID) value. For example, the LCID for US English is 1033. For more information, see KB221435: List of supported locale identifiers in Word.
   - **Name** For the rest of this procedure, assume the file is named `QTNE.cfg`. The name of the file isn't important, but be sure to enclose the value in quotation marks so the file is saved as QTNE.cfg and not QTNE.cfg.txt.

For example, for a 32-bit US English version of Outlook 2013 installed on a 64-bit version of Windows, save the file as:

```
"C:\Program Files (x86)\Microsoft Office\Office15\Forms
\1033\QTNE.cfg"
```

Step 2: Configure Outlook to use the custom Outlook form

Use one of the following procedures based on the version of Outlook that's installed on your computer.

Configure Outlook 2010 or Outlook 2013

1. In Outlook 2010 or Outlook 2013, click **File** > **Options** > **Advanced**.
2. In the **Developers** section, click **Custom Forms**.
3. In the **Options** dialog box, click **Manage Forms**.
4. In the **Forms Manager** dialog box, click **Install**. Browse to the location of the `QTNE.cfg` file, select it, click **Open**, and then click **OK** to install the Quarantine Extension Form in your Personal Forms library.
5. In the **Forms Manager** dialog box, click **Close**. Click **OK** twice to close the remaining dialog boxes and return to the main Outlook interface.
6. On the **Home** tab in the **Mail** view of the Inbox, right-click the column heading row (you may need to expand the width of the message list to see the columns), and then select **View Settings**.
7. In the **Advanced View Settings** dialog box, click **Columns**.
8. In the **Show Columns** dialog box, in the **Select available columns from** drop-down list, scroll to the end of the list and select **Forms**.
9. In the **Select Enterprise forms for this folder** dialog box, in the **Selected Forms** field, select **Message** and click **Remove**. In the **Personal Forms** field, select **Quarantine Extension Form**, and then click **Add**. When you are finished, click **Close**.
10. In the **Show Columns** dialog box, in the **Available Columns** section, select one or more of the

following fields and click **Add** after each field you select.

- **ReceivedRepresentingEmailAddress** Original sender
- **To** Original recipient
- **OriginalScl** Original SCL

Use the **Move Up** or **Move Down** buttons to position the columns in the view. When you are finished, click **OK** twice to return to the main Outlook interface.

Configure Outlook 2007

1. In Outlook 2007, click **Tools** > **Options**.
2. In the **Options** dialog box, click the **Other** tab, and then under **General**, click **Advanced Options**.
3. In the **Advanced Options** dialog box, click **Custom Forms**, and then in the **Custom Forms** dialog box, click **Manage Forms**.
4. In the **Forms Manager** dialog box, click **Install**. Browse to the location of the `QTNE.cfg` file, select it, click **Open**, and then click **OK** to install the Quarantine Extension Form in your Personal Forms library.
5. Close the **Forms Manager** dialog box, and then click **OK** to close the remaining dialog boxes and return to the main Outlook 2007 interface.
6. In the default message view of Outlook 2007, in the Inbox, right-click the column heading row, and then select **Field Chooser**.

Note:
If you don't see Field Chooser as an option, you may need to expand the width of your message list.

7. In the **Field Chooser** drop-down menu, click **Forms**. You may have to scroll to find **Forms**.
8. In the **Select Enterprise forms for this Column** dialog box, from the drop-down menu, select **Personal Forms**, expand the **Standard** form, and then select **Quarantine Extension Form**. Click **Add**, and then click **Close**.

Note:
In some cases, you may have to remove the default **Message** form to add the **Quarantine Extension Form**.

9. In the **Field Chooser** dialog box, drag one or more of the following properties into the column heading row.
   - **ReceivedRepresentingEmailAddress** Original sender
   - **To** Original recipient
   - **OriginalScl** Original SCL

How do you know this worked?

You know this procedure worked if you can see the original sender, original recipient, or original SCL values for quarantined messages in the spam quarantine mailbox using Outlook.

Release quarantined messages from the spam quarantine mailbox

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

You can use Microsoft Outlook to recover a quarantined message from the spam quarantine mailbox.

Spam quarantine is a feature of the Content Filter agent that reduces the risk of losing legitimate messages. When a message meets the spam quarantine threshold, it's wrapped in a non-delivery report (NDR) and delivered to the spam quarantine mailbox. For more information about the spam quarantine feature, see Spam quarantine.

What do you need to know before you begin?

- Estimated time to complete each procedure: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Mailbox access" entry in the Mail flow permissions topic.
- This procedure requires that you've configured the anti-spam quarantine mailbox. For more information, see Configure a spam quarantine mailbox.
- To access the quarantine mailbox, you need to configure an Outlook profile for that mailbox and then open the mailbox using Outlook. For more information about configuring and using multiple Outlook profiles, see Overview of Outlook e-mail profiles.
- To make it easier to locate the message you want to recover, you can create a custom Outlook form and modify the default view to expose the original sender address in the list of messages. For detailed steps, see Configure Outlook to show the original sender in the quarantine mailbox.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use Outlook 2010 or Outlook 2013 to release a message

from the spam quarantine mailbox

1. Open the quarantine mailbox using Outlook 2010 or Outlook 2013 on a client computer.
2. In the **Mail** view, find the message you want to recover in the **Inbox**, and then double-click the message to open it.
3. In the **Move** section of the Ribbon, click **Actions** > **Resend this Message**.
4. When the message opens, click **Send** to resend the message to the intended recipient.

Use Outlook 2007 to release a message from the spam quarantine mailbox

1. Open the quarantine mailbox using Outlook 2007 on a client computer.
2. In the **Mail Folders** view, find the message you want to recover in the **Inbox**, and then double-click the message to open it.
3. On the **Report** tab, in the **Respond** group, click **Send Again**.
4. When the message opens, click **Send** to resend the message to the intended recipient.

How do you know this worked?

To verify that you have successfully released the message from the spam quarantine mailbox, contact the recipient and verify they received the message.

Anti-spam stamps

Exchange Server 2013 > Anti-spam and anti-malware protection > Anti-spam protection >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-16*

Anti-spam stamps help you diagnose spam-related problems by applying diagnostic metadata, or stamps, such as sender-specific information, puzzle validation results, and content filtering results, to messages as they pass through the anti-spam features that filter inbound messages from the Internet. There are three anti-spam stamps: the phishing confidence level stamp, the spam confidence level stamp, and the Sender ID stamp.

You can use anti-spam stamps as diagnostic tools to determine what actions to take on false-positives and on suspected spam messages that individuals receive in their mailboxes.

Viewing anti-spam stamps

You can view anti-spam stamps by using Microsoft Outlook. For more information, see View anti-spam stamps in Outlook.

Understanding the anti-spam report

The anti-spam report is a summary report of the anti-spam filter results that have been applied to an email message. The Content Filter agent applies this stamp to the message envelope in the form of an X-header as follows.

```
X-MS-Exchange-Organization-Antispam-Report:
DV:<DATVersion>;CW:CustomList;PCL:PhishingVerdict
<verdict>;P100:PhishingBlock;PP:Presolve;SID:SenderIDStatus
<status>;TIME:<SendReceiveDelta>;MIME:MimeCompliance
```

The following table describes the filter information that can appear in an anti-spam report.

Note:

The anti-spam report only displays information from the filters that were applied to the specific message. An anti-spam report doesn't usually contain all the information listed in the following table. For example, you may receive the following anti-spam report: `DV:3.1.3924.1409;SID:SenderIDStatus Fail;PCL:PhishingLevel SUSPICIOUS;CW:CustomList;PP:Presolved;TIME:TimeBasedFeatures`.

Filter information in an anti-spam report

Stamp	Description
SID	The Sender ID (SID) stamp is based on the sender policy framework (SPF) that authorizes the use of domains in email. The SPF is displayed in the message envelope as `Received-SPF`. The Sender ID evaluation process generates a Sender ID status for the message. This status can be returned as one of the following values: • **Pass** Both the IP address and Purported Responsible Address (PRA) passed the Sender ID verification check. • **Neutral** Published Sender ID data is explicitly inconclusive. • **Soft fail** The IP address for the PRA may be in the not permitted set. • **Fail** The IP Address is not permitted; no PRA is found in the incoming mail or the sending domain does not exist. • **None** No published SPF data exists in the sender's DNS. • **TempError** A temporary DNS failure occurred, such as an unavailable DNS server. • **PermError** The DNS record is invalid, such as an error in the record format.

	The Sender ID stamp is displayed as an X-Header in the message envelope as follows: `X-MS-Exchange-Organization-SenderIdResult:<status>` For more information about Sender ID, see Sender ID.
DV	The DAT version (DV) stamp indicates the version of the spam definition file that was used when scanning the message.
SA	The signature action (SA) stamp indicates that the message was either recovered or deleted because of a signature that was found in the message.
SV	The signature DAT version (SV) stamp indicates the version of the signature file that was used when scanning the message.
PCL	The phishing confidence level (PCL) stamp displays the rating of the message based on its content and is applied when the message is processed by the Content Filter agent. This status can be returned as one of the following values: • **Neutral** The message's content isn't likely to be phishing. • **Suspicious** The message's content is likely to be phishing. The PCL value can range from 1 through 8. A PCL rating from 1 through 3 returns a status of `Neutral`. This means that the message's content isn't likely to be phishing. A PCL rating from 4 through 8 returns a status of `Suspicious`. This means that the message is likely to be phishing. The values are used to determine what action Outlook takes on messages. Outlook uses the PCL stamp to block the content of suspicious messages. The PCL stamp is displayed as an X-header in the message envelope as follows: `X-MS-Exchange-Organization-PCL:<status>`
SCL	The spam confidence level (SCL) stamp of the message displays the rating of the message based on its content. The Content Filter agent uses Microsoft SmartScreen technology to assess the contents of a message and to assign an SCL rating to each message. The SCL value is from 0 through 9, where 0 is considered less likely to be spam, and 9 is considered more likely to be spam. The actions that Exchange and Outlook take depend on your SCL threshold settings.

	The SCL stamp is displayed as an X-header in the message envelope as follows: `X-MS-Exchange-Organization-SCL:<status>` For more information about SCL thresholds and actions, see Spam Confidence Level Threshold.
CW	The custom weight (CW) stamp of a message indicates that the message contains an unapproved word or phrase and that the SCL value, or weight, of that unapproved word or phrase was applied to the final SCL score: • Unapproved phrases, or Block phrases, have maximum weight and change the SCL score to 9. • Approved words or phrases, or Allow phrases, have minimum weight and change the SCL score to 0. For more information about how to add approved and unapproved words or phrases to the Content Filtering agent, see Manage content filtering.
PP	The presolved puzzle (PP) stamp indicates that if a sender's message contains a valid, solved computational postmark, based on Outlook E-mail Postmark validation functionality, it's unlikely that the sender is a malicious sender. In this case, the Content Filter agent would reduce the SCL rating. The Content Filter agent doesn't change the SCL rating if the E-mail Postmark validation feature is enabled and either of the following conditions is true: • An inbound message doesn't contain a computational postmark header. • The computational postmark header isn't valid. For more information about the postmark validation feature, see Content filtering.
TIME:TimeBasedFeatures	The TIME stamp indicates that there was a significant time delay between the time that the message was sent and the time that the message was received. The TIME stamp is used to determine the final SCL rating for the message.
MIME:MIMECompliance	The MIME stamp indicates that the email message isn't MIME compliant.
P100:Phish	The P100 stamp indicates that the message contains a URL that's present in a

ingBlock	phishing definition file.
IPOnAllowList	The IPOnAllowList stamp indicates that the sender's IP address is on the IP Allow list. For more information about the IP Allow list, see Understanding Connection Filtering.
MessageSecurityAntispamBypass	The MessageSecurityAntispamBypass stamp indicates that the message wasn't filtered for content and that the sender has been granted permission to bypass the anti-spam filters.
SenderBypassed	The SenderBypassed stamp indicates that the Content Filter agent doesn't process any content filtering for messages that are received from this sender. For more information, see Manage content filtering.
AllRecipientsBypassed	The AllRecipientsBypassed stamp indicates that one of the following conditions was met for all recipients listed in the message: • The *AntispamBypassedEnabled* parameter on the recipient's mailbox is set to `$true`. This is a per-recipient setting that can only be set by an administrator using the **Set-Mailbox** cmdlet. • The message sender is in the recipient's Outlook Safe Senders List. For more information about the Safe Senders List, see Manage safelist aggregation. • The Content Filter agent doesn't process any content filtering for messages that are sent to this recipient. For more information about recipient exceptions, see Manage content filtering.

Anti-malware protection

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-08-07*

The Microsoft Exchange Server 2013 anti-malware protection feature helps combat malware in your email messaging environment. *Malware* is comprised of viruses and spyware. *Viruses* infect other programs and data, and they spread throughout your computer looking for programs to infect. *Spyware* refers to malware that gathers your personal information, such as sign-in information and personal data, and sends it back to its author.

There are several anti-malware protection options in Exchange 2013:

- **Built-in anti-malware protection in Exchange 2013** You can use the built-in Exchange on-premises anti-malware protection feature in order to help you combat malware. This basic anti-malware protection can be turned off, replaced, or paired with a cloud-based service (such as Microsoft Exchange Online Protection or Microsoft Forefront Online Protection for Exchange) to provide a layered defense. For more information about typical questions and answers regarding the product's built-in anti-malware capabilities, see Anti-malware FAQ. For information about configuring your anti-malware policies so that they are tailored to best meet the needs of your organization, see Configure anti-malware policies.
- **Cloud-hosted anti-malware protection** You can elect to purchase the Microsoft Forefront Online Protection for Exchange (FOPE) hosted email filtering service or the next version of this service, Exchange Online Protection (EOP). The service leverages partnerships with several best of breed anti-malware engines, thereby providing efficient, cost effective, multi-layered anti-malware protection.

Note:

EOP anti-malware protection features are included in Microsoft Exchange Online. For more information about these features, see **Anti-Malware Protection**.

- **Third-party anti-malware protection** You can also use a third-party anti-malware protection program. In this case, you may want to disable the built-in anti-malware protection; for more information, see Disable or bypass anti-malware scanning.

Anti-malware FAQ

Exchange Server 2013 > Anti-spam and anti-malware protection > Anti-malware protection >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-01-07*

This topic provides frequently asked questions about malware filtering (scanning) in Microsoft Exchange Server 2013.

Q. Where does malware scanning occur?

A. Malware scanning is performed on messages sent to or received from a mailbox server. Malware scanning is not performed on a message accessed from a mailbox because it should have already been scanned. If a message is re-sent from a mailbox, it's rescanned.

Q. Do I need Internet access in order to download engine and definition updates?

A. To download updates, you must be able to access the Internet and be able to establish a connection on TCP port 80 (HTTP). We strongly recommend that you manually download anti-malware engine and definition updates on your Exchange server prior to placing it in production. For more information, see Download engine and definition updates.

Q. How often are the malware definitions updated?

A. Each server checks for new malware definitions every hour.

What are some advantages of pairing the built-in malware scanning feature with the FOPE cloud-hosted email filtering service (or the next version of this service, Exchange Online Protection (EOP))?

A. There are several advantages:

- The service uses multiple anti-malware engines whereas the built-in anti-malware protection uses a single engine.
- The service has reporting capabilities including malware statistics.
- The service provides the message trace feature for self-troubleshooting mail flow problems including malware detections.

Q. Why did this malware make it past the filter?

A. There are two possible reasons why you may have received malware.

The first, and more likely scenario, is that the attachment received does not contain any active malicious code. In these situations, some anti-malware engines that run on computers may be more

aggressive and stop messages with truncated payloads.

The second is that the malware you received is a new variant and our anti-malware engine has not yet released a pattern file for the service to deploy.

Q. How can I submit malware that made it past the filter to Microsoft?

A. If you have received malware such as a virus that made it past the filter, please save a copy of the email message with its attached virus, go to the Malware Protection Center and submit a sample using the detailed instructions on that page. When submitting the file, in the **Product** drop-down list select **Other**, select the **I believe this file contains malware** option, and in the **Comments** field specify **Exchange Server 2013**. After we receive the sample, we'll investigate and if it's determined that the sample contains malware, we'll take corrective action to prevent the virus from going undetected.

Q. How can I submit a file that I believe was incorrectly detected as malware?

A. Similar to submitting malware, go to the Malware Protection Center and submit a sample using the detailed instructions on that page. When submitting the file, in the **Product** drop-down list select **Other**, select the **I believe this file should not be detected as malware** option, and in the **Comments** field specify **Exchange Server 2013**. After we receive the sample, we'll investigate and if it's determined that the sample is clean, we'll take corrective action to prevent the file from being detected as malware.

Q. I received an email with an attachment that I am not familiar with. Is this malware or can I disregard this attachment?

A. We strongly advise that you do not open any attachments that you do not recognize. If you would like us to investigate the attachment, go to the Malware Protection Center and submit the possible malware to us as described previously.

Q. Where can I get the messages that have been deleted by the malware filter?

A. The messages contain active malicious code and therefore we do not allow access to these messages. They are simply deleted.

Q. I am not able to receive a specific attachment because it's being falsely filtered by your malware filter. Can I allow this attachment through via Exchange transport rules?

A. No. Transport rules cannot be used to bypass the malware filter. If you would like this attachment to bypass the malware filter, send the attachment to the intended recipient within a password protected .zip file. Any password protected file is bypassed by malware filtering.

Q. Can I turn off the product's built-in anti-malware protection?

A. The built-in anti-malware scanning can be permanently disabled or temporarily bypassed by following the steps in Disable or bypass anti-malware scanning.

Configure anti-malware policies

Download engine and definition updates

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-10-22*

Microsoft Exchange Server 2013 administrators can manually download anti-malware engine and definition (signature) updates. We strongly recommend that you download engine and definition updates on your Exchange server prior to placing it in production.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes
- To download updates, your computer must be able to access the Internet and be able to establish a connection on TCP port 80 (HTTP).
- You can only use the Shell to perform this procedure.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Anti-malware" entry in the Anti-spam and anti-malware permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to manually download engine and definition updates

To download engine and definition updates, run the following command:

```
& $env:ExchangeInstallPath\Scripts\Update-MalwareFilteringServer.ps1 -Identity <FQDN of server>
```

This example manually downloads the engine and definition updates on a server named mailbox01.contoso.com:

```
& $env:ExchangeInstallPath\Scripts\Update-
MalwareFilteringServer.ps1 -Identity mailbox01.contoso.com
```

Optionally, you can specify the –EngineUpdatePath parameter which lets you download updates from somewhere other than the default of http://forefrontdl.microsoft.com/server/scanengineupdate. This can be an HTTP address or a UNC path; if the latter then the network service must have access to the path. This example manually downloads engine and definition updates from a local directory onto a server named mailbox01.contoso.com:

```
& $env:ExchangeInstallPath\Scripts\Update-
MalwareFilteringServer.ps1 -Identity mailbox01.contoso.com
-EngineUpdatePath \\Server\sharename
```

How do you know this worked?

In order to verify that updates were downloaded successfully, you need to access Event Viewer and view the event log. We recommend that you filter only FIPFS events, as described in the following procedure.

1. From the **Start** menu, click **All Programs** > **Administrative Tools** > **Event Viewer**.
2. In Event Viewer, expand the **Windows Logs** folder, and then click **Application**.
3. In the **Actions** menu, click **Filter Current Log**.
4. In the **Filter Current Log** dialog box, from the **Event sources** drop-down list, select the **FIPFS** check box, and then click **OK**.

If engine updates were downloaded successfully, you will see Event ID 6033, which will appear similar to the following:

```
MS Filtering Engine Update process performed a successful scan engine update.

Scan Engine: Microsoft

Update Path: http://forefrontdl.microsoft.com/server/scanengineupdate

Last Update time: 2012-08-16T13:22:17.000Z

Engine Version: 1.1.8601.0

Signature Version: 1.131.2169.0
```

For more information

Configure anti-malware policies

Configure anti-malware policies

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-08-07*

By default, malware filtering is enabled in Microsoft Exchange Server 2013. The default anti-malware policy controls your company-wide malware filtering settings. As an administrator, you can view and edit, but not delete, the default anti-malware policy so that it is tailored to best meet the needs of your organization. For greater granularity, you can also create custom malware filter policies and apply them to specified users, groups, or domains in your organization. Custom policies always take precedence over the default policy, but you can change the priority (that is, the running order) of your custom policies. For more information, see Use the EAC to configure the default anti-malware policy.

What do you need to know before you begin?

- We recommend that you manually download anti-malware engine and definition updates on your Exchange server prior to placing it in production. For more information, see Download engine and definition updates.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Anti-malware" entry in the Anti-spam and anti-malware permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to configure the default anti-malware policy

1. In the Exchange admin center (EAC), navigate to **Protection** > **Malware filter**.
2. Do one of the following:
   - Double-click the default policy in order to edit this company-wide policy.
   - Click the **+ New** icon in order to create a new policy that can be applied to users, groups, and domains in your organization. You can also edit existing custom policies by double-clicking them.
3. For custom policies only, specify a name for this policy. You can optionally specify a more detailed description as well. You cannot rename the default policy.

Note:

When creating a new policy, all configuration settings appear on a single screen, whereas when editing a policy you must navigate through different screens. The settings are the same in either case, but the rest of this procedure describes how to access these settings when editing a policy.

4. Click the **Settings** menu option. In the **Malware Detection Response** section, use the option buttons to select the action to take when malware is detected in a message:
   - **Delete the entire message** Prevents the entire message, including attachments, from being delivered to the intended recipients. This is the default value.
   - **Delete all attachments and use default alert text** Deletes all message attachments, not just the infected one, and inserts the following default alert text into a text file that replaces the attachments: "Malware was detected in one or more attachments included with this email. All attachments have been deleted."
   - **Delete all attachments and use custom alert text** Deletes all message attachments, not just the infected one, and inserts a custom message into a text file that replaces the attachments. Selecting this option enables the **Custom alert text** field where you must type a custom message.

Important:

If malware is detected in the message body, the entire message, including all attachments, will be deleted regardless of which option you select. This action is applied to both inbound and outbound messages.

5. In the **Notifications** section, you have the option to send a notification email message to senders or administrators when a message is detected as malware and is not delivered. These notifications are only sent when the entire message is deleted.
   - In the **Sender Notifications** section, select the check boxes to **Notify internal senders** (those within your organization) or to **Notify external senders** (those outside your organization) when a detected message is not delivered.
   - Similarly, in the **Administrator Notifications** section, select the check boxes to **Notify administrator about undelivered messages from internal senders** or to **Notify administrator about undelivered messages from external senders**. Specify the email address or addresses of the administrator in their respective **Administrator email address** fields after selecting one or both of these check boxes. Use a semicolon to separate multiple addresses.

The default notification text is "This message was created automatically by mail delivery software. Your email message was not delivered to the intended recipients because malware was detected." The language in which the default notification text is sent is dependent on the locale of the message being processed.

   - In the **Customize Notifications** section, you can create customized notification text to be used in place of the default notification text for sender and administrator notifications. Select the **Use customized notification text** check box, and then specify values in the following required fields:
     - **From name** The name you want to be used as the sender of the customized notification.
     - **From address** The email address you want to be used as the sender of the customized

notification.

- **Messages from internal senders** The **Subject** and **Message** of the notification if the detected message originated from an internal sender.
- **Messages from external senders** The **Subject** and **Message** of the notification if the detected message originated from an external sender.

Note:

The default Subject text is "Undeliverable message."

- For custom policies only, click the **Apply to** menu item and then create a condition-based rule to specify the users, groups, and/or domains for whom to apply this policy. You can create multiple conditions provided that they are unique.
  - To select users, select **The recipient is**. In the subsequent dialog box, select one or more senders from your company from the user picker list and then click **add**. To add senders who aren't on the list, type their email addresses and click **Check names**. In this box, you can also use wildcards for multiple email addresses (for example: *@*domainname*). When you are done with your selections, click **ok** to return to the main screen.
  - To select groups, select **The recipient is a member of** and then, in the subsequent dialog box, select or specify the groups. Click **ok** to return to the main screen.
  - To select domains, select **The recipient domain is** and then, in the subsequent dialog box, add the domains. Click **ok** to return to the main screen.

You can create exceptions within the rule, for example you can filter messages from all domains except for a certain domain. Click **add exception** and then create your exception conditions similar to the way you created the other conditions.

- Click **Save**. A summary of your default policy settings appears in the right pane.

Tip:

- You can select or clear the check boxes in the **ENABLED** column to enable or disable your custom policies. All policies are enabled by default, and the default policy cannot be disabled.
- To delete a custom policy, select the policy, click the **Delete** icon, and then confirm that you want to delete the policy. The default policy cannot be deleted.
- Custom policies always take precedence over the default policy. Custom policies run in the reverse order that you created them (from oldest to newest), but you can change the priority (running order) of your custom policies by clicking the up arrow and down arrow. The policy with a **PRIORITY** of **0** will run first, followed by **1**, then **2**, and so on.

How do you know this worked?

The following procedure provides instructions for using the EICAR.TXT antivirus test file to verify that malware filtering is working correctly.

Important:

The EICAR.TXT file is not a virus. However, because users often have the need to test that installations function correctly, the antivirus industry, through the European Institute for

Computer Antivirus Research, has adopted the EICAR standard in order to meet this need.

1. Create a new text file, and then name the file EICAR.TXT.
2. Copy the following line into the text file:

```
X5O!P%@AP[4\PZX54(P^)7CC)7}$EICAR-STANDARD-ANTIVIRUS-TEST-FILE!$H+H*
```

Make sure that this is the only string in the file. When done, you will have a 68-byte file.

Note:

If you are using a desktop antivirus program, make sure that the folder you are saving the file to is excluded from scanning.

3. Attach this file to an email message that will be filtered by Exchange 2013.

Check the recipient mailbox of the test message. Depending on the malware detection response you have configured, the entire message will be deleted, or the attachment will be deleted and replaced with the alert text file. Any configured notifications will also be distributed.

4. Delete the EICAR.TXT file after testing is completed so that other users are not unnecessarily alarmed.

Anti-malware FAQ

Rescan messages already malware scanned by the hosted filtering service

Disable or bypass anti-malware scanning

Rescan messages already malware scanned by the hosted filtering service

Exchange Server 2013 > Anti-spam and anti-malware protection > Anti-malware protection >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-18*

You can configure Microsoft Exchange Server 2013 to rescan email messages already scanned for malware by the hosted email filtering service. Enabling this functionality provides another layer of defense against malware because the cloud-hosted filtering only scans inbound and outbound messages. Internal messages are scanned by the built-in anti-malware protection capabilities of Exchange 2013. By default, messages scanned in the cloud are not resubmitted for malware scanning on-premises.

Note:
This topic only applies to Microsoft Exchange Server 2013 customers who are using cloud-hosted email filtering.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You can only use the Shell to perform this procedure.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Anti-malware" entry in the Anti-spam and anti-malware permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to rescan messages already malware scanned by the hosted filtering service

1. To rescan messages already malware scanned by the hosted filtering service, run the following command:

```
Set-MalwareFilteringServer -ForceRescan $true
```

Note:
To return to the default setting of not rescanning messages, re-set the above parameter to `$false`.

How do you know this step worked?

To verify that your Exchange 2013 server is rescanning messages for malware, run the following command and confirm that it returns a value of True:

```
Get-MalwareFilteringServer | Format-List ForceRescan
```

Disable or bypass anti-malware scanning

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-04-03*

In Microsoft Exchange Server 2013, you can disable or bypass malware filtering of all email messages in transit on a server. This must be done on a Mailbox server.

You may want to disable Exchange 2013 malware filtering if you are using another product for malware filtering. When malware filtering is disabled, the Exchange malware agent is unhooked and not running, and engine updates are not kept up-to-date.

Important:

Bypassing malware filtering should *only* be done when troubleshooting a problem. When malware filtering is bypassed, the Exchange malware agent remains hooked, and engine updates are kept up-to-date. However, malware filtering is skipped while you attempt to resolve whatever problems you are encountering. After you have finished troubleshooting, you should restore malware filtering.

What do you need to know before you begin?

- Estimated time to complete each procedure: 15 minutes
- You can only use the Shell to perform this procedure.
- Disabling or enabling malware filtering restarts the Microsoft Exchange Transport service on the server. This may temporarily disrupt mail flow in your organization.
- Bypassing or restoring malware filtering doesn't require you to restart any services. However, changes to the setting may take up to 10 minutes to take effect.
- If you have multiple Exchange servers performing malware filtering, you must perform these steps on each server.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Anti-malware" entry in the Anti-spam and anti-malware permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to disable malware filtering on a specific Exchange server

To disable malware filtering, run the following command:

```
& $env:ExchangeInstallPath\Scripts\Disable-
Antimalwarescanning.ps1
```

Note:

To re-enable malware filtering, use `Enable-Antimalwarescanning.ps1` instead of `Disable-Antimalwarescanning.ps1`.

How do you know this step worked?

To verify that malware filtering is disabled, run the following command and confirm that it returns a value of False:

```
Get-TransportAgent "Malware Agent"
```

Use the Shell to temporarily bypass malware filtering on a specific Exchange server

Important:

Bypassing malware filtering should *only* be done when troubleshooting a problem. You should restore malware filtering after you have finished troubleshooting.

To temporarily bypass malware filtering, run the following command:

```
Set-MalwareFilteringServer <ServerIdentity> -
BypassFiltering $true
```

To restore malware filtering, run the following command:

```
Set-MalwareFilteringServer <ServerIdentity> -
BypassFiltering $false
```

How do you know this step worked?

To verify that malware filtering is being bypassed, run the following command and confirm that it returns a value of True:

```
Get-MalwareFilteringServer | Format-List BypassFiltering
```

Anti-Virus Software in the Operating

System on Exchange Servers

Topic Last Modified: *2014-09-02*

This topic describes the effects of file-level antivirus programs on computers that are running Microsoft Exchange Server 2013. If you implement the recommendations described in this topic, you can help enhance the security and health of your Exchange organization.

File-level scanners are frequently used. However, if they are configured incorrectly, they can cause problems in Exchange 2013. There are two types of file-level scanners:

- *Memory-resident file-level scanning* refers to a part of file-level antivirus software that is loaded in memory at all times. It checks all the files that are used on the hard disk and in computer memory.
- *On-demand file-level scanning* refers to a part of file-level antivirus software that you can configure to scan files on the hard disk manually or on a schedule. Some versions of antivirus software start the on-demand scan automatically after virus signatures are updated to make sure that all files are scanned with the latest signatures.

The following problems may occur when you use file-level scanners with Exchange 2013:

- File-level scanners may scan a file when the file is being used or at a scheduled interval. This can cause the scanners to lock or quarantine an Exchange log or a database file while Exchange 2013 tries to use the file. This behavior may cause a severe failure in Exchange 2013 and may also cause -1018 event log errors.
- File-level scanners don't provide protection against email viruses, such as Storm Worm. Storm Worm was a backdoor Trojan horse program that propagated itself through email messages. The worm joined the infected computer to a botnet, where the computer was used to send spam in periodic bursts.

Recommendations for using file-level scanning with Exchange 2013

If you're deploying file-level scanners on Exchange 2013 servers, make sure that the appropriate exclusions, such as directory exclusions, process exclusions, and file name extension exclusions, are in place for both memory-resident and file-level scanning. This section describes recommended directory exclusions, process exclusions, and file name extension exclusions.

Contents

Directory exclusions

You must exclude specific directories for each Exchange server on which you run a file-level antivirus scanner. This section describes the directories that you should exclude from file-level scanning.

Mailbox servers

- **Mailbox databases**
  - Exchange databases, checkpoint files, and log files. By default, these are located in sub-folders under the %ExchangeInstallPath%Mailbox folder. To determine the location of a mailbox database, transaction log, and checkpoint file, run the following command: `Get-MailboxDatabase -Server <servername>| Format-List *path*`
  - Database content indexes. By default, these are located in the same folder as the database file.
  - Group Metrics files. By default, these files are located in the %ExchangeInstallPath% GroupMetrics folder.
  - General log files, such as message tracking and calendar repair log files. By default, these files are located in subfolders under the %ExchangeInstallPath%TransportRoles\Logs folder and % ExchangeInstallPath%Logging folder. To determine the log paths being used, run the following command in the Exchange Management Shell: `Get-MailboxServer <servername> | Format-List *path*`
  - The Offline Address Book files. By default, these are located in subfolders under the % ExchangeInstallPath%ClientAccess\OAB folder.
  - IIS system files in the %SystemRoot%\System32\Inetsrv folder.
  - The Mailbox database temporary folder: %ExchangeInstallPath%Mailbox\MDBTEMP
- **Members of Database Availability Groups**
  - All the items listed in the **Mailbox databases** list, and the cluster quorum database that exists at %Windir%\Cluster.
  - The witness directory files. These files are located on another server in the environment, typically a Client Access server that isn't installed on the same computer as a Mailbox server. By default, the witness directory files are located in %SystemDrive%:\DAGFileShareWitnesses \<DAGFQDN>.
- **Transport service**
  - Log files, for example, message tracking and connectivity logs. By default, these files are located in subfolders under the %ExchangeInstallPath%TransportRoles\Logs folder. To determine the log paths being used, run the following command in the Exchange Management Shell: `Get-TransportService <servername> | Format-List *logpath*,*tracingpath*`
  - Pickup and Replay message directory folders. By default, these folders are located under the % ExchangeInstallPath%TransportRoles folder. To determine the paths being used, run the following command in the Exchange Management Shell: `Get-TransportService <servername>| Format-List *dir*path*`
  - The queue databases, checkpoints, and log files. By default, these are located in the % ExchangeInstallPath%TransportRoles\Data\Queue folder.
  - The Sender Reputation database, checkpoint, and log files. By default, these are located in the %ExchangeInstallPath%TransportRoles\Data\SenderReputation folder.

- The temporary folders that are used to perform conversions:
  - By default, content conversions are performed in the Exchange server's %TMP% folder.
  - By default, rich text format (RTF) to MIME/HTML conversions are performed in %ExchangeInstallPath%Working\OleConverter folder.
- The content scanning component is used by the Malware agent and data loss prevention (DLP). By default, these files are located in the %ExchangeInstallPath%FIP-FS folder.

○ **Mailbox Transport service**

- Log files, for example, connectivity logs. By default, these files are located in subfolders under the %ExchangeInstallPath%TransportRoles\Logs\Mailbox folder. To determine the log paths being used, run the following command in the Exchange Management Shell: `Get-MailboxTransportService <servername> | Format-List *logpath*`

○ **Unified Messaging**

- The grammar files for different locales, for example en-EN or es-ES. By default, these are stored in the subfolders in the %ExchangeInstallPath%UnifiedMessaging\grammars folder.
- The voice prompts, greetings and informational message files. By default, these are stored in the subfolders in the %ExchangeInstallPath%UnifiedMessaging\Prompts folder
- The voicemail files that are temporarily stored in the %ExchangeInstallPath%UnifiedMessaging\voicemail folder.
- The temporary files generated by Unified Messaging. By default, these are stored in the %ExchangeInstallPath%UnifiedMessaging\temp folder.

Client Access servers

○ **Web components**

- For servers using Internet Information Services (IIS) 7.0, the compression folder that is used with Microsoft Outlook Web App. By default, the compression folder for IIS 7.0 is located at %SystemDrive%\inetpub\temp\IIS Temporary Compressed Files.
- IIS system files in the %SystemRoot%\System32\Inetsrv folder
- Inetpub\logs\logfiles\w3svc

○ **POP3 and IMAP4 protocol logging**

- POP3 folder: %ExchangeInstallPath%Logging\POP3
- IMAP4 folder: %ExchangeInstallPath%Logging\IMAP4

○ **Front End Transport service**

- Log files, for example, connectivity logs and protocol logs. By default, these files are located in subfolders under the %ExchangeInstallPath%TransportRoles\Logs\FrontEnd folder. To determine the log paths being used, run the following command in the Exchange Management Shell: `Get-FrontEndTransportService <servername> | Format-List *logpath*`

Return to top

Process exclusions

Many file-level scanners now support the scanning of processes, which can adversely affect Microsoft Exchange if the incorrect processes are scanned. Therefore, you should exclude the following processes from file-level scanners.

Process	Path	Comments	Servers
Dsamain.exe	%SystemRoot%\System32	Active Directory Lightweight Directory Services (AD LDS) on subscribed Edge Transport servers.	Edge Transport servers
EdgeTransport.exe	%ExchangeInstallPath%Bin	Exchange transport worker process (MSExchangeTransport)	Mailbox servers Edge Transport servers
fms.exe	%ExchangeInstallPath%FIP-FS\Bin	Content scanning component that's used by the Malware agent and DLP.	Mailbox servers
hostcontrollerservice.exe	%ExchangeInstallPath%Bin\Search\Ceres\HostController	Microsoft Exchange Search Host Controller service (HostControllerService)	Mailbox servers Client Access servers
inetinfo.exe	%SystemRoot%\System32\inetsrv	Internet Information Services (IIS)	Mailbox servers Client Access servers
Microsoft.Exchange.AntispamUpdateSvc.exe	%ExchangeInstallPath%Bin	Microsoft Exchange Anti-spam Update service (MSExchangeAntispamUpdate)	Mailbox servers Edge Transport servers
Microsoft.Exchange.ContentFilter.Wrapper.exe	%ExchangeInstallPath%TransportRoles\agents\Hygiene	Content Filter agent	Mailbox servers Edge Transport servers
Microsoft.Exchange.Dia	%ExchangeInstallPath%	Microsoft Exchange	Mailbox servers

gnostics.Service.exe	Bin	Diagnostics service (MSExchangeDiagnostics)	Client Access servers Edge Transport servers
Microsoft.Exchange.Directory.TopologyService.exe	%ExchangeInstallPath%Bin	Microsoft Exchange Active Directory Topology service (MSExchangeADTopology)	Mailbox servers Client Access servers
Microsoft.Exchange.EdgeCredentialSvc.exe	%ExchangeInstallPath%Bin	Microsoft Exchange Credential Service (MSExchangeEdgeCredential)	Edge Transport servers
Microsoft.Exchange.EdgeSyncSvc.exe	%ExchangeInstallPath%Bin	Microsoft Exchange EdgeSync service (MSExchangeEdgeSync)	Mailbox servers
Microsoft.Exchange.Imap4.exe	ExchangeInstallPath%FrontEnd\PopImap	Microsoft Exchange IMAP4 service (MSExchangeImap4)	Client Access servers
Microsoft.Exchange.Imap4service.exe	%ExchangeInstallPath%ClientAccess\PopImap	Microsoft Exchange IMAP4 Backend service (MSExchangeIMAP4BE)	Mailbox servers
Microsoft.Exchange.Pop3.exe	%ExchangeInstallPath%FrontEnd\PopImap	Microsoft Exchange POP3 service (MSExchangePop3)	Client Access servers
Microsoft.Exchange.Pop3service.exe	%ExchangeInstallPath%ClientAccess\PopImap	Microsoft Exchange POP3 Backend service (MSExchangePOP3BE)	Mailbox servers
Microsoft.Exchange.Pro	%ExchangeInstallPath%	Microsoft Exchange	Mailbox servers

tectedServiceHost.exe	Bin	Service Host service (MSExchangeServiceHost)	Client Access servers Edge Transport servers
Microsoft.Exchange.RPCClientAccess.Service.exe	%ExchangeInstallPath%Bin	Microsoft Exchange RPC Client Access service (MSExchangeRPC)	Mailbox servers
Microsoft.Exchange.Search.Service.exe	%ExchangeInstallPath%Bin	Microsoft Exchange Search service (MSExchangeFastSearch)	Mailbox servers
Microsoft.Exchange.Servicehost.exe	%ExchangeInstallPath%Bin	Microsoft Exchange Service Host service (MSExchangeServiceHost)	Mailbox servers Client Access servers Edge Transport servers

File name extension exclusions

In addition to excluding specific directories and processes, you should exclude the following Exchange-specific file name extensions in case directory exclusions fail or files are moved from their default locations.

Application-related extensions:

- .config
- .dia
- .wsb

Database-related extensions:

- .chk
- .edb
- .jrs
- .jsl
- .log
- .que

Offline address book-related extensions:

- .lzx

Content Index-related extensions:

- .ci
- .dir
- .wid
- .000
- .001
- .002

Unified Messaging-related extensions:

- .cfg

- .grxml

Group Metrics-related extensions:

- .dsc
- .txt

Mail flow

Topic Last Modified: *2014-02-17*

In Microsoft Exchange Server 2013, mail flow occurs through the transport pipeline. The *transport pipeline* is a collection of services, connections, components, and queues that work together to route all messages to the categorizer in the Transport service on a Mailbox server inside the organization.

Looking for a list of all mail flow topics? See Mail flow documentation.

For information about how to configure mail flow in a new Exchange 2013 organization, see Configure mail flow and client access.

Contents

The transport pipeline

The transport pipeline consists of the following services:

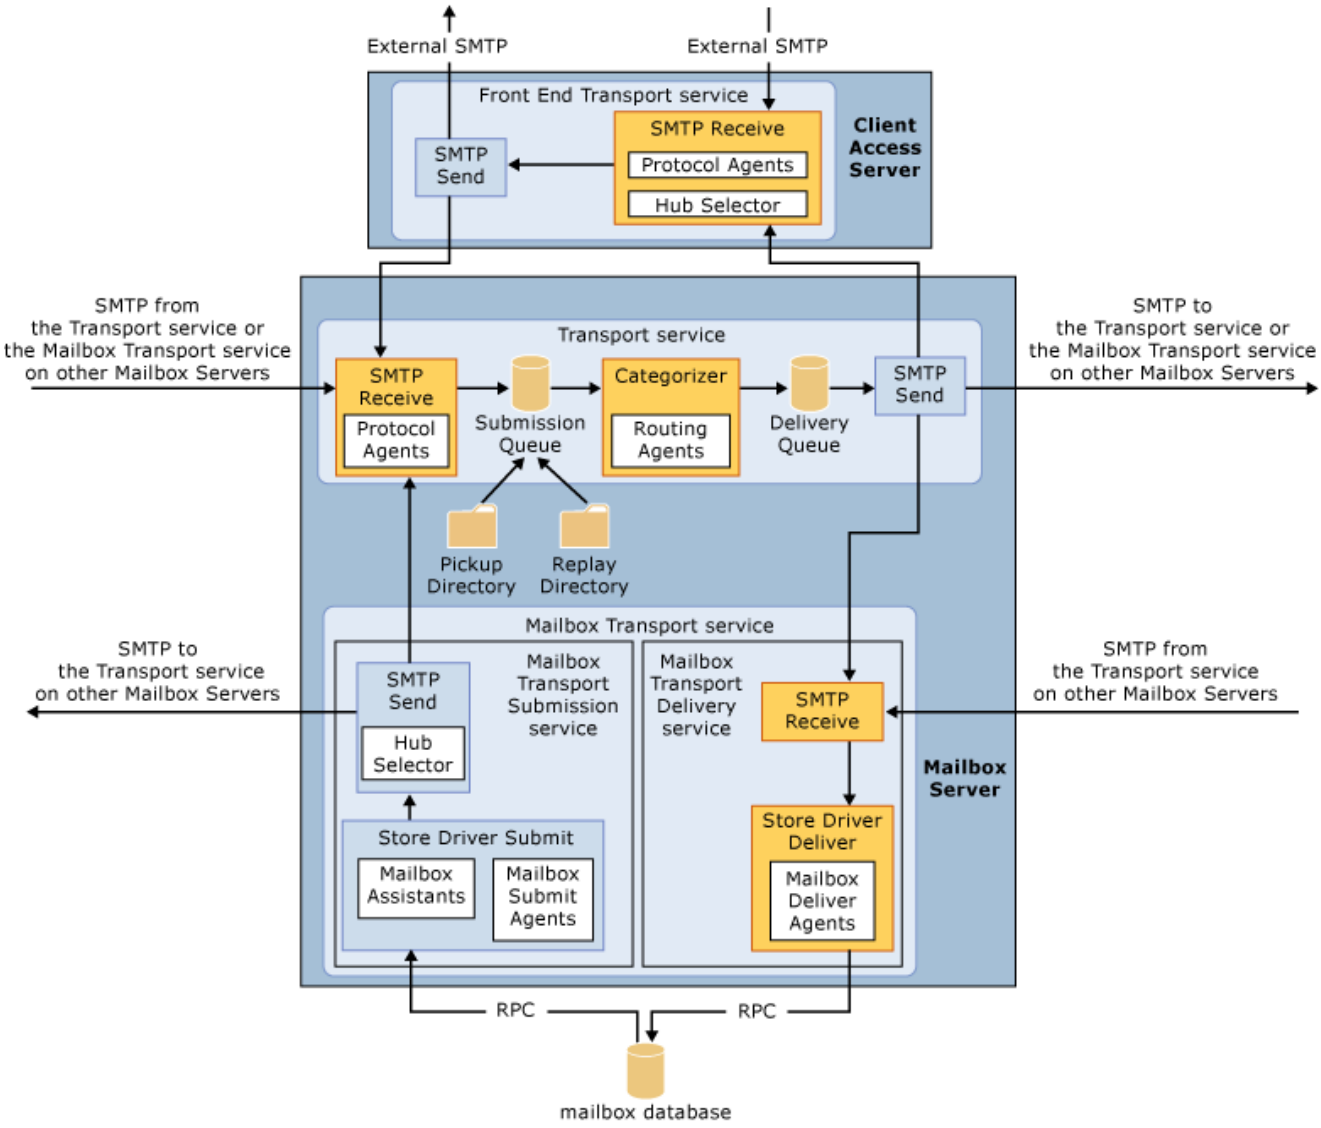
- **Front End Transport service on Client Access servers** This service acts as a stateless proxy for all inbound and (optionally) outbound external SMTP traffic for the Exchange 2013 organization. The Front End Transport service doesn't inspect message content, doesn't communicate with the Mailbox Transport service on Mailbox servers, and doesn't queue any messages locally.
- **Transport service on Mailbox servers** This service is virtually identical to the Hub Transport server role in previous versions of Exchange. The Transport service handles all SMTP mail flow for the organization, performs message categorization, and performs message content inspection. Unlike previous versions of Exchange, the Transport service never communicates directly with mailbox databases. That task is now handled by the Mailbox Transport service. The Transport service routes messages between the Mailbox Transport service, the Transport service, the Front End Transport service, and (depending on your configuration) the Transport service on Edge

Transport servers. The Transport service on Mailbox servers is described in more detail later in this topic.

- **Mailbox Transport service on Mailbox servers** This service consists of two separate services: the Mailbox Transport Submission service and Mailbox Transport Delivery service. The Mailbox Transport Delivery service receives SMTP messages from the Transport service on the local Mailbox server or on other Mailbox servers, and connects to the local mailbox database using an Exchange remote procedure call (RPC) to deliver the message. The Mailbox Transport Submission service connects to the local mailbox database using RPC to retrieve messages, and submits the messages over SMTP to the Transport service on the local Mailbox server, or on other Mailbox servers. The Mailbox Transport Submission service has access to the same routing topology information as the Transport service. Like the Front End Transport service, the Mailbox Transport service also doesn't queue any messages locally.
- **Transport service on Edge Transport servers** This service is very similar to the Transport service on Mailbox servers. If you have an Edge Transport server installed in the perimeter network, all mail coming from the Internet or going to the Internet flows through the Transport service Edge Transport server. This service is described in more detail later in this topic.

The following figure shows the relationships among the components in the Exchange 2013 transport pipeline.

Overview of the transport pipeline in Exchange 2013.



Messages from external senders

Messages from outside the organization enter the transport pipeline through a Receive connector in the Front End Transport service on the Client Access server and are then routed to the Transport service on the Mailbox server.

If you have an Exchange 2013 Edge Transport server installed in the perimeter network, messages from outside the organization enter the transport pipeline through a Receive connector in the Transport service on the Edge Transport server. Where the messages go next depends on how your internal Exchange servers are configured.

- **Mailbox server and Client Access server installed on the same computer** In this configuration, the Client Access server is used for inbound mail flow. Mail flows from the Transport service on the Edge Transport server to the Front End Transport service on the Client Access server, and then to the Transport service on the Mailbox server.
- **Mailbox server and Client Access server installed on different computers** In this configuration, the Client Access server is bypassed for inbound mail flow. Mail flows from the Transport service on the Edge Transport server to the Transport service on the Mailbox server.

Note:

If you have an Exchange 2010 or Exchange 2007 Edge Transport server installed in your perimeter network, mail flow always occurs directly between the Edge Transport server and the Transport service on the Mailbox server. For more information, see Use an Exchange 2010 or 2007 Edge Transport server in Exchange 2013.

Messages from internal senders

SMTP messages from inside the organization enter the transport pipeline through the Transport service on a Mailbox server in one of the following ways:

- Through a Receive connector.
- From the Pickup directory or the Replay directory.
- From the Mailbox Transport service.
- Through agent submission.

The message is routed based on the routing destination or delivery group. For more information, see Mail routing.

If the message has external recipients, the message is routed from the Transport service on the Mailbox server to the Internet, or from the Mailbox server to the Front End Transport service on a Client Access server and then to the Internet if the Send connector is configured to proxy outbound connections through the Client Access server. For more information, see Create a Send connector for email sent to the Internet.

If you have an Edge Transport server installed in the perimeter network, messages that have external recipients are never routed through the Front End Transport service on a Client Access server. The message is routed from the Transport service on a Mailbox server to the Transport service on the Edge Transport server

Transport service on Mailbox servers

Every message that's sent or received in an Exchange 2013 organization must be categorized in the Transport service on a Mailbox server before it can be routed and delivered. After a message has been categorized, it's put in a delivery queue for delivery to the destination mailbox database, the destination database availability group (DAG), Active Directory site, or Active Directory forest, or to the destination domain outside the organization.

The Transport service on a Mailbox server consists of the following components and processes:

- **SMTP Receive** When messages are received by the Transport service, message content inspection is performed, transport rules are applied, and anti-spam and anti-malware inspection is performed if they are enabled. The SMTP session has a series of events that work together in a specific order to validate the contents of a message before it's accepted. After a message has passed completely through SMTP Receive and isn't rejected by receive events, or by an anti-spam and anti-malware agent, it's put in the Submission queue.
- **Submission** Submission is the process of putting messages into the Submission queue. The categorizer picks up one message at a time for categorization. Submission happens in three ways:

- From SMTP Receive through a Receive connector.
- Through the Pickup directory or the Replay directory. These directories exist on Mailbox servers and Edge Transport servers. Correctly formatted message files that are copied into the Pickup directory or the Replay directory are put directly into the Submission queue.
- Through a transport agent.

- **Categorizer** The categorizer picks up one message at a time from the Submission queue. The categorizer completes the following steps:
  - Recipient resolution, which includes top-level addressing, expansion, and bifurcation.
  - Routing resolution.
  - Content conversion.

Additionally, mail flow rules that are defined by the organization are applied. After messages have been categorized, they're put into a delivery queue that's based on the destination of the message. Messages are queued by the destination mailbox database, DAG, Active Directory site, Active Directory forest or external domain.

- **SMTP Send** How messages are routed from the Transport service depends on the location of the message recipients relative to the Mailbox server where categorization occurred. The message could be routed to one of the following locations:
  - To the Mailbox Transport service on the same Mailbox server.
  - To the Mailbox Transport service on a different Mailbox server that's part of the same DAG.
  - To the Transport service on a Mailbox server in a different DAG, Active Directory site, or Active Directory forest.
  - For delivery to the Internet through a Send connector on the same Mailbox server, through the Transport service on a different Mailbox server, through the Front End Transport service on a Client Access server, or through the Transport service on an Edge Transport server in the perimeter network.

Transport service on Edge Transport servers

The components of the Transport service on Edge Transport servers are identical to the components of the Transport service on Mailbox servers. However, what actually happens during each stage of processing on Edge Transport servers is different. The differences are described in the following list.

- **SMTP Receive** When an Edge Transport server is subscribed to an internal Active Directory site, the default Receive connector is automatically configured to accept mail from internal Mailbox servers and from the Internet. When Internet messages arrive at the Edge Transport server, anti-spam agents filter connections and message contents, and help identify the sender and the recipient while the message is being accepted into the organization. The anti-spam agents are installed and enabled by default. Additional attachment filtering and connection filtering features are available, but built-in malware filtering is not. Also, transport rules are controlled by the Edge Rule agent. Compared to the Transport Rule agent on Mailbox servers, only a small subset of transport rule conditions are available on Edge Transport servers. But, there are unique transport rule actions related to SMTP connections that are available only on Edge Transport servers.

- **Submission** On an Edge Transport server, messages typically enter the Submission queue through a Receive connector. However, the Pickup directory and the Replay directory are also available.
- **Categorizer** On an Edge Transport server, categorization is a short process in which the message is put directly into a delivery queue for delivery to internal or external recipients.
- **SMTP Send** When an Edge Transport server is subscribed to an internal Active Directory site, two Send connectors are automatically created and configured. One is responsible for sending outbound mail to Internet recipients; the other is responsible for sending inbound mail from the Internet to internal recipients. Inbound mail is sent to the Transport service on an available Mailbox server in the subscribed Active Directory site.

Mail flow documentation

The following table contains links to topics that will help you learn about and manage mail flow in Exchange 2013.

Topic	Description
Mail routing	Mail routing describes how messages are transmitted between messaging servers.
Connectors	Connectors define where and how messages are transmitted to and from Exchange servers.
Domains	Accepted domains define the SMTP address spaces that are used in the Exchange organization. Remote domains configure message formatting and encoding settings for messages sent to external domains.
Transport agents	Transport agents act on messages as they travel through the Exchange transport pipeline.
Transport high availability	Transport high availability describes how Exchange 2013 keeps redundant copies of messages during transit and after delivery.
Transport logs	Transport logs record what happens to messages as they flow through the transport pipeline.

Managing message approval	Moderated transport requires approval for messages sent to specific recipients.
Content conversion	Content conversion controls the Transport Neutral encoding format (TNEF) message conversion options for external recipients, and the MAPI conversion options for internal recipients.
DSNs and NDRs	Delivery status notifications (DSNs) are the system messages that are sent to message senders, for example, non-delivery reports (NDRs).
Track messages with delivery reports	Delivery Reports is a message tracking tool that you can use to search for delivery status on email messages sent to or from users in your organization's address book, with a certain subject. You can track delivery information about messages sent by or received from any specific mailbox in your organization.
Message size limits	This topic describes the size and individual component limits that are imposed on messages.
Queue Viewer	You use the Queue Viewer in the Exchange Toolbox to view and act upon queues and message in queues.
Pickup directory and Replay directory	The pickup and replay directories are used to insert message files into the transport pipeline.
Use an Exchange 2010 or 2007 Edge Transport server in Exchange 2013	This topic describes the considerations for using an Edge Transport server from previous

	versions of Exchange in Exchange 2013.

Mail routing

Exchange Server 2013 > Mail flow >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-17*

The primary task of the Transport service that exists on all Mailbox servers in your Microsoft Exchange Server 2013 organization is to route messages received from users and external sources to their ultimate destinations. Routing decisions are made during message categorization. The categorizer is a component of the Transport service on a Mailbox server that processes all incoming messages and determines what to do with the message based on information about their destinations.

Routing in Exchange 2013 is now fully aware of Database Availability Groups (DAGs), and uses DAG membership as a routing boundary. Why? In Exchange 2013, all Mailbox servers host the Transport service. Therefore, when a Mailbox server belongs to a DAG, the primary mechanism for routing messages is closely aligned with the DAG. And when a DAG spans multiple Active Directory sites, using the Active Directory site as the primary routing boundary is inefficient. Exchange 2013 also uses Active Directory site membership as a routing boundary for Mailbox servers that don't belong to DAGs, and for routing interoperability with previous versions of Exchange. Other notable changes to Exchange 2013 routing include:

- The Transport service on a Mailbox server never communicates directly with a mailbox database. Instead, the Transport service communicates with the Mailbox Transport service on the Mailbox server. Only the Mailbox Transport service communicates with the mailbox database on the local Mailbox server. When the Mailbox server is a member of a DAG, only the Mailbox Transport service on the Mailbox server that holds the active copy of the mailbox database accepts the message for the destination recipient.
- Remote procedure calls (RPCs) are only used by the Mailbox Transport service when sending messages to or receiving messages from the local mailbox database. When the Mailbox server is a member of a DAG, the Mailbox Transport service only uses RPCs to communicate locally with the active copies of the mailbox databases. In other words, RPC is never used for cross-server communication. Instead, the Mailbox Transport service and the Transport service on different Mailbox servers always communicate using SMTP.
- Exchange 2013 uses more precise queuing for remote destinations. Instead of using one queue for all destinations in a remote Active Directory site, Exchange 2013 queues messages for specific destinations within the Active Directory site, such as individual Send connectors.
- Linked connectors have been deprecated. A linked connector was a Receive connector that was

linked to a Send connector. All messages received by the Receive connector were automatically forwarded to the Send connector.

Contents

Routing components

When a message is received by the Transport service on an Exchange 2013 Mailbox server, the message must be categorized. The first phase of message categorization is recipient resolution. After the recipient has been resolved, the ultimate destination can be determined. The next phase, routing, determines how to best reach that destination. Routing in Exchange 2013 has been generalized for increased flexibility and decreased complexity by introducing the concepts of routing destinations and delivery groups.

Routing destinations

In Exchange 2013, the ultimate destination for a message is called a *routing destination*. The following routing destinations exist in Exchange 2013:

- **A mailbox database** This is the routing destination for any recipient with a mailbox on a Mailbox server in the Exchange organization. In Exchange 2013, public folders are a type of mailbox, so routing messages to public folder recipients is the same as routing messages to mailbox recipients.
- **A connector** A connector is a Send connector for SMTP messages when used as a routing destination. A Delivery Agent connector or a Foreign connector is used as a routing destination for non-SMTP messages.
- **A distribution group expansion server** This is the routing destination when a distribution group has a designated expansion server that's responsible for expanding the membership list of the group. A distribution group expansion server is always a Hub Transport server or an Exchange 2013 Mailbox server.

Note that these same routing destinations also existed in previous versions of Exchange.

Return to top

Delivery groups

Each routing destination in Exchange 2013 has a collection of one or more transport servers that are responsible for delivering messages to that routing destination. This collection of transport servers is called a *delivery group*. A transport server could be an Exchange 2013 Mailbox server, or an Exchange 2010 server or Exchange 2007 server that has the Hub Transport server role installed. When the routing destination is a mailbox database, the transport servers in the delivery group are the same version of Exchange as the mailbox database. When the routing destination is a connector or a distribution group expansion server, the delivery group may contain a mixture of Exchange 2013 Mailbox servers and Exchange 2010 or Exchange 2007 Hub Transport servers. How the message is routed depends on the relationship between the source transport server and the destination delivery group:

- If the source transport server is in the destination delivery group, the routing destination itself is the next hop for the message. The message is delivered by the source transport server to the mailbox database or connector on a transport server in the delivery group. Note that when a distribution group expansion server is the routing destination, the distribution group is already expanded by the time messages reach the routing stage of categorization on the distribution group expansion server. Therefore, the routing destination from the distribution group expansion server is always a mailbox database or a connector.
- If the source transport server is outside the destination delivery group, the message is relayed along the least-cost routing path to the destination delivery group. Depending on the size and complexity of the Exchange topology, the message is relayed to other transport servers along the least cost routing path, or the message is relayed directly to a transport server in the destination delivery group.

The following types of delivery groups exist in Exchange 2013:

- **Routable DAG** This is a collection of Exchange 2013 Mailbox servers that belong to one DAG. The mailbox databases in the DAG are the routing destinations that are serviced by this delivery group. After the message arrives at the Transport service on a Mailbox server that belongs to the DAG, the Transport service routes the message to the Mailbox Transport service on the Mailbox server in the DAG that currently holds the active copy of the destination mailbox database. The Mailbox Transport service on the destination Mailbox server then delivers the message to the local mailbox database. Although a DAG may contain Mailbox servers located in different Active Directory sites, the DAG is the delivery group boundary.
- **Mailbox delivery group** This is a collection of Exchange servers of the same version located in one Active Directory site. The Active Directory site is the delivery group boundary. The routing destinations and the delivery groups that service them are separated by the major release versions of Exchange in the Active Directory site. The mailbox databases located on Exchange 2010 Mailbox servers are serviced by the Exchange 2010 Hub Transport servers located in the Active Directory site. The mailbox databases located on Exchange 2007 Mailbox servers are serviced by the Exchange 2007 Hub Transport servers located in the Active Directory site. The mailbox databases located on Exchange 2013 Mailbox servers in Active Directory site that don't

belong to a DAG are serviced by the Transport service on Exchange 2013 Mailbox servers in the Active Directory site. How the message is delivered to the mailbox database depends on version of Exchange:

  - **Exchange 2013** After the message arrives at the destination Mailbox server in the destination Active Directory site, the Transport service uses SMTP to transfer the message to the Mailbox Transport service. The Mailbox Transport service then delivers the message to the local mailbox database using RPC.
  - **Exchange 2010 or Exchange 2007** After the message arrives at a random Hub Transport server of the same version in the destination Active Directory site, the store driver on the Hub Transport server uses RPC to write the message to the mailbox database.

- **Connector source servers** This is a mixed collection of Exchange 2010 or Exchange 2007 Hub Transport servers, or Exchange 2013 Mailbox servers that are scoped as the source server for a Send connector, a Delivery Agent connector or a Foreign connector. The connector is the routing destination that's serviced by this routing group. When a connector is scoped to a specific server, only that server is allowed to route messages to destination defined by the connector. This delivery group may contain Exchange 2010 or Exchange 2007 Hub Transport servers, or Exchange 2013 Mailbox servers located in different Active Directory sites.
- **AD site** In some circumstances, an Active Directory site isn't the ultimate destination of a message, but the message must pass through an Exchange 2010 or Exchange 2007 Hub Transport server or Exchange 2013 Mailbox server in that Active Directory site. Those circumstances include:
  - When the Active Directory site is configured as a hub site. When the hub site exists on the least-cost routing path for message delivery, the messages queue and are processed by a transport server in the hub site before they're relayed to their ultimate destination.
  - When an Edge Transport server is subscribed to the Active Directory site. These subscribed Edge Transport servers aren't directly accessible from other Active Directory sites. Note that the Edge Transport server could be Exchange 2013, Exchange 2010 or Exchange 2007.

Note:
Delayed fan-out is only used when the delivery group is an Active Directory site. Delayed fan-out attempts to reduce the number of message transmissions when multiple recipients share any part of the least-cost routing path.

- **Server list** This is a collection of one or more Exchange 2010 or Exchange 2007 Hub Transport servers or Exchange 2013 Mailbox servers that are configured as distribution group expansion servers. The distribution group expansion server is the routing destination serviced by this delivery group.

Delivery group membership isn't mutually exclusive. For example, an Exchange 2013 Mailbox server that's a member of a DAG can also be the source server of a scoped Send connector. This Mailbox server would belong to the routable DAG delivery group for the mailbox databases in the DAG, and also a connector source server delivery group for the scoped Send connector.

The following table maps the routing destinations to the delivery group based on the version of Exchange involved:

	Exchange 2013	**Exchange 2010 or**	**Edge Transport**

	Mailbox server	Exchange 2007 Hub Transport server	server in the perimeter network
Mailbox database in a DAG	Routable DAG	Mailbox delivery group	n/a
Mailbox database not in a DAG	Mailbox delivery group	Mailbox delivery group	n/a
Connector	Connector source servers	Connector source servers	AD site
Distribution group expansion server	Server list	Server list	n/a

Return to top

Queues

From the perspective of the sending server, each delivery queue represents the destination for a particular message. When the Transport service on the Exchange 2013 Mailbox server selects the destination for a message, the destination is stamped on the recipient as the **NextHopSolutionKey** attribute. If a single message is being sent to more than one recipient, each recipient has the **NextHopSolutionKey** attribute. The receiving server also performs message categorization and queues the message for delivery. After a message is queued, you can examine the delivery type for a particular queue to determine whether a message will be relayed again when it reaches the next hop destination. Every unique value of the **NextHopSolutionKey** attribute corresponds to a separate delivery queue.

For more information, see the "NextHopSolutionKey" section in the Queues topic.

Return to top

Routing messages

When a message needs to be delivered to a remote delivery group, a routing path must be determined for the message. Exchange 2013 uses the following logic to select the routing path for a message. This logic is basically unchanged from Exchange 2010:

1. Calculate the least-cost routing path by adding the cost of the IP site links that must be traversed to reach the destination. If the destination is a connector, the cost assigned to the address space is added to the cost to reach the selected connector. If multiple routing paths are possible, the routing path with the lowest aggregate cost is used.
2. If more than one routing path has the same aggregate cost, the number of hops in each path is

evaluated and the routing path with the least number of hops is used.

3. If more than one routing path is still available, the name assigned to the Active Directory sites before the destination is considered. The routing path where the Active Directory site nearest the destination is lowest in alphanumeric order is used. If the site nearest the destination is the same for all routing paths being evaluated, an earlier site name is considered.

In Exchange 2010, each message recipient is always associated with only one Active Directory site, and there is only one least cost routing from the source Active Directory site to the destination Active Directory site. In Exchange 2013, a delivery group may span multiple Active Directory sites, and there may be multiple least-cost routing paths to those multiple Active Directory sites. Exchange 2013 designates a single Active Directory site in the destination delivery group as the *primary site*. The primary site is closest Active Directory site based on the routing logic described earlier. To successfully route messages between delivery groups, Exchange 2013 takes the following issues into consideration:

- **The presence of one or more hub sites along the least-cost routing path** If the least-cost routing path to the primary site contains any hub sites, the message must be routed through the hub sites. The closest hub site along the least-cost routing path is selected as a new delivery group of the type **AD site**, which includes all transport servers in the hub site. After the message traverses the hub site, routing of the message along the least-cost routing path continues. If the primary site happens to be a hub site, the primary site is still considered a hub site for the following reasons:
  - If the destination delivery group spans multiple Active Directory sites, the source server should only attempt to connect to the servers in the hub site.
  - The servers in the hub site that actually belong to the target delivery group are preferred.

As in previous version of Exchange, any hub sites that aren't in the least-cost routing path to the primary site are ignored.

- **The target Exchange server to select in the destination routing group** When the destination delivery group spans multiple Active Directory sites, the routing path to specific servers within the delivery group may have different costs. Servers located in the closest Active Directory site are selected as the target servers for the delivery group based on the least-cost routing path, and the Active Directory site those servers are in is selected as the primary site.
- **Fallback options when connection attempts to all servers in the destination routing group fail** If the destination delivery group spans multiple Active Directory sites, the first fallback option is all other servers in the destination delivery group in other Active Directory sites that aren't selected as target servers. Server selection is made based on the cost of the routing path to those other Active Directory sites. If the destination delivery group has any servers in the local Active Directory site, there are no other fallback options because the message is already as close to the target routing destination as possible. If the destination delivery group has servers in remote Active Directory sites, the option is to try to connect to all other servers in the primary site. If that fails, a backoff path in the least-cost routing path to the primary site is used. Exchange 2013 tries to deliver the message as close to the destination as possible by backing off, hop by hop, along the least-cost routing path until a connection is made.

Return to top

Routing messages between Active Directory sites

The way that Exchange 2013 routes messages between Active Directory sites is virtually the same as Exchange 2010. For more information, see Route mail between Active Directory sites.

Return to top

Routing in the Front End Transport service on Client Access servers

This acts as a stateless proxy for all inbound and (optionally) outbound external SMTP traffic for the Exchange 2013 organization. For outgoing messages, the Transport service uses Send connectors to communicate with the Front End Transport service on a Client Access server. Specifically, outgoing messages are proxied through the Front End Transport service when the *FrontEndProxyEnabled* parameter on an applicable Send connector is set to `$true`, or when the **Proxy through Client Access server** option is selected in the Send Connector properties in the Exchange admin center (EAC). Any Client Access server in the local Active Directory site will be selected. Note that the Front End Transport service doesn't have Send connectors.

For incoming messages, the Front End Transport service must quickly find a single, healthy Transport service on a Mailbox server to receive the message transmission, regardless of the number or type of recipients. Failure to do so results in the email service being perceived as unavailable by the external senders. Like the Transport service, the Front End Transport service loads routing tables based on information from Active Directory, and uses delivery groups to determine how to route messages. However, the routing tables used by the Front End Transport service have the following unique characteristics:

- The Front End Transport service is never considered a member of a delivery group, even when the Mailbox server and the Client access server are installed on the same physical server. This forces the Front End Transport service to communicate with the Transport service only.
- The routing tables don't contain any Send connector routes.
- The routing tables contain a special list of Mailbox servers in the local Active Directory site for fast fail-over purposes.

Routing in the Front End Transport service resolves message recipients to mailbox databases. The list of Mailbox servers used by the Front End Transport service is based on the mailbox databases of the message recipients. Note that it's possible that none of the recipients have mailboxes, for example, if the recipient is a distribution group or a mail user. For each mailbox database, the Front End Transport service looks up the delivery group and the associated routing information. The delivery groups used by the Front End Transport service are:

- Routable DAG
- Mailbox delivery group

- AD site

Depending on the number and type of recipients, the Front End Transport service performs one of the following actions:

- For messages with a single mailbox recipient, select a Mailbox server in the target delivery group, and give preference to the Mailbox server based on the proximity of the Active Directory site. Routing the message to the recipient may involve routing the message through a hub site.
- For messages with multiple mailbox recipients, use the first 20 recipients to select a Mailbox server in the closest delivery group, based on the proximity of the Active Directory site. Note that message bifurcation doesn't occur in Front-End Transport, so only one Mailbox server is ultimately selected, regardless of number of recipients in a message.
- If the message has no mailbox recipients, select a random Mailbox server in the local Active Directory site.

Return to top

Routing in the Mailbox Transport service on Mailbox servers

This consists of two separate services: the Mailbox Transport Submission service and Mailbox Transport Delivery service. For incoming messages, the Mailbox Transport Delivery service receives SMTP messages from the Transport service, and connects to the local mailbox database using RPC to deliver the message. For outgoing messages, the Mailbox Transport Submission service connects to the local mailbox database using RPC to retrieve messages, and submits the messages over SMTP to the Transport service. The Mailbox Transport service is stateless, and doesn't queue any messages locally.

Like the Transport service, the Mailbox Transport service loads routing tables based on information from Active Directory, and uses delivery groups to determine how to route messages. However, there are routing aspects that are unique to the Mailbox Transport service:

- Because the Transport service and the Mailbox Transport service exist on the same Exchange 2013 Mailbox server, the Mailbox Transport service always belongs to the same delivery group as the Mailbox server. This delivery group is referred to as the *local delivery group*.
- The Mailbox Transport Submission service doesn't automatically send messages to the Transport service on the local Mailbox server or on other Mailbox servers in its own local delivery group. The Mailbox Transport Submission service has access to the same routing topology information as the Transport service, so the Mailbox Transport submission service can send messages to the Transport service on Mailbox servers outside the delivery group. The Mailbox servers in the local delivery group are used as fallback options, and for delivery to non-mailbox recipients.
- The Mailbox Transport service only communicates with the Transport service on Exchange 2013 Mailbox servers.
- The Mailbox Transport service only communicates with mailbox databases on the local Exchange 2013 Mailbox server. The Mailbox Transport service never communicates with mailbox databases

on other Mailbox servers.

When a user sends a message from their mailbox, the Mailbox Transport Submission service resolves the message recipients to mailbox databases. The list of Mailbox servers used by the Mailbox Transport Submission service is based on the mailbox databases of the message recipients. Note that it's possible that none of the recipients have mailboxes, for example, if the recipient is a distribution group or a mail user. For each mailbox database, the Mailbox Transport Submission service looks up the delivery group and the associated routing information. The delivery groups used by the Mailbox Transport Submission service are:

- Routable DAG
- Mailbox delivery group
- AD site

Depending on the number and type of recipients, the Mailbox Transport Submission service performs one of the following actions:

- For messages with a single mailbox recipient, select a Mailbox server in the target delivery group, and give preference to the Mailbox server based on the proximity of the Active Directory site. Routing the message to the recipient may involve routing the message through a hub site.
- For messages with multiple mailbox recipients, use the first 20 recipients to select a Mailbox server in the closest delivery group, based on the proximity of the Active Directory site.
- If the message has no mailbox recipients, select a Mailbox server in the local delivery group.

When the Mailbox Transport Delivery service receives a message from the Transport service, it accepts or rejects the message for delivery to a local mailbox database. The Mailbox Transport Delivery service can deliver the message if the recipient resides in an active copy of a local mailbox database. But, if the recipient doesn't reside in an active copy of a local mailbox database, the Mailbox Transport Delivery service can't deliver the message, and must provide a non-delivery response to the Transport service. For example, if the active copy of the mailbox database recently moved to another server, the Transport service might erroneously transmit a message to a Mailbox server that now holds an inactive copy of the mailbox database. The non-delivery responses that the Mailbox Transport Delivery service returns to the Transport service include:

- Retry delivery
- Generate an NDR
- Reroute the message

Return to top

Routing in the Transport service on Edge Transport servers

If you have an Edge Transport server installed in your perimeter network, the Transport service on the Edge Transport server provides SMTP relay and smart host services for all Internet-facing mail flow. Messages that come and go from the Internet are queued locally on the Edge Transport server. The queues correspond to external domains or Send connectors. For more information, see the "NextHopSolutionKey" section in the Queues topic.

Typically, when you install an Edge Transport server in your perimeter network, you subscribe the Edge Transport server to an Active Directory site. The Active Directory site contains the Mailbox servers that will relay messages to and from the Edge Transport server. The Edge Subscription process creates an Active Directory site membership affiliation for the Edge Transport server. The site affiliation enables the Mailbox servers in the Active Directory site to relay messages to the Edge Transport server for delivery to the Internet without having to configure explicit Send connectors.

In multi-site configurations, outbound mail from internal recipients to external recipients is first routed to the subscribed Active Directory site. The target Active Directory site is the delivery group. The routing destination is the intra-organization Send connector in the Transport service on any of the Mailbox servers in the subscribed Active Directory site. The *intra-organization Send connector* is special Send connector that exists in the Transport service on every Mailbox server. This Send connector is implicitly created, invisible, requires no management, and is used to relay messages between Exchange servers.

Outbound mail for external recipients is routed from the Mailbox server to the Edge Transport server. The Client Access server is not involved in routing mail to a subscribed Edge Transport server. Mail is transmitted from the intra-organization Send connector in the Transport service on the Mailbox server to a Receive connector in the Transport service on the Edge Transport server. On a subscribed Edge Transport server, the default Receive connector is configured to listen for connections from internal Mailbox servers in the subscribed Active Directory site and anonymous connections from the Internet. After the message is categorized by the Transport service on the Edge Transport server, the message is queued locally for delivery to the Internet by using the dedicated Send connector that's created during the Edge Subscription.

Inbound mail from external recipients arrives on the Edge Transport through the default Receive connector, and the messages are categorized and queued for delivery. The messages are relayed through the dedicated Send connector that's created by the Edge Subscription to send mail into the Exchange organization. Where the messages go next depends on how the internal Exchange servers are configured.

- **Mailbox server and Client Access server installed on the same computer** In this configuration, the Client Access server is used for inbound mail flow. Mail flows from the Send connector in the Transport service on the Edge Transport server to the default Receive connector in the Front End Transport service on the Client Access server, and then to the default Receive connector in the Transport service on the Mailbox server.
- **Mailbox server and Client Access server installed on different computers** In this configuration, the Client Access server is bypassed for inbound mail flow. Mail flows from the Send connector in the Transport service on the Edge Transport server to the default Receive connector in the Transport service on the Mailbox server.

If you have an Exchange 2007 or Exchange 2010 Edge Transport server installed in the perimeter network, inbound and outbound mail flow always occurs directly between the Edge Transport server and the Mailbox server. The Client Access server isn't used.

Return to top

Planning to use Active Directory sites for routing mail

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-05-21*

Microsoft Exchange Server 2013 recognizes Active Directory sites and database availability groups (DAGs) as routing boundaries. However, Exchange 2013 still uses Active Directory site topology to determine how messages are transported between Exchange servers in different DAGs or sites within the organization. For more information, see Mail routing.

The Transport service on a Mailbox server provides message transport inside the Exchange organization. When you're deploying a pure Exchange 2013 organization, or introducing Exchange 2013 into a pure Exchange Server 2010 organization, no additional configuration is required to establish routing in the forest.

Contents

How Exchange 2013 uses Active Directory site membership

Exchange 2013 is a site-aware application. Site-aware applications can determine their own Active Directory site membership and the site membership of other servers by querying Active Directory. Exchange 2013 uses site membership to determine which domain controllers and global catalog servers to use for processing Active Directory queries. Additionally, when a server running Exchange has to determine the Active Directory site membership of another Exchange server, it can query Active Directory to retrieve the site name.

In Exchange 2013, the Microsoft Exchange Active Directory Topology service is responsible for updating the site attribute of the Exchange server object. Because the Active Directory site membership is a server object attribute, Exchange doesn't have to query DNS to resolve a server address to a subnet associated with an Active Directory site. Stamping the Active Directory site

attribute on an Exchange server object also enables Active Directory site membership to be assigned to a server that isn't a domain member, such as a subscribed Edge Transport server.

The Exchange 2013 servers use Active Directory site membership information as follows:

- **Mail submission** The Mailbox Transport Submission service on an Exchange 2013 Mailbox server uses Active Directory site membership information to determine the other Exchange 2013 Mailbox servers that are located in the same Active Directory site. If the source Mailbox server doesn't belong to a DAG, or if the DAG doesn't span multiple Active Directory sites, the Mailbox Transport Submission service on the source Mailbox server submits messages for routing and transport to the Transport service on an Exchange 2013 Mailbox server in the same Active Directory site.
- **Mail delivery** The Transport service on an Exchange 2013 Mailbox server performs recipient resolution and queries Active Directory to match an email address to a recipient account. The recipient account information includes the fully qualified domain name (FQDN) of the user's mailbox database. The Transport service queries Active Directory to determine the Active Directory site of the user's mailbox database. If the mailbox database doesn't belong to a DAG, it will deliver the message to that Mailbox server. Otherwise, it will relay the message to another Mailbox server in the same site as the target Mailbox server for delivery.
- **Message routing** The Transport service on Exchange 2013 Mailbox servers retrieves information from Active Directory to determine how mail should be routed inside the organization. Exchange 2013 uses the concept of *delivery groups* to determine where and how to route messages. Depending on the destination, the message could be routed to the Transport service or the Mailbox Transport Delivery service on an Exchange 2013 Mailbox server, or to a Hub Transport server that's running a previous version of Exchange. For more information, see Mail routing.
- **Unified Messaging message submission** The Unified Messaging service on Exchange 2013 Mailbox servers uses Active Directory site membership information to find the other Mailbox servers that are located in the same Active Directory site. The Unified Messaging service submits messages for routing to the Transport service on a Mailbox server within the same Active Directory site. The Transport service server performs recipient resolution and queries Active Directory to match a telephone number, E.164 number, or a SIP address to a recipient account. After the recipient resolution completes, the Transport service delivers the message to the target mailbox in the same way as a regular email message.
- **Client connections to Client Access server** When the Client Access server receives a user connection request, it queries Active Directory to determine which Mailbox server is hosting the user's mailbox. The Client Access server then retrieves the Active Directory site membership of that Mailbox server and proxies the connection to the Mailbox server.

Determine Active Directory site membership

Active Directory clients assume site membership by matching their assigned IP address to a subnet defined in Active Directory Sites and Services and associated with an Active Directory site. The client then uses this information to determine which domain controllers and global catalog servers exist in that site and communicates with those directory servers for authentication and

authorization purposes. Exchange 2013 takes advantage of this relationship by also preferring to retrieve information about recipients from directory servers in the same site as the Exchange 2013 server.

All computers that are part of the same Active Directory site are considered well connected, with a high-speed, reliable network connection. By default, when an Active Directory forest is first deployed, there's a single site named `Default-First-Site-Name`. If no other sites are manually configured by the administrator, all server and client computers in the forest are considered members of `Default-First-Site-Name`.

When more than one site is defined, the Active Directory administrator must define the subnets present in the organization and associate those subnets with Active Directory sites.

The Microsoft Exchange Active Directory Topology service checks the site membership attribute on the Exchange server object when the server starts. If the site attribute has to be updated, the Microsoft Exchange Active Directory Topology service stamps the attribute with the new value. The Microsoft Exchange Active Directory Topology service verifies the site attribute value every 15 minutes and updates the value if site membership has changed. The Microsoft Exchange Active Directory Topology service uses the Net Logon service to obtain current site membership. The Net Logon service updates site membership every five minutes. This means that up to a 20 minute latency period may pass between the time that site membership changes and the new value is stamped on the site attribute.

Overview of IP site links

Relationships between Active Directory sites are defined by IP site links. The IP site link consists of two or more Active Directory sites. All Active Directory sites that are part of the link communicate at the same cost. The IP site link properties include a cost assignment, a schedule, and an interval. The schedule and interval properties are only used for determining Active Directory replication frequency. Exchange 2013 uses the cost assignment to determine the lowest cost route for traffic to follow when multiple paths exist to the destination. The cost of the route is determined by aggregating the cost of all site links in a transmission path. The Active Directory administrator assigns the cost to a link based on relative network speed and available bandwidth compared to other available connections.

By default, the Transport service on a Mailbox server always tries a direct connection to the Transport service or the Mailbox Transport Delivery service on a Mailbox server in another Active Directory site. Messages in transport don't relay through the Transport service on each Mailbox server in a site link path. However, Mailbox servers in intermediate Active Directory sites along the routing path may perform message relay in the following scenarios:

- Direct relay between Mailbox servers won't occur when a hub site exists along the least cost routing path. You can configure an Active Directory site as a hub site so that messages are routed through the hub site before the messages are relayed to the target server. Hub sites are discussed later in this topic.

- Exchange 2013 uses the routing path derived from IP site link information when communication to the destination Active Directory site fails. If no Mailbox server in the destination Active Directory site responds, message delivery backs off along the least cost routing path until a connection is made to a Mailbox server in an Active Directory site along the routing path. The messages are queued in that Active Directory site and the queue will be in a retry state. This behavior is called *queue at point of failure*.
- In Exchange 2013 organizations without DAGs, the Transport service on a Mailbox server can also use the IP site link information to optimize routing of messages sent to multiple recipients. The Mailbox server delays bifurcation of messages until it reaches a fork in the routing paths to the recipients. The bifurcated message is relayed to each recipient destination by a Mailbox server in the Active Directory site that represents the fork in the individual routing paths. This functionality is called *delayed fan-out*.

Designate hub sites

You can use the **Set-AdSite** cmdlet to configure an Active Directory site as a hub site. When a hub site exists along the least cost routing path between two transport servers, messages are routed through the hub site for processing before they are relayed to the destination server. For this routing behavior to occur, the hub site must exist along the least cost routing path between two transport servers. This configuration should only be used when it's required by the network topology, such as when firewalls exist between Active Directory sites and prevent direct relay of SMTP communications. For more information, see Configure Exchange mail routing settings in Active Directory.

Set an Exchange-specific cost on an IP site link

You can use the **Set-AdSiteLink** cmdlet in the Exchange Management Shell to configure an Exchange-specific cost to an Active Directory IP site link. The Exchange-specific cost is a separate attribute used instead of the Active Directory-assigned cost to determine the Exchange routing path. This configuration is useful when the Active Directory IP site link costs don't result in an optimal Exchange message routing topology. For more information, see Configure Exchange mail routing settings in Active Directory.

Set message size restrictions on IP site links

By default, Exchange 2013 doesn't impose a maximum message size limit on messages relayed between Mailbox servers in different Active Directory sites. If you use the **Set-AdSiteLink** cmdlet to configure a maximum message size on an Active Directory IP site link, routing generates a non-delivery report (NDR) for any message that has a size larger than the maximum message size limit configured on any Active Directory site link in the least cost routing path. This configuration is useful for restricting the size of messages sent to remote Active Directory sites that must communicate over low-bandwidth connections.

Exchange 2013 server placement in Active Directory sites

For message routing between Exchange 2013 servers to occur correctly, all Exchange servers deployed in the forest must belong to an Active Directory site. Make sure that the IP addresses that you have assigned are in subnets that are correctly associated with Active Directory sites.

The first step in planning the placement of Exchange 2013 servers in the Active Directory site topology is to document the current topology. Your documentation should include the following:

- Sites
- Subnets and their site association
- IP site links and their member sites
- IP site link costs
- Directory servers in each site
- Physical network connections
- Firewall locations

After you have diagrammed these objects, plan the placement of Exchange servers. Consider the following information when deciding where to put servers:

- A Mailbox server needs to communicate directly with a global catalog server to perform Active Directory lookups.
- We recommend that you deploy more than one Mailbox server in each Active Directory site to provide load balancing and fault tolerance.
- DAGs and site resilience
- The Unified Messaging service on Mailbox servers submits voice mail messages to the Transport service on Mailbox servers for delivery to mailboxes. The Client Access server that's running the Unified Messaging Call Router service may be located in a hub site or near the IP or Voice over IP (VoIP) gateway, IP Private Branch eXchange (IP PBX), SIP-enabled PBX, or session border controllers (SBC). The Transport service on a Mailbox server that has the same site membership as the Client Access server will receive voice mail messages for transport and route the messages to the Transport service on other Mailbox servers in the organization.
- Client Access servers provide a connectivity point to the Exchange organization for users who are accessing Exchange remotely. A Client Access server must be deployed in each Active Directory site that contains Mailbox servers.

After you plan your Exchange 2013 server placement, you may identify areas where you can modify the Active Directory site topology to improve communication flow. You may want to adjust IP site links and site link costs to optimize mail delivery. An efficient Active Directory topology doesn't require any changes to support Exchange 2013

Configure Exchange mail routing

settings in Active Directory

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

By default Microsoft Exchange Server 2013 references the IP site link objects in Active Directory to help determine the least-cost routing path. However, if you determine the Active Directory IP site link costs and traffic flow patterns aren't optimal for mail routing in Exchange, you can configure settings in Active Directory that are only used by Exchange to help optimize mail flow.

What do you need to know before you begin?

- Estimated time to complete each procedure: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Active Directory site and site link management" entry in the Mail flow permissions topic.
- You can only use the Shell to perform this procedure.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to configure an Exchange-specific cost on an Active Directory IP site link

Determine the name of the Active Directory IP site link for which you want to set an Exchange cost. A lower cost value indicates a more preferred route. You can examine the contents of the routing table logs and view the data in the **ADTopologyPath ID** section to view details about the calculated least cost routing path between two Active Directory sites.

To set an Exchange-specific cost on an Active Directory site link, run the following command:

```
Set-AdSiteLink <ADSiteLinkIdentity> -ExchangeCost <Integer
| $null>
```

This example sets an Exchange-specific cost of 10 on the IP site link named IPSiteLinkAB.

```
Set-AdSiteLink IPSiteLinkAB -ExchangeCost 10
```

This example clears the Exchange cost from the IP site link named IPSiteLinkAB.

```
Set-AdSiteLink IPSiteLinkAB -ExchangeCost $null
```

How do you know this worked?

To verify that you have successfully set an Exchange cost on an Active Directory site link, do the following:
1. Run the following command:

```
Get-AdSiteLink | Format-List Name,ExchangeCost
```

2. Verify the Exchange cost is configured on the Active Directory site link.

Use the Shell to configure an Active Directory site as a hub site

When a hub site exists along the least cost routing path for a message, the message must be routed through the hub site. Examine the contents of the routing table logs and view the data in the **ADTopologyPath ID** section to verify that the selected site exists along the least cost routing path between two Active Directory sites. If this isn't the case, you need to assign Exchange-specific costs to the IP site links to make the least cost routing path go through the selected sites.

To configure an Active Directory site as a hub site, run the following command:

```
Set-AdSite <ADSiteIdentity> -HubSiteEnabled $true
```

This example configures the Active Directory site named Site A as a hub site.

```
Set-AdSite "Site A" -HubSiteEnabled $true
```

This example removes the hub site attribute from the Active Directory site named Site B.

```
Set-AdSite "Site B" -HubSiteEnabled $false
```

How do you know this worked?

To verify that you have successfully configured an Active Directory site as a hub site, do the following:
1. Run the following command:

```
Get-AdSite | Format-List Name,HubSiteEnabled
```

2. Verify the *HubSiteEnabled* value is `True` for the Active Directory site.

Route mail between Active Directory sites

Topic Last Modified: *2012-12-10*

An Active Directory site is a logical configuration component that's based on the physical aspects of the network. The primary purpose for creating an Active Directory site is to define which subnets in the network are connected in a way that optimizes control of Active Directory replication traffic. Microsoft Exchange Server 2013 recognizes both database availability groups (DAGs) and Active Directory sites as routing boundaries, and Exchange 2013 servers make routing decisions based on the Active Directory site topology.

By default, an Active Directory forest contains only one Active Directory site. The default name for this Active Directory site is `Default-First-Site-Name`. If no other Active Directory sites are created, all domain member computers in the forest are members of `Default-First-Site-Name`. You don't have to configure a subnet-to-site association. If additional Active Directory sites are created, you need specify the subnets that are assigned to that Active Directory site.

Contents

Determining site membership

Each Active Directory site is associated with one or more IP subnets. An administrator assigns Active Directory site membership to computers that are configured as domain controllers and global catalog servers. Other domain member computers, such as Exchange servers, are assigned Active Directory site membership automatically when they're configured to use an IP address that's in an IP subnet that's associated with an Active Directory site. Computers that have the same Active Directory site membership are presumed to have good network connectivity. A server is always a member of a single Active Directory site.

When an application can determine the Active Directory site membership of the computer where it's installed and of other computers in the forest, and then use that information to control communication flow, it's a site-aware application. When site-aware applications must use the

services of another server, such as a domain controller or global catalog server, priority is given to the servers that have the same Active Directory site membership as the computer that's requesting those services.

Exchange 2013 is a site-aware application and uses the Active Directory topology for message routing and to communicate with the services that are running on other Exchange 2013 computers. The Active Directory site isn't only a routing boundary. It's also a service discovery boundary.

Determining site membership for a domain member computer depends on a series of DNS queries to compare the local IP address to defined subnets and then determine the appropriate site membership association. To reduce the overhead that's associated with DNS queries, the Exchange 2013 Active Directory schema additions include the **msExchServerSite** attribute for the Exchange server object. The value of this attribute is the distinguished name of the Active Directory site of an Exchange server. This attribute is a property of each Exchange server object. When site membership affinity is stored as an attribute of the server object, the current topology can be read directly from Active Directory instead of relying on DNS queries and a site membership association is enabled for a non-domain computer, such as a subscribed Edge Transport server.

The value for the **msExchServerSite** attribute is populated and kept up to date by the Microsoft Exchange Active Directory Topology service. When a Windows-based computer starts, the Net Logon service determines site membership for the computer. The Net Logon service uses that information to locate domain controllers that are located in the same Active Directory site as the local computer and then directs authorization and authentication requests to those servers. The Microsoft Exchange Active Directory Topology service uses the **DsGetSiteName** API call to retrieve the site membership value from the Net Logon service and writes the Active Directory site's distinguished name to the **msExchServerSite** attribute for the Exchange server object in Active Directory.

The following table shows how an organization might define Active Directory sites. In this example, three Active Directory sites are defined, and each Active Directory site is associated with more than one IP subnet.

Example of an Active Directory site-to-subnet association

Active Directory site name	Associated IP subnets
Site A	192.168.1.0/24 192.168.2.0/24
Site B	192.168.3.0/24 192.168.4.0/24
Site C	192.168.5.0/24 192.168.6.0/24

If a server named Mailbox01 has the IP address of 192.168.1.1, it's a member of Site A. By changing the IP address of a server, you may change its site membership. If you change the IP address of Mailbox01 to 192.168.2.1, it won't change the server's Active Directory site membership because that subnet is also associated with Site A. However, if you move the server and the IP address changes to 192.168.3.1, the server would be considered a member of Site B.

A change in site membership can also occur if you change the association of subnets to Active Directory sites. For example, if you remove the subnet 192.168.3.0 from association with Site B and associate it with Site A, the site membership of a server that has the IP address of 192.168.3.1 also changes to Site A. Whenever a change in site membership occurs, Exchange must update its configuration data so that the change is considered when Exchange makes routing decisions. Some latency occurs between the time that a change in an Active Directory site membership occurs and the topology change is fully propagated.

Return to top

IP site links

Site links are logical paths between Active Directory sites. A site link object represents a set of sites that can communicate at a uniform cost. Site links don't correspond to the actual path taken by network packets on the physical network. However, the cost assigned to the site link by the administrator typically relates to the underlying network reliability, speed, and available bandwidth. For example, the Active Directory administrator would assign a lower cost to a network connection with a speed of 100 megabits per second (Mbps) than to a network connection with a speed of 10 Mbps.

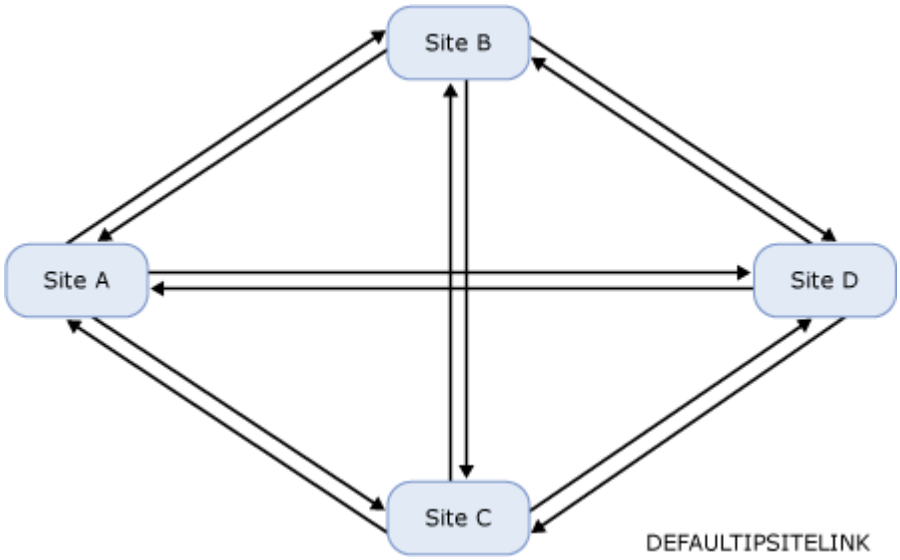
By default, all site links are transitive. This means that if Site A has a link to Site B, and Site B has a link to Site C, Site A is transitively linked to Site C. The transitive link between Site A and Site C is also known as a *site-link bridge*.

Exchange uses only IP site links to determine its Active Directory site routing topology. The cost that's assigned to the IP site link will be considered by the routing component of Exchange when calculating a routing table. These costs are used to calculate the least-cost routing path to the ultimate destination for a message.

Every Active Directory site must be associated with at least one IP site link. There is a single default IP site link named `DEFAULTIPSITELINK`. When you create an Active Directory site, you need to associate that site to an IP site link. You can create additional IP site links to implement the desired topology, or you can associate every Active Directory site to the `DEFAULTIPSITELINK`. Each Active Directory site that's part of an IP site link can communicate directly with every other site in that link at a uniform cost.

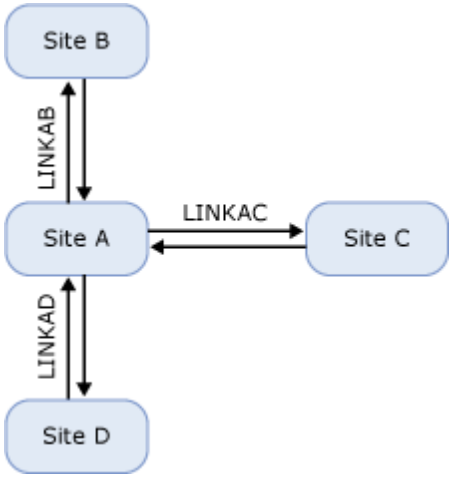
In the following figure, four Active Directory sites are configured in the forest. Every site has been associated with the `DEFAULTIPSITELINK`. Therefore, each Active Directory site communicates directly with every other site by using the same cost metric. More than one communication path is indicated, but only a single IP site link is defined.

Full mesh topology with a single IP site link



In the following figure, four Active Directory sites are configured in the forest. In this topology, the administrator has configured IP site links to create a *hub-and-spoke topology* of Active Directory sites. Each spoke site can communicate directly with the central site, and the spoke sites can communicate with one another by using the transitive IP site links.

Hub-and-spoke topology of Active Directory IP site links



It's important to note that Exchange uses site links when determining the least-cost path, but will always try to deliver messages directly to the destination Exchange server. For example, if a user in Site B in the topology shown in the preceding figure sends a message to another user in Site C, the Mailbox server in Site B will connect directly to the Mailbox server in Site C. If you want to force messages to go through Site A, you must enable that site as a hub site. For more information about hub sites, see "Implementing Hub Sites" later in this topic.

An Active Directory administrator implements the topology that best represents the connectivity and communication requirements of the forest. Because the same topology is used by Exchange, you need to make sure that the current topology supports efficient messaging communication.

The default cost for a site link is 100. A valid site link cost can be any number from 1 through 99,999. If you specify redundant links, the link with the lowest cost assignment is always preferred. An Exchange organization administrator can assign an Exchange-specific cost to an IP site link. If an

Exchange cost is assigned to an IP site link, it will be used by Exchange. Otherwise, the Active Directory cost is used. For more information about how to set an Exchange cost on an IP site link, see "Controlling IP Site Link Costs" later in this topic. An administrator who has membership in the Enterprise Administrators group can create additional IP site links.

For more information about Active Directory site configuration, see Designing the Site Topology.

Return to top

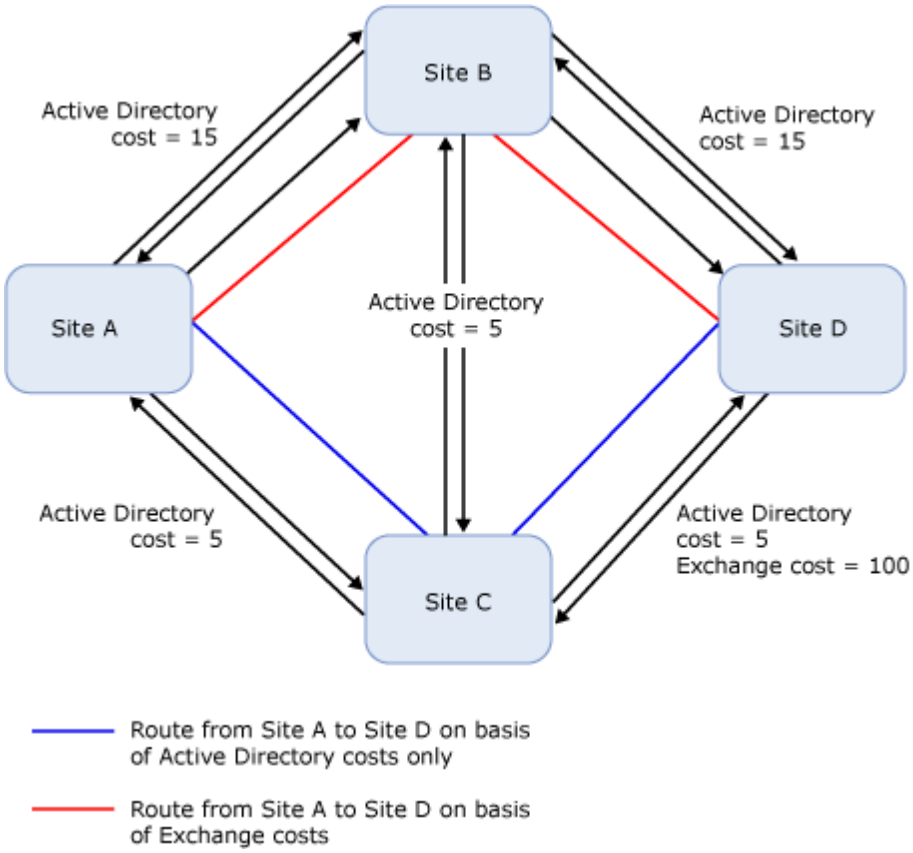
Controlling IP site link costs

Active Directory IP site links costs are based on relative network speed compared to all network connections in the WAN and are designed to produce a reliable and efficient replication topology. Therefore, in most cases, the existing IP site link costs should work well for Exchange message routing. However, if after documenting the existing Active Directory site and IP site link topology, you verify that the Active Directory IP site link costs and traffic flow patterns aren't optimal for Exchange, you can make adjustments to the costs evaluated by Exchange. Changing the cost assigned to the IP site link by using Active Directory tools would impact the entire environment. Instead, use the **Set-AdSiteLink** cmdlet in the Exchange Management Shell to assign an Exchange-specific cost to the IP site link. For example, to configure the Exchange-specific cost value of 25 on the IP site link named SITELINKAB, run the following command in the Shell: `Set-AdSiteLink SITELINKAB -ExchangeCost 25`.

When an Exchange-specific cost is assigned to an IP site link, the Exchange cost overrides the Active Directory cost for message routing purposes, and routing only considers the Exchange cost when it evaluates the least-cost routing path.

Adjusting IP site link costs can be useful when the message routing topology has to diverge from the Active Directory replication topology. Exchange costs can be used to force all message routes to use a hub site. Exchange costs can also be used to control where messages are queued when communication to an Active Directory site fails. The following figure shows an Active Directory topology with four sites.

Topology with Exchange costs configured on IP site links



In the preceding figure, the network connection between Site C and Site D is a low bandwidth connection that's only used for Active Directory replication and shouldn't be used for message routing. However, the Active Directory IP site link costs cause that link to be included in the least-cost routing path from any other Active Directory site to Site D. Therefore, messages are delivered to the Site D queue in Site C. The Exchange administrator prefers that the least-cost routing path include Site B instead so that if Site D is unavailable, the messages will queue at Site B. Configuring a high Exchange cost on the IP site link between Site C and Site D prevents that IP site link from being included in the least-cost routing path to Site D.

Exchange provides support for configuration of a maximum message size limit on an Active Directory IP site link. By default, Exchange doesn't impose a maximum message size limit on messages that are relayed between Exchange servers in different Active Directory sites. If you use the **Set-AdSiteLink** cmdlet to configure a maximum message size on an Active Directory IP site link, routing generates a non-delivery report (NDR) for any message that has a size larger than the maximum message size limit that's configured on any Active Directory site link in the least-cost routing path. This configuration is useful for restricting the size of messages that are sent to remote Active Directory sites that must communicate over low-bandwidth connections. For more information, see Message size limits.

Return to top

Implementing hub sites

In your Exchange organization, you may want to force all message delivery through a specific Active Directory site. You can use the Shell to designate an Active Directory site as a hub site. When

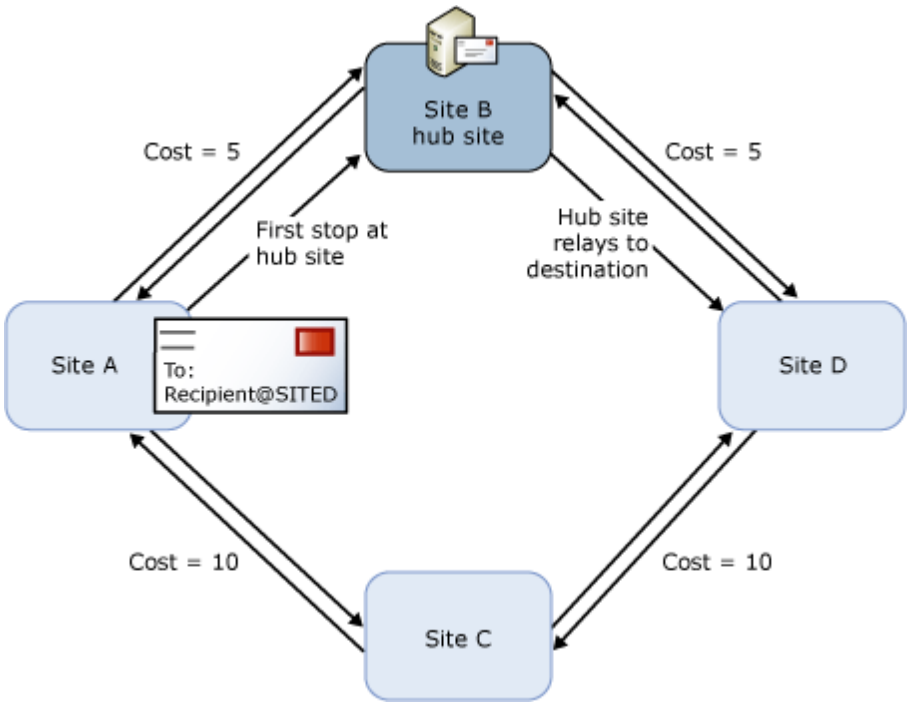
you do this, you cause additional overall overhead because more servers are involved in message delivery. For example, consider a message that's sent from Site A to Site E. If the least-cost routing path is Site A-Site B-Site C-Site D-Site E, and you designate Site C as a hub site, the message is relayed from Site A to Site C and then relayed from Site C to Site E.

You use the **Set-AdSite** cmdlet to specify an Active Directory site as a hub site. Whenever a hub site exists along the least-cost routing path for message delivery, the messages are queued and are processed by the Transport service on Mailbox servers in the hub site before they're relayed to their ultimate destination.

After the least-cost routing path is chosen, routing determines whether there's a hub site along that routing path. If a hub site is configured, messages stop at a Mailbox server in the hub site before they're relayed to the target destination. If there's more than one hub site along the least-cost routing path, messages stop at each hub site along the routing path.

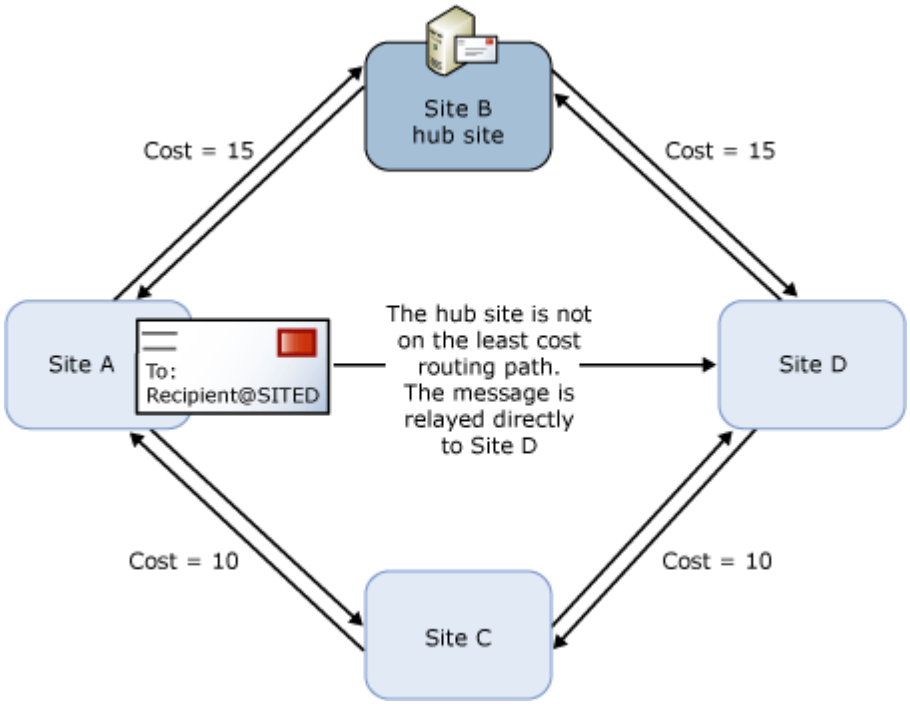
This variation to direct relay routing only is in effect when the hub site is located along the least-cost routing path. The following figure shows the correct use of a hub site. In this diagram, Site B is configured as a hub site. Messages that are relayed from Site A to Site D are relayed through Site B before they're delivered to Site D.

Message delivery with a hub site



The following figure shows how IP site link costs affect routing to a hub site. In this scenario, Site B has been designated as a hub site. However, Site B doesn't exist along the least-cost routing path between any other sites. Therefore, messages that are relayed from Site A to Site D are never relayed through Site B. An Active Directory site is never used as a hub site if it isn't on the least-cost routing path between two other sites.

Misconfigured hub site



You can configure any Active Directory site as a hub site. However, for this configuration to work correctly, you must have at least one Mailbox server in the hub site.

Return to top

Topology discovery

The Active Directory topology is made available to Exchange by the following required elements:

- The Microsoft Exchange Active Directory Topology service.
- The topology discovery module inside the Microsoft Exchange Transport service.

The Microsoft Exchange Active Directory Topology service runs on all Exchange 2013 Client Access servers and Mailbox servers. These servers use the Microsoft Exchange Active Directory Topology service to discover the domain controllers and global catalog servers that can be used by the Exchange servers to read and write Active Directory data. Exchange 2013 binds to the identified directory servers whenever Exchange has to read from or write to Active Directory.

The topology discovery module is part of the Microsoft Exchange Transport service and provides information about the Active Directory topology to Exchange servers. This API discovers the Exchange servers and roles in the organization and determines their relationship to the Active Directory configuration objects. Configuration data is retrieved from Active Directory and then cached so that it can be accessed by the Exchange services that are running on that computer.

The topology discovery module performs the following steps to generate an Exchange routing topology:

1. Data is read from Active Directory. All the following objects are retrieved:
   - Active Directory sites.
   - IP site links.
   - All Exchange servers.
2. The data that's retrieved in step 1 is used to create the initial topology and to begin linking and

mapping the related configuration objects.
3. Exchange servers are matched to Active Directory sites by retrieving the site attribute value from the Exchange server object that's stored in Active Directory.
4. Routing tables are updated with the collection of information retrieved.

This process makes every Exchange 2013 server aware of the other Exchange servers in the organization and of how close the Exchange servers are to one another.

Return to top

Recipient resolution

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-22*

Recipient resolution is the process of expanding and resolving all the recipients in a message. The act of resolving the recipients matches a recipient to the corresponding Active Directory object in the Microsoft Exchange organization. The act of expanding the recipients expands all distribution groups into a list of individual recipients. Recipient resolution allows message limits and alternative recipients to be applied correctly to each recipient.

In a Microsoft Exchange Server 2013 organization, recipient resolution is performed by the categorizer in the Transport service on Mailbox servers. Categorization on each message happens after a newly arrived message is put in the Submission queue. Recipient resolution, in addition to content conversion and routing, is performed on the message before the message is put in a delivery queue. The categorizer performs recipient resolution before routing. The component of the categorizer that's responsible for recipient resolution is frequently called the *resolver*.

Contents

Top-level resolution

Top-level resolution is the first stage of recipient resolution. Top-level resolution associates each recipient in an incoming message to a matching recipient object in Active Directory. During top-level resolution, the categorizer creates a list that contains the sender and the initial, unexpanded

recipient email addresses that exist within the message. The categorizer then uses that list of email addresses to query Active Directory to find any mail-enabled objects that have matching email address attributes. When a match is found, the properties of matching Active Directory objects are cached for later use. Any sender message restrictions are also enforced.

Recipient email addresses

Top-level resolution begins with a message and the initial, unexpanded list of recipients from the *message envelope*. The message envelope contains the commands that are used to transmit messages among SMTP messaging servers. The sender's email address is contained in the **MAIL FROM:** command. Each recipient's email address is contained in a separate **RCPT TO:** command. The envelope sender and envelope recipients are typically created from the sender and recipients in the `To:`, `From:`, `Cc:`, and `Bcc:` header fields in the message header. However, this isn't always true. The `To:`, `From:`, `Cc:`, and `Bcc:` header fields in a message are easily forged and may not match the actual sender or recipient email addresses that were used to transmit the message.

Encapsulated email addresses

Standard SMTP email addresses follow the specifications of RFC 2821 and RFC 2822, such as chris@contoso.com, for example. However, an email address can also be a non-SMTP email address that's encapsulated inside a valid SMTP address. Exchange supports encapsulated addresses that use the Internet Mail Connector Encapsulated Address (IMCEA) encapsulation method.

This encapsulation method requires the encoding of any characters that are invalid in SMTP email addresses. Alphanumeric characters, the equal sign (=) and the hyphen (-) don't require encoding. Other characters use the following encoding syntax:

- A forward slash (/) is replaced by an underscore (_).
- Other US-ASCII characters are replaced by a plus sign (+) and the two digits of its ASCII value are written in hexadecimal. For example, the space character has the encoded value `+20`.

The IMCEA encapsulation method uses the following syntax: `IMCEA<Type>-<address>@<domain>`

The placeholder <*Type*> identifies the type of non-SMTP address, for example `EX`, `X400`, or `FAX`.

Note:

Although `SMTP` and `X500` are theoretically valid values for <*Type*>, Exchange recipient resolution rejects any IMCEA-encoded addresses that use either of these types.

The placeholder <*address*> is the encoded original address. The placeholder <*domain*> represents the SMTP domain that's used to encapsulate the non-SMTP address, for example, contoso.com

With the IMCEA encapsulation method, addresses are unencapsulated only when the domain matches the default authoritative domain in the Exchange organization. For more information about accepted domains, see Accepted domains.

The maximum length for an SMTP email address in Exchange is 571 characters. This limit includes the following:

- 315 characters for the name part of the address
- 255 characters for the domain name
- The at sign (@) character that separates the name part of the address from the domain name

Note that Exchange doesn't support messages that are encoded with the IMCEA encapsulation method when the name part of the address exceeds 315 characters, even if the complete email address is less than 571 characters.

Address resolution

For each message, the sender email address and all recipient email addresses are added to a list that's used to query Active Directory. Any encapsulated addresses are unencapsulated before they're added to the list of email addresses. The Active Directory query is performed on up to 20 email addresses at a time. If the Active Directory query encounters any transient errors, the message is returned to the Submission queue and deferred for the time that's specified by the *ResolverRetryInterval* key in the `%ExchangeInstallPath%Bin\EdgeTransport.exe.config` XML application configuration file that's associated with the Microsoft Exchange Transport service. The default value is 30 minutes.

The following table describes the recipient objects that are found in Active Directory. For more information about Exchange recipient types, see Recipients.

Recipient objects in Active Directory

Active Directory recipient type	Description
DistributionGroup	Any mail-enabled group object. The distribution group object types are as follows: • **MailUniversalDistributionGroup** A universal distribution group object • **MailUniversalSecurityGroup** A universal security group (USG) object that has an email address • **MailNonUniversalGroup** A local security group object or global security group object that has an email address
DynamicDistributionGroup	An object that has the Active Directory class **msExchDynamicDistributionList**. For more information, see Manage dynamic distribution groups.

Mailbox	A user object that has an email address and a defined *Database* parameter
MailUser	A user object that has an email address without a defined *Database* parameter. For more information, see Manage mail users.
MailContact	A contact object that has an email address. Typically, a mail contact is used for recipients outside the Exchange organization. A mail contact is also used in cross-forest Exchange environments. For more information, see Manage mail contacts.
MailPublicFolder	A public folder object that has an email address.
MicrosoftExchangeRecipient	An object that has the Active Directory class **msExchExchangeServerRecipient**. For more information about the Microsoft Exchange recipient object, see Recipients.
SystemAttendantMailbox	An object that has the Active Directory class **exchangeAdminService**. There should be only one system attendant mailbox in the Exchange organization.
SystemMailbox	A user object that has an email address and that's located in the Microsoft Exchange System Objects container. There should be one system mailbox for each mailbox database in the Exchange organization.

An object that contains missing or malformed critical properties is classified by the Active Directory query as an invalid object. For example, a dynamic distribution group object without an email address is considered invalid. Messages that are sent to recipients that are classified as invalid objects generate a non-delivery report (NDR).

For each email address, a single initial query is performed for all possible recipient properties, such

as the recipient identifiers, recipient type, message limits, email addresses, and alternative recipients. The applicable properties for the recipient are cached for later use. Recipient resolution classifies the recipients based on similarities in how the recipients are resolved, and the similarity of the applicable recipient properties.

The LDAP filter that's used for address resolution is described as follows:

- For the **EX** email address type, the LDAP filter is based on the recipient **legacyExchangeDN** Active Directory attribute or the recipient **proxyAddresses** Active Directory attribute. The **legacyExchangeDN** Active Directory attribute takes precedence.
- For all other email addresses types, the recipient **proxyAddresses** Active Directory attribute is used as the LDAP filter.

If the email address that's used in the message doesn't match the primary SMTP address of the corresponding Active Directory object, the categorizer rewrites the email address in the message to match the primary SMTP address. The original email address is saved in the ORCPT= entry in the **RCPT TO:** command in the message envelope.

Sender message restrictions

The size that's used for the sender message size restriction is the value of the **X-MS-Exchange-Organization-OriginalSize:** header field in the message header. Exchange uses this header field to record the original message size of the message when it entered the Exchange organization. Whenever the message is checked against the specified message size limits, the lower value of the current message size or the original message size header is used. The size of the message can change because of content conversion, encoding, and agent processing. If this header field doesn't exist, it's created by using the current message size value. If the message is too large, an NDR is generated and additional message processing is stopped.

The sender recipient limit is only enforced in the Transport service on the first Mailbox server that processes the message. The original, unexpanded message envelope recipient count is compared to the sender recipient limit. The original, unexpanded message envelope recipient count is used to avoid the partial message delivery problems that occured in Microsoft Exchange Server 2003 when nested distribution lists used remote expansion servers.

The message sender and all recipients are marked as resolved by stamping an extended property in the message. This extended property allows the message to bypass top-level resolution if the message must go through recipient resolution again. A message may have to go through recipient resolution again because the Microsoft Exchange Transport service restarted.

Return to top

Expansion

Expansion occurs after top-level resolution. Expansion completely expands nested levels of recipients into individual recipients. Expansion may require multiple trips through the expansion

process to expand all recipients. Not all recipients have to be expanded. However, all recipients must go through the expansion process. The expansion process also enforces recipient message restrictions for all kinds of recipients.

The following list describes the kinds of recipients that require expansion:

- **Distribution groups and dynamic distribution groups** Distribution groups are expanded based on the **memberOf** Active Directory property. Dynamic distribution groups are expanded by using the Active Directory query definition. If the *ExpansionServer* parameter is set on the group, the group isn't expanded by the current server. The distribution group is routed to the specified server for expansion.

Note:

If you select a specific transport server in your organization as the expansion server, the distribution group usage becomes dependent on the availability of the expansion server. If the expansion server is unavailable, any messages that are sent to the distribution group can't be delivered. If you plan to use specific expansion servers for your distribution groups, to reduce the risk of service interruption, you should consider implementing high availability solutions for these servers.

- **Alternative recipients** The *ForwardingAddress* parameter may be set on mailboxes and mail-enabled public folders. The *ForwardingAddress* parameter redirects all messages to the specified alternative recipient. This is known as a *forwarded recipient*. When an alternative delivery address is specified in the *ForwardingAddress* parameter and the *DeliverToMailboxAndForward* parameter is set to `$true`, the message is delivered to the original recipient and the alternative recipient. This is known as *delivered and forwarded recipient*.
- **Contact chains** A *contact chain* is a mail user or mail contact that has the *ExternalEmailAddress* parameter set to the email address of another recipient in the Exchange organization.

Detection of recipient loops

As the distribution groups, alternative recipients, and contacts chains are expanded, the categorizer checks for *recipient loops*. A recipient loop is a recipient configuration problem that causes message delivery to the same recipients in an endless circle. The following list describes the different types of recipient loops:

- **Harmless recipient loop** A harmless recipient loop results in successful message delivery. The following list describes two scenarios when harmless recipient loops occur:
  - When two distribution groups contain one another as members.
  - When mailboxes or mail-enabled public folders are set to deliver and forward to one another. This happens when the *DeliverToMailboxAndForward* parameter of both recipients is set to `$true` and the *ForwardingAddress* parameter is set to one another.

When a harmless recipient loop is detected, the message is delivered to the recipient, but no additional attempts are made to deliver the message to the same recipient.

- **Broken recipient loop** A broken recipient loop can't result in successful message delivery. An example of a broken recipient loop is when mailboxes or mail-enabled public folders have the *ForwardingAddress* parameter set to one another. When the categorizer detects a broken recipient

loop, expansion activity for the current recipient stops, and an NDR is generated for the recipient.

Detection of recipient loops doesn't prevent duplicate message delivery. For example, Distribution Group C will experience duplicate message delivery if the following conditions are true:

- Distribution Group B and Distribution Group C are members of Distribution Group A.
- Distribution Group C is also a member of Distribution Group B.

Delivery report redirection for distribution groups

When a distribution group is expanded, the message type is checked to determine whether it's a delivery report message. If the message is a delivery report, the redirection settings of the distribution group are checked to determine whether redirection of the delivery report is required. You may want to suppress the delivery reports because the delivery reports may disclose unwanted information about the distribution group and its membership.

The following list describes the delivery report redirection settings that are available for distribution groups and dynamic distribution groups:

- **ReportToManagerEnabled** This parameter enables delivery reports to be sent to the distribution group manager. Valid values are `$true` or `$false`. The default value is `$false`. For a distribution group, the manager is controlled by the *ManagedBy* parameter in the **Set-Group** cmdlet. For a dynamic distribution group, the manager is controlled by the *ManagedBy* parameter in the **Set-DynamicDistributionGroup** cmdlet.
- **ReportToOriginatorEnabled** This parameter enables delivery reports to be sent to the sender of email messages that are sent to this distribution group. Valid values are `$true` or `$false`. The default value is `$true`.

Note:

The values of the *ReportToManagerEnabled* parameter and *ReportToOriginatorEnabled* parameter can't both be `$true`. If one parameter is set to `$true`, the other must be set to `$false`. The values of both parameters can be `$false`. This suppresses all redirection of all delivery report messages.

The following list describes the available delivery report messages:

- **Delivery receipt (DR)** This report confirms that a message was delivered to its intended recipient.
- **Delivery status notification (DSN)** This report describes the result of an attempt to deliver a message. For more information about DSN messages, see DSNs and NDRs.
- **Message disposition notification (MDN)** This report describes the status of a message after it has been successfully delivered to a recipient. A read notification (RN) and a non-read notification (NRN) are both examples of an MDN message. MDN messages are defined in RFC 2298 and are controlled by the **Disposition-Notification-To:** header field in the message header. MDN settings that use the `Disposition-Notification-To:` header field are compatible with many different message servers. MDN settings can also be defined by using MAPI properties in Microsoft Outlook and Exchange.
- **Non-delivery report (NDR)** This report indicates to the message sender that the message

couldn't be delivered to the specified recipients.

- **Non-read notification (NRN)** This report indicates that a message was deleted before it was read.
- **Out of office (OOF)** This report indicates that the recipient won't respond to email messages. The acronym OOF dates back to the original Microsoft messaging system where the corresponding notification was named "out of facility."
- **Read notification (RN)** This report indicates that a message was read.
- **Recall Report** This report indicates the status of a recall request for a specific recipient. A recall request is when a sender tries to recall a sent message by using Outlook.

When a delivery report message is sent to a distribution group, the following settings cause the report message to be deleted:

- Report redirection isn't set. Alternatively, report redirection is set to the message sender.
- Report redirection is set to the distribution group manager, and the delivery report message isn't an NDR.

When a delivery report message is sent to a distribution group, the delivery report message may be delivered to the distribution group manager. This happens when report redirection is set to the distribution group manager, and the report message is an NDR.

When a message that isn't a delivery report message is sent to a distribution group, the message is delivered to the distribution group members. The report request settings are summarized in the following list:

- If report redirection is set to the message sender, the report request settings aren't modified.
- If report redirection isn't set, all report request settings are suppressed. The `NOTIFY=NEVER` entry is added to **RCPT TO:** for each recipient in the message envelope.
- If report redirection is set to the distribution group manager, all report request settings are suppressed except NDR messages that are sent to the distribution group manager.

Message restrictions on recipients

The expansion process also enforces any message restrictions that are configured for recipients. These restrictions may be configured individually for each recipient or organizationally for all Hub Transport servers in the Exchange organization. The following table describes the message restrictions that are configured for recipients.

Message restrictions on recipients

Source	Parameter	Description
Set-DistributionGroup **Set-DynamicDistributionGroup** **Set-Mailbox**	*MaxReceiveSize*	The *MaxReceiveSize* parameter specifies the size that's used for message restrictions that are configured for recipients is the value of the **X-MS-Exchange-**

Set-MailContact **Set-MailPublicFolder** **Set-MailUser** **Set-TransportConfig**		**Organization-OriginalSize:** header field in the message header. Exchange uses this header field to record the original message size of the message when it entered the Exchange organization. Whenever the message is checked against the specified message size limits, the lower value of the current message size or the original message size header is used. The size of the message can change because of content conversion, encoding, and agent processing. If this header field doesn't exist, it's created by using the current message size value. If the message is too large, an NDR is generated and additional message processing is stopped.
Set-DistributionGroup **Set-DynamicDistributionGroup** **Set-Mailbox** **Set-MailContact** **Set-MailPublicFolder** **Set-MailUser**	*RequireSenderAuthenticationEnabled*	The *RequireSenderAuthenticationEnabled* parameter requires that all messages that are sent to the recipient come from authenticated senders. When the value of this parameter is set to `$true`, messages from unauthenticated senders are

		rejected. All senders who send messages to the System and System Attendant mailboxes must be authenticated.
Set-DistributionGroup **Set-DynamicDistributionGroup** **Set-Mailbox** **Set-MailContact** **Set-MailPublicFolder** **Set-MailUser**	*AcceptMessagesOnlyFromSendersOrMembers* *RejectMessagesFromSendersOrMembers*	The *AcceptMessagesOnlyFromSendersOrMembers* parameter specifies the senders or distribution groups whose members are allowed to send messages to the recipient. Note that this parameter combines the functionality of the older *AcceptMessagesOnlyFrom* and *AcceptMessagesOnlyFromDLMembers* parameters. The *RejectMessagesFromSendersOrMembers* parameter specifies the senders or distribution groups whose members aren't allowed to send messages to the recipient. Note that this parameter combines the functionality of the older *RejectMessagesFrom* and *RejectMessagesFromDLMembers* parameters. The categorizer checks the recipient permission in two passes. The first pass determines whether the sender

		is present in the *AcceptOnlyMessagesFromSendersOrMembers* or *RejectMessagesFromSendersOrMembers* parameter. If the sender isn't found in either parameter, the distribution groups in those parameters are fully expanded. This complete expansion of distribution groups may take some time. We recommend that you minimize the depth of nested distribution groups in those parameters.

Certain types of messages that are sent by authenticated senders are exempt from restrictions. The following list describes the messages that are exempt from recipient restrictions:

- **All messages that are sent by the Microsoft Exchange recipient** These messages include DSN messages, journal reports, quota messages, and other system-generated messages that are sent to internal message senders. For more information about the Microsoft recipient, see Recipients.
- **All messages that are sent by the external postmaster address** These messages include DSN messages and other system-generated messages that are sent to external message senders. For more information about the external postmaster address, see Configure the external postmaster address.

Certain types of messages are blocked when they are sent from the Exchange organization to external domains. The settings are controlled by the following parameters in the **Set-RemoteDomain** cmdlet:

- *AllowedOOFType*
- *AutoForwardEnabled*
- *AutoReplyEnabled*
- *DeliveryReportEnabled*
- *NDREnabled*

For more information, see Remote domains.

Return to top

Bifurcation and controlling recipient expansion

Because the complete list of message recipients is expanded and resolved by recipient resolution, there are occasions when different copies of the same message must be created. These occasions are described by the following scenarios:

- **When message recipients require different message settings** Message properties such as read receipts may have to be enabled for some recipients and blocked for other recipients. Creating a new version of the message that has slightly different properties than the original message is called *bifurcation*.
- **To limit the number of envelope recipients in a single message** The recipient expansion process can generate thousands of individual recipients when large distribution groups are expanded. In Exchange, instead of creating a single copy of the message that has thousands of envelope recipients, multiple copies of the same message that have a limited number of envelope recipients are created.

Bifurcation

Recipient resolution bifurcates a message if the following conditions are true:

- When the message sender in **MAIL FROM:**, in the message envelope, is updated. An example is when the *ReportToManagerEnabled* parameter on a distribution group has a value of `$true`.
- When auto-response messages, such as DSNs, OOF messages, and recall reports must be suppressed.
- When alternative recipients are expanded.
- When a **Resent-From:** header field must be added to the message header. Resent header fields are informational header fields that can be used to determine whether a message has been forwarded by a user. Resent header fields are used so that the message appears to the recipient as if it was sent directly by the original sender. The recipient can view the message header to discover who forwarded the message. Resent header fields are defined in section 3.6.6 of RFC 2822.
- When the history of the expansion of the distribution group must be transmitted.

Controlling recipient expansion

When the number of expanded recipients is too large, the categorizer splits the message into multiple copies. This is done to reduce system resource use during message expansion. The maximum number of envelope recipients in a message is controlled by the *ExpansionSizeLimit* key in the `%ExchangeInstallPath%Bin\EdgeTransport.exe.config` application configuration file. The default value is 1000.

Caution:
We recommend that you don't modify the value of the *ExpansionSizeLimit* key on an Exchange transport server in a production environment.

Return to top

Recipient resolution diagnostics

Reporting and diagnostic information for recipient resolution is provided by performance counters, message tracking log entries, and recipient resolution logging. These sources can help you identify and diagnose problems with recipient resolution.

Recipient resolution performance counters

The following table describes the performance counters that are available for recipient resolution.

Recipient resolution performance counters

Counter name	Display name	Description
AmbiguousRecipientsTotal	Ambiguous Recipients	This is the total number of ambiguous recipients that were detected during recipient resolution. Ambiguous recipients are different recipients that have matching **legacyExchangeDN** Active Directory attributes or matching **proxyAddresses** Active Directory attributes.
AmbiguousSendersTotal	Ambiguous Senders	This is the number of ambiguous senders that were detected during recipient resolution. Ambiguous senders are different senders that have matching **legacyExchangeDN** Active Directory attributes or matching **proxyAddresses** Active Directory attributes.
FailedRecipientsTotal	Failed Recipients	This is the number of failed recipients that were detected

		during recipient resolution.
LoopRecipientsTotal	Loop Recipients	This is the number of recipients that failed recipient resolution because of recipient loops.
MessagesChippedTotal	Messages Chipped	This is the total number of copies of the same message that were created during recipient resolution to control the number of envelope recipients in a single message. In Exchange, this process is referred to as *chipping*.
MessagesCreatedTotal	Messages Created	This is the number of messages that were created during recipient resolution.
MessagesRetriedTotal	Messages Retried	This is the number of messages that were scheduled for retry during recipient resolution.
UnresolvedOrgRecipientsTotal	Unresolved Org Recipients	This is the number of unresolved recipients from an authoritative domain that were detected during recipient resolution.
UnresolvedOrgSendersTotal	Unresolved Org Senders	This is the number of unresolved senders from an authoritative domain that were detected during recipient resolution.

Recipient resolution events in the message tracking log

The following table describes the recipient resolution events that are written in the message tracking log.

Recipient resolution events in the message tracking log

Message tracking event	Description
EXPAND	This event indicates that a distribution group was expanded.
REDIRECT	This event indicates that a message sent to a mailbox recipient or a mail-enabled public folder recipient was redirected to an alternative recipient as specified by the *ForwardingAddress* parameter.
RESOLVE	This event indicates that a recipient email address was changed to the primary SMTP email address of the corresponding Active Directory recipient object.
TRANSFER	This event indicates that message bifurcation or chipping occurred.

For more information about message tracking, see Message tracking.

Recipient resolution logging

Recipient resolution logging is controlled by the *ResolverLogLevel* key in the `%ExchangeInstallPath%Bin\EdgeTransport.exe.config` application configuration file. The valid values for this key are `Disabled`, `Enabled`, and `FullContent`. The default value is `Disabled`. When the value is set to `Enabled`, only message envelope data is logged. When the value is set to `FullContent`, message envelope data and message header data is logged. The log files are stored at `%ExchangeInstallPath%Logging\Resolver`.

Note:

Any customized per-server settings you make in Exchange XML application configuration files, for example, web.config files on Client Access servers or the EdgeTransport.exe.config file on Mailbox servers, will be overwritten when you install an Exchange Cumulative Update (CU). Make sure that you save this information so you can easily re-configure your server after the install. You must re-configure these settings after you install an Exchange CU.

Return to top

DNS query failure sensitivity

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-22*

In Microsoft Exchange Server 2013, you can adjust the DNS query sensitivity for slightly faster message delivery when DNS errors are encountered for the destination domain. However, depending on the DNS errors, this adjustment may cause delivery failures in certain circumstances.

DNS queries and remote message delivery

The Exchange server that's responsible for delivering messages to external recipients must be able to find a destination messaging server that accepts mail for the external recipients. Depending on the destination, the messages are put in one or more remote delivery queues as they await delivery to the remote recipients. For more information about delivery queues, see Queues.

The Exchange server queries the configured DNS servers to find the DNS records that are required to deliver the message. The DNS servers are queried in the order in which they're listed. If one of the DNS servers is unavailable, the query goes to the next DNS server on the list. The DNS servers are queried for the following information:

- **Mail exchange (MX) records for the domain part of the external recipient** The MX record contains the fully qualified domain name (FQDN) of the messaging server that's responsible for accepting messages for the domain, and a preference value for that messaging server. A lower preference value indicates a preferred messaging server. The preference value is important if the domain has more than one MX record. To optimize fault tolerance, most organizations use multiple messaging servers and multiple MX records that have different preference values.
- **Address (A) records for the destination messaging servers** Every messaging server that's used in an MX record should have a corresponding A record. The A record is used to find the IP address of the destination messaging server. The subscribed Edge Transport server uses the IP address to open an SMTP connection with the destination messaging server. Although it's technically possible to use the FQDN of a canonical name (CNAME) record in an MX record, this practice violates RFC 974, RFC 1034, RFC 1912, and RFC 2181, and is therefore not supported by most messaging servers.

The required combination of iterative DNS queries and recursive DNS queries that start with a root DNS server is used to resolve the FQDN of the messaging server that's found in the MX record into an IP address.

In Exchange 2013, there's a DNS query limit that's not configurable of 5 seconds for each DNS server, and a one-minute limit for the entire DNS query.

Potential DNS problems

Even when the DNS settings on the Exchange server are configured correctly, problems with the DNS records for a specific domain or problems with any of the DNS servers that are used to find the authoritative DNS server for a specific domain may still occur. Generally, these problems are beyond your control and need to be resolved by the parties that own those DNS servers. These DNS-related errors may be caused by one or more of the following conditions:

- Invalid DNS records for the destination domain
- Problems with DNS server utilization
- Problems with DNS server replication

In Exchange 2013, when a DNS query results in errors, the query continues to the next DNS server only if that DNS server hasn't already returned an error for the current query.

You can control the DNS query failure sensitivity by modifying the `%ExchangeInstallPath%bin\EdgeTransport.exe.config` XML application configuration file. This file is associated with the Microsoft Exchange Transport service. Changes you save to this file are applied after you restart the Microsoft Exchange Transport service. When you restart this service, mail flow on the server is temporarily interrupted. The DNS query failure sensitivity is controlled by the *DnsFaultTolerance* key in the EdgeTransport.exe.config file. This key uses the following values:

- **Lenient** When the DNS query encounters a combination of valid MX records and invalid MX records, the DNS query continues until the DNS query time-out value of one minute is reached. The invalid MX records are discarded, and the valid MX record that has the lowest preference value is used to deliver the message to the destination messaging server. This is the default value.
- **Normal** When the DNS query first encounters an invalid MX record, any resolved MX records that have a preference value that's greater than or equal to the invalid MX records are immediately discarded. The remaining MX record that has the lowest preference value is used to deliver the message to the destination messaging server without waiting for the whole DNS query to time out. Although this behavior may result in faster message delivery, the potential drawback of this behavior is the DNS query may have no valid MX records if the following conditions are true:
  - The invalid MX record is the first MX record for the destination domain.
  - The valid MX records have the same precedence value as the invalid MX records.

In both `Normal` mode and `Lenient` mode, the results of the DNS query for an invalid MX record are never cached. The next time that a DNS query is executed, it will try to resolve the MX records for the destination domain.

Note:

Any customized per-server settings you make in Exchange XML application configuration files, for example, web.config files on Client Access servers or the EdgeTransport.exe.config file on Mailbox servers, will be overwritten when you install an Exchange Cumulative Update (CU). Make sure that you save this information so you can easily re-configure your server after the install. You must re-configure these settings after you install an Exchange CU.

Use Telnet to test SMTP communication

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-10*

This topic explains how to use Telnet to test Simple Mail Transfer Protocol (SMTP) communication between messaging servers. By default, SMTP listens on port 25. If you use Telnet on port 25, you can enter the SMTP commands that are used to connect to an SMTP server and send a message exactly as if your Telnet session was an SMTP messaging server. You can see the success or failure of each step in the connection and message submission process.

Here are the scenarios where you may want to use Telnet to test SMTP communication to or from the transport servers that exist in your Microsoft Exchange organization:

- Connect to your organization's Internet-facing Exchange server from a host that is located outside your perimeter network and send a test message.
- Connect to a remote messaging server from your organization's Internet-facing Exchange server and send a test message.

The procedure in this topic shows you how to use Telnet Client, which is a component that is included with Microsoft Windows. Third-party Telnet clients may require a syntax that is different from that of the Windows Telnet component.

What do you need to know before you begin?

- Estimated time to complete: 30 minutes
- Exchange permissions don't apply to the procedures in this topic. These procedures are performed in the operating system of the Exchange Server or a client computer.
- The procedures in this topic are best used to connect to and from Internet-facing servers that allow anonymous connections. Message transmission between internal Exchange servers is encrypted and authenticated. To use Telnet to connect to the Hub Transport service on a Mailbox server, you'll need to create a Receive connector that's configured to allow anonymous access or Basic authentication to receive messages. If the connector allows Basic authentication, you need a utility to convert the text strings that are used for the username and password into the Base64 format. Because the user name and password are easily discernible when Basic authentication is used, we don't recommend Basic authentication without encryption.
- If you connect to a remote messaging server, consider performing the procedures in this topic on your Internet-facing Exchange server. This will help to avoid rejection of the test message by remote messaging servers that are configured to validate the source IP address, the

corresponding domain name system (DNS) domain name, and the reverse lookup IP address of any Internet host that tries to send a message to the server.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

How do you do this?

Step 1: Install the Telnet Client in Windows

By default, the Telnet Client isn't installed in most client or server versions of the Microsoft Windows operating systems. To install it, see Install Telnet Client.

Step 2: Use Nslookup to find the FQDN or IP address in the MX record of the remote SMTP server

To connect to a destination SMTP server by using Telnet on port 25, you must use the fully qualified domain name (FQDN) or the IP address of the SMTP server. If the FQDN or IP address is unknown, the easiest way to find this information is to use the Nslookup command-line tool to find the MX record for the destination domain.

1. At a command prompt, type **nslookup**, and then press ENTER. This command opens the Nslookup session.
2. Type **set type=mx** and then press ENTER.
3. Type **set timeout=20** and then press ENTER. By default, Windows DNS servers have a 15-second recursive DNS query time-out limit.
4. Type the name of the domain for which you want to find the MX record. For example, to find the MX record for the fabrikam.com domain, type **fabrikam.com.**, and then press ENTER.

Note:

The trailing period (**.**) indicates a FQDN. The use of the trailing period prevents any default DNS suffixes that are configured for your network from being unintentionally added to the domain name.

The output of the command will resemble the following:

```
fabrikam.com mx preference=10, mail exchanger =
mail1.fabrikam.com
fabrikam.com mx preference=20, mail exchanger =
mail2.fabrikam.com
```

```
mail1.fabrikam.com internet address = 192.168.1.10
mail2 fabrikam.com internet address = 192.168.1.20
```

You can use any of the host names or IP addresses that are associated with the MX records as the destination SMTP server. A lower value of preference indicates a preferred SMTP server. You can use multiple MX records and different values of preference for load balancing and fault tolerance.

5. When you're ready to end the Nslookup session, type **exit**, and then press ENTER.

Note:

Firewall or Internet proxy restrictions that are imposed on your organization's internal network may prevent you from using the Nslookup tool to query public DNS servers on the Internet.

Step 3: Use Telnet on Port 25 to test SMTP communication

In this example, the following values are used:

- **Destination SMTP server** mail1.fabrikam.com
- **Source domain** contoso.com
- **Sender's e-mail address** chris@contoso.com
- **Recipient's e-mail address** kate@fabrikam.com
- **Message subject** Test from Contoso
- **Message body** This is a test message

Note:

- The commands in Telnet Client are not case-sensitive. The SMTP command verbs are capitalized for clarity.
- You can't use the backspace key after you have connected to the destination SMTP server within the Telnet session. If you make a mistake as you type an SMTP command, you must press ENTER and then type the command again. Unrecognized SMTP commands or syntax errors result in an error message that resembles the following:

```
500 5.3.3 Unrecognized command
```

1. At a command prompt, type **telnet**, and then press ENTER. This command opens the Telnet session.
2. Type **set localecho** and then press ENTER. This optional command lets you view the characters as you type them. This setting may be required for some SMTP servers.
3. Type **set logfile** <*filename*>. This optional command enables logging of the Telnet session to the specified log file. If you only specify a file name, the location of the log file is the current working directory. If you specify a path and a file name, the path must be local to the computer. Both the path and the file name that you specify must be entered in the Microsoft DOS 8.3 format. The path that you specify must already exist. If you specify a log file that doesn't exist, it will be created for you.
4. Type **open mail1.fabrikam.com 25** and then press ENTER.

5. Type **EHLO contoso.com** and then press ENTER.
6. Type **MAIL FROM:chris@contoso.com** and then press ENTER.
7. Type **RCPT TO:kate@fabrikam.com NOTIFY=success,failure** and then press ENTER. The optional NOTIFY command defines the particular delivery status notification (DSN) messages that the destination SMTP server must provide to the sender. DSN messages are defined in RFC 1891. In this case, you're requesting a DSN message for successful or failed message delivery.
8. Type **DATA** and then press ENTER. You will receive a response that resembles the following:

```
354 Start mail input; end with <CLRF>.<CLRF>
```

9. Type **Subject: Test from Contoso** and then press ENTER.
10. Press ENTER. RFC 2822 requires a blank line between the `Subject:` header field and the message body.
11. Type **This is a test message** and then press ENTER.
12. Press ENTER, type a period (`.`) and then press ENTER. You will receive a response that resembles the following:

```
250 2.6.0 <GUID> Queued mail for delivery
```

13. To disconnect from the destination SMTP server, type **QUIT** and then press ENTER. You will receive a response that resembles the following:

```
221 2.0.0 Service closing transmission channel
```

14. To close the Telnet session, type **quit** and then press ENTER.

Step 4: Evaluate the Results of the Telnet Session

This section provides information about responses that may be provided to the following commands, which were used in the previous example:

- Open mail1.fabrikam.com 25
- EHLO contoso.com
- MAIL FROM:chris@contoso.com
- RCPT TO:kate@fabrikam.com NOTIFY=success,failure

Note:
The 3-digit SMTP response codes that are defined in RFC 2821 are the same for all SMTP messaging servers. The text descriptions may differ slightly for some SMTP messaging servers.

Open mail1.fabrikam.com 25

Successful Response `220 mail1.fabrikam.com Microsoft ESMTP MAIL Service ready at <day-date-time>`

Failure Response `Connecting to mail1.fabrikam.com...Could not open connection to the host, on port 25: Connect failed`

Possible Reasons for Failure

- The destination SMTP service is unavailable.

- There are restrictions on the destination firewall.
- There are restrictions on the source firewall.
- An incorrect FQDN or IP address for the destination SMTP server was specified.
- An incorrect port number was specified.

EHLO contoso.com

Successful Response `250 mail1.fabrikam.com Hello [<sourceIPaddress>]`

Failure Response `501 5.5.4 Invalid domain name`

Possible Reasons for Failure There are invalid characters in the domain name. Alternatively, there are connection restrictions on the destination SMTP server.

Note:

EHLO is the Extended Simple Message Transfer Protocol (ESMTP) verb that is defined in RFC 2821. ESMTP servers can advertise their capabilities during the initial connection. These capabilities include their maximum accepted message size and their supported authentication methods. HELO is the older SMTP verb that is defined in RFC 821. Most SMTP messaging servers support ESMTP and EHLO.

MAIL FROM:chris@contoso.com

Successful Response `250 2.1.0 Sender OK`

Failure Response `550 5.1.7 Invalid address`

Possible Reasons for Failure There is a syntax error in the sender's e-mail address.

Failure Response `530 5.7.1 Client was not authenticated`

Possible Reasons for Failure The destination server does not accept anonymous message submissions. You receive this error if you try to use Telnet to submit a message directly to a Hub Transport server.

RCPT TO:kate@fabrikam.com NOTIFY=success,failure

Successful Response `250 2.1.5 Recipient OK`

Failure Response `550 5.1.1 User unknown`

Possible Reasons for Failure The specified recipient does not exist in the organization.

Configure the external postmaster address

Exchange Server 2013 > Mail flow > Mail routing >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-01-30*

The external postmaster address is used as the sender for system-generated messages and notifications sent to message senders that exist outside of your Microsoft Exchange Server 2013 organization. An external sender is any sender that has an email address in a domain that isn't configured as an accepted domain in your organization.

By default, the value of the external postmaster address setting is blank. This default value causes the following behavior in your Exchange organization:

- The external postmaster address is postmaster@<*Default accepted domain*> for all Mailbox servers and subscribed Edge Transport servers.
- The external postmaster address is postmaster@<*Edge Transport server FQDN*> for all unsubscribed Edge Transport servers.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport configuration" entry in the Mail flow permissions topic.
- When you configure a custom external postmaster address, that value applies to all Exchange 2013 Mailbox servers and Exchange 2010 Hub Transport servers in your Exchange organization. However, that value isn't replicated to Edge Transport servers. If you specify a custom value for the external postmaster address, you need to manually configure the external postmaster address value on any Edge Transport servers.
- If you have any Exchange 2007 Hub Transport servers or Edge Transport servers in your organization, you need to configure the custom external postmaster address on each one of those servers using the **Set-TransportServer** cmdlet. For more information, see Managing the External Postmaster Address.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

What do you want to do?

Use the EAC to configure the external postmaster address

1. In the EAC, navigate to **Mail flow** > **Receive connectors** > **More options** ··· > **Organization transport settings** > **Delivery** tab.
2. In the **External postmaster address** field, enter the SMTP email address, for example, `postmaster@contoso.com`. If you want to return the external postmaster address to the default value, delete any existing value so the field is blank.
3. When you're finished, click **Save**.

Use the Shell to configure the external postmaster address

To configure the external postmaster address, use the following syntax.

```
Set-TransportConfig -ExternalPostmasterAddress <postmaster address>
```

For example, to set the external postmaster address to the value `postmaster@contoso.com`, run the following command

```
Set-TransportConfig -ExternalPostmasterAddress postmaster@contoso.com
```

To return the external postmaster address to the default value, run the following command:

```
Set-TransportConfig -ExternalPostmasterAddress $null
```

How do you know this worked?

To verify that you have successfully configured the external postmaster address, do the following:

1. Run the following command on a Mailbox server to verify the external postmaster address value:

```
Get-TransportConfig | Format-List ExternalPostmasterAddress
```

2. From an external email account, send a message to your Exchange organization that will generate a delivery status notification (DSN). For example, you can configure a transport rule to send a non-delivery report (NDR) for a message from that sender that contains specific keywords. Verify the sender's email address in the DSN matches the value you specified.

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Connectors

Exchange Server 2013 > Mail flow >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-12*

Connectors are used to control inbound and outbound mail flow in Microsoft Exchange Server 2013. With connectors, you can route mail to and receive mail from recipients outside of your organization, a partner through a secure channel, or a message-processing appliance.

The most commonly used connector types are Send connectors, which control outbound messages, and Receive connectors, which control inbound messages.

For more information

Receive connectors

Create a Send connector for email sent to the Internet

Create a secure Receive connector to receive email from a partner

Send connectors

Exchange Server 2013 > Mail flow > Connectors >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-15*

In Microsoft Exchange Server 2013, a Send connector controls the flow of outbound messages to the receiving server. They are configured on Mailbox servers running the Transport service. Most commonly, you configure a Send connector to send outbound email messages to a smart host or directly to their recipient, using DNS.

Exchange 2013 Mailbox servers running the Transport service require Send connectors to deliver messages to the next hop on the way to their destination. Send connectors that are created on Mailbox servers are stored in Active Directory and are available to all Mailbox servers running the Transport service in the organization.

Important:
When you deploy Exchange 2013, outbound mail flow cannot occur until you configure a Send connector to route outbound mail to the Internet. For more information, see Create a Send connector for email sent to the Internet.

Selecting the Type for a Send connector

Typically you create a Send connector in the **Mail flow** section of the Exchange Administration Center (EAC). When you create a new Send connector, you choose an available **Type** appropriate to your connection scenario. The type determines the default permission sets that are assigned on the connector and grants those permissions to trusted security principals. Security principals include users, computers, and security groups.

Procedures that explain specific **Type** selections include Create a Send connector to route

outbound email through a smart host and Create a Send connector to send email to a partner, with Transport Layer Security (TLS) applied.

In you prefer using the Exchange Management Shell to the EAC, you can create a Send connector and specify a type by using the New-SendConnector cmdlet.

New Send connector features in Exchange 2013

With the relationship between the Front End Transport service on Client Access servers and the Transport service on Mailbox servers in Exchange 2013 comes new behavior for Send connectors. Firstly, you can set a Send connector in the Transport service of a Mailbox server to route outbound mail through a Front End transport server in the local Active Directory site, by means of the *FrontEndProxyEnabled* parameter of the Set-SendConnector cmdlet, thus consolidating how email is routed from the Transport service. Mail routing provides more information about transport services, routing behavior, and destinations in Exchange 2013. Mail flow provides an overview of the transport pipeline and descriptions of each transport service.

The *IsCoexistenceConnector* parameter has been deprecated. In most cases, when you want to configure a hybrid environment, where a portion of your mailboxes are hosted on-premises and a portion are hosted in the cloud, we recommend that you use the Hybrid Configuration Wizard.

LinkedReceiveConnector has been deprecated. This parameter was used to create connectors that could route messages to a third-party anti-spam service, for instance. Now, in most cases, you route mail to your anti-spam service by means of your MX record, and the linked-connector behavior is not necessary.

The default maximum message size, specified by the *MaxMessageSize* parameter, has been increased from 10MB to 25MB. Set-SendConnector provides more information on how to set parameters on a Send connector.

TlsCertificateName has been added. It is used to authenticate the local certificate to be used for outbound connections and minimize the risk of fraudulent certificates.

Create a Send connector for email sent to the Internet

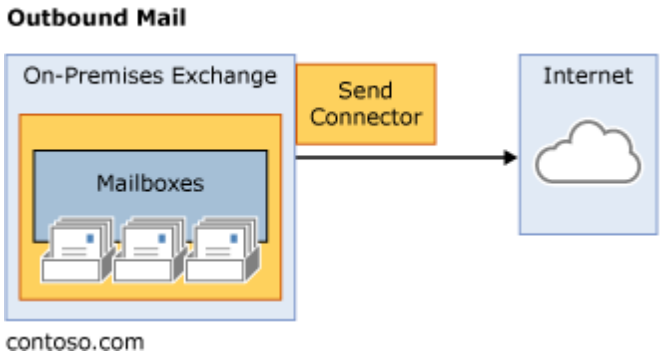
Mail flow > Connectors > Send connectors >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-03-29*

By default, Microsoft Exchange Server 2013 doesn't allow you to send mail outside of your domain.

To send mail outside your domain, you need to create a Send connector. The following graphic illustrates mail flow when you create a Send connector to send mail to the Internet.



Interested in scenarios where this procedure is used? See the following topics:

- Configure mail flow and client access

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Send connectors" entry in the Mail flow permissions topic.
- See Deploy a new installation of Exchange 2013 if you are beginning your installation. After the installation you can use the steps in this topic to create your outbound connector.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to create a send connector for email sent to the Internet

1. In the EAC, navigate to **Mail flow** > **Send connectors**, and then click **Add +**.
2. In the **New send connector** wizard, specify a name for the send connector and then select **Internet** for the **Type**. Click **Next**.
3. Verify that **MX record associated with recipient domain** is selected, which specifies that the connector uses the domain name system (DNS) to route mail. Click **Next**.
4. Under **Address space**, click **Add +**. In the **Add domain** window, make sure SMTP is listed as the **Type**. For **Fully Qualified Domain Name (FQDN)**, enter *, which indicates that this send connector applies to messages addressed to any domain. Click **Save**.
5. Make sure **Scoped send connector** is not selected and then click **Next**.

6. For **Source server**, click **Add +**. In the **Select a server** window, select a Mailbox server that will be used to send mail to the Internet via the Client Access server and click **Add +**. After you've selected the server, click **Add +**. Click **OK**.
7. Click **Finish**.

Once you have created the Send connector, it appears in the Send connector list.

Use the Shell to route mail through the Client Access server

In Exchange 2013 you can use the *FrontendProxyEnabled* parameter of the **Set-SendConnector** cmdlet to route outbound messages through the Client Access server. This parameter is not set to `$true` by default, but in many cases it can consolidate and simplify mail flow, especially if you are working with an environment with a large number of messaging servers.

This example sets the *FrontendProxyEnabled* parameter to `$true` on a Send connector.

```
Set-SendConnector "Contoso.com Send Connector" -
FrontendProxyEnabled $true
```

How do you know this worked?

To verify that you have successfully created a Send Connector for email sent to the Internet, send mail from one of your users to an outside recipient and verify that the message arrives successfully.

For more information

Send connectors

Create a Send connector to route outbound email through a smart host

Create a Send connector to route outbound email through a smart host

Mail flow > Connectors > Send connectors >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-07*

In some situations you may want to route email through a third-party smart host, such as in an

instance where you have a network appliance that you want to perform policy checks on outbound messages.

Note:
The third-party smart host must use SMTP for transport. If it does not, you should use a Foreign connector or Delivery Agent connector.

Interested in scenarios where this procedure is used? See the following topics:

- Configure mail flow and client access

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Send connectors" entry in the Mail flow permissions topic.
- See Deploy a new installation of Exchange 2013 if you are beginning your installation. After the installation you can use the steps in this topic to create your outbound connector.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the EAC to create a Send connector to route outbound email through a smart host

1. In the EAC, navigate to **Mail flow** > **Send connectors**, and then click **Add +**.
2. In the **New send connector** wizard, specify a name for the send connector and then select **Custom** for the **Type**. You typically choose this selection when you want to route messages to computers not running Microsoft Exchange Server 2013. Click **Next**.
3. Choose **Route mail through smart hosts**, and then click **Add +**. In the **Add smart host** window, specify the IP address, such as 192.168.100.1, or the fully qualified domain name (FQDN), such as contoso.com. Click **Save**.

For **Smart host authentication**, choose the type of authentication required by the smart host. If you choose **Basic authentication**, you must provide a user name and password.

Note:
If you choose Basic authentication, we recommend that you use an encrypted connection because the user name and password are sent in clear text.

4. Under **Address space**, click **Add +**. In the **Add domain** window, make sure SMTP is listed as the **Type**. For **Fully Qualified Domain Name (FQDN)**, enter * to specify that this send connector applies to messages sent to any domain. Click **Save**.

5. For **Source server**, click **Add +**. In the **Select a server** window, choose a server and click **Add +**. Click **OK**.
6. Click **Finish**.

Once you have created the send connector, it appears in the Send connector list.

How do you know this worked?

To verify that you have successfully created a Send connector to route outbound email through a smart host, send a message from a user in your organization (you can use the Outlook Web App) to the domain you specified for the **Address space**. If the recipient receives the message, you've successfully configured the send connector.

For more information

Create a Send connector for email sent to the Internet

Send connectors

Create a Send connector to send email to a partner, with Transport Layer Security (TLS) applied

Mail flow > Connectors > Send connectors >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-15*

If you want to ensure secure, encrypted communication with a partner, you can create a Send connector that is configured to enforce Transport Layer Security (TLS) for messages sent to a partner domain. TLS provides secure communication over the Internet.

Interested in scenarios where this procedure is used? See the following topics:

- Configure mail flow and client access

What do you need to know before you begin?

- Estimated time to complete: 10 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Send connectors" entry in the Mail flow permissions

topic.

- See Deploy a new installation of Exchange 2013 if you are beginning your installation. After the installation you can use the steps in this topic to create your outbound connector.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the EAC to create a Send connector to send email to a partner, with TLS applied

To create a Send connector for this scenario, log in to the EAC and perform the following steps:

1. In the EAC, navigate to **Mail flow** > **Send connectors**, and then click **Add +**.
2. In the **New send connector** wizard, specify a name for the send connector and then select **Partner** for the **Type**. When you select **Partner**, the connector is configured to allow connections only to servers that authenticate with TLS certificates. Click **Next**.
3. Verify that **MX record associated with recipient domain** is selected, which specifies that the connector uses the domain name system (DNS) to route mail. Click **Next**.
4. Under **Address space**, click **Add +**. In the **Add domain** window, make sure SMTP is listed as the **Type**. For **Fully Qualified Domain Name (FQDN)**, enter the name of your partner domain. Click **Save**.
5. For **Source server**, click **Add +**. In the **Select a server** window, select a Mailbox server that will be used to send mail to the Internet via the Client Access server and click **Add +**. After you've selected the server, click **Add +**. Click **OK**.
6. Click **Finish**.

Once you have created the Send connector, it appears in the Send connector list.

How do you know this worked?

To verify that you have successfully created a Send connector to send email to a partner, with TLS applied, send a message from a user in your organization to a recipient at the partner organization. If the recipient receives the message, the connector was created successfully.

For more information

Create a Send connector for email sent to the Internet

Create a Send connector to route outbound email through a smart host

Configure a cross-forest Send connector

Mail flow > Connectors > Send connectors >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-21*

In Active Directory, the *forest* represents the outer boundary of your directory service. You can create Send connectors to enable communication between forests. In this example, the connectors use Basic authentication.

For additional management tasks related to configuring connectors, see Connectors.

Interested in scenarios where this procedure is used? See the following topics:

- Deploy Exchange 2013 in a cross-forest topology

What do you need to know before you begin?

- Estimated time to complete: 20 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Send connectors" entry and “Receive connectors” entry in the Mail flow permissions topic.
- See Deploy a new installation of Exchange 2013 if you are beginning your installation. After the installation you can use the steps in this topic to create connectors to configure a cross-forest topology.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Create a user account in each forest

You must create a user account in each forest to use for Basic authentication. Create an account in each forest and add each to the universal security group of the Exchange Server used for communication. This account is used by the Send connector to authenticate to the server receiving mail in the other forest. For example, provide a user account that has the user principal name (UPN)

FourthCoffee@Contoso.com as the credentials that must be used for authentication by the Exchange server in the Fourth Coffee domain when mail is sent to the Exchange server in the Contoso domain.

Use the EAC to create a send connector to route email to another Exchange 2013 forest

Establish cross-forest mail flow using Basic authentication.

1. In the EAC, navigate to **mail flow** > **send connectors**. Click **Add +**.
2. In the **new send connector** wizard, specify a name for the send connector and then select **Internal** for the **Type**. Click **next**.
3. Choose **Route mail through smart hosts**, and then click **Add +**. In the **add smart host** window, specify the IP address of the target server in the second forest, such as 64.4.6.100. Click **save** and then **next**.

For **Smart host authentication**, choose **Basic authentication** and provide a user name and password. Here you can choose **Offer basic authentication only after starting TLS** for secure communication over TLS.

Note:

If you use Basic authentication over TLS, the target server must be configured to use an X.509 certificate.

4. Under **Address space**, click **Add +**. In the **add domain** window, make sure SMTP is listed as the **Type**. For **Fully Qualified Domain Name (FQDN)**, enter the receiving domain, such as fourthcoffee.com. Click **save** and then **next**.
5. For **Source server**, click **Add +**. In the **Select a server** window, choose the server to use and click **add +**. Click **ok**.
6. Click **finish**. The connector appears in the list of Send connectors.

After you create your Send connector, create a Send connector in the second forest that sends mail to the original forest. In this case, the Fully Qualified Domain Name (FQDN) you specify will be the domain name of the first forest. For example, contoso.com.

Use the Shell to set permissions on the Send connector

This example uses the Enable-CrossForestConnector.ps1 script in the Shell to set permissions on the Send connector for use in a cross-forest topology.

```
.\Enable-CrossForestConnector.ps1 -Connector "Cross-Forest"
-user "ANONYMOUS LOGON"
```

How do you know this worked?

To verify that you have successfully created Send connectors to route email to a second forest, send a message from a user in your organization (you can use the Outlook Web App) to the domain you specified for the **Address space**. If the recipient receives the message, you've successfully configured the send connector.

Create a Send connector for email sent to the Internet

Send connectors

Receive connectors

Exchange Server 2013 > Mail flow > Connectors >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-03-19*

Receive connectors control the flow of inbound messages to your Exchange organization. They are configured on computers running Microsoft Exchange Server 2013 with the Transport service, or in the Front End service on a Client Access server. They can be created in the Exchange Administration Center (EAC), or in the Exchange Management Shell.

By default, the Receive connectors that are required for internal mail flow are automatically created when a Client Access server or Mailbox server is installed.

Exchange 2013 servers running the Transport service require Receive connectors to receive messages from the Internet, from email clients, and from other email servers. A Receive connector controls inbound connections to the Exchange organization.

Each Receive connector listens for inbound connections that match the settings of the Receive connector. A Receive connector listens for connections that are received through a particular local IP address and port, and from a specified IP address range. You can create a Receive connector when you want to control which servers receive messages from a particular IP address or IP address range, and when you want to configure special connector properties for messages that are received from a particular IP address, such as allowing larger messages or more recipients per message. You can also scope the Receive connector using the *TlsCertificateName* parameter of the **Set-ReceiveConnector** cmdlet, which allows you to specify the certificate to use for the connector.

Receive connectors are scoped to a single server and determine how that specific server listens for connections. When you create a Receive connector on a Mailbox server running the Transport service, the Receive connector is stored in Active Directory as a child object of the server on which it's created.

If you need additional Receive connectors for specific scenarios, you can create them by using the Exchange Administration Center (EAC) or the Exchange Management Shell. Each Receive connector must use a unique combination of IP address bindings, port number assignments, and remote IP address ranges from which mail is accepted.

For more information about how to create a Receive Connector, see Receive connector procedures.

Contents

Default Receive connectors created during setup

Certain Receive connectors are created by default when you install the Mailbox server role.

Default Receive connectors created on a Mailbox server running the Transport service

When you install a Mailbox server running the Transport service, two Receive connectors are created. No additional Receive connectors are needed for typical operation, and in most cases the default Receive connectors don't require a configuration change. These connectors are the following:

- **Default <server name>** Accepts connections from Mailbox servers running the Transport service and from Edge servers.
- **Client Proxy <server name>** Accepts connections from front-end servers. Typically, messages are sent to a front-end server over SMTP.

Each connector is assigned a *TransportRole* value. You can use it to determine the role the connector is running in. This can be helpful in cases where you are running multiple roles on a single server. In the case of each Receive connector previously mentioned, their *TransportRole* value is **HubTransport**.

To view the default Receive connectors and their parameter values, you can use the Get-

ReceiveConnector cmdlet.

Default Receive connectors created on a Front End Transport server

During installation, three Receive connectors are created on the Front End transport, or Client Access server. The default Front End Receive connector is configured to accept SMTP communications from all IP address ranges. Additionally, there is a Receive connector that can act as an outbound proxy for messages sent to the front-end server from Mailbox servers. Finally, there is a secure Receive connector configured to accept messages encrypted with Transport Layer Security (TLS). These connectors are the following:

- **Default FrontEnd <server name>** Accepts connections from SMTP senders over port 25. This is the common messaging entry point into your organization.
- **Outbound Proxy Frontend <server name>** Accepts messages from a Send Connector on a back-end server, with front-end proxy enabled.
- **Client Frontend <server name>** Accepts secure connections, with Transport Layer Security (TLS) applied.

In a typical installation, no additional Receive connectors are required.

Receive connector types

The type determines the default security settings for each Receive connector.

The security settings for a Receive connector specify the permissions that are granted to sessions that connect to the Receive connector and the supported authentication mechanisms.

When you use the EAC to configure a Receive connector, the new receive connector page prompts you to select the type for the connector. Based on your selection, parameters are set to conform to the configuration you have chosen. Specific procedures contain more information about Receive connector type settings. Examples of these procedures are Create a Receive connector to receive email from the Internet and Create a secure Receive connector to receive email from a partner.

Receive connector permission groups

A permission group is a predefined set of permissions that's granted to well-known security principals and assigned to a Receive connector. Security principals include users, computers, and security groups. The use of permission groups simplifies the configuration of permissions on Receive connectors. The **PermissionGroups** property defines the groups or roles that can submit messages to the Receive connector and the permissions that are assigned to those groups.

Permission groups include *Anonymous*, *ExchangeUsers*, *ExchangeServers*, *ExchangeLegacyServers*, and *Partner*.

Receive connector type specifications

The type determines the default permission groups that are assigned to the Receive connector and the default authentication mechanisms that are available for session authentication. The following list describes the available types:

1. **Client** Typically used to connect to clients not using Microsoft Office Outlook. It can use TLS authentication.
2. **Custom** Typically used in a cross-forest scenario, or in a scenario where your organization receives messages from an SMTP message transfer agent.
3. **Internal** Used for communication between servers running the Transport service, or between Mailbox servers running the Transport service and third-party transfer agents.
4. **Internet** Used to receive SMTP mail from the Internet.
5. **Partner** Use this type when you want to configure secure communication with a partner.

Each type is appropriate for a specific connection scenario. Select the type that has the default settings most applicable to the configuration that you want. You can modify permissions by using the **Add-ADPermission** and **Remove-ADPermission** cmdlets. For more information, see the following topics:

- Add-ADPermission
- Remove-ADPermission

Receive connector permissions

Receive connector permissions are assigned to security principals when you specify the permission groups for the connector. When a security principal establishes a session with a Receive connector, the Receive connector permissions determine whether the session is accepted and how the received messages are processed. You can set Receive connector permissions by using the EAC or by using the *PermissionGroups* parameter with the **Set-ReceiveConnector** cmdlet in the Shell. To modify the default permissions for a Receive connector, you can also use the **Add-ADPermission** cmdlet.

Receive connector permissions contains a table that lists security principals and permissions types in detail.

Receive connector authentication settings

In the EAC, you use the authentication settings for a Receive connector to specify the authentication mechanisms that are supported by the Exchange 2010 transport server. In the Shell, you use the *AuthMechanisms* parameter to specify the supported authentication mechanisms. You can configure more than one authentication mechanism for a Receive connector. The following table lists the available authentication mechanisms for a Receive connector.

New Receive connector features in Exchange 2013

The following features were added in Exchange 2013:

- With the *TlsCertificateName* parameter you can specify the local Certificate Authority (CA) issued certificate to use for secure mail. It helps minimize the risk of fraudulent certificates.
- The *TransportRole* parameter designates the server role associated with this connector. It is typically used to specify the server role when you host multiple server roles on a single computer.

See New-ReceiveConnector for more information about these parameters and other parameters for Receive connectors.

Receive connector permissions

Mail flow > Connectors > Receive connectors >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-11*

The following table lists permission types and a description for each.

Receive connector permission	Description
ms-Exch-SMTP-Submit	The session must be granted this permission or it will be unable to submit messages to this Receive connector. If a session doesn't have this permission, the MAIL FROM and AUTH commands will fail.
ms-Exch-SMTP-Accept-Any-Recipient	This permission allows the session to relay messages through this connector. If this permission isn't granted, only messages that are addressed to recipients in accepted domains are accepted by this connector.
ms-Exch-SMTP-Accept-Any-Sender	This permission allows the session to bypass the sender address spoofing check.
ms-Exch-SMTP-Accept-Authoritative-Domain-Sender	This permission allows senders that have e-mail addresses in authoritative domains to

	establish a session to this Receive connector.
ms-Exch-SMTP-Accept-Authentication-Flag	This permission allows Exchange 2003 servers to submit messages from internal senders. Exchange 2010 will recognize the messages as being internal. The sender can declare the message as trusted. Messages that enter your Exchange system through anonymous submissions will be relayed through your Exchange organization with this flag in an untrusted state.
ms-Exch-Accept-Headers-Routing	This permission allows the session to submit a message that has all received headers intact. If this permission isn't granted, the server will strip all received headers.
ms-Exch-Accept-Headers-Organization	This permission allows the session to submit a message that has all organization headers intact. Organization headers all start with **X-MS-Exchange-Organization-**. If this permission isn't granted, the receiving server will strip all organization headers.
ms-Exch-Accept-Headers-Forest	This permission allows the session to submit a message that has all forest headers intact. Forest headers all start with **X-MS-Exchange-Forest-**. If this permission isn't granted, the receiving server will strip all forest headers.
ms-Exch-Accept-Exch50	This permission allows the session to submit a message that contains the XEXCH50 command. This command is needed for interoperability with Exchange 2003. The XEXCH50 command provides data such as the spam confidence

	level (SCL) for the message.
ms-Exch-Bypass-Message-Size-Limit	This permission allows the session to submit a message that exceeds the message size restriction configured for the connector.
Ms-Exch-Bypass-Anti-Spam	This permission allows the session to bypass anti-spam filtering.

Receive connector authentication mechanisms

Mail flow > Connectors > Receive connectors >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-03-19*

The Receive connector authentication mechanisms are the following:

Authentication mechanism	Description
None	No authentication.
TLS	Advertise STARTTLS. Requires availability of a server certificate to offer TLS.
Integrated	NTLM and Kerberos (Integrated Windows authentication).
BasicAuth	Basic authentication. Requires an authenticated logon.
BasicAuthRequireTLS	Basic authentication over TLS. Requires a server certificate.
ExchangeServer	Exchange Server authentication (Generic Security Services application programming interface (GSSAPI) and Mutual GSSAPI).

ExternalAuthoritative	The connection is considered externally secured by using a security mechanism that's external to Exchange. The connection may be an Internet Protocol security (IPsec) association or a virtual private network (VPN). Alternatively, the servers may reside in a trusted physically controlled network. The `ExternalAuthoritative` authentication method requires the `ExchangeServers` permission group. This combination of authentication method and security group permits the resolution of anonymous sender email addresses for messages that are received through this connector.

For more information about Receive Connector authentication mechanisms, see New-ReceiveConnector.

Receive connector procedures

Mail flow > Connectors > Receive connectors >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-23*

Create a Receive connector to receive email from the Internet

Create a secure Receive connector to receive email from a partner

Create a Receive connector to receive email from a system not running Exchange

Create a Receive connector to receive messages from an internal Exchange server

Create a Receive connector to receive email from the Internet

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-15*

This procedure shows you how to configure a Receive connector to receive email from the Internet.

Note:

In most cases, you won't need to explicitly set up a Receive connector to receive mail from the Internet, because a Receive connector to accept mail from the Internet is implicitly created upon installation of Exchange. See Receive connectors for more information.

Interested in scenarios where this procedure is used? See the following topics:

- Configure mail flow and client access

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Receive connectors" entry in the Mail flow permissions topic.
- See Deploy a new installation of Exchange 2013 if you are beginning your installation. After the installation you can use the steps in this topic to create your receive connector.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the EAC to Create a Receive Connector to Receive Messages from the Internet

1. In the EAC, navigate to **Mail flow** > **Receive connectors**. Click **Add +** to create a Receive connector.
2. On the **New receive connector** page, specify a name for the Receive connector and then select **Frontend transport** for the **Role**. Since you are receiving mail from the Internet in this case, we recommend that you initially route mail to your Front End server or servers, to simplify and consolidate your mail flow.
3. Choose **Internet** for the type. The Receive connector will receive mail from Internet senders.
4. For the **Network adapter bindings**, observe that **All available IPV4** is listed in the **IP addresses** list and the **Port** is 25. (Simple Mail Transer Protocol (SMTP) uses port 25.) This indicates that the connector listens for connections on all IP addresses assigned to network adapters on the local server.

Note:

If you have multiple network adapters, on this page you can add an IP address that is assigned to a specific network adapter on the local server, but this isn't required.

5. Click the **Finish** button to create your connector.

Once you have created the Receive connector, it appears in the Receive connector list. If you would like to see an example of how to create a Receive connector with a cmdlet, see New-ReceiveConnector.

How do you know this worked?

To verify that you have successfully created a Receive connector to receive messages from the Internet, test that you can send mail from an outside source and one of your users can receive it. If you can receive mail, you know that the configuration worked successfully.

Connectors > Receive connectors > Receive connector procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

This procedure shows you how to configure a Receive connector to receive secure email from a partner. Use this procedure when you are required to encrypt communication between you and a trusted partner. The connector is configured to accept connections only from servers that authenticate with Transport Layer Security (TLS).

Interested in scenarios where this procedure is used? See the following topics:

- Configure mail flow and client access

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To

see what permissions you need, see the "Receive connectors" entry in the Mail flow permissions topic.

- See Deploy a new installation of Exchange 2013 if you are beginning your installation. After the installation you can use the steps in this topic to create your receive connector.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the EAC to Create a Receive Connector to Receive Secure Messages from a Partner

1. In the EAC, navigate to **Mail flow** > **Receive connectors**. Click **Add +** to create a new Receive connector.
2. On the **New receive connector** page, specify a name for the Receive connector and then select **Frontend Transport** for the **Role**. Since you are receiving mail from a partner in this case, we recommend that you initially route mail to your front end server to simplify and consolidate your mail flow.
3. Choose **Partner** for the type. The Receive connector will receive mail from a trusted third party.
4. For the **Network adapter bindings**, observe that **All available IPV4** is listed in the **IP addresses** list and the **Port** is 25. (Simple Mail Transfer Protocol uses port 25.) This indicates that the connector listens for connections on all IP addresses assigned to network adapters on the local server. Click **Next**.
5. If the Remote network settings page lists 0.0.0.0-255.255.255.255, which means that the Receive connector receives connections from all IP addresses, click **Remove —** to remove it. Click **Add +**, add the IP address for your partner's server, and click **Save**.

Note:

You can also specify an IP address range with CIDR notation, such as 64.4.6.100/24.

6. Click **Finish** to create the connector.

Once you have created the Receive connector, it appears in the Receive connector list. If you would like to see an example of how to create a Receive connector with a cmdlet, see New-ReceiveConnector.

How do you know this worked?

To verify that you have successfully created a Receive connector to receive messages from a partner, test that the partner can send mail to one of your users and that the user successfully receives it. If you can receive encrypted mail (you can verify that TLS is used by checking the message header), you know that the configuration worked successfully.

Receive connectors

Create a Receive connector to receive email from a system not running Exchange

Connectors > Receive connectors > Receive connector procedures >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

You may have a situation where you want to receive messages from a system not running Exchange. For instance, if you have a network appliance that performs policy checks and then routes messages to your Exchange server. We assume in this case that the appliance uses SMTP. If not, you should use a Foreign connector or a Delivery Agent connector.

Interested in scenarios where this procedure is used? See the following topics:

- Configure mail flow and client access

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Receive connectors" entry in the Mail flow permissions topic.
- See Deploy a new installation of Exchange 2013 if you are beginning your installation. After the installation you can use the steps in this topic to create your receive connector.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the EAC to Create a Receive Connector to Receive

Messages from a Messaging Appliance

1. In the EAC, navigate to **Mail flow** > **Receive connectors**. Click **Add +** to create a Receive connector.
2. On the **New receive connector** page, specify a name for the Receive connector and then select **Hub Transport** for the **Role**. In this case, you want your Mailbox server running the Transport service to receive messages from the appliance.
3. Choose **Custom** for the type, since the Receive connector will receive mail from an appliance not running Microsoft Exchange Server 2013.
4. For the **Network adapter bindings**, observe that **All available IPV4** is listed in the **IP addresses** list. Click **Next**.
5. For **Remote network settings**, click **Remove —** to remove **0.0.0.0-255.255.255.255** from the **IP addresses** list, since you want to specify that the connector accepts mail from a specific appliance. Click **Add +** to add a new IP address, and in the **Add IP address** window, add the IP address of your appliance. Click **Save**.
6. Click the **Finish** button to create your connector.

Once you have created the Receive connector, it appears in the Receive connector list. If you would like to see an example of how to create a Receive connector with a cmdlet, see New-ReceiveConnector.

How do you know this worked?

To verify that you have successfully created a Receive connector to receive messages from a messaging appliance, test that you can receive mail from the appliance. If you can receive mail, you know that the configuration worked successfully.

For more information

Create a Receive connector to receive email from the Internet

Create a Receive connector to receive messages from an internal Exchange server

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

You create a Receive connector of the **Internal** type when you want to receive mail from an Exchange server. Use this type of connector to control mail routing within your organization: for example, when you want to route mail from the Transport service on a Mailbox server to a specific Edge Transport server, or from one Mailbox server to another.

Interested in scenarios where this procedure is used? See the following topics:

- Configure mail flow and client access

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Receive connectors" entry in the Mail flow permissions topic.
- See Deploy a new installation of Exchange 2013 if you are beginning your installation. After the installation you can use the steps in this topic to create your receive connector.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Create a Receive Connector to Receive Messages from an Internal Exchange Server

1. In the EAC, navigate to **Mail flow** > **Receive connectors**. Click **Add +** to create a new Receive connector.
2. On the **New receive connector** page, specify a name for the Receive connector and then select **Hub transport** for the **Role**. In this case we assume you want to route mail within your network, not into and out of the organization.
3. Choose **Internal** for the type. The connector is configured with Exchange server authentication.
4. If the Remote network settings page lists 0.0.0.0-255.255.255.255, which means that the Receive connector receives connections from all IP addresses, click **Remove −** to remove it. Click **Add +**, add the IP address for the server you want to receive mail from, such as 192.168.1.1, and click **Save**.
5. Click **Finish** to create the connector.

Once you have created the Receive connector, it appears in the Receive connector list. If you would like to see an example of how to create a Receive connector with a cmdlet, see New-

ReceiveConnector.

How do you know this worked?

To verify that you have successfully created a Receive connector to receive messages from an internal server, test that messages from the sending server travel successfully to the recipient server. One way to do this is to use the Exchange Management Shell to set the *ProtocolLoggingLevel* for the Receive connector you created to `verbose`, using the Set-ReceiveConnector cmdlet, and check the logs to ensure message delivery.

Create a Receive connector to receive email from the Internet

Create a secure Receive connector to receive email from a partner

Modify the SMTP banner on a Receive connector

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-03-04*

The *SMTP banner* is the SMTP connection response that a remote SMTP messaging server receives after it connects to a Receive connector that's configured on a computer running Microsoft Exchange Server 2013.

This is the default response received by a remote SMTP messaging server after it connects to the Receive connector:

```
220 <Servername> Microsoft ESMTP MAIL service ready at
<RegionalDay-Date-24HourTimeFormat>
<RegionalTimeZoneOffset>
```

When you specify a custom value for SMTP banner on a Receive connector, a remote SMTP messaging server that connects to that SMTP Receive connector receives the following response.

```
220 <Banner Text>
```

You may want to modify the SMTP banner for Internet-facing SMTP Receive connectors so the

server name and messaging server software aren't disclosed by the SMTP banner.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Receive connectors" entry in the Mail flow permissions topic.
- You can only use the Shell to perform this procedure.
- The replacement SMTP banner text string must always start with `220`. As defined in RFC 2821, the default service ready SMTP response code is 220.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to modify the SMTP banner on a Receive connector

Run the following command:

```
Set-ReceiveConnector <ConnectorIdentity> -Banner "220
<Banner Text>"
```

This example modifies the SMTP banner on the existing Receive connector named From the Internet so the SMTP banner displays `220 Contoso Corporation`.

```
Set-ReceiveConnector "From the Internet" -Banner "220
Contoso Corporation"
```

This example removes the custom SMTP banner on the Receive connector named From the Internet, which returns the SMTP banner to the default value.

```
Set-ReceiveConnector "From the Internet" -Banner $null
```

How do you know this worked?

To verify that you have successfully modified the SMTP banner on a Receive connector, do the following:

1. Open a telnet client on a computer that can access the Receive connector, and run the following

command:

```
open <Connector FQDN or IP address> <Port>
```

2. Verify the response from the Receive connector contains the SMTP banner you configured.

Note that this procedure only works on Receive connectors that allow anonymous or Basic authentication. For more information, see Use Telnet to test SMTP communication.

Foreign connectors

Exchange Server 2013 > Mail flow > Connectors >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-25*

A Foreign connector delivers messages to a server or foreign system that does not use SMTP as its primary transport mechanism. An example of this can be a fax-gateway server. A Foreign connector uses a local or shared Drop directory to send outbound messages, by means of a file transfer, to the foreign system. Foreign connectors are created in the Transport service of a Microsoft Exchange Server 2013 Mailbox server.

Foreign gateway servers can send messages into the Exchange 2013 organization by using the Pickup or Replay directories that exist in the Transport service of a Mailbox server. Correctly formatted email message files that you copy to each directory are submitted for delivery to an Exchange mailbox.

Tip:

In most cases where you must deliver outbound messages to a non-SMTP system, we recommend Delivery Agent connectors, because they allow for queue management of messages, messages do not have to be written to the file system, and other benefits. The Delivery agents and Delivery Agent connectors topic provides more details.

For more information

Create a Foreign connector to deliver messages to a non-SMTP fax gateway

Delivery agents and Delivery Agent connectors

Set-ForeignConnector

Create a Foreign connector to deliver messages to a non-SMTP fax gateway

Mail flow > Connectors > Foreign connectors >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-17*

You may have a scenario where you want to send messages to and receive messages from a fax-gateway server that doesn't use SMTP as its primary transport mechanism. Follow the steps outlined in this procedure to create a Foreign connector that delivers messages to and receives messages from the foreign system.

Tip:

In most cases where you must deliver outbound messages to a non-SMTP system, we recommend Delivery Agent connectors, because they allow for queue management of messages, messages do not have to be written to the file system, and other benefits. The Delivery agents and Delivery Agent connectors topic provides more details.

Interested in scenarios where this procedure is used? See the following topics:

- Planning and deployment

What do you need to know before you begin?

- Estimated time to complete this task: 30 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Foreign connectors" entry in the Mail flow permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

How do you do this?

Step 1: Use the Shell to create a Foreign connector that sends messages to a non-SMTP gateway server

1. Run the following command to create the Foreign connector:

```
New-ForeignConnector -Name "Contoso Foreign Connector" -
AddressSpaces "X400:c=US;a=Fabrikam;P=Contoso;5" -
SourceTransportServers Hub01,Hub02
```

In this example, Hub01 and Hub02 are source servers in your organization that you designate to deliver messages to the foreign system. Using more than one source server provides fault tolerance.

Once you have created the Foreign Connector, you can configure the Drop Pickup, and Replay directories, depending on the requirements for your organization.

How do you know this step worked?

To verify that the Foreign connector was created successfully, run the following command:

```
Get-ForeignConnector | Format-List Name
```

Verify that the name for the Foreign connector you created appears.

Step 2: Use the Shell to configure the Drop directory for a Mailbox server running the Transport service

The Drop directory for a Mailbox server running the Transport service is used to deliver outbound messages from your Foreign connector.

You create a directory to use as the Drop directory on your local file system. You can also use a directory on a network file share.

1. Run the following script to specify the Drop directory for your Foreign connector (change the value for the *DropDirectory* parameter to a path appropriate for your environment):

```
Set-ForeignConnector "Contoso Foreign Connector" -
DropDirectory "C:\Drop Directory"
```

How do you know this step worked?

To verify that you have set the Drop Directory correctly, you can run the following cmdlet script and verify the value for the *DropDirectory* parameter:

```
Get-ForeignConnector "Contoso Foreign Connector" | Format-
List
```

Once you have created your Foreign connector and specified your Drop directory, you can send a message using the Mailbox server where you created your Foreign connector and verify that a file is delivered to the Drop directory.

Step 3: Use the Shell to configure the Pickup directory for the Transport service on a Mailbox server

The Pickup directory for the Transport service on a Mailbox server is used to collect messages generated by non-SMTP systems. Use this procedure in cases where you want to gather new messages generated by a non-SMTP system, such as a fax gateway server, by means of file transfer.

For detailed instructions for configuring your Pickup directory, see Configure the Pickup directory and the Replay directory.

How do you know this step worked?

To verify that you have set the Pickup directory correctly, you can run the following command and verify the value for the *PickupDirectoryPath* parameter:

```
Get-TransportService | Format-List PickupDirectoryPath
```

Step 4: Use the Shell to configure the Replay directory for the Transport service on a Mailbox server

The Replay directory for the Transport service on a Mailbox server is used to collect messages generated by non-SMTP systems. Use this procedure to configure the Replay directory in cases where you want to resubmit email messages, typically from a non-SMTP foreign gateway server, that were generated in your Exchange environment and exported from Exchange transport.

For detailed instructions for configuring your Pickup directory, see Configure the Pickup directory and the Replay directory.

How do you know this step worked?

To verify that you have set the Replay directory correctly, you can run the following command and verify the value for the *ReplayDirectoryPath* parameter:

```
Get-TransportService | Format-List ReplayDirectoryPath
```

For more information

Foreign connectors

Delivery agents and Delivery Agent connectors

Delivery agents and Delivery Agent connectors

Exchange Server 2013 > Mail flow > Connectors >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-04-09*

A delivery agent can deliver messages from your SMTP Exchange Server environment to a system that doesn't use the SMTP protocol. Each delivery agent is associated with a Delivery Agent connector, which queues messages routed to the delivery agent for processing and delivery to the non-SMTP device or system.

Tip:

While the Foreign connector architecture remains in Microsoft Exchange 2013, we recommend using delivery agents for routing messages to non-SMTP systems whenever possible. The primary reasons for this are that you can use queue management for messages, there is no need to manage file transfer to a Drop directory, and you can verify message delivery.

Contents

Function and benefits of Delivery Agents

A delivery agent is a component installed in the Transport service of a Mailbox server that can perform the following tasks:

- Establish a connection to the foreign system for message delivery.
- Retrieve messages from the delivery queues on Mailbox servers.
- Deliver messages to the foreign system.
- Provide acknowledgement for each successful message delivery.

While the Foreign connector architecture remains in Microsoft Exchange Server 2013, we recommend using delivery agents for routing messages to non-SMTP systems whenever possible. Delivery agents provide the following benefits:

- They allow queue management of messages routed to foreign systems.
- Because the messages no longer need to be written to and read from the file system, message delivery performance is improved.

- They provide access to message properties with rich events for agent developers.
- Development time for a delivery agent is faster than implementing a Foreign connector because the delivery agent can use the message representation and management features of Exchange.
- You can verify that the messages are delivered to the foreign system, rather than simply written to the Drop directory.
- The use of Delivery Agent connectors allows service level agreement (SLA) analysis because it's possible to track the latency of message delivery to the foreign system.

Adding Delivery Agents to your organization

To use a delivery agent in your organization, you have to complete the following:

1. Acquire the delivery agent. Typically, delivery agents are written by third parties. Exchange 2013 comes with only one Delivery Agent connector by default: the Text Messaging Delivery Agent connector.
2. Install the delivery agent in the Transport service of your Mailbox servers that will act as source servers for the Delivery Agent connectors.
3. Create a Delivery Agent connector for the specific protocol.

When all of these steps are completed, messages to the foreign systems will be routed through the Delivery Agent connectors and processed by the delivery agent.

Microsoft.Exchange.Data.Transport.Delivery Namespace provides more information about developing a delivery agent.

Delivery Agent connectors

A Delivery Agent connector in Exchange 2013 is similar to the Delivery Agent connector introduced in Exchange 2010. They route messages addressed to foreign systems that do not use the SMTP protocol. When a message is routed to a Delivery Agent connector, the associated delivery agent performs the content conversion and message delivery. Typically, delivery agents are created by a third-party and configured to work with a Delivery Agent connector in your organization.

A Delivery Agent connector cannot be created in the Exchange Administration Center. Rather, you create a Delivery Agent connector in the Exchange Management Shell with the New-DeliveryAgentConnector cmdlet and edit the Delivery Agent connector's properties with Set-DeliveryAgentConnector. You can specify one or more host Mailbox servers for the connector, by using the optional *SourceTransportServers* parameter.

Default text messaging Delivery Agent connector

You can use the Text Messaging Delivery Agent connector to route messages to mobile devices. On your Exchange server, run `Get-DeliveryAgentConnector | fl` to view the connector and all of its parameters. Note that the *DeliveryProtocol* is set to `MOBILE`.

Header firewall

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-01-31*

In Microsoft Exchange Server 2013, *header firewall* is a mechanism that removes specific header fields from inbound and outbound messages. There are two different types of header fields that are affected by header firewall:

- **X-headers** An *X-header* is a user-defined, unofficial header field. X-headers aren't specifically mentioned in RFC 2822, but the use of an undefined header field starting with **X-** has become an accepted way to add unofficial header fields to a message. Messaging applications, such as anti-spam, antivirus, and messaging servers may add their own X-headers to a message. In Exchange, the X-header fields contain details about the actions that are performed on the message by the Transport service, such as the spam confidence level (SCL), content filtering results, and rules processing status. Revealing this information to unauthorized sources could pose a potential security risk.
- **Routing headers** Routing headers are standard SMTP header fields that are defined in RFC 2821 and RFC 2822. Routing headers stamp a message by using information about the different messaging servers that were used to deliver the message to the recipient. Routing headers that are inserted into messages by malicious users can misrepresent the routing path that a message traveled to reach a recipient.

Header firewall prevents the spoofing of these Exchange-related X-headers by removing them from inbound messages that enter the Exchange organization from untrusted sources. Header firewall prevents the disclosure of these Exchange-related X-headers by removing them from outbound messages sent to untrusted destinations outside the Exchange organization. Header firewall also prevents the spoofing of standard routing headers that are used to track the routing history of a message.

Contents

Message header fields affected by header firewall in Exchange

The following types of X-headers and routing headers are affected by header firewall:

- **Organization X-headers** These X-header fields start with **X-MS-Exchange-Organization-**.
- **Forest X-headers** These X-header fields start with **X-MS-Exchange-Forest-**.

For examples of organization X-headers and forest X-headers, see the Organization X-headers and forest X-headers in Exchange section at the end of this topic.

- **Received: routing headers** A different instance of this header field is added to the message header by every messaging server that accepted and forwarded the message to the recipient. The **Received:** header typically includes the name of the messaging server and a date-timestamp.
- **Resent-*: routing headers** Resent header fields are informational header fields that can be used to determine whether a message has been forwarded by a user. The following resent header fields are available: **Resent-Date:**, **Resent-From:**, **Resent-Sender:**, **Resent-To:**, **Resent-Cc:**, **Resent-Bcc:**, and **Resent-Message-ID:**. The **Resent-** fields are used so that the message appears to the recipient as if it was sent directly by the original sender. The recipient can view the message header to discover who forwarded the message.

Exchange uses two different ways to apply header firewall to organization X-headers, forest X-headers, and routing headers that exist in messages:

- Permissions are assigned to Send connectors or Receive connectors that can be used to preserve or remove specific types of headers in messages when the message travels through the connector.
- Header firewall is automatically implemented for specific types of headers in messages during other types of message submission.

Return to top

How header firewall is applied to Receive connectors and Send connectors

Header firewall is applied to messages that travel through Send connectors and Receive connectors based on specific permissions that are assigned to the connectors.

If the permission is assigned to the Receive connector or Send connector, header firewall isn't applied to the messages that travel through the connector. The affected header fields are preserved in the messages.

If the permission isn't assigned to the Receive connector or Send connector, header firewall is applied to the messages that travel through the connector. The affected header fields are removed from the messages.

The following table describes the permissions on Send connectors and Receive connectors that are used to apply header firewall, and the affected header fields.

Connector type	Permission	Description
Receive connector	**Ms-Exch-Accept-Headers-Organization**	This permission affects organization X-header fields that start with **X-MS-Exchange-Organization-** in inbound messages.
Receive connector	**Ms-Exch-Accept-Headers-Forest**	This permission affects forest X-header fields that start with **X-MS-Exchange-Forest-** in inbound messages.
Receive connector	**Ms-Exch-Accept-Headers-Routing**	This permission affects **Received:** and **Resent-*:** routing header fields in inbound messages.
Send connector	**Ms-Exch-Send-Headers-Organization**	This permission affects organization X-header fields that start with **X-MS-Exchange-Organization-** in outbound messages.
Send connector	**Ms-Exch-Send-Headers-Forest**	This permission affects forest X-header fields that start with **X-MS-Exchange-Forest-** in outbound messages.
Send connector	**Ms-Exch-Send-Headers-Routing**	This permission affects **Received:** and **Resent-*:** routing header fields in outbound messages.

Header firewall for inbound messages on Receive connectors

The following table describes the default application of the header firewall permissions on Receive connectors.

Permission	Default Exchange security principals that have the permission assigned	Permission group that has the security principals as members	Default usage type that assigns the permission groups to the Receive connector
Ms-Exch-Accept-Headers-Organization and **Ms-Exch-Accept-Headers-Forest**	• Hub Transport servers • Edge Transport servers • Exchange Servers **Note:** On Hub Transport servers only	**ExchangeServers**	`Internal`
Ms-Exch-Accept-Headers-Routing	Anonymous user account	**Anonymous**	`Internet`
Ms-Exch-Accept-Headers-Routing	Authenticated user accounts	**ExchangeUsers**	`Client` (unavailable on Edge Transport servers)
Ms-Exch-Accept-Headers-Routing	• Hub Transport servers • Edge Transport servers • Exchange Servers **Note:** Hub Transport servers only • Externally Secured servers	**ExchangeServers**	`Internal`
Ms-Exch-Accept-Headers-Routing	Partner Server account	**Partner**	`Internet` and `Partner`

Return to top

Header firewall on custom Receive connectors

If you want to apply header firewall to messages in a custom Receive connector scenario, use any of the following methods:

- Create the Receive connector with a usage type that automatically applies header firewall to messages. Note that you can set the usage type only when you create the Receive connector.
  - To remove the organization X-headers or forest X-headers from messages, create a Receive connector and select a usage type other than `Internal`.
  - To remove the routing headers from messages, do one of the following actions:
    - Create a Receive connector and select the usage type `Custom`. Don't assign any permission groups to the Receive connector.
    - Modify an existing Receive connector, and set the *PermissionGroups* parameter to the value `None`.

Note that if you have a Receive connector that has no permission groups assigned to it, you need to add security principals to the Receive connector as described in the last step.

- Use the **Remove-ADPermission** cmdlet to remove the **Ms-Exch-Accept-Headers-Organization** permission, the **Ms-Exch-Accept-Headers-Forest** permission, and the **Ms-Exch-Accept-Headers-Routing** permission from a security principal that's configured on the Receive connector. This method doesn't work if the permission has been assigned to the security principal using a permission group on the Receive connector, because you can't modify the permissions assignments or the group membership of a permission group.
- Use the **Add-ADPermission** cmdlet to add the appropriate security principals that are required for mail flow on the Receive connector. Make sure that no security principals have the **Ms-Exch-Accept-Headers-Organization** permission, the **Ms-Exch-Accept-Headers-Forest** permission, and the **Ms-Exch-Accept-Headers-Routing** permission assigned to them. If necessary, use the **Add-ADPermission** cmdlet to deny the **Ms-Exch-Accept-Headers-Organization** permission, the **Ms-Exch-Accept-Headers-Forest** permission, and the **Ms-Exch-Accept-Headers-Routing** permission to the security principals that are configured on the Receive connector.

For more information, see the following topics:

- Receive connectors
- Add-ADPermission
- Remove-ADPermission

Return to top

Header firewall for outbound messages on Send connectors

The following table describes the default application of the header firewall permissions on Send connectors.

Permission	Default Exchange security principals that have the permission assigned	Default usage type that assigns the security principals to the Send

		connector
Ms-Exch-Send-Headers-Organization and **Ms-Exch-Send-Headers-Forest**	• Hub Transport servers • Edge Transport servers • Exchange Servers **Note:** On Hub Transport servers only • Externally Secured servers • **ExchangeLegacyInterop** universal security group	`Internal`
Ms-Exch-Send-Headers-Routing	• Hub Transport servers • Edge Transport servers • Exchange Servers **Note:** On Hub Transport servers only • Externally Secured servers • **ExchangeLegacyInterop** universal security group	`Internal`
Ms-Exch-Send-Headers-Routing	Anonymous User Account	`Internet`
Ms-Exch-Send-Headers-Routing	Partner Servers	`Partner`

Return to top

Header firewall on custom Send connectors

If you want to apply header firewall to messages in a custom Send connector scenario, use the any of the following methods:

- Create the Send connector with a usage type that automatically applies header firewall to messages. Note that you can set the usage type only when you create the Send connector.
  - To remove the organization X-headers or forest X-headers from messages, create a Send connector and select a usage type other than `Internal` or `Partner`.
  - To remove the routing headers from messages, create a Send connector and select the usage type `Custom`. The **Ms-Exch-Send-Headers-Routing** permission is assigned to all Send connector usage types except `Custom`.
- Remove a security principal that assigns the **Ms-Exch-Send-Headers-Organization** permission, the **Ms-Exch-Send-Headers-Forest**, and the **Ms-Exch-Send-Headers-Routing** permission from

the connector.

- Use the **Remove-ADPermission** cmdlet to remove the **Ms-Exch-Send-Headers-Organization** permission, the **Ms-Exch-Send-Headers-Forest** permission, and the **Ms-Exch-Send-Headers-Routing** permission from one of the security principals that's configured on the Send connector.
- Use the **Add-ADPermission** cmdlet to deny the **Ms-Exch-Send-Headers-Organization** permission, the **Ms-Exch-Send-Headers-Forest** permission, and the **Ms-Exch-Send-Headers-Routing** permission to one of the security principals that are configured on the Send connector.

For more information, see the following topics:

- Send connectors
- Add-ADPermission
- Remove-ADPermission

Return to top

Header firewall for other message sources

Messages can enter the transport pipeline on a Mailbox server or an Edge Transport server without using Send connectors or Receive connectors. Header firewall is applied to these other message sources as described in the following list:

- **Pickup directory and Replay directory** The Pickup directory is used by administrators or applications to submit message files. The Replay directory is used to resubmit messages that have been exported from Exchange message queues. For more information about the Pickup and Replay directories, see Pickup directory and Replay directory.

Organization X-headers, forest X-headers, and routing headers are removed from the message files in the Pickup directory.

Routing headers are preserved in messages submitted by the Replay directory.

Whether or not organization X-headers and forest X-headers are preserved or removed from messages in the Replay directory is controlled by the **X-CreatedBy:** header field in the message file:

  - If the value of **X-CreatedBy:** is `MSExchange15`, organization X-headers and forest X-headers are preserved in messages.
  - If the value of **X-CreatedBy:** isn't `MSExchange15`, organization X-headers and forest X-headers are removed from messages.
  - If the **X-CreatedBy:** header field doesn't exist in the message file, organization X-headers and forest X-headers are removed from messages.

- **Drop directory** The Drop directory is used by Foreign connectors on Mailbox servers to send messages to messaging servers that don't use SMTP to transfer messages. For more information about Foreign connectors, see Foreign connectors.

Organization X-headers and forest X-headers are removed from message files before they're put in the Drop directory.

Routing headers are preserved in messages submitted by the Drop directory.

- **Mailbox Transport** The Mailbox Transport service exists on Mailbox servers to transmit

messages to and from mailboxes on Mailbox servers. For more information about the Mailbox Transport service, see Mail flow.

Organization X-headers, forest X-headers, and routing headers are removed from outgoing messages that are sent from mailboxes by the Mailbox Transport Submission service.

Routing headers are preserved for inbound messages to mailbox recipients by the Mailbox Transport Delivery service. The following organization X-headers are preserved for inbound messages to mailbox recipients by the Mailbox Transport Delivery service:

- **X-MS-Exchange-Organization-SCL**
- **X-MS-Exchange-Organization-AuthDomain**
- **X-MS-Exchange-Organization-AuthMechanism**
- **X-MS-Exchange-Organization-AuthSource**
- **X-MS-Exchange-Organization-AuthAs**
- **X-MS-Exchange-Organization-OriginalArrivalTime**
- **X-MS-Exchange-Organization-OriginalSize**

- **DSN messages** Organization X-headers, forest X-headers, and routing headers are removed from the original message or the original message header that's attached to the DSN message. For more information about DSN messages, see DSNs and NDRs.
- **Transport agent submission** Organization X-headers, forest X-headers, and routing headers are preserved in messages that are submitted by transport agents.

Return to top

Organization X-headers and forest X-headers in Exchange

The Transport service on Mailbox servers or Edge Transport servers insert custom X-header fields into the message header.

Organization X-headers start with **X-MS-Exchange-Organization-**. Forest X-headers start with **X-MS-Exchange-Forest-**. The following table describes some of the organization X-headers and forest X-headers that are used in messages in an Exchange organization.

X-header	Description
X-MS-Exchange-Forest-RulesExecuted	Transport rules that acted on the message.
X-MS-Exchange-Organization-Antispam-Report	A summary of the anti-spam filter results that have been applied to the message by the Content Filter agent.
X-MS-Exchange-Organization-AuthAs	Specifies the authentication source. This X-header is always present when the security of a message has been evaluated. The possible values are `Anonymous`, `Internal`, `External`, or

	`Partner`.
X-MS-Exchange-Organization-AuthDomain	Populated during Domain Secure authentication. The value is the FQDN of the remote authenticated domain.
X-MS-Exchange-Organization-AuthMechanism	Specifies the authentication mechanism for the submission of the message. The value is a 2-digit hexadecimal number.
X-MS-Exchange-Organization-AuthSource	Specifies the FQDN of the server computer that evaluated the authentication of the message on behalf of the organization.
X-MS-Exchange-Organization-Journal-Report	Identifies journal reports in transport. As soon as the message leaves the transport service, the header becomes **X-MS-Journal-Report**.
X-MS-Exchange-Organization-OriginalArrivalTime	Identifies the time when the message first entered the Exchange organization.
X-MS-Exchange-Organization-Original-Sender	Identifies the original sender of a quarantined message when it first entered the Exchange organization.
X-MS-Exchange-Organization-OriginalSize	Identifies the original size of a quarantined message when it first entered the Exchange organization.
X-MS-Exchange-Organization-Original-Scl	Identifies the original SCL of a quarantined message when it first entered the Exchange organization.
X-MS-Exchange-Organization-PCL	Identifies the phishing confidence level. The possible phishing confidence level values are from 1 through 8. A larger value indicates a suspicious message. For more information, see

	Anti-spam stamps.
X-MS-Exchange-Organization-Quarantine	Indicates the message has been quarantined in the spam quarantine mailbox and a delivery status notification (DSN) has been sent. Alternatively, it indicates that the message was quarantined and released by the administrator. This X-header field prevents the released message from being submitted to the spam quarantine mailbox again. For more information, see Release quarantined messages from the spam quarantine mailbox.
X-MS-Exchange-Organization-SCL	Identifies the SCL of the message. The possible SCL values are from 0 through 9. A larger value indicates a suspicious message. The special value -1 exempts the message from processing by the Content Filter agent. For more information, see Content filtering.
X-MS-Exchange-Organization-SenderIdResult	Contains the results of the Sender ID agent. The Sender ID agent uses the sender policy framework (SPF) to compare the message's source IP address to the domain that's used in the sender's email address. The Sender ID results are used to calculate the SCL of a message. For more information, see Sender ID.

Domains

Exchange Server 2013 > Mail flow >

Applies to: *Office 365*

Topic Last Modified: *2012-10-11*

Domains represent SMTP namespaces for which email directories and mailboxes are set up. By configuring the domains that interact with your Microsoft Exchange Server 2013 organization, you can configure how email to and from various domains is processed by Exchange.

Accepted domains

An accepted domain is any SMTP namespace for which your Exchange organization sends or receives email. Accepted domains include those domains for which the Exchange organization is authoritative, as well as internal relay domains and external relay domains. An Exchange organization is authoritative when it handles mail delivery for recipients in the accepted domain. Accepted domains also include domains for which the Exchange organization receives mail and then relays it to an email server that's outside the organization.

For more information about accepted domains, see Accepted domains.

Remote domains

In Exchange 2013, you create remote domain entries to define the settings for message transfer between your Exchange organization and domains outside of your organization. When you create a remote domain entry, you control the types of messages that are sent to that domain. You can also apply message format policies and acceptable character sets for messages that are sent from users in your organization to the remote domain.

Settings for remote domains are global configuration settings for your Exchange organization. Remote domain settings are applied to messages during categorization. When recipient resolution occurs, the recipient domain is matched against the configured remote domains. If a remote domain configuration blocks a specific message type from being sent to recipients in that domain, the message is deleted. If you specify a particular message format for the remote domain, the message headers and content are modified. The settings apply to all messages that are processed by the Exchange organization.

For more information about remote domains, see Remote domains.

Accepted domains

Exchange Server 2013 > Mail flow > Domains >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-17*

An accepted domain is any SMTP namespace for which a Microsoft Exchange Server 2013

organization sends or receives email. Accepted domains include those domains for which the Exchange organization is authoritative. An Exchange organization is authoritative when it handles mail delivery for recipients in the accepted domain. Accepted domains also include domains for which the Exchange organization receives mail and then relays it to an email server that's outside the organization for delivery to the recipient.

Contents

Configuring accepted domains

Accepted domains are configured as global settings for the Exchange organization. You need to configure every domain for which your Exchange organization relays or delivers messages as an accepted domain in your organization.

There are three types of accepted domains: authoritative, internal relay, and external relay. These accepted domain types are described in the following sections.

Note:

If you have a subscribed Edge Transport server in your perimeter network, you configure accepted domains on a Mailbox server in your Exchange organization. The accepted domains configuration is replicated to the Edge Transport server during EdgeSync synchronization. For more information, see Edge Subscriptions.

Authoritative domains

An organization may have more than one SMTP domain. The set of email domains for an organization are the authoritative domains. In Exchange 2013, an accepted domain is considered authoritative when the Exchange organization hosts mailboxes for recipients in this SMTP domain.

By default, when the first Exchange 2013 Mailbox server is installed, one accepted domain is configured as authoritative for the Exchange organization. The default accepted domain is the fully qualified domain name (FQDN) for your forest root domain. Frequently, the internal domain name differs from the external domain name. For example, your internal domain name may be contoso.local, although your external domain name is contoso.com. The DNS mail exchanger (MX) record for your organization references contoso.com. Contoso.com is the SMTP namespace that you assign to users when you create an email address policy. You need to create an accepted

domain to match your external domain name.

To learn more, see:

- Configure an accepted domain within your Exchange organization as authoritative
- Configure Exchange to accept mail for multiple authoritative domains

Relay domains

Typically, most Internet-facing messaging servers are configured to not allow for other domains to be relayed through them. However, there are scenarios where you may want to let partners or subsidiaries relay email through your Exchange servers. In Exchange 2013, you can configure accepted domains as relay domains. Your organization receives the email messages and then relays the messages to another email server.

You can configure a relay domain as an internal relay domain or as an external relay domain. These two relay domain types are described in the following sections.

Internal relay domain

When you configure an internal relay domain, some or all of the recipients in this domain don't have mailboxes in this Exchange organization. Mail from the Internet is relayed for this domain through Transport servers in this Exchange organization. This configuration is used in the scenarios that are described in this section.

An organization may have to share the same SMTP address space between two or more different messaging systems. For example, you may have to share the SMTP address space between Exchange and a third-party messaging system, or between Exchange environments that are configured in different Active Directory forests. In these scenarios, users in each email system have the same domain suffix as part of their email addresses.

To support these scenarios, you need to create an accepted domain that's configured as an internal relay domain. You also need to add a Send connector that's sourced on a Mailbox server and configured to send email to the shared address space. If an accepted domain is configured as authoritative and a recipient isn't found in Active Directory, a non-delivery report (NDR) is returned to the sender. The accepted domain that's configured as an internal relay domain first tries to deliver to a recipient in the Exchange organization. If the recipient isn't found, the message is routed to the Send connector that has the closest address space match.

If an organization contains more than one forest and has configured global address list (GAL) synchronization, the SMTP domain for one forest may be configured as an internal relay domain in a second forest. Messages from the Internet that are addressed to recipients in internal relay domains are relayed to the Mailbox servers in the same organization. The receiving Mailbox servers then route the messages to the Mailbox servers in the recipient forest. You configure the SMTP domain as an internal relay domain to make sure that email that's addressed to that domain is accepted by the Exchange organization. The connector configuration of your organization

determines how messages are routed.

To learn more, see Configure an accepted domain for a business unit with mailboxes outside your Exchange organization.

External relay domain

When you configure an external relay domain, messages are relayed to an email server that's outside your Exchange organization and outside the organization's network perimeter.

For more information, see Configure an accepted domain for an independent business unit.

Accepted domains and email address policies

You need to configure an accepted domain before that SMTP address space can be used in an email address policy. When you create an accepted domain, you can use a wildcard character (*) in the address space to indicate that all subdomains of the SMTP address space are also accepted by the Exchange organization. For example, to configure contoso.com and all its subdomains as accepted domains, enter *.contoso.com as the SMTP address space. The accepted domain entries are automatically available for use in an email address policy.

If you delete an accepted domain that's used in an email address policy, the policy is no longer valid, and recipients with email addresses in that SMTP domain will be unable to send or receive email.

Configure an accepted domain within your Exchange organization as authoritative

Mail flow > Domains > Accepted domains >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-17*

If a domain belonging to your organization hosts mailboxes for all the recipients within an SMTP namespace, that domain is considered to be authoritative. By default, one accepted domain is configured as authoritative for the Exchange organization. If your organization has more than one SMTP namespace, you can configure more than one accepted domain as authoritative.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Accepted domains" entry in the Mail flow permissions topic.
- If you have a subscribed Edge Transport server in your perimeter network, you configure accepted domains on a Mailbox server in your Exchange organization. The accepted domains configuration is replicated to the Edge Transport server during EdgeSync synchronization. For more information, see Edge Subscriptions.
- You can't create an accepted domain that has the same name as an already configured remote domain. For example, if you have fabrikam.com configured as a remote domain, you can't create an accepted domain for fabrikam.com.
- Before you configure an accepted domain, you must verify that a public Domain Name System (DNS) MX resource record for that SMTP namespace exists and that the MX resource record references a server name and an IP address associated with your Exchange organization.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the EAC to configure an accepted domain as authoritative

If an accepted domain for your Exchange organization hosts all the mailboxes for recipients within that domain's SMTP namespace, you may want to configure it as an authoritative domain.

1. In the EAC, navigate to **Mail flow** > **Accepted domains**, and click **Add +**.
2. In the **Name** field, enter the display name for the accepted domain. Each accepted domain for your organization must have a unique display name This may be different than the accepted domain. For example, the domain contoso.com could have a display name of Contoso Local Accepted Domain.
3. In the **Accepted domain** field, enter the accepted domain. Specify an SMTP namespace for which your organization accepts email messages. (for example, Contoso.com).
4. Select **Authoritative domain**. This option is for email relayed to servers within your Exchange organization for an accepted domain that hosts mailboxes for all the recipients within an SMTP namespace.
5. Click **Save**.

Tip:
To configure an accepted domain that has already been created, select the domain from the

accepted domains list and click **Edit** . You can configure more than one domain as authoritative.

How do you know this worked?

Your new accepted domain will appear in the accepted domains list in the EAC. To verify that you have successfully configured the accepted domain as authoritative, send mail to the domain and verify that it is received.

Configure an accepted domain for an independent business unit

Mail flow > Domains > Accepted domains >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-17*

In some situations you may want to configure an accepted domain for an independent business unit with email servers outside your Exchange organization. In such scenarios, you can configure the accepted domain as an external relay domain.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Accepted domains" entry in the Mail flow permissions topic.
- If you have a subscribed Edge Transport server in your perimeter network, you configure accepted domains on a Mailbox server in your Exchange organization. The accepted domains configuration is replicated to the Edge Transport server during EdgeSync synchronization. For more information, see Edge Subscriptions.
- You can't create an accepted domain that has the same name as an already configured remote domain. For example, if you have fabrikam.com configured as a remote domain, you can't create an accepted domain for fabrikam.com.
- Before you configure an accepted domain, you must verify that a public Domain Name System (DNS) MX resource record for that SMTP namespace exists and that the MX resource record references a server name and an IP address associated with your Exchange organization.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the EAC to configure the an accepted domain as an external relay domain

You may want to configure an accepted domain for a business unit with email servers outside your Exchange organization.

1. In the EAC, navigate to **Mail flow** > **Accepted domains**, select the domain you wish to configure, and click **Edit** .
2. In the **Name** field, enter the display name for the accepted domain. Each accepted domain for your organization must have a unique display name. This may be different than the accepted domain. For example, the domain Contoso.com could have a display name of Contoso Local Accepted Domain.
3. Select **External Relay Domain**. This option is for email is relayed to a server outside your Exchange organization.
4. Click **Save**.

How do you know this worked?

To verify that you have successfully configured an accepted domain as an external relay domain, send a message from the accepted domain you've configured as an external relay domain, and verify that it is received.

Configure an accepted domain for a business unit with mailboxes outside your Exchange organization

Mail flow > Domains > Accepted domains >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-08-06*

In some instances, you may want to configure an accepted domain for a business unit in which some or all recipients in the domain don't have mailboxes in your Exchange organization. This can occur, for example, when an organization shares the same SMTP address space between two or

more different email systems. For such scenarios, you can configure an accepted domain as an internal relay domain.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Accepted domains" entry in the Mail flow permissions topic.
- If you have a subscribed Edge Transport server in your perimeter network, you configure accepted domains on a Mailbox server in your Exchange organization. The accepted domains configuration is replicated to the Edge Transport server during EdgeSync synchronization. For more information, see Edge Subscriptions.
- Before you configure an accepted domain, you must verify that a public Domain Name System (DNS) MX resource record for that SMTP namespace exists and that the MX resource record references a server name and an IP address associated with your Exchange organization.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the EAC to configure an accepted domain as an internal relay domain

1. In the EAC, navigate to **Mail flow** > **Accepted domains**, select the domain you wish to configure, and then click **Edit** .
2. In the **Name** field, enter the display name for the accepted domain. Each accepted domain for your organization must have a unique display name. This may be different than the accepted domain. For example, the domain Contoso.com could have a display name of Contoso Local Accepted Domain.
3. Select **Internal Relay Domain**.
4. Click **Save**.

How do you know this worked?

To verify that you have successfully configured an accepted domain as an internal relay domain, send a message from the internal relay domain to a mailbox within your Exchange organization and verify that it is received.

Configure Exchange to accept mail for multiple authoritative domains

Mail flow > Domains > Accepted domains >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-02-17*

In Microsoft Exchange Server 2013, it's easy to add multiple authoritative domains to your organization. However, after you add the authoritative domain, you need to decide how to use the authoritative domain in your organization. For example:

- If you want to add an email address in the new authoritative domain for recipients in your organization, do you want to replace the existing primary (reply to) address for the recipients, or add the new email address as a proxy (secondary) address?
- Do you want the email address in the new authoritative domain to apply to all recipients, and all recipient types? Or do you want the new email address to apply to specific types of recipients, or specific recipients based on their user properties, for example, only users in the Finance department?

The following examples are scenarios in which your Exchange organization may have to receive and process email for more than one authoritative SMTP domain:

- You are changing your SMTP domain name, but have to continue to accept email for the old domain name for a time, in case customers send email messages to the previous email addresses. You can set the new email address as the primary (reply to) address. This means that the new address will be the default email address displayed on all email messages sent by the recipient. You can set the old email address as a secondary address. This will enable the recipient to continue to receive email sent to the old email address.
- You want to provision different email addresses for business units within your organization. For example, if the contoso.com Active Directory forest contains subdomains for the subsidiaries Tailspin Toys and Fourth Coffee, you may want to assign the SMTP domain names contoso.com, tailspintoys.com, and fourthcoffee.com to the recipients in those respective business units.
- You provide email hosting services and have to accept email for more than one SMTP domain name.

What do you need to know before you begin?

- Estimated time to complete this task: 30 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Accepted domains" entry in the Mail flow permissions topic and the "Email address policies" entry in the Recipients Permissions topic.
- If you have a subscribed Edge Transport server in your perimeter network, you configure accepted

domains on a Mailbox server in your Exchange organization. The accepted domains configuration is replicated to the Edge Transport server during EdgeSync synchronization. For more information, see Edge Subscriptions.

- When you create an accepted domain, you can use a wildcard character (*) in the address space to indicate that all subdomains of the SMTP address space are also accepted by the Exchange organization. For example, to configure contoso.com and all its subdomains as accepted domains, enter ***.contoso.com** as the SMTP address space. However, if the subdomain names will be used in an email address policy, each subdomain must have an explicit accepted domain entry.
- An MX record in public DNS is required for each SMTP domain for which you accept email from the Internet. Each MX record should resolve to the Internet-facing server that receives email for your organization.
- You need to configure Send connectors and Receive connectors so your Exchange organization can send email to and receive email from the Internet. The configuration of the Internet Send connectors and Receive connectors is determined by your Exchange topology. For more information about configuring connectors, see Connectors.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

How do you do this?

Step 1: Create an authoritative domain

Use the Exchange Administration Center to create an authoritative domain

1. In the EAC, navigate to **Mail flow** > **Accepted domains**, and click **Add +**.
2. In the **Name** field, enter the display name for the accepted domain. Each accepted domain for your organization must have a unique display name. This may be different than the accepted domain. For example, the domain contoso.com could have a display name of Contoso Local Accepted Domain.
3. In the **Accepted domain** field, specify an SMTP namespace for which your organization accepts email messages. For example, contoso.com.
4. Select **Authoritative domain**.
5. Click **Save**.

Use the Shell to create an authoritative domain

To create a new authoritative domain, use the following syntax.

```
New-AcceptedDomain -Name "<Unique Name>" -DomainName <SMTP
```

```
domain> -DomainType Authoritative
```

For example, to create a new authoritative domain named "Fourth Coffee subsidiary" for the domain fourthcoffee.com, run the following command:

```
New-AcceptedDomain -Name "Fourth Coffee subsidiary" -
DomainName fourthcoffee.com -DomainType Authoritative
```

How do you know this step worked?

To verify that you have successfully created an authoritative domain, do one of the following:

- In the EAC, navigate to **Mail flow** > **Accepted domains**. Verify the accepted domain you created is displayed, and the **Domain Type** value is **Authoritative**.
- In the Shell, run the command **Get-AcceptedDomain**. Verify the domain you created is displayed, and the **DomainType** value is `Authoritative`.

Step 2: Configure an email address policy for the authoritative domain

To use the authoritative accepted domain you created, you need to configure an email address policy for the authoritative domain that meets the objectives of your scenario. For example, you may need to create a new email address policy, or modify an existing policy. You may elect to replace the primary email address for some or all of your recipients, and you can elect to keep or remove the old primary email address. Two example scenarios are presented in this section.

Change the existing primary email address

To change the primary (reply to) email address assigned to recipients and keep the old primary email address as a proxy (secondary) email address, follow these steps:

Use the EAC to change the existing primary email address

1. In the EAC, navigate to **Mail flow** > **Email address policies**. Select the email address policy you want to modify, and click **Edit** .
2. On the **Email Address Policy** page, click the **Email address format** tab. In the **Email address format** section, click **Add+**.
3. On the **Email Address Format** page that appears, make the following selections:
   - **Select an accepted domain** Click the drop-down list, and select the new authoritative domain.
   - Select **Make this format the reply email address**.

When you are finished, click **Save**.

4. On the **Email Address Policy** page, click **Save** to save your changes to the policy.
5. You'll get a warning that the email address policy won't be applied until you update it. After it's created, select it, and then, in the details pane, click **Apply**.

Use the Shell to change the existing primary email address

In the Shell, you use two separate commands: one command to modify the existing email address policy, and another command to apply the updated email address policy to the recipients in your organization.

To change the existing primary email address, and keep the old primary email address as a proxy address, run the following command:

```
Set-EmailAddressPolicy <EmailAddressPolicyIdentity> -
EnabledEmailAddressTemplates
SMTP:<NewPrimaryEmailAddress>,smtp:<OldPrimaryEmailAddress>
```

For example, suppose the email address policy in your organization uses the email addresses format *useralias*`@contoso.com`. This example changes the domain of primary (reply to) address in the email address policy named "Default Policy" to `@fourthcoffee.com`, and keeps the old primary reply address in the `@contoso.com` domain as a proxy (secondary) address.

```
Set-EmailAddressPolicy "Default Policy" -
EnabledEmailAddressTemplates
SMTP:@fourthcoffee.com,smtp:@contoso.com
```

Note:

The `SMTP` qualifier in uppercase lettersspecifies the primary (reply to) address. The `smtp` qualifier in lowercase letters specifies a proxy (secondary) address.

To apply the updated email address policy to recipients, use the following syntax.

```
Update-EmailAddressPolicy <EamilAddressPolicyIdentity>
```

For example, to apply the updated email address policy named "Default Policy", run the following command:

```
Update-EmailAddressPolicy "Default Policy"
```

Replace the existing primary email address for a filtered set of recipients

You can't modify the default email address policy to apply to a filtered set of recipients. You need to create a new email address policy, or modify an existing custom email address policy. The examples in this section create a new email address policy. In these examples, the primary (reply to) address in the new accepted domain replaces the old primary address for the specified recipients without keeping the old primary address as a proxy (secondary) email address. Therefore, the affected recipients can no longer receive email at their old primary email address.

Also, email address policies that apply to specific users should have a higher priority (indicated by a lower integer value) than other email address policies, including the default policy, so the specific

policy is applied first. Because two policies can't have the same priority value, you may first need lower the priority of your organization's default email address policy.

Use the EAC to replace the existing primary email address for a filtered set of recipients

To create additional email addresses that will be used as the primary email address for a filtered set of recipients, follow these steps.

1. In the EAC, navigate to **Mail flow** > **Email address policies**, and then click **Add +**.
2. On the **Email Address Policy** page, complete the following fields:
   a. **Policy name** Enter a unique, descriptive name.
   b. **Email address format** Click **Add +**. On the **Email Address Format** page that appears, make the following selections:
      - **Select an accepted domain** Click the drop-down list, and select the new authoritative domain.
      - **Email address format** Select the appropriate email address format for your organization.
      - Select **Make this format the reply email address**.

   When you are finished, click **Save**.
3. **Run this policy in this sequence with other policies** Typically, policies that apply to specific users should have a higher priority (indicated by a lower integer value) than other email address policies, including the default policy.
4. **Specify the types of recipients this email address will apply to** Select the recipient types to which you want the email address policy applied.
5. **Create rules to further define the recipients that this email address policy applies to** Click **Add a rule** to restrict the recipients that this policy will apply to. This creates a Boolean **And** statement. Repeat this step as many times as necessary.

> **Caution:**
> If you apply too many rules, it's possible to restrict the email address policy to the point that it doesn't contain any users.

6. Click **Preview recipients the policy applies to** to view the recipients that policy will apply to.
7. Click **Save** to save your changes and create the policy.
8. You'll get a warning that the email address policy won't be applied until you update it. After it's created, select it, and then, in the details pane, click **Apply**.

Use the Shell to replace the existing primary email address for a filtered set of recipients

To replace the primary email address for a filtered set of recipients, use the following command:

```
New-EmailAddressPolicy -Name <Policy Name> -Priority
<Integer> -IncludedRecipients <RecipientTypes> <Conditional
Recipient Properties> -EnabledEmailAddressTemplates
SMTP:@<NewPrimaryEmailAddress>
```

This example creates an email address policy named "Fourth Coffee Recipients", assigns that policy to mailbox users in the Fourth Coffee department, and sets the highest priority for that email

address policy so the policy is applied first. Note that the old primary email address isn't preserved for these recipients, so they can't receive email at their old primary email address.

```
New-EmailAddressPolicy -Name "Fourth Coffee Recipients" -
Priority 1 -IncludedRecipients MailboxUsers -
ConditionalDepartment "Fourth Coffee" -
EnabledEmailAddressTemplates SMTP:@fourthcoffee.com
```

To apply the new email address policy to the affected recipients, run the following command:.

```
Update-EmailAddressPolicy "Fourth Coffee Recipients"
```

How do you know this step worked?

To verify that you have successfully configured an email address policy for the authoritative domain, do one of the following:

- In the EAC, navigate to **Mail flow** > **Email address policies**. Verify the policies are applied in the correct order. Also, select any new or updated policies, and in the details pane, verify the email address format, included recipients, and if the policy has been applied,
- In the Shell, run the commands **Get-EmailAddressPolicy** and `Get-EmailAddressPolicy "<Policy Name>"| Format-List` to verify the details of the policies.

How do you know this task worked?

To verify that you have configured Exchange to accept mail for multiple authoritative domains, do the following:

1. Send test messages to an affected recipient from a mailbox outside your Exchange organization. Verify the email addresses that successfully accept mail.
2. Send test messages from an affected recipient mailbox to an external recipient, and verify the From address of the message.

Remote domains

Exchange Server 2013 > Mail flow > Domains >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-11*

You can create remote domain entries to define the settings for message transfer between the Microsoft Exchange Server 2013 organization and domains outside your Exchange organization. When you create a remote domain entry, you control the types of messages that are sent to that domain. You can also apply message format policies and acceptable character sets for messages

that are sent from users in your organization to the remote domain. The settings for remote domains are global configuration settings for the Exchange organization.

The remote domain settings are applied to messages during categorization in the Transport service on Mailbox servers. When recipient resolution occurs, the recipient domain is matched against the configured remote domains. If a remote domain configuration blocks a specific message type from being sent to recipients in that domain, the message is deleted. If you specify a particular message format for the remote domain, the message headers and content are modified. The settings apply to all messages that are processed by the Exchange organization.

Note:

If you configure message settings per user, the per-user settings override the organizational configuration.

By default, there's a single remote domain entry. The domain address space is configured as an asterisk (*). This represents all remote domains. If you don't create additional remote domain entries, all messages that are sent to all recipients in all remote domains have the same settings applied to them.

When you configure remote domains, you can prevent certain types of messages from being sent to that domain. These message types include out-of-office messages, auto-reply messages, non-delivery reports (NDRs), and meeting forward notifications. If you have a multiple forest environment, you may want to allow the sending of those types of messages to those domains. However, if you have identified a domain from which spam originates, you may want to block sending of those types of messages to those remote domains.

Contents

Message format

You can specify the message format and the character set to use for email messages that are sent to remote domains. These settings can be useful to make sure that email sent by senders in your domain to the remote domain is compatible with the receiving email system. For example, if you know that the remote domain's messaging system is Exchange, you can specify to always use Exchange rich text format (RTF). For more information, see Content conversion.

Automatic replies settings

In Exchange 2013, users can specify different automatic replies for internal and external recipients. Furthermore, the types of automatic replies available in your organization also depend on the Microsoft Outlook version in use.

In Exchange 2013, there are two types of automatic replies:

- **External** Supported by Exchange 2013 and Exchange 2010. Can only be set by Outlook 2010 or Office Outlook 2007, or using Microsoft Office Outlook Web App.
- **Internal** Supported by Exchange 2013 and Exchange 2010. Can only be set by Outlook 2010 or Outlook 2007, or using Outlook Web App.

The following table describes various client and server combinations and the types of automatic replies that can be used in each scenario.

Client and server support for automatic replies

Client version	Exchange version	Automatic replies supported
Outlook 2010 or Outlook 2007	Exchange 2013 Exchange 2010 Exchange 2007	Internal, External
Outlook Web App	Exchange 2013 Exchange 2010 Exchange 2007	Internal, External

Controlling NDR information

As mentioned at the beginning of this topic, you can prevent NDRs from being sent to a remote domain. By blocking NDRs from being sent to a remote domain, you can prevent the information contained within the NDR message from leaving your organization, thereby limiting the knowledge that a malicious user can obtain about your organization. However, this also prevents legitimate senders from receiving NDRs, resulting in confusion and lost productivity.

Exchange 2013 provides you with granular control over the contents of an NDR destined for a remote domain. With Exchange 2013, you can allow NDRs to a remote domain, while stripping any diagnostic information. This way, you can still prevent information about your Exchange deployment from leaving your organization while at the same time providing NDR notifications to external senders.

This feature is controlled with the *NDRDiagnosticInfoEnabled* parameter on the **Set-RemoteDomain** cmdlet. Because this setting is configurable for each remote domain, you can have different settings based on your needs. For example, you can choose to remove the NDR diagnostic information for the default remote domain, but allow full NDR diagnostic information for the remote domains that represent your partners.

For more information about this new setting, see Set-RemoteDomain.

Manage remote domains

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-18*

Remote domains are SMTP domains that are external to your Microsoft Exchange organization. You can create remote domain entries to define the settings for message transferred between your Exchange organization and specific external domains. The settings in the remote domain entry for a specific external domain override the settings in the default remote domain that normally apply to all external recipients. The remote domain settings are global for the Exchange organization.

If you remove a remote domain entry, the settings for message transfer no longer apply to messages sent to the remote domain. Removing a remote domain entry doesn't disable mail flow to the remote domain. After a remote domain entry is removed, the configuration settings of the default remote domain apply to new messages sent to that domain. You can't remove the default remote domain.

What do you need to know before you begin?

- Estimated time to complete each procedure: 10 minutes.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Remote domains" entry in the Mail flow permissions topic.
- You can only use the Shell to perform this procedure.
- You can't create a remote domain for an address space that's configured as an accepted domain in your organization. For example, if your organization accepts mail for fabrikam.com, you can't create a remote domain for fabrikam.com.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What Do You Want to Do?

Use the Shell to create a remote domain

To create a new remote domain entry, use the following syntax.

```
New-RemoteDomain -Name <Descriptive Name> -DomainName <SMTP address space>
```

This example creates a remote domain entry for messages sent to the contoso.com domain.

```
New-RemoteDomain -Name Contoso -DomainName contoso.com
```

This example creates a remote domain entry for messages sent to the fabrikam.com domain and all subdomains.

```
New-RemoteDomain -Name Fabrikam -DomainName *.fabrikam.com
```

How do you know this worked?

To verify that you have successfully created a remote domain, do the following:

1. Run the command **Get-RemoteDomain** and verify that the remote domain is listed.
2. Run the command `Get-RemoteDomain <Remote Domain Name> | Format-List` to verify the settings on the new remote domain. Send a test message to a recipient in the address space that's specified in the new remote domain entry, and verify that the message settings match those specified by the new remote domain entry.

Use the Shell to configure a remote domain

You configure the settings in the remote domain entry using the **Set-RemoteDomain** cmdlet. There are many different settings that relate to automatic replies, message format and encoding, and other message settings. For more information, see Set-RemoteDomain.

To configure remote domains for specific scenarios, see the following topics:

- Configure remote domain out of office replies
- Configure remote domain automatic replies
- Configure remote domain message reporting

Use the Shell to remove a remote domain

To remove a remote domain entry, use the following syntax.

```
Remove-RemoteDomain <RemoteDomainName>
```

This example removes the remote domain entry named Contoso

```
Remove-RemoteDomain Contoso
```

How do you know this worked?

To verify that you have successfully removed the remote domain, do the following:

1. Run the command **Get-RemoteDomain** and verify that the remote domain is isn't listed.
2. Run the command `Get-RemoteDomain Default | Format-List` to verify the settings on the default remote domain. Send a test message to a recipient in the address space that was specified in the removed remote domain, and verify that the message settings match those specified by the default remote domain.

Configure remote domain out of office replies

Mail flow > Domains > Remote domains >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-11*

You can use the Exchange Management Shell to configure the way emails are sent and received through remote domains. The following demonstrates how to use the Exchange Management Shell to configure the way Exchange handles out of office replies.

What do you need to know before you begin?

- Estimated time to complete: 10 minutes
- You can only use the Shell to perform this procedure.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Remote domains" entry in the Mail flow permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to configure out-of-office replies

You can use the **Set-RemoteDomain** cmdlet to configure the properties of a remote domain.

This example disables out-of-office messages for the remote domain named Contoso.

```
Set-RemoteDomain Contoso -AllowedOOFType None
```

This example allows only external out-of-office messages.

```
Set-RemoteDomain Contoso -AllowedOOFType External
```

Configure remote domain automatic

replies

Mail flow > Domains > Remote domains >

Use the Shell to configure automatic replies

You can use the **Set-RemoteDomain** cmdlet to configure the properties of a remote domain.

This example allows automatic replies to the remote domain named Contoso. This setting is disabled by default.

```
Set-RemoteDomain Contoso -AutoReplyEnabled $true
```

This example allows automatic forwards to the remote domain. This setting is disabled by default.

```
Set-RemoteDomain Contoso -AutoForwardEnabled $true
```

Configure remote domain message reporting

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-26*

You can use the Exchange Management Shell to configure the way emails are sent and received through remote domains. The following demonstrates how to use the Exchange Management Shell configure the way Exchange handles delivery and non-delivery reports.

What do you need to know before you begin?

- Estimated time to complete: 10 minutes
- You can only use the Shell to perform this procedure.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Remote domains" entry in the Mail flow permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Use the Shell to configure message reporting

You can use the **Set-RemoteDomain** cmdlet to configure the properties of a remote domain.

This example disables delivery reports to the remote domain named Contoso. This setting is enabled by default.

```
Set-RemoteDomain Contoso -DeliveryReportEnabled $false
```

This example disables non-delivery reports to the remote domain. This setting is enabled by default.

```
Set-RemoteDomain Contoso -NDREnabled $false
```

Supported character sets for remote domains

Mail flow > Domains > Remote domains >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-07-21*

The following character sets can be specified for messages sent to remote domains.

- In the Exchange admin center (EAC), on the **Remote domain** settings page, select the name from the **MIME character set** and **Non-MIME character set** drop-down lists.
- In the Shell, use the value in the Name column in the following table for the *CharacterSet* parameter or *NonMimeCharacterSet* parameter in the Set-RemoteDomain cmdlet.

Supported character sets for remote domain configuration

Name	Description
big5	Chinese Traditional (Big5)
DIN_66003	German (IA5)
euc-jp	Japanese (EUC)

Transport agents

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-08-08*

Transport agents let you install custom software that is created by Microsoft, by third-party vendors, or by your organization, on an Exchange server. This software can then process email messages that pass through the transport pipeline. In Microsoft Exchange Server 2013, the transport pipeline is made of the following processes:

- The Front End Transport service on Client Access servers
- The Transport service on Mailbox servers
- The Mailbox Transport service on Mailbox servers
- The Transport service on Edge Transport servers

For more information about the transport pipeline, see Mail flow

Like the previous version of Exchange, Exchange 2013 transport provides extensibility through the Microsoft Exchange Server 2013 Transport Agents SDK. The Exchange 2013 version of the SDK is based on the Microsoft .NET Framework version 4.0 and allows third parties to implement the following predefined classes:

- **SmtpReceiveAgent**
- **RoutingAgent**
- **DeliveryAgent**

When complied against libraries in the SDK, the resulting assemblies are registered with Exchange 2013, which loads the agents and invokes their event handlers during specific stages of the SMTP sessions or message processing. These stages, or events, are part of the agent definitions. The agent registration information is stored in an XML configuration file.

The following list explains the requirements for using transport agents in Exchange 2013.

- The Transport service on Mailbox servers and Edge Transport servers fully supports all the predefined classes in the SDK, and therefore any third party transport agents written for the Hub Transport or Edge Transport server roles in Microsoft Exchange Server 2010 should work in the Transport service in Exchange 2013.
- The Front End Transport service only supports the **SmtpReceiveAgent** class in the SDK, and third party agents can't operate on the **OnEndOfData** SMTP event.
- The Mailbox Transport service doesn't support the SDK at all, so you can't use any third party agents in the Mailbox Transport service.

Support for legacy transport agents based on versions of the .NET Framework prior to version 4.0 isn't enabled by default, but you can enable it. For instructions, see Enable support for legacy transport agents.

Contents

Updates to transport agent management

Due to the updates to the Exchange 2013 transport pipeline, the transport agent cmdlets need to distinguish between the Transport service and the Front End Transport service, especially if the Client Access server and the Mailbox server are installed on the same computer. For more information, see Manage transport agents.

Transport Agent management cmdlets manipulate a configuration file located at `%ExchangeInstallPath%TransportRoles\Shared`. For the Transport service on Mailbox servers and Edge Transport servers, the file is `agents.config`. For the Front End Transport service on Client Access servers, the file is `fetagents.config`. Both files use the same format as in Exchange 2010. For more information about managing transport agents, see Manage transport agents.

Return to top

Transport agents and SMTP events

Transport agents use SMTP events. These events are triggered as messages move through the transport pipeline. SMTP events give transport agents access to messages at specific points during the SMTP conversation and during routing of messages through the organization.

Note that there are new SMTP Receive events in Exchange 2013. SMTP Receive exists in the Front End Transport service on Client Access servers, the Transport service on Mailbox servers and Edge Transport servers and the Mailbox Transport Delivery service on Mailbox servers. The categorizer exists only in the Transport service on Mailbox servers and Edge Transport servers. For more information about transport services and the categorizer, see Mail routing.

The following tables list the SMTP events that provide access to messages in the transport pipeline.

SMTP Receive events

Sequence	SMTP event	Description
1	**OnConnectEvent**	This event is triggered by the initial connection from a remote SMTP host.

2	**OnHeloCommand**	This event is triggered when the HELO command is issued by the remote SMTP host.
3	**OnEhloCommand**	This event is triggered when the EHLO command is issued by the remote SMTP host.
4	**OnStartTlsCommand**	This event is triggered when the STARTTLS command is issued by the remote SMTP host.
5	**OnAuthCommand**	This event is triggered when the AUTH command is issued by the remote SMTP host.
6	**OnProcessAuthentication**	This event is triggered when authentication with the remote SMTP host is being processed.
7	**OnEndOfAuthentication**	This event is triggered when the remote SMTP host has completed authentication.
8	**OnXSessionParamsCommand**	This event is triggered when the XSESSIONPARAMS command is issued by the remote SMTP host.
9	**OnMailCommand**	This event is triggered when the MAIL FROM command is issued by the remote SMTP host.
10	**OnRcptToCommand**	This event is triggered when the RCPT TO command is

		issued by the remote SMTP host.
11	**OnDataCommand**	This event is triggered when the DATA (text) or BDAT (binary data) command is issued by the remote SMTP host.
12	**OnEndOfHeaders**	This event is triggered when the remote SMTP host has completed submitting the email message headers. This is indicated by a blank line (<CRLF>) that separates the message headers and the message body.
13	**OnProxyInboundMessage**	This event is triggered when an inbound SMTP session is relayed or *proxied* by the Front End Transport service on a Client Access server to the Transport service on a Mailbox server.
14	**OnEndOfData**	This event is triggered when the remote SMTP host issues an end of data command. For text sessions started by the DATA command, the end of data indicator is <CRLF>.<CRLF>. For binary sessions started by the BDAT command, the end of data indicator is BDAT LAST.

**	**OnHelpCommand**	This event is triggered if the HELP command is issued by the remote SMTP host.
**	**OnNoopCommand**	This event is triggered if the NOOP command is issued by the remote SMTP host.
**	**OnReject**	This event is triggered if the receiving SMTP host issues a temporary or permanent delivery status notification (DSN) code to the sending SMTP host.
**	**OnRsetCommand**	This event is triggered if the RSET command is issued by the sending SMTP host.
15	**OnDisconnectEvent**	This event is triggered by the disconnection of the SMTP conversation by either the receiving or sending SMTP host. Typically, this happens when the QUIT command is issued by the remote SMTP host.

** These events can occur at any time after **OnConnectEvent** but before **OnDisconnectEvent**.

Categorizer events

Sequence	Categorizer event	Description
1	**OnSubmittedMessage**	This event is triggered when a message arrives in the Submission queue in the Transport service on the

		receiving Mailbox server or Edge Transport server.
2	**OnResolvedMessage**	This event is triggered after all the recipients have been resolved, but before the next hop has been determined for each recipient. The **OnResolvedMessage** routing event enables subsequent events to override the default routing behavior by using the per-recipient **SetRoutingOverride** method.
3	**OnRoutedMessage**	This event is triggered after messages have been categorized, distribution lists have been expanded, and recipients have been resolved.
4	**OnCategorizedMessage**	This event is triggered when the categorizer completes processing the message.

Return to top

Priority of transport agents

There are two factors that determine the order that transport agents act on messages in the transport pipeline:

1. The SMTP event where the transport agent is registered, and when that SMTP event encounters messages.
2. The priority value that's assigned to the transport agent if there are multiple agents registered to the same SMTP event. The highest priority is 1. A higher integer value indicates a lower agent priority.

For example, suppose you configured the following transport agents:

- Transport Agent A with a priority of 1 and Transport Agent C with a priority of 2 are registered to the **OnEndOfHeaders** SMTP event.
- Transport Agent B with a priority of 4 is registered to the **OnMailCommand** SMTP event.

Transport Agent B is applied to messages first because the **OnMailCommand** event encounters messages before the **OnEndOfHeaders** event. When messages reach the **OnEndOfHeaders** event, Transport Agent A is applied before Transport Agent C because Transport Agent A has a higher priority (lower integer value) than Transport Agent C.

Built-in transport agents

Exchange 2013 includes many built-in transport agents that provide features such as anti-spam, transport rules and journaling. Most of the built-in transport agents on Exchange 2013 Mailbox servers and Client Access servers are invisible and unmanageable by the transport agent management cmdlets. Virtually all of the built-in transport agents that are visible and manageable are in the Transport service on Mailbox servers and on Edge Transport servers.

The more interesting built-in transport agents on Mailbox servers are described in the following table. Note that this table doesn't include many of the invisible and unmanageable transport agents.

Interesting built-in transport agents on Mailbox servers

Agent name	Manageable?	Priority	SMTP or categorizer events
Transport Rule Agent	Yes	1	**OnResolvedMessage**
Malware Agent	Yes	2	**OnSubmittedMessage**
Text Messaging Routing Agent	Yes	3	**OnSubmittedMessage**
Text Messaging Delivery Agent	Yes	4	n/a
Journal Agent	No	Not configurable	**OnRoutedMessage**
Journal Report Decryption Agent	No	Not configurable	**OnCategorizedMessage**
RMS Decryption Agent	No	Not configurable	**OnSubmittedMessage**

RMS Encryption Agent	No	Not configurable	**OnSubmittedMessage**, **OnRoutedMessage**
RMS Protocol Decryption Agent	No	Not configurable	**OnEndOfData**

On Edge Transport servers, most of the built-in transport agents are visible and manageable by the transport agent management cmdlets or by other feature-specific cmdlets.

The more interesting built-in transport agents on Edge Transport servers are described in the following table. Note that this table doesn't include invisible or unmanageable transport agents.

Interesting built-in transport agents on Edge Transport servers

Agent name	Manageable?	Priority	SMTP or categorizer events
Connection Filtering Agent	Yes	1	**OnConnectEvent**, **OnMailCommand**, **OnRcptComand**, **OnEndOfHeaders**
Address Rewriting Inbound Agent	Yes	2	**OnRcptCommand**, **OnEndOfHeaders**
Edge Rule Agent	Yes	3	**OnEndOfData**
Content Filter Agent*	Yes	4	**OnEndOfData**
Sender ID Agent*	Yes	5	**OnEndOfHeaders**
Sender Filter Agent*	Yes	6	**OnMailCommand**, **OnEndOfHeaders**
Recipient Filter Agent	Yes	7	**OnRcptCommand**
Protocol Analysis Agent*	Yes	8	**OnConnectEvent**, **OnEndOfHeaders**, **OnEndOfData**, **OnReject**, **OnRsetCommand**, **OnDisconnectEvent**

Attachment Filtering Agent	Yes	9	**OnEndOfData**
Address Rewriting Outbound Agent	Yes	10	**OnSubmittedMessage**, **OnRoutedMessage**

* You can also install and configure these anti-spam agents on Mailbox servers. For more information, see Enable anti-spam functionality on Mailbox servers.

Return to top

Troubleshoot transport agents

To help you troubleshoot issues with transport agents, you can use the following features:

- **Get-TransportPipeline** This cmdlet shows the SMTP events and the corresponding transport agents that encounter messages on the Exchange server. For more information, see View transport agents in the transport pipeline.
- **Pipeline Tracing** Pipeline tracing creates an exact snapshot of a message before and after it encounters each transport agent. This allows you to find a transport agent that's causing unexpected results. For more information, see Pipeline tracing.

Return to top

Enable support for legacy transport agents

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-22*

In Microsoft Exchange Server 2013, transport agents that were created using the Microsoft .NET Framework version 4.0 are supported by default. Exchange 2013 supports transport agents that were created using previous versions of the .NET Framework, but support for these legacy transport agents isn't enabled by default. To enable support for legacy transport agents, you need to modify the appropriate XML application configuration file. The files you need to modify depend on where the transport agent is installed:

Server	Application configuration files	Microsoft Windows service
Client Access server	%ExchangeInstallPath%Bin	Microsoft Exchange Front End

	\MSExchangeFrontendTransport.exe.config	Transport (MSExchangeFrontendTransport)
Mailbox server	• %ExchangeInstallPath%Bin\EdgeTransport.exe.config • %ExchangeInstallPath%Bin\MSExchangeTransport.exe.config	Microsoft Exchange Transport (MSExchangeTransport)

Support for legacy transport agents is controlled by keys in the application configuration files. By default, none of the required keys are present in the application configuration files. You must add the keys manually. The following table explains each key in more detail.

Key	Description
useLegacyV2RuntimeActivationPolicy	This key enables or disables support for legacy transport agents. Valid values for this key are `true` or `false`. If this key isn't specified, the default value is `false`.
supportedRuntime version	This key specifies the version of the Microsoft .NET Framework that's required by the agent. Valid values for this key are: • `v4.0` or `v4.0.30319` • `v3.5` or `v3.5.21022` • `v3.0` or `v3.0.4506` • `v2.0` or `v2.0.50727` You specify multiple values using multiple separate instances of the *supportedRuntime version* key. When you enable legacy transport agent support using the *useLegacyV2RuntimeActivationPolicy* key, you should always specify the value `v4.0` in addition to the values required by the legacy transport agent.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- Exchange permissions don't apply to the procedures in this topic. These procedures are performed in the operating system of the Exchange Server.
- Changes you save to an application configuration file are applied after you restart the corresponding service.
- When you restart any of the services that are associated with the application configuration files, mail flow on the server is temporarily interrupted.
- Any customized per-server settings you make in Exchange XML application configuration files, for example, web.config files on Client Access servers or the EdgeTransport.exe.config file on Mailbox servers, will be overwritten when you install an Exchange Cumulative Update (CU). Make sure that you save this information so you can easily re-configure your server after the install. You must re-configure these settings after you install an Exchange CU.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Command Prompt to configure support for legacy transport agents

Use the following procedure to enable support for legacy transport agents:

1. In a Command prompt window, on the Exchange 2013 server where you want to configure the legacy transport agent support, open the appropriate application configuration file in Notepad by running the following command:

```
Notepad %ExchangeInstallPath%Bin\<AppConfigFile>
```

For example, to open the EdgeTransport.exe.config file on a Mailbox server, run the following command:

```
Notepad %ExchangeInstallPath%Bin\EdgeTransport.exe.config
```

2. Locate the *</configuration>* key at the end of the file, and paste the following keys before the *</configuration>* key:

```
<startup useLegacyV2RuntimeActivationPolicy="true">
    <supportedRuntime version="v4.0" />
    <supportedRuntime version="v3.5" />
    <supportedRuntime version="v3.0" />
    <supportedRuntime version="v2.0" />
</startup>
```

3. When you are finished, save and close the application configuration file.
4. Repeat Steps 1 through 3 to modify the other application configuration files.
5. Restart the associated Windows service by running the following command:

```
net stop <service> && net start <service>
```

For example, if you modified the EdgeTransport.exe.config file, you need to restart the Microsoft Exchange Transport service by running the following command:

```
net stop MSExchangeTransport && net start
MSExchangeTransport
```

6. Repeat Step 5 to restart services associated with the other modified application configuration files.

How do you know this worked?

You'll know this procedure works if the legacy transport agent installs successfully. If you try to install a legacy transport agent without performing the procedures in this topic, you'll receive an error that's similar to the following:

```
Mixed mode assembly is built against version '<version>' of
the runtime and cannot be loaded in the 4.0 runtime without
additional configuration information.
```

Manage transport agents

Exchange Server 2013 > Mail flow > Transport agents >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

Transport agents use SMTP events to operate on messages as the messages move through the transport pipeline. Most of the built-in transport agents that are included with Microsoft Exchange Server 2013 are invisible and unmanageable. However, you can install and configure third-party transport agents on Exchange servers in your organization. For more information about transport agents, see Transport agents.

What do you need to know before you begin?

- Estimated time to complete each procedure: 10 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport agents" entry in the Mail flow permissions

topic.

- You can only use the Shell to perform this procedure.
- Support for legacy transport agents isn't enabled by default, but you can enable it. For instructions, see Enable support for legacy transport agents.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

About transport agent procedures in the Front End Transport service on Client Access servers

You can't use the Exchange Management Shell to manage transport agent in the Front End Transport service on a Client Access server. Instead, you need to open Windows PowerShell on the Client Access server, and then import the Exchange cmdlets into the Windows PowerShell session.

Caution:

Running Exchange cmdlets in Windows PowerShell for tasks other than managing transport agents in the Front End Transport service is not supported. There are serious consequences that can result if you bypass the Exchange Management Shell and role-based access control (RBAC) by running Exchange cmdlets in Windows PowerShell. You should always run Exchange cmdlets in the Exchange Management Shell. For more information, see Release notes for Exchange 2013.

To perform any of the Transport Agent procedures described in this topic in the Front End Transport service, you need to perform the following additional steps:

1. On the Client Access server, open Windows PowerShell and run the following command:

```
Add-PSSnapin
Microsoft.Exchange.Management.PowerShell.SnapIn
```

2. Run the command as described, but add the following value to the command: `-TransportService FrontEnd`.

For example, to view the transport agents in the Front End Transport service on a Client Access server, run the following command:

```
Get-TransportAgent -TransportService FrontEnd
```

Use the Shell to install a transport agent

When you install a transport agent, Exchange only registers the DLLs associated with the transport agent. You need to make sure all files, registry keys, and other objects that the transport agent depends on are installed correctly and configured. After Exchange loads the DLLs, it continues to reference the DLLs after the command has completed.

Transport agents have full access to all e-mail messages that they encounter. Exchange puts no restrictions on a transport agent's behavior. Transport agents that are unstable or contain security flaws may affect the stability and security of Exchange. Therefore, you should only install transport agents that you fully trust and that have been fully tested in a test environment.

Transport agents are installed in a disabled state to make sure mail flow isn't affected by transport agents that haven't been configured. Therefore, after a transport agent has been configured correctly, you need to enable the transport agent.

Use the following syntax to install a transport agent.

```
Install-TransportAgent -Name <TransportAgentIdentity> -
TransportAgentFactory <"TransportAgentFactory"> -
AssemblyPath <"FilePath">
```

This example installs a fictitious transport agent named Contoso Transport Agent in the Transport service on a Mailbox server.

```
Install-TransportAgent -Name "Contoso Transport Agent" -
TransportAgentFactory
"vendor.exchange.ContosoTransportAgentfactory" -
AssemblyPath "C:\Program Files\Vendor\TransportAgent
\ContosoTransportAgentFactory.dll"
```

How do you know this worked?

To verify that you have successfully installed the transport agent, run the command `Get-TransportAgent` and verify the transport agent is listed.

Use the Shell to enable a transport agent

Use the following syntax to enable a transport agent.

```
Enable-TransportAgent <TransportAgentIdentity>
```

This example enables the transport agent named Contoso Transport Agent in the Transport service on a Mailbox server.

```
Enable-TransportAgent "Contoso Transport Agent"
```

How do you know this worked?

To verify that you have successfully enabled a transport agent, run the command `Get-TransportAgent | Format-List Name,Enabled` and verify the transport agent is enabled.

Use the Shell to disable a transport agent

Use the following syntax to disable a transport agent:

```
Disable-TransportAgent <TransportAgentIdentity>
```

This example disables the transport agent named Fabirkam Transport Agent in the Transport service on a Mailbox server.

```
Disable-TransportAgent "Fabrikam Transport Agent"
```

How do you know this worked?

To verify that you have successfully disabled a transport agent, run the command `Get-TransportAgent | Format-List Name,Enabled` and verify the transport agent is disabled.

Use the Shell to view transport agents

To view a summary list of transport agents, run the following command:

```
Get-TransportAgent
```

To view the detailed configuration of a specific transport agent, run the following command:

```
Get-TransportAgent <TransportAgentIdentity> | Format-List
```

This example provides detailed configuration of the transport agent named Transport Rule Agent.

```
Get-TransportAgent "Transport Rule Agent" | Format-List
```

Use the Shell to configure the priority of a transport agent

Transport agents with a priority closest to 0 process email messages first. However, the SMTP event in the transport pipeline where the transport agent is registered may cause a lower priority agent to act on the message before a higher priority agent.

To modify the priority of an existing transport agent, run the following command:

```
Set-TransportAgent <TransportAgentIdentity> -Priority
<Integer>
```

This example sets the priority agent value of 3 for the existing transport agent named Contoso Transport Agent in the Transport service on a Mailbox server.

```
Set-TransportAgent "Contoso Transport Agent" -Priority 3
```

How do you know this worked?

To verify that you have successfully configured the priority of a transport agent, run the command `Get-TransportAgent | Format-List Name,Priority` and verify the priority value of the transport agent.

Use the Shell to uninstall a transport agent

When the transport agent is uninstalled, Exchange unregisters the DLL files used with the agent. Exchange doesn't remove any files, registry keys, or other objects added by the installation of the transport agent.

To uninstall a transport agent, run the following command:

```
Uninstall-TransportAgent <TransportAgentIdentity>
```

This example uninstalls the transport agent named Fabrikam Transport Agent from the Transport service on a Mailbox server.

```
Uninstall-TransportAgent "Fabrikam Transport Agent"
```

How do you know this worked?

To verify that you have successfully uninstalled the transport agent, run the command `Get-TransportAgent` and verify the transport agent isn't listed.

View transport agents in the transport pipeline

Exchange Server 2013 > Mail flow > Transport agents >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-01-21*

You can use the Exchange Management Shell to view a list of transport agents in the transport pipeline on Microsoft Exchange Server 2013 Mailbox servers and Client Access servers. Specifically, the **Get-TransportPipeline** cmdlet shows information about the following types of transport

agents in the transport pipeline:

- Agents based on the **SmtpReceiveAgent**, **RoutingAgent**, **DeliveryAgent**, and **StorageAgent** classes in the Transport service on Mailbox servers.
- Agents based on the **SmtpReceiveAgentClass** in the Mailbox Transport Delivery service on Mailbox servers.
- Agents based on the **SmtpReceiveAgentClass** in the Front End Transport service on Client Access servers.

You can view a list of all the enabled transport agents that have encountered messages in the transport pipeline and the SMTP events they are registered on. For more information about transport agents, see Transport agents.

What do you need to know before you begin?

- Estimated time to complete: 5 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport agents" entry in the Mail flow permissions topic.
- You can only use the Shell to perform this procedure.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to view a list of transport agents in the transport pipeline

To use the Shell to view a list of transport agents in the transport pipeline on an Exchange server, run the following command:

```
Get-TransportPipeline | Format-List
```

To export the results to a text file named C:\My Documents\Transport Agents.txt, run the following command:

```
Get-TransportPipeline | Format-List > "C:\My Documents
\Transport Agents.txt"
```

How do you know this worked?

Only transport agents that have encountered messages in the transport pipeline between the time when the transport service was started and the time when the **Get-TransportPipeline** cmdlet was run are displayed by the cmdlet. A transport agent that hasn't encountered a message in the transport pipeline won't appear in the results displayed by the **Get-TransportPipeline** cmdlet, even if that transport agent is enabled.

Transport high availability

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-15*

In Microsoft Exchange Server 2013, transport high availability is responsible for keeping redundant copies of messages before and after the messages are successfully delivered. Exchange 2013 improves upon the transport high availability features introduced in Exchange Server 2010, for example, shadow redundancy and the transport dumpster, to help ensure messages aren't lost in transit.

Here's a summary of the major transport high availability improvements in Exchange 2013:

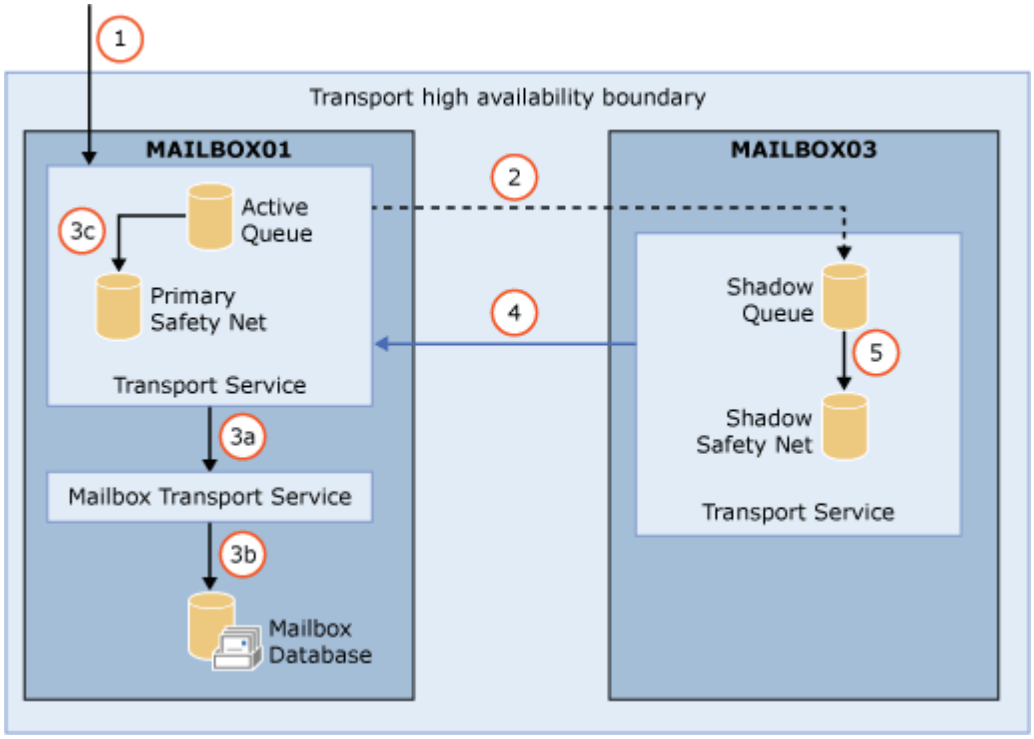
- Shadow redundancy creates a redundant copy of the message on another server before the message is accepted or acknowledged. The sending server's support or lack of support for shadow redundancy is irrelevant.
- Shadow redundancy recognizes both database availability groups (DAGs) and Active Directory sites as transport high availability boundaries. This reduces the number of servers that can hold redundant copies of messages, and eliminates unnecessary redundant message maintenance traffic across DAGs or Active Directory sites.

For more information, see Shadow redundancy.

- The transport dumpster has been improved and is now named *Safety Net*. Safety Net stores messages that were successfully processed by the Transport service on Mailbox servers. Safety Net works best for Mailbox servers in a DAG, but Safety Net also works for multiple Mailbox servers in the same Active Directory site that don't belong to a DAG.
- Safety Net itself is now made redundant on another server. This is important to avoid a single point of failure in Exchange 2013, because the Transport service and the mailbox databases are both located on the Mailbox server.

For more information, see Safety Net.

The following diagram provides a high-level overview of how transport high availability works in Exchange 2013.



1. An Exchange 2013 Mailbox server named Mailbox01 receives a message from an SMTP server that's outside the transport high availability boundary. The *transport high availability boundary* is a DAG or an Active Directory site in non-DAG environments. The message could come from a third-party SMTP server, from an Internet SMTP server proxied through a Client Access server, or from another Exchange 2013 server.
2. Before acknowledging receipt of the message, Mailbox01 initiates a new SMTP session to another Exchange 2013 Mailbox server named Mailbox03 that's within the Transport high availability boundary, and Mailbox03 makes a shadow copy of the message. In DAG environments, a shadow server in a remote Active Directory site is preferred. Mailbox01 is the primary server holding the primary message, and Mailbox03 is the shadow server holding the shadow message.
3. The Transport service on Mailbox01 processes the primary message.
   a. In this example, the recipient's mailbox is located on Mailbox01, so the Transport service transmits the message to the local Mailbox Transport service.
   b. The Mailbox Transport service delivers the message to the local mailbox database.
   c. Mailbox01 queues a discard status for Mailbox03 that indicates the primary message was successfully processed, and Mailbox01 moves a copy of the primary message into the local Primary Safety Net. Note that the message moves between queues within the same queue database.
4. Mailbox03 periodically polls Mailbox01 for the discard status of the primary message.
5. When Mailbox03 determines Mailbox01 successfully processed the primary message, Mailbox03 moves the shadow message into the local Shadow Safety Net. Note that the message moves between queues within the same queue database.

The message is retained in Primary Safety Net and Shadow Safety Net until the message expires based on a configurable timeout value. If a mailbox database failover occurs before the message expires, the Primary Safety Net on Mailbox01 resubmits the message. If the Mailbox01 isn't available, the Shadow Safety Net on Mailbox03 takes over and resubmits the message.

Message redundancy in the Front End Transport service on Client Access servers

A Client Access server has no message queues. It's a stateless proxy server that uses the Front End Transport service to accept incoming SMTP connections and proxy them to the Transport service on a Mailbox server. The Front End Transport service keeps the SMTP session with the sending server open while the primary message is transmitted to the Transport service on a Mailbox server, and a shadow copy of the message is made by the Transport service on a different Mailbox server within the transport high availability boundary. Only after both the primary message and shadow message are successfully created, the end of data SMTP command is sent back to the sending SMTP server through the Client Access server.

Shadow redundancy

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-03-18*

Shadow redundancy was introduced in Microsoft Exchange Server 2010 to provide redundant copies of messages before they're delivered to mailboxes. In Exchange 2010, shadow redundancy delayed deleting a message from the transport database on a transport server until the server verified the next hop in the message delivery path completed delivery. If the next hop failed before reporting successful delivery back to the transport server, the transport server resubmitted the message to that next hop. Exchange 2010 servers used the XSHADOW verb to advertise their shadow redundancy support. If an SMTP server didn't support shadow redundancy, Exchange 2010 used delayed acknowledgement based on a configured time interval on the Receive connector to make a redundant copy of the message.

The major improvement to shadow redundancy in Microsoft Exchange Server 2013 is that the transport server now makes a redundant copy of any messages it receives before it acknowledges successfully receiving the message back to the sending server. The sending server's support or lack of support for shadow redundancy doesn't matter. This helps to ensure that all messages in the Exchange 2013 transport pipeline are made redundant while they're in transit. If Exchange 2013 determines the original message was lost in transit, the redundant copy of the message is redelivered.

Contents

Shadow redundancy components

The following table describes the components of shadow redundancy. These terms are used throughout the topic.

Term	Description
Transport server	An Exchange server that has message queues and is responsible for routing messages. In Exchange 2013, a transport server is a Mailbox server (the Transport service on the Mailbox server).
Transport database	The message queue database on an Exchange 2013 transport server. Shadow queues and Safety Net are also stored in the transport database.
Transport high availability boundary	A database availability group (DAG) in DAG environments, or an Active Directory site in non-DAG environments. When a message arrives on a transport server in the transport high availability boundary, Exchange tries to maintain 2 redundant copies of the message on transport servers within the boundary. When a message leaves the transport high availability boundary, Exchange stops maintaining redundant copies of the message.
Primary message	The message submitted into the transport

	pipeline for delivery.
Shadow message	The redundant copy of the message that the shadow server retains until it confirms the primary message was successfully processed by the primary server.
Primary server	The transport server that's currently processing the primary message.
Shadow server	The transport server that holds the shadow message for the primary server. A transport server may be the primary server for some messages and the shadow server for other messages simultaneously.
Shadow queue	The delivery queue where the shadow server stores shadow messages. For messages with multiple recipients, each next hop for the primary message requires separate shadow queues.
Discard status	The information a transport server maintains for shadow messages that indicate the primary message has been successfully processed.
Discard notification	The response a shadow server receives from a primary server indicating a shadow message is ready to be discarded.
Safety Net	The Exchange 2013 improved version of the transport dumpster. Messages that are successfully processed or delivered to a mailbox recipient by the Transport service on a Mailbox server are moved into Safety Net. For more information, see Safety Net.

Shadow Redundancy Manager	The transport component that manages shadow redundancy.
Heartbeat	The process that allows primary servers and shadow servers to verify the availability of each other.

Return to top

Requirements for shadow redundancy

Although it may seem obvious, shadow redundancy requires multiple Exchange 2013 Mailbox servers. The Mailbox server can be standalone servers, or Mailbox servers and Client Access servers installed on the same computer.

- If the Mailbox server isn't a member of a DAG, the other Mailbox servers must be in the local Active Directory site.
- If the Mailbox server is a member of a DAG, the other Mailbox servers must belong to the same DAG. The other Mailbox servers that belong to the DAG can be in the local Active Directory site or in a remote Active Directory site. If the DAG spans multiple Active Directory sites, shadow redundancy prefers creating a redundant copy of the message in a remote Active Directory site for site resiliency.

These are the situations where shadow redundancy can't protect messages in transit:

- In single Exchange server environments.
- In under-provisioned DAGs.
- During the simultaneous failure of two or more transport servers involved in the shadow redundancy of a message.

Return to top

Shadow redundancy is enabled by default

By default, shadow redundancy is enabled globally in the Transport service on all Mailbox servers by using the *ShadowRedundancyEnabled* parameter on the **Set-TransportConfig** cmdlet. By default, if the Transport service on a Mailbox server can't create a redundant copy of a message, the message is not rejected. However, you can configure Exchange 2013 to reject a message if a redundant copy of the message isn't created by using the *RejectMessageOnShadowFailure* parameter on the **Set-TransportConfig** cmdlet. The message is rejected with a transient failure, but the sending server can transmit the message again. The SMTP response code is `451 4.4.0 Message failed to be made redundant.` You should configure Exchange 2013 to reject messages that can't be made redundant only when your organization has multiple Exchange 2013 Mailbox servers available.

The following table describes the parameters that enable shadow redundancy.

Parameters that enable shadow redundancy

Parameter	Default value	Description
ShadowRedundancyEnabled on **Set-TransportConfig**	`$true`	• `$true` enables shadow redundancy on all transport servers in the organization. • `$false` disables shadow redundancy on all transport servers in the organization.
RejectMessageOnShadowFailure on **Set-TransportConfig**	`$false`	• `$false` When a shadow copy of the message can't be created, the primary message is accepted anyway by transport servers in the organization. Those messages aren't redundantly persisted while they're in transit. • `$true` No message is accepted or acknowledged by any transport server in the organization until a shadow copy of the message is successfully created. If a shadow copy of the message can't be created, the primary message is rejected with a transient error. All messages in the organization are redundantly persisted while they're in transit. You should set this value to `$true` only if you have multiple Exchange 2013 Mailbox servers in a DAG or Active Directory site where a shadow copy of the message can be created. This parameter is only meaningful when *ShadowRedundancyEnabled* is `$true`.

Return to top

How shadow messages are created

The main goal of shadow redundancy is to always have two copies of a message within a transport high availability boundary while the message is in transit. Where and when the redundant copy of the message is created depends on where the message came from and where the message is going. There are three major determining factors:

- Messages received from outside a transport high availability boundary.
- Messages sent outside a transport high availability boundary.
- Messages received from the Mailbox Transport Submission service from a Mailbox server within the transport high availability boundary.

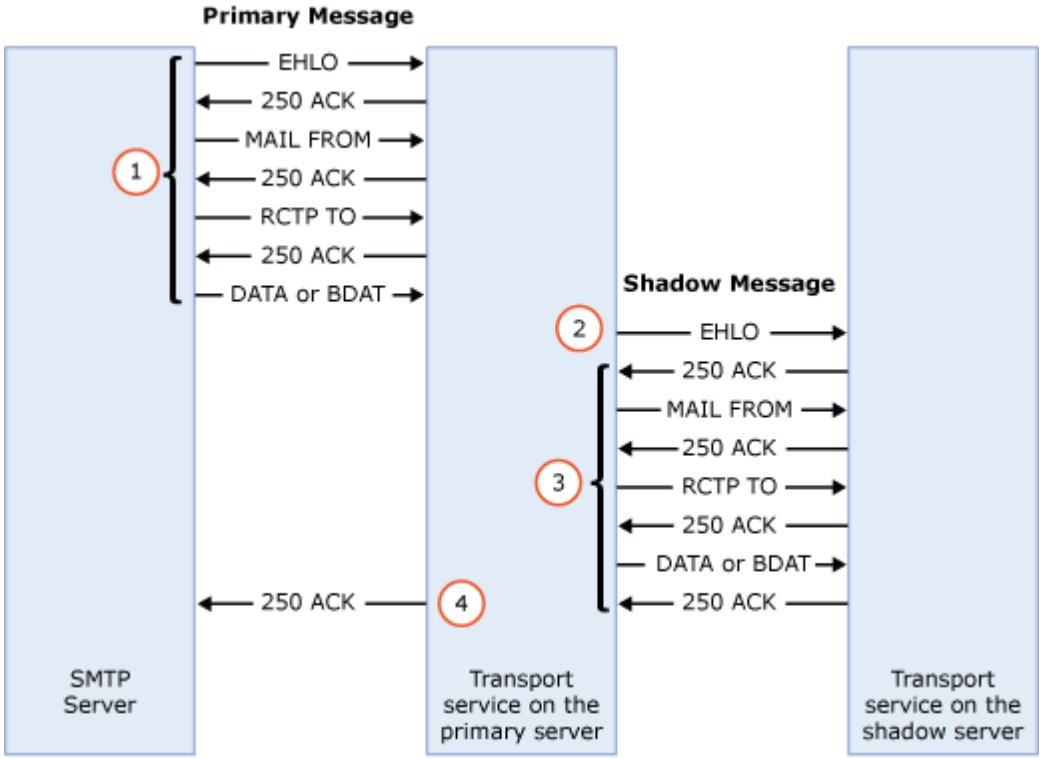
A *transport high availability boundary* is one of the following:

- A DAG, for Mailbox servers that are members of a DAG. This includes a DAG that spans multiple Active Directory sites.
- An Active Directory site, for Mailbox servers that don't belong to a DAG.

Shadow redundancy never tracks shadow messages across a transport high availability boundary. When a message crosses the transport high availability boundary, shadow redundancy begins or restarts. This reduces shadow message maintenance traffic and prevents shadow message resubmissions from occurring across the transport high availability boundary. Exchange 2010 Hub Transport servers are a special case, and are discussed later in this topic.

Messages received from outside a transport high availability boundary

When the Transport service on an Exchange 2013 Mailbox server receives a message from outside the transport high availability boundary, the Mailbox server isn't concerned about the support or lack of support for shadow redundancy by the sending server. As long as shadow redundancy is enabled, the Mailbox server that receives the message makes a redundant copy of the message on another Mailbox server within the transport high availability boundary before acknowledging receipt of the message back to the sending server. Here's an example of how the process works:



1. An SMTP server transmits a message to the Transport service on a Mailbox server. The Mailbox server is the primary server, and the message is the primary message.
2. While the original SMTP session with the SMTP server is still active, the Transport service on primary server opens a new, simultaneous SMTP session with the Transport service on a different Mailbox server in the organization to create a redundant copy of the message.
   - If the primary server is a member of a DAG, the primary server connects to a different Mailbox server in the same DAG. If the DAG spans multiple Active Directory sites, a Mailbox server in a different Active Directory site is preferred by default. This setting is controlled by the *ShadowMessagePreference* parameter on the **Set-TransportService** cmdlet. The default value is `PreferRemote`, but you can change it to `RemoteOnly` or `LocalOnly`.
   - If the primary server isn't a member of a DAG, the primary server connects to a different Mailbox server in the same Active Directory Site, regardless of the value of the *ShadowMessagePreference* parameter.
3. The primary server transmits a copy of the message to the Transport service on other Mailbox server, and Transport service on the other Mailbox server acknowledges that the copy of the message was created successfully. The copy of the message is the shadow message, and the Mailbox server that holds it is the shadow server for the primary server. The message exists in a shadow queue on the shadow server.
4. After the primary server receives acknowledgement from the shadow server, the primary server acknowledges the receipt of the primary message to the original SMTP server in the original SMTP session, and the SMTP session is closed.

Messages sent outside a transport high availability boundary

When an Exchange 2013 transport server transmits a message outside the transport high availability boundary, and the SMTP server on the other side acknowledges successful receipt of the message, the transport server moves the message into Safety Net. No resubmission of the message from Safety Net can occur after the primary message has been successfully transmitted across the transport high availability boundary. For more information about Safety Net, see Safety Net.

Messages transmitted within a transport high availability boundary

Message routing is optimized in Exchange 2013 so that when the ultimate destination is in a DAG or Active Directory site, multiple hops between the Transport service on Mailbox servers in that DAG or Active Directory site aren't typically required. Once the message is accepted by the Transport service on a Mailbox server in the DAG or Active Directory site that holds the ultimate destination for the message, the next hop for the message is typically the ultimate destination itself. Shadow redundancy's goal of keeping two copies of a message in transit is fulfilled when one shadow copy of the message exists anywhere within the DAG or Active Directory site. Typically, only failover scenarios in a DAG that require the **Redirect-Message** cmdlet to drain the active queues on a Mailbox server would require multiple hops within the same transport high availability boundary.

Shadow redundancy with Exchange 2010 Hub Transport servers in the same Active Directory site

When an Exchange 2010 Hub Transport server transmits a message to an Exchange 2013 Mailbox server in the same Active Directory site, the Exchange 2010 Hub Transport server advertises support for shadow redundancy using the XSHADOW command, but the Mailbox server doesn't advertise support for shadow redundancy. This prevents the Exchange 2010 Hub Transport server from creating a shadow copy of the message on an Exchange 2013 Mailbox server.

When the Transport service on an Exchange 2013 Mailbox server transmits a message to an Exchange 2010 Hub Transport in the same Active Directory site, the Exchange 2013 Mailbox server shadows the message for the Exchange 2010 Hub Transport server. After the Exchange 2013 Mailbox server receives acknowledgement from the Exchange 2010 Hub Transport server that the message was successfully received, the Exchange 2013 Mailbox server moves the successfully processed message into Safety Net. However, the successfully processed messages stored in Safety Net by Exchange 2013 Mailbox are never resubmitted to the Exchange 2010 Hub Transport servers.

Return to top

SMTP timeouts

During the attempt to make a redundant copy of the message, the SMTP connection between the sending SMTP server and the primary server, or the SMTP session between the primary server and the shadow server could timeout. Receive connectors and Send connectors both have a *ConnectionInactivityTimeOut* parameter for when data is actually being transmitted on the connector. Receive connectors also have an absolute *ConnectionTimeOut* parameter.

If any of the SMTP sessions time out before the shadow copy of the message is successfully created and acknowledged, the result is controlled by the *RejectMessageOnShadowFailure* parameter on the **Set-TransportConfig** cmdlet. By default, the value of this parameter is `$false`, which means the primary message is accepted without a shadow copy being created. If the value of this parameter is `$true` the primary message is rejected with the transient error `451 4.4.0`.

If the shadow copy of a message is successfully created, but the SMTP session between the sending SMTP server and the primary server times out, the primary server accepts and processes the primary message. The sending SMTP server will re-deliver the unacknowledged message, but duplicate message detection will prevent Exchange mailbox users from seeing the duplicate messages. When the sending SMTP server resubmits the message, the primary server will create another shadow copy of the message. There's no relationship between the shadow messages created during message resubmissions by the sending SMTP server.

The following table describes the parameters that control the creation of shadow messages

Shadow message creation parameters

Source	Default value	Description
ShadowMessagePreferenceSetting on **Set-TransportConfig**	`PreferRemote`	• `PreferRemote` Try to make a shadow copy of the message on a Mailbox server in a different Active Directory site. If the operation fails, try make a shadow copy of the message on a server in the local Active Directory site. • `LocalOnly` A shadow copy of the message should only be made on a transport server in the local Active Directory site. • `RemoteOnly`: A shadow copy of the message should only be made on a transport server in a different Active Directory site. This parameter is only meaningful when the primary server that's trying to make a shadow copy of the message is a Mailbox server that's a

		member of a DAG that spans multiple Active Directory sites.
MaxRetriesForRemoteSiteShadow on **Set-TransportConfig**	4	This parameter is used when the Mailbox server is a member of a DAG that spans multiple Active Directory sites. • If *ShadowMessagePreferenceSetting* is set to `PreferRemote`, first the Mailbox server tries to create a shadow copy of the message on another Mailbox server in a remote Active directory site up to the number of times specified by *MaxRetriesForRemoteSiteShadow*. If this fails, the Mailbox server tries to create a shadow copy of the message on a different Mailbox server in the local Active Directory site up to the number of times specified by *MaxRetriesForLocalSiteShadow*. • If *ShadowMessagePreferenceSetting* is set to `RemoteOnly`, the Mailbox server only tries to create a shadow copy of the message on a Mailbox server in a remote Active Directory site up to the number of times specified by *MaxRetriesForRemoteSiteShadow*. • The

		When a shadow copy of the message can't be successfully created: • If *RejectMessageOnShadowFailure* is `$true`, the primary message is rejected with a transient error. • If *RejectMessageOnShadowFailure* is `$false`, the primary message is accepted anyway, but isn't redundantly persisted.
MaxRetriesForLocalSiteShadow on **Set-TransportConfig**	2	This parameter is used in the following circumstances: • If the Mailbox server is a member of a DAG that spans multiple Active Directory sites. 1. If *ShadowMessagePreferenceSetting* is set to `PreferRemote`, first the Mailbox server tries to create a shadow copy of the message on another Mailbox server in a remote Active directory site up to the number of times specified by *MaxRetriesForRemoteSiteShadow*. If this fails, the Mailbox server tries to create a shadow copy of the message on a different Mailbox server in the local Active Directory site up to the number of times specified by *MaxRetriesForLocalSiteShadow*. 2. If *ShadowMessagePreferenceSetting* is set to `LocalOnly`, the

		Mailbox server only tries to create a shadow copy of the message on a different Mailbox server in the local Active Directory site up to the number of times specified by the *MaxRetriesForLocalSiteShadow*. • If the Mailbox server isn't a member of a DAG, or if the Mailbox server is a member of a DAG that's in one Active Directory site, the Mailbox server only tries to create a shadow copy of the message on a different Mailbox server in the local Active Directory site up to the number of times specified by *MaxRetriesForLocalSiteShadow*. When a shadow copy of the message can't be successfully created: • If *RejectMessageOnShadowFailure* is `$true`, the primary message is rejected with a transient error. • If *RejectMessageOnShadowFailure* is `$false`, the primary message is accepted anyway, but isn't redundantly persisted.
ConnectionInactivityTimeout on **Set-ReceiveConnector**	5 minutes in the Transport service on Mailbox servers 5 minutes in the Front End Transport service on Client Access servers.	This parameter specifies the maximum time that an open SMTP connection with a source messaging server can remain idle before the connection is closed. The value of this parameter must be smaller than

	1 minute on Edge Transport servers.	the value specified by the *ConnectionTimeout* parameter.
ConnectionTimeout on **Set-ReceiveConnector**	10 minutes in the Transport service on Mailbox servers 10 minutes in the Front End Transport service on Client Access servers. 5 minutes on Edge Transport servers.	This parameter specifies the maximum time that an SMTP connection with a source messaging server can remain open, even if the source messaging server is transmitting data. The value of this parameter must be larger than the value specified by the *ConnectionInactivityTimeout* parameter.
ConnectionInactivityTimeOut on **Set-SendConnector**	10 minutes	This parameter specifies the maximum time that an open SMTP connection with a destination messaging server can remain idle before the connection is closed.

Return to top

How shadow messages are maintained

After a shadow message is successfully created, the work of shadow redundancy has only just begun. The primary server and the shadow server need to stay in contact with each other to track the progress of the message.

When the primary server successfully transmits the message to the next hop, and the next hop acknowledges receipt of the message, the primary server updates the *discard status* of the message as delivery complete. The discard status is basically a message that contains of list of messages that are being monitored. A successfully delivered message doesn't need to be kept in a shadow queue, so once the shadow server knows the primary server has successfully transmitted the message to the next hop, the shadow server moves the shadow message from the shadow queue into Safety Net.

The shadow server determines the discard status of the shadow messages in its shadow queues by querying the primary server. If the shadow server opens an SMTP session with the primary server for any reason, including the transmission of other unrelated messages, the shadow server issues the **XQDISCARD** command to determine the discard status of the primary messages. If the shadow

server hasn't opened an SMTP session with the primary server after a preconfigured time interval, the shadow server will open an SMTP session with the primary server and issue the **XQDISCARD** command. The time interval is controlled by the *ShadowHeartbeatFrequentcy* parameter on the **Set-TransportConfig** cmdlet. The default value is 2 minutes. After the shadow server opens an SMTP session with the primary server, the primary server responds with the *discard notifications* for messages that apply to the querying shadow server. In Exchange 2013, discard notifications are stored on disk, not in memory. Therefore, if the Microsoft Exchange Transport service restarts, the discard notifications are persisted. After the service starts, the primary server still knows about the messages it successfully processed, and that information is available to the shadow server.

The SMTP communication between the shadow server and the primary server is used as the *heartbeat* that determines the availability of the servers. If the shadow server can't open an SMTP session with the primary server after a preconfigured time interval, or if the transport database of the primary server has a different database ID, the shadow server promotes itself as the primary server, promotes the shadow messages as primary messages, and transmits the messages to the next hop. The time interval is controlled by the *ShadowResubmitTimeSpan* parameter on the **Set-TransportConfig** cmdlet. The default value is 3 hours.

Shadow Redundancy Manager is the core component of an Exchange 2013 transport server that's responsible for managing shadow redundancy. Shadow Redundancy Manager is responsible for maintaining the following information for all the primary messages that a server is currently processing:

- The shadow server for each primary message being processed.
- The discard status to be sent to shadow servers.

Shadow Redundancy Manager is responsible for the following for all the shadow messages that a shadow server has in its shadow queues:

- Maintaining the list of primary servers for each shadow message.
- Comparing the original database ID and the current database ID of the queue database where the primary copy of the message is stored.
- Checking the availability of each primary server for which a shadow message is queued.
- Processing discard notifications from primary servers.
- Removing the shadow messages from the shadow queues after all expected discard notifications are received.
- Deciding when the shadow server should take ownership of shadow messages, becoming a primary server.
- Tracking message bifurcations and other side-effect messages like delivery status notifications (DSNs) and journal reports to verify the redundant copy of the message isn't released until all forks of the message are fully processed.

The following table describes the parameters that control how shadow messages are maintained.

Parameter	Default value	Description
ShadowHeartbeatFrequency	2 minutes	The maximum amount of time

on **Set-TransportConfig**		a shadow server waits before opening an SMTP connection to the primary server to check the discard status of messages.
ShadowResubmitTimeSpan on **Set-TransportConfig**	3 hours	How long a server waits before deciding that a primary server has failed and assumes ownership of shadow messages in the shadow queue for the primary server that's unreachable.
ShadowMessageAutoDiscardInterval on **Set-TransportConfig**	2 days	How long a server retains discard events for successfully delivered messages. A primary server queues discard events until queried by the shadow server. However, if the shadow server doesn't query the primary server for the duration specified in this parameter, the primary server deletes the queued discard events.
SafetyNetHoldTime on **Set-TransportConfig**	2 days	How long successfully processed messages are retained in Safety Net. Unacknowledged shadow messages eventually expire from Safety Net after the sum of *SafetyNetHoldTime* and *MessageExpirationTimeout* on **Set-TransportService**.

MessageExpirationTimeout on **Set-TransportService**	2 days	How long a message can remain in a queue before it expires.

Return to top

Message processing after an outage

Shadow redundancy minimizes message loss due to server outages. When a transport server comes back online after an outage, there are two scenarios:

- **The server comes back online with a new transport database** In this scenario, the transport database is unrecoverable due to data corruption or hardware failure. In this case, because the transport server will have a new database ID, it will be recognized as a new route by the other transport servers in the organization. This also applies to the situation where a server couldn't be recovered, and a new server was provisioned as a replacement.
- **The server comes back online with the same transport database** In this scenario, the particular transport server didn't fail, but was offline long enough for the shadow server to assume ownership of the messages and resubmit them. For example, a network card failure, or a long maintenance on the server would cause this scenario.

The following table summarizes how shadow redundancy reacts to these two scenarios. For clarity, assume that the server that had an outage is named Mailbox01.

Message processing in recovery scenarios

Recovery scenario	Actions taken
Mailbox01 comes back online with a new database.	When Mailbox01 becomes unavailable, each server that has shadow messages queued for Mailbox01 will assume ownership of those messages and resubmit them. The messages then get delivered to their destinations. The maximum delay for messages is the value of the *ShadowHeartbeatFrequency* parameter on the **Set-TransportConfig** cmdlet. The default value is 2 minutes.
Mailbox01 comes back online with the same database.	After Mailbox01 comes back online, it will deliver the messages in its queues, which have already been delivered by the servers that hold

	shadow copies of messages for Mailbox01. This will result in duplicate delivery of these messages. Exchange mailbox users won't see duplicate messages due to duplicate message detection. However, recipients on non-Exchange messaging systems may receive duplicate copies of messages. The maximum delay for messages is the value of the *ShadowResubmitTimeSpan* parameter on the **Set-TransportConfig** cmdlet. The default value is 3 hours.

Return to top

Safety Net

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-26*

In Microsoft Exchange Server 2013, the primary mechanism of mailbox high availability is the database availability group (DAG). For more information about DAGs, see Managing database availability groups. The *transport dumpster* was first introduced in Exchange 2007, and was further improved in Exchange 2010 to provide redundant copies of messages after they're successfully delivered to mailboxes in DAGs. In Exchange 2010, the transport dumpster helped protect against data loss by maintaining a queue of successfully delivered messages that hadn't replicated to the passive mailbox database copies in the DAG. When a mailbox database or server failure required the promotion of an out-of-date copy of the mailbox database, the messages in the transport dumpster were automatically resubmitted to the new active copy of the mailbox database.

The transport dumpster has been improved in Exchange 2013 and is now called *Safety Net*.

Here's how Safety Net is similar to the transport dumpster in Exchange 2010:

- Safety Net is a queue that's associated with the Transport service on a Mailbox server. This queue stores copies of messages that were successfully processed by the server.
- You can specify how long Safety Net stores copies of the successfully processed messages before they expire and are automatically deleted. The default is 2 days.

Here's how Safety Net is different in Exchange 2013:

- Safety Net doesn't require DAGs. For Mailbox servers that don't belong to a DAGs, Safety Net stores copies of the delivered messages on other Mailbox servers in the local Active Directory site.
- Safety Net itself is now redundant, and is no longer a single point of failure. This introduces the concept of the *Primary Safety Net* and the *Shadow Safety Net*. If the Primary Safety Net is unavailable for more than 12 hours, resubmit requests become shadow resubmit requests, and messages are re-delivered from the Shadow Safety Net.
- Safety Net takes over some responsibility from shadow redundancy in DAG environments. Shadow redundancy doesn't need to keep another copy of the delivered message in a shadow queue while it waits for the delivered message to replicate to the passive copies of mailbox database on the other Mailbox servers in the DAG. The copy of the delivered message is already stored in Safety Net, so the message can be resubmitted from Safety Net if necessary.
- In Exchange 2013, transport high availability is more than just a best effort for message redundancy. Exchange 2013 attempts to guarantee message redundancy. Because of this, you can't specify a maximum size limit for Safety Net. You can only specify how long Safety Net stores messages before they're automatically deleted.

Contents

How Safety Net works

Shadow redundancy keeps a redundant copy of the message while the message is in transit. Safety Net keeps a redundant copy of a message after the message is successfully processed. So, Safety Net begins where shadow redundancy ends. The same concepts about shadow redundancy, including the transport high availability boundary, primary messages, primary servers, shadow messages and shadow servers also apply to Safety Net. For more information, see Shadow redundancy.

The Primary Safety Net exists on the Mailbox server that held the primary message before the message was successfully processed by the Transport service. This could mean the message was delivered to the Mailbox Transport service on the destination Mailbox server. Or, the message could have been relayed through the Mailbox server in an Active Directory site that's designated as a hub site on the way to the destination DAG or Active Directory site. After the primary server processes the primary message, the message is moved from the active queue into the Primary Safety Net on the same server.

The Shadow Safety Net exists on the Mailbox server that held the shadow message. After the shadow server determines the primary server has successfully processed the primary message, the shadow server moves the shadow message from the shadow queue into the Shadow Safety Net on

the same server. Although it may seem obvious, the existence of the Shadow Safety Net requires shadow redundancy to be enabled, and shadow redundancy is enabled by default in Exchange 2013.

The parameters used by Safety Net are described in the following table.

Parameter	Default value	Description
SafetyNetHoldTime on **Set-TransportConfig**	2 days	The length of time successfully processed primary messages are stored in Primary Safety Net, and acknowledged shadow messages are stored in Shadow Safety Net. You can also specify this value in the Exchange Administration Center (EAC) at **Mail flow** > **Receive connectors** > **More options ···** > **Organization transport settings** > **Safety Net** > **Safety Net hold time**. Unacknowledged shadow messages eventually expire from Shadow Safety Net after the sum of *SafetyNetHoldTime* and *MessageExpirationTimeout* on **Set-TransportService**. To avoid data loss during Safety Net resubmits, the value of *SafetyNetHoldTime* must be greater than or equal to the value of *ReplayLagTime* on **Set-MailboxDatabaseCopy** for the lagged copy of the mailbox database.
ReplayLagTime on **Set-**	Not configured	The amount of time that the

MailboxDatabaseCopy		Microsoft Exchange Replication service should wait before replaying log files that have been copied to the passive database copy. Setting this parameter to a value greater than 0 creates a lagged copy of the mailbox database. The maximum value is 14 days. To avoid data loss during Safety Net resubmits, the value of *ReplayLagTime* must be less than or equal to the value of *SafetyNetHoldTime* on **Set-TransportConfig** for the lagged copy of the mailbox database.
MessageExpirationTimeout on **Set-TransportService**	2 days	How long a message can remain in a queue before it expires.
ShadowRedundancyEnabled on **Set-TransportConfig**	`$true`	• `$true` enables shadow redundancy on all transport servers in the organization. • `$false` disables shadow redundancy on all transport servers in the organization. A redundant Safety Net requires shadow redundancy to be enabled.

Return to top

Message resubmission from Safety Net

Message resubmissions from Safety Net are initiated by the Active Manager component of the Microsoft Exchange Replication service that manages DAGs and mailbox database copies. No manual actions are required to resubmit messages from Safety Net. For more information about

Active Manager, see Active Manager.

There are two basic Safety Net message resubmission scenarios:

- After the automatic or manual failover of a mailbox database in a DAG.
- After you active a lagged copy of a mailbox database.

A *lagged mailbox database copy* or *lagged copy* is a passive copy of a mailbox database where updates to the database are intentionally delayed to protect against logical corruption of the mailbox database. For more information, see Managing mailbox database copies.

The only significant difference between the two scenarios is how far back in time to go to resubmit messages from Safety Net. Typically, for failover in a DAG, the new active copy of the mailbox database is typically several minutes to several hours behind the old active copy. A lagged copy of a mailbox database is typically several days behind the old active copy.

The main requirement for successful resubmission from Safety Net for a lagged copy is the amount of time messages are stored in Safety Net must be greater than or equal to the lag time of lagged copy of the mailbox database. In other words, the value of *SafetyNetHoldTime* on **Set-TransportConfig** must be greater than or equal to the value of the *ReplayLagTime* on **Set-MailboxDatabaseCopy** for the lagged copy.

Return to top

Message resubmission from Shadow Safety Net

Like message resubmission from Primary Safety Net, message resubmissions from Shadow Safety Net are fully automated, and require no manual intervention.

When the Active Manager requests message resubmission from Safety Net over a specific time period, the request goes to the Transport service on the Mailbox servers where Primary Safety Net is holding the message copies for the required time period. In large Exchange organizations, it's likely that the required messages exist in Safety Net on multiple Mailbox servers, particularly if the required time period is large.

Without optimization, resubmitting messages from Safety Net would result in potentially large numbers of duplicate deliveries. Duplicate deliveries within the Exchange organization aren't a problem, because duplicate message detection prevents mailbox users from seeing duplicate copies of a message. But duplicate message delivery to recipients outside the Exchange organization will result in duplicate copies of messages. Fortunately, the resubmission of messages from Safety Net has been optimized in Exchange 2013 to reduce duplicate message delivery.

If the Primary Safety Net is initially unresponsive, or becomes unresponsive during message resubmission, Active Manager continues to attempt to contact it for 12 hours before giving up. After 12 hours, a broadcast is sent to the Transport service on all the Mailbox servers in the transport high availability bound requesting resubmission of message from Safety Net for the required time interval for the required mailbox database. When a Shadow Safety Net responds, it resubmits the messages for the required mailbox database during the required time interval only.

There are some important considerations for the shadow messages stored in Shadow Safety Net:

- Shadow Safety Net doesn't know where the primary server transmitted the primary message.
- The shadow messages in Shadow Safety Net only contain original message envelope recipients, not the actual recipients where the primary message was delivered. For example, the message envelope recipient may be a distribution group that requires expansion.
- The messages in Shadow Safety net don't have any of the message updates that occurred after the primary server processed the message. For example, message encoding or content conversion.

Shadow message resubmitted from Shadow Safety Net require full categorization and processing through the Transport service on the Mailbox server. Resubmission of large numbers of shadow messages from Shadow Safety Net can be expensive in terms of Mailbox server resources. Fortunately, resubmission of shadow messages from Shadow Safety Net is also optimized so only messages in the Shadow Safety Net for the requested time interval and the requested mailbox database are resubmitted.

The interaction of Primary Safety Net and Shadow Safety Net during message resubmission is described in the following scenario.

1. Active Manager requests a resubmission of messages from Safety Net for a mailbox database for the time interval 5:00 to 9:00. However, the Mailbox server that holds the Primary Safety Net has crashed due to a hardware failure. Active Manager repeatedly tries to contact the Primary Safety Net for 12 hours.
2. After 12 hours, Active Manager sends a broadcast message to the Transport service on all Mailbox servers in the transport high availability boundary looking for other Safety Nets that contain messages for the target mailbox database for the time interval 5:00 to 9:00. The Shadow Safety Net responds are resubmits messages for the mailbox database for the time interval 5:00 to 9:00.

An interesting interaction occurs if the Primary Safety Net was offline during part of the requested resubmit interval as described in the following scenario.

1. The queue database on Mailbox server that holds the Primary Safety Net is corrupt, and a new queue database is created at 7:00. All of the primary messages stored in the Primary Safety Net from 1:00 to 7:00 are lost, but the server is able to store copies of successfully delivered messages in Safety Net starting at 7:00.
2. Active Manager requests a resubmission of messages from Safety Net for a mailbox database for the time interval 1:00 to 9:00.
3. The Primary Safety Net resubmits messages for the time interval 7:00 to 9:00.
4. The Primary Safety Net sends a broadcast message to the Transport service on all Mailbox servers in the transport high availability boundary looking for other Safety Nets that contain messages for the target mailbox database for the time interval 1:00 to 7:00 for which the Primary Safety Net has no message. The Shadow Safety Net generates a second resubmit request on behalf of the Primary Safety Net for resubmitting the shadow messages for the target mailbox database for the time interval 1:00 to 7:00.

There are some other issues to consider when messages are resubmitted from Safety Net.

1. All delivery status notifications (DSNs) and non-delivery reports (NDRs) are suppressed for Safety Net resubmits. For example, if the primary message resulted in an NDR, the NDR for the resubmitted message won't be delivered.
2. Users removed from a distribution group may not receive a resubmitted message when the Shadow Safety Net resubmits the message. For example, a message is sent to a group containing User A and User B, and both recipients receive the message. User B is subsequently removed from the group. Later, a resubmit request from Primary Safety Net is made for the mailbox database that holds User B's mailbox. However, the Primary Safety Net is unavailable for more than 12 hours, so the Shadow Safety Net server responds and resubmits the affected message. During resubmission when the distribution group is expanded, User B isn't a member of the group, and won't receive a copy of the resubmitted message.
3. New Users added to a distribution group may receive an old resubmitted message when the Shadow Safety Net resubmits the message. For example, a message is sent to a group containing User A and User B, and both recipients receive the message. User C is subsequently added to the group. Later, a resubmit request from Primary Safety Net is made for the mailbox database that holds User C's mailbox. However, the Primary Safety Net server is unavailable for more than 12 hours, so the Shadow Safety Net server responds and resubmits the affected messages. During resubmission when the distribution group is expanded, User C is a member of the group, and will receive a copy of the resubmitted message.

Return to top

Transport logs

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-01-28*

Transport logs provide information about what's happening in the transport pipeline. The following transport logs are available in Microsoft Exchange Server 2013:

Agent logs Agent logging records the actions performed on a message by specific anti-spam agents. Agent logging is available in the Transport service on a Mailbox server. For more information, see Anti-spam agent logging.

Connectivity logs Connectivity logging records the outbound connection activity transport services. Connectivity logging is available in the Front End Transport service on Client Access servers, the Transport service on Mailbox servers, and the Mailbox Transport service on Mailbox servers. For more information, see Connectivity logging.

Message tracking and delivery reports Message tracking logs the details of all message activity as messages are transferred to and from an Exchange 2013 Mailbox server. Message tracking is

available in the Transport service on Mailbox servers, and in the Mailbox Transport service on Mailbox servers. For more information, see Message tracking.

Delivery reports uses the information stored in the message tracking log to search for information about messages sent to or sent from a specific mailbox. For more information, see Delivery reports for administrators.

Pipeline tracing Pipeline tracing records snapshots of messages before and after the message is affected by transport agents in the Transport service on Mailbox servers, and in the Mailbox Transport Delivery service on Mailbox servers. For more information, see Pipeline tracing.

Protocol logs Protocol logging records the SMTP conversations that occur on Send connectors and Receive connectors as part of message delivery. Protocol logging is available in the Front End Transport service on Client Access servers, the Transport service on Mailbox servers, and the Mailbox Transport service on Mailbox servers. For more information, see Protocol logging.

Routing table logs Routing table logging periodically records a snapshot of the routing table that's used by Exchange 2013 to route messages to their destinations. Routing table logging is available in the Transport service on Mailbox servers.

Anti-spam agent logging

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-14*

Agent logs record the actions performed on a message by specific anti-spam agents in Microsoft Exchange Server 2013. Only the following agents can write information to the agent log:

- Connection Filtering agent
- Content Filter agent
- Edge Rules agent
- Recipient Filter agent
- Sender Filter agent
- Sender ID agent

Note:
The Connection Filtering agent and the Edge Rules agent aren't available on Mailbox servers.

The information written to the agent log depends on the agent, the SMTP event, and the action performed on the message.

You use the **Set-TransportService** cmdlet in the Exchange Management Shell to perform all agent log configuration tasks. The following options are available for the agent logs:

- Enable or disable agent logging. The default is enabled.

- Specify the location of the agent log files. The default value is %ExchangeInstallPath% TransportRoles\Logs\Hub\AgentLog.
- Specify a maximum size for the individual agent log files. The default size is 10 megabytes (MB).
- Specify a maximum size for the directory that contains agent log files. The default size is 250 MB.
- Specify a maximum age for the agent log files. The default age is 7 days.

Exchange uses circular logging to limit the agent logs based on file size and file age to help control the hard disk space used by the log files.

Contents

Overview of transport agents

Agents can only act upon messages at specific points in the SMTP command sequence used to transport the messages through the Transport service on a Mailbox server or an Edge Transport server. These access points in the SMTP command sequence are called *SMTP events*. Each agent has a priority value that can be assigned. However, the SMTP events must always occur in a specific order. Therefore, the agent priority depends on the SMTP event. If two agents can act on a message during the same SMTP event, the agent that has the highest priority will act on the message first.

The following table lists the SMTP events in order of occurrence and the agents that write information to the agent log in order of priority from highest to lowest for each SMTP event.

SMTP events in order of occurrence and the agents that write information to the agent log in order of priority for each SMTP event

SMTP event	Agent
OnConnect	Connection Filtering agent
OnMailCommand	Connection Filtering agent Sender Filter agent
OnRcptCommand	Connection Filtering agent Recipient Filter agent
OnEndOfHeaders	Connection Filtering agent Sender ID agent

	Sender Filter agent
OnEndOfData	Edge Rules agent Content Filtering agent

Note:
The Connection Filtering agent and the Edge Rules agent aren't available on Mailbox servers.

For more information about agents, SMTP events, and agent priority, see Transport agents.

Return to top

Structure of the agent log files

The agent logs exist in %ExchangeInstallPath%TransportRoles\Logs\Hub\AgentLog.

The naming convention for the agent log files is AGENTLOG*yyyymmdd-nnnn*.log. The placeholders represent the following information:

- The placeholder *yyyymmdd* is the Coordinated Universal Time (UTC) date that the log file was created. The placeholder *yyyy* = year, *mm* = month, and *dd* = day.
- The placeholder *nnnn* is an instance number that starts at the value of 1 for each day.

Information is written to the log file until the file size reaches its maximum specified value, and a new log file that has an incremented instance number is opened. This process is repeated throughout the day. Circular logging deletes the oldest log files when the agent log directory reaches its maximum specified size, or when a log file reaches its maximum specified age.

The agent log files are text files that contain data in the comma-separated value file (CSV) format. Each agent log file has a header that contains the following information:

- **#Software** Name of the software that created the agent log file. Typically, the value is Microsoft Exchange Server.
- **#Version** Version number of the software that created the agent log file. Currently, the value is 15.0.0.0.
- **#Log-Type** Log type value, which is Agent Log.
- **#Date** UTC date-time when the log file was created. The UTC date-time is represented in the ISO 8601 date-time format: *yyyy-mm-dd*T*hh:mm:ss.fff*Z, where *yyyy* = year, *mm* = month, *dd* = day, T indicates the beginning of the time component, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and Z signifies Zulu, which is another way to denote UTC.
- **#Fields** Comma delimited field names used in the agent log files.

Return to top

Information written to the agent log

The agent log stores each agent transaction on a single line in the log. The information stored on each line is organized by fields. These fields are separated by commas. The field name is generally descriptive enough to determine the type of information it contains. However, some of the fields may be blank. Or the type of information stored in the field may change based on the agent or the action performed on the message by the agent. The following table describes the fields used to classify each agent transaction.

Fields used to classify each agent transaction

Field name	Description
Timestamp	UTC date-time of the agent event. The UTC date-time is represented in the ISO 8601 date-time format: *yyyy-mm-dd*T*hh:mm:ss.fff*Z, where *yyyy* = year, *mm* = month, *dd* = day, T indicates the beginning of the time component, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and Z signifies Zulu, which is another way to denote UTC.
SessionId	Unique SMTP session identifier. This identifier is represented as a 16-digit hexadecimal number.
LocalEndpoint	Local IP address and port number that accepted the message. SMTP sessions typically use port 25.
RemoteEndpoint	IP address and port number of the previous SMTP server that connected to this server to deliver the message. When Internet mail flows through an Edge Transport server in the perimeter network, the value of **RemoteEndpoint** in the agent log on the Mailbox server will be the IP address of the Edge Transport server. Even though the message is transmitted by SMTP, the port number used by the sending server will be a random number larger than 1,024.

EnteredOrgFromIP	IP address of the remote SMTP server that first connected to the Exchange organization to deliver the message. On an Edge Transport server, the value of **RemoteEndpoint** and **EnteredOrgFromIP** are the same. Anti-spam agents use the IP address in **EnteredOrgFromIP** to examine a message.
MessageId	Value of the `MessageID` header field. If this value is blank, the Exchange transport server assigns an arbitrary value, but only if the message is accepted. After a value is assigned, the value of `MessageID` is constant for the lifetime of the message.
P1FromAddress	Sender email address specified in `MAIL FROM` in the message envelope. This value is used to transport the message between SMTP messaging servers. This value serves as a comparison to the value of **P2FromAddresses** to determine whether the sender address in the message header is forged.
P2FromAddresses	Sender email address specified in the `From` header field or in the `Sender` header field in the message header.
Recipient	Email address of the recipients. Although the original message may contain multiple recipients, only one recipient is displayed per line in the agent log.
NumRecipients	Total number of recipients in the original message.
Agent	Name of the agent that took the action. The

	possible values are as follows: • Content Filter agent • Recipient Filter agent • Sender Filter agent • Sender ID agent
Event	SMTP event where the action was taken by the agent. The value of **Event** depends on the agent. The SMTP events available to each agent are described in the first table earlier in this topic. The possible values for **Event** are as follows: • OnConnect • OnEndOfHeaders • OnEndOfData • OnMailCommand • OnRcptCommand
Action	Action performed on the message by the agent. The possible values for **Action** are as follows: • AcceptMessage • DeleteMessage • DeleteRecipients • Disconnect • QuarantineMessage • QuarantineRecipients • RejectAuthentication • RejectCommand • RejectConnection • RejectMessage • RejectRecipients
SmtpResponse	Enhanced SMTP response as defined in RFC 2034.
Reason	Reason for the action supplied by the agent.

ReasonData	Descriptive details for the action supplied by the agent.

Return to top

Search the agent logs

You can use the **Get-AgentLog** cmdlet and the **Get-AntiSpamFilteringReport.ps1** script to search the agent logs.

The **Get-AntiSpamFilteringReport.ps1** script is located in `%ExchangeInstallPath%Scripts`. You need to run the script in the Shell from the Scripts folder. To change your location in the Shell to the Scripts folder, run the following command:

```
Cd $env:ExchangeInstallPath\Scripts
```

To run the script in the Scripts folder, use the following syntax:

```
.\Get-AntiSpamFilteringReport.ps1 -report <ReportValue>
[<OptionalParameters>]
```

For details about using the script, run the following command:

```
Get-Help -Detailed .\Get-AntiSpamFilteringReport.ps1
```

Return to top

Configure anti-spam agent logging

Mail flow > Transport logs > Anti-spam agent logging >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-03*

Agent logging records the actions performed by specific Exchange anti-spam agents. The information written to the agent log depends on the agent, the SMTP event, and the action performed on the message.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To

see what permissions you need, see the "Transport Service" and "Edge Transport server" entries in the Mail flow permissions topic.

- By default, anti-spam features aren't enabled in the Transport service on a Mailbox server. Typically, you only enable the anti-spam features on a Mailbox server if your Exchange organization doesn't do any prior anti-spam filtering before accepting incoming messages. For more information, see Enable anti-spam functionality on Mailbox servers.
- You can only use the Shell to perform this procedure.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the Shell to configure anti-spam agent logging

Run the following command:

```
Set-TransportService <ServerIdentity> -AgentLogEnabled
<$true | $false> -AgentLogMaxAge <dd.hh:mm:ss> -
AgentLogMaxDirectorySize <Size> -AgentLogMaxFileSize <Size>
-AgentLogPath <LocalFilePath>
```

This example sets the following agent log settings on the Mailbox server named Mailbox01:

Sets the location of the agent log files to D:\Anti-Spam Agent Log. Note that if the folder doesn't exist, it will be created for you.

Sets the maximum size of an agent log file to 20 MB.

Sets the maximum size of the agent log directory to 400 MB.

Sets the maximum age of an agent log file to 14 days.

```
Set-TransportService Mailbox01 -AgentLogPath "D:\Anti-Spam
Agent Log" -AgentLogMaxFileSize 20MB -
AgentLogMaxDirectorySize 400MB -AgentLogMaxAge 14.00:00:00
```

Note:

- If you set the *AgentLogPath* parameter to the value `$null`, you effectively disable agent logging. However, if you set *AgentLogPath* to `$null` when the value of the *AgentLogEnabled* parameter is `$true`, event log errors are generated. The preferred method to disable agent

logging is to set *AgentLogEnabled* to `$false`.

- Setting the *AgentLogMaxAge* parameter to the value `00:00:00` prevents the automatic removal of agent log files because of their age.

For detailed syntax and parameter information, see the *AgentLog* parameters in Set-TransportService.

How do you know this worked?

To verify that you have successfully configured anti-spam agent logging, do the following:
1. In the Shell, run the following command:

```
Get-TransportService <ServerIdentity> | Format-List AgentLog*
```

2. Verify the values displayed are the values you configured.

Connectivity logging

Exchange Server 2013 > Mail flow > Transport logs >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-15*

Connectivity logging records the outbound connection activity that's used to transmit messages from a transport service on the Exchange server. The purpose of the connectivity log isn't to track the transmission of individual email messages. Rather, the connectivity log tracks the connection activity from source to the destination, regardless of how many messages are transmitted. Connectivity logging is available in the Front End Transport service on Client Access servers, the Transport service on Mailbox servers, and the Mailbox Transport service on Mailbox servers. The following list describes the type of information recorded in the connectivity log:

- Source
- Destination
- DNS resolution information
- Detailed information about connection failures
- Number of messages and bytes transmitted

You use the **Set-TransportService**, **Set-FrontEndTransportService** and **Set-MailboxTransportService** cmdlets in the Exchange Management Shell to perform all connectivity log configuration tasks. The following options are available for the connectivity logs:

- Enable or disable connectivity logging. The default is enabled.

- Specify the location of the connectivity log files.
- Specify a maximum size for the individual connectivity log files. The default size is 10 megabytes (MB).
- Specify a maximum size for the directory that contains connectivity log files. The default size is 1000 MB.
- Specify a maximum age for the connectivity log files. The default age is 30 days.

By default, Exchange uses circular logging to limit the connectivity logs based on file size and file age to help control the hard disk space used by the connectivity log files.

Contents

Structure of the connectivity log files

By default, the connectivity log files exist in the following locations:

- **Transport service** %ExchangeInstallPath%TransportRoles\Logs\Hub\Connectivity
- **Front End Transport service** %ExchangeInstallPath%TransportRoles\Logs\FrontEnd\Connectivity
- **Mailbox Transport service** %ExchangeInstallPath%TransportRoles\Logs\Mailbox\Connectivity

The naming convention for the connectivity log files is CONNECTLOG*yyyymmdd-nnnn*.log. The placeholders represent the following information:

- The placeholder *yyyymmdd* is the Coordinated Universal Time (UTC) date that the log file was created. The placeholder *yyyy* = year, *mm* = month, and *dd* = day.
- The placeholder *nnnn* is an instance number that starts at the value of 1 for each day.

Information is written to the log file until the file size reaches its maximum specified value, and a new log file that has an incremented instance number is opened. This process is repeated throughout the day. Circular logging deletes the oldest log files when the connectivity log directory reaches its maximum specified size, or when a log file reaches its maximum specified age.

The connectivity log files are text files that contain data in the comma-separated value file (CSV) format. Each connectivity log file has a header that contains the following information:

- **#Software** Name of the software that created the connectivity log file. Typically, the value is Microsoft Exchange Server.
- **#Version** Version number of the software that created the connectivity log file. Currently, the value is 15.0.0.0.
- **#Log-Type** Log type value, which is Transport Connectivity Log.
- **#Date** UTC date-time when the log file was created. The UTC date-time is represented in the ISO 8601 date-time format: *yyyy-mm-dd*T*hh:mm:ss.fff*Z, where *yyyy* = year, *mm* = month, *dd* = day, T indicates the beginning of the time component, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and Z signifies Zulu, which is another way to denote UTC.
- **#Fields** Comma delimited field names used in the connectivity log files.

Return to top

Information written to the connectivity log

The connectivity log stores each outbound transport service connection event on a single line in the connectivity log. The information stored on each line is organized by fields. These fields are separated by commas. The following table describes the fields used to classify each outgoing connection event.

Fields used to classify each connection event

Field name	Description
date-time	UTC date-time of the connection event. The UTC date-time is represented in the ISO 8601 date-time format: *yyyy-mm-dd*T*hh:mm:ss.fff*Z, where *yyyy* = year, *mm* = month, *dd* = day, T indicates the beginning of the time component, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and Z signifies Zulu, which is another way to denote UTC.
session	GUID that's unique for each SMTP session but is the same for each event associated with that SMTP session. For MAPI sessions in the Mailbox Transport service, the session field is blank.
source	**SMTP** for SMTP connections, **MAPI** for Mailbox Transport service connections to the local mailbox database.
destination	Name of the destination.
direction	Single character that represents the start, middle, or end of the connection. The possible values for the direction field are as follows: • **+** Connect • **-** Disconnect • **>** Send

description	Text information associated with the connection event. The following values are examples of values for the description field: • Number and size of messages that were transmitted • DNS MX resource record resolution information for destination domains • DNS resolution information for destination Mailbox servers • Connection establishment messages • Connection failure messages

When transport service establishes a connection to a destination, the transport service may be prepared to send one message or several messages. The connection and message transmission processes generate multiple events written on multiple lines in the connectivity log. Simultaneous connections to different destinations create connectivity log entries related to different destinations that are interlaced. However, you can use the date-time, session, source, and direction fields to arrange the connectivity log entries for each separate connection from start to finish.

Return to top

Configure connectivity logging

Mail flow > Transport logs > Connectivity logging >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-18*

Connectivity logging records the outbound connection activity that's used to transmit messages from a transport service on an Exchange server. Connectivity logging records the connection source, destination, number of messages and bytes transmitted, and connection failure information.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport service", "Front End Transport service", and "Mailbox Transport service" entries in the Mail flow permissions topic.
- You can use the Exchange admin center (EAC) to enabled or disabled connectivity logging, or set

the connectivity log path for the Transport service only. For all other connectivity logging options in other transport services, you need to use the Shell.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to configure connectivity logging in the Transport service

1. In the EAC, navigate to **Servers** > **Servers**.
2. Select the Mailbox server you want to configure, and then click **Edit** .
3. On the server properties page, click **Transport Logs**.
4. In the **Connectivity log** section, change any of the following:
   - **Enable connectivity log** To disable connectivity logging on the server, clear the check box. To enable connectivity logging on the server, select the check box.
   - **Connectivity log path** The value you specify must be on the local Exchange server. If the folder doesn't exist, it will be created for you when you click **Save**.

When you are finished, click **Save**.

Use the Shell to configure connectivity logging

To configure connectivity logging, run the following command:

```
<Set-TransportService | Set-MailboxTransportService | Set-
FrontEndTransportService> <ServerIdentity> -
ConnectivityLogEnabled <$true | $false> -
ConnectivityLogMaxAge <dd.hh:mm:ss> -
ConnectivityLogMaxDirectorySize <Size> -
ConnectivityLogMaxFileSize <Size> -ConnectivityLogPath
<LocalFilePath>
```

This example sets the following connectivity log settings in the Transport service on the Mailbox server named Mailbox01:

Sets the location of the connectivity log files to D:\Hub Connectivity Log. Note that if the folder doesn't exist, it will be created for you.

Sets the maximum size of a connectivity log file to 20 MB.

Sets the maximum size of the connectivity log directory to 1.5 GB.

Sets the maximum age of a connectivity log file to 45 days.

```
Set-TransportService Mailbox01 -ConnectivityLogPath "D:\Hub
Connectivity Log" -ConnectivityLogMaxFileSize 20MB -
ConnectivityLogMaxDirectorySize 1.5GB -
ConnectivityLogMaxAge 45.00:00:00
```

Note:

- To configure the connectivity log settings in the Mailbox Transport service on a Mailbox server, use the **Set-MailboxTransportService** cmdlet. To configure the connectivity log settings in the Front End Transport service on a Client Access server, use the **Set-FrontEndTransportService** cmdlet.
- Setting the *ConnectivityLogPath* parameter to the value `$null`, effectively disables connectivity logging. However, if the value of the *ConnectivityLogEnabled* parameter is `$true`, event log errors are generated.
- Setting the *ConnectivityLogMaxAge* parameter to the value `00:00:00` prevents the automatic removal of connectivity log files because of their age.

How do you know this worked?

To verify that you have successfully configured connectivity logging, do the following:
1. In the Shell, run the following command:

```
<Get-TransportService | Get-FrontEndTransportService | Get-
MailboxTransportService> <ServerIdentity> | Format-List
ConnectivityLog*
```

2. Verify the values displayed are the values you configured.

Pipeline tracing

Exchange Server 2013 > Mail flow > Transport logs >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-01-28*

Pipeline tracing captures copies of email messages from a specific sender as they move through the Transport service on Mailbox servers, the Mailbox Transport Delivery service on Mailbox servers, and through Edge Transport servers.. Pipeline tracing captures verbose information about the changes that each transport agent applies to messages in the transport pipeline in message snapshot files. By examining the contents of the message snapshot files, you can determine whether the transport agents have applied the changes to the messages in the transport pipeline that you expected. If you are troubleshooting a problem, you should determine which transport agent is at fault. Then you can focus your troubleshooting efforts on that agent to resolve the problem. You can then view the message snapshot files again to verify that your solution is successful.

Caution:

- Pipeline tracing copies the complete contents of email messages that are sent from the sender's email address. To avoid unwanted exposure of confidential information, you need to set appropriate security permissions on the pipeline tracing folder.
- Don't enable pipeline tracing for long periods of time. Pipeline tracing creates files that can accumulate quickly. Always monitor available disk space when pipeline tracing is enabled.

Configure pipeline tracing

Before you enable pipeline tracing, you need to specify the sender's email address you want to monitor. Pipeline tracing is designed to log messages sent from a specific email address. The sender's email address can be internal or external to your Exchange organization. Alternatively, you can enable pipeline tracing for system messages generated by the transport service on the specified Mailbox or Edge Transport server, such as automatic replies, delivery status notification (DSN) messages, journal reports, and other system-generated messages You can also modify the location of the pipeline tracing folder.

The parameters that you use to configure pipeline tracing are summarized in the following table

Cmdlet	Parameter	Default value	Description
Set-TransportService **Set-MailboxTransportService**	*PipelineTracingSenderAddress*	Blank (`$null`)	Specify the email address of the sender you want to monitor. Specify the value **"<>"** to monitor system-generated messages sent by the specified transport service on the

			server.
Set-TransportService **Set-MailboxTransportService**	*PipelineTracingPath*	**Transport service** `%ExchangeInstallPath%TransportRoles\Logs\Hub\PipelineTracing` **Mailbox Transport service** `%ExchangeInstallPath%TransportRoles\Logs\Mailbox\PipelineTracing`	The path must be on the local server. UNC paths aren't supported. The specified path contains the `MessageSnapshots` folder where pipeline tracing files are stored.
Set-TransportService **Set-MailboxTransportService**	*PipelineTracingEnabled*	`$false`	You can only enable pipeline tracing for the specified transport service on the server after you configure the sender address you want to monitor.

For more information about how to enable pipeline tracing and configure the sender address for pipeline tracing, see Configure pipeline tracing.

Message snapshot files

Message snapshots are files that capture any changes made to a message by transport agents in the Transport service or the Mailbox Transport Delivery service. These files are stored in the `MessageSnapshots` folder in the corresponding pipeline tracing path for the transport service.

In the `MessageSnapshots` folder, Exchange creates one folder for each message sent by the monitored sender that flows through the specified transport service. Each folder is named after a GUID that's assigned to the message. If you enable pipeline tracing for the Transport service and the Mailbox Transport service on the same Mailbox server, a different GUID is assigned to the same message by each transport service, so the folder name for a message in the `MessageSnapshots` folder for the Transport service is different than the folder name for the same message in the `MessageSnapshots` folder for the Mailbox Transport service. If you enable pipeline tracing on more than one Exchange server, a different GUID is assigned to the same message as it travels through the specified transport service on each Exchange server.

In each message folder, Exchange creates several message snapshot files that have .eml file extensions. These message snapshot files contain the contents of the message as it encounters each

SMTP event and transport agent.

If a transport agent is registered on an SMTP event, Exchange creates a message snapshot of the message before the message encounters any transport agents. This gives you a copy of the message before the message encounters transport agents that are registered on that event. Then, a new message snapshot is created for each transport agent that the message encounters, regardless of whether a transport agent modifies the contents of the message. However, if no agents are registered on an event, Exchange doesn't create any messages snapshots for that event.

For example, if three agents are registered on the **OnEndofData** event but only two of the transport agents modify a message, four message snapshots are created. The first message snapshot captures the message as it encounters the **OnEndofData** event before any modifications that are made by the transport agents that registered on that event. Then, one message snapshot is created for each transport agent regardless of whether a transport agent modifies the message.

The message snapshot files that are created are described in the following list:

- **Original.eml** This file contains the original unmodified contents of the email message before it encounters any SMTP events or transport agents.
- **Routingnnnn.eml** These files contain the contents of the email message as it encounters transport the SMTP events and transport agents registered on those events in the categorization part of the Transport service. The placeholder *nnnn* represents an integer value that starts with `0001`. The value is incremented for every SMTP event and transport agent registered on those events in the order in which the events and agents act on the message. The Mailbox Transport Delivery service doesn't generate these **Routing** snapshot files.
- **SmtpReceivennnn.eml** These files contain the contents of the email message as it encounters the **OnEndofData** and **OnEndOfHeaders** SMTP events and transport agents registered on those events during the SMTP receive part of the Transport service or the Mailbox Transport Delivery service. The placeholder *nnnn* represents an integer value that starts with `0001`. The value is incremented for every SMTP event and transport agent registered on those events in the order in which the events and agents act on the message.

You can open the message snapshot files by using Notepad or any text editor.

Each message snapshot file starts with headers that are added to the message contents and list the SMTP event and transport agent that the message snapshot file relates to. These headers start with `X-CreatedBy: MessageSnapshot-Begin injected headers` and end with `X-EndOfInjectedXHeaders: MessageSnapshot-End injected headers`. These headers are replaced in each message snapshot file by each subsequent transport agent and SMTP event. The following is an example of the headers that are added to an email message file:

```
X-CreatedBy: MessageSnapshot-Begin injected headers
X-MessageSnapshot-UTC-Time: 2013-01-23T23:20:18.138Z
X-MessageSnapshot-Record-Id: 21474836486
X-MessageSnapshot-Source: OnSubmittedMessageX-Sender:
michelle@nwtraders.com
```

```
X-Receiver: chris@contoso.com
X-EndOfInjectedXHeaders: MessageSnapshot-End injected
headers
```

After the message snapshot headers, the file contains the contents of the message including all the original message headers. If a transport agent modifies the contents of the message, the changes appear integrated with the message. As the message is processed by each transport agent, the changes that are made by each agent are applied to the message contents. If a transport agent makes no changes to the message contents, the message snapshot that is created by that agent will be identical to the message snapshot created by the previous transport agent.

Configure pipeline tracing

Mail flow > Transport logs > Pipeline tracing >

Topic Last Modified: *2013-11-08*

Pipeline tracing captures copies of email messages as they move through the transport pipeline in the Transport service or the Mailbox Transport service on Mailbox server and on Edge Transport servers.

What do you need to know before you begin?

- Estimated time to complete this procedure: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the"Transport Service" and "Mailbox Transport Service" entries in the Mail flow permissions topic.
- You can only use the Shell to perform this procedure.
- Pipeline tracing copies the complete contents of email messages that are sent from the sender's email address. To avoid unwanted exposure of confidential information, you need to set appropriate security permissions on the location of the pipeline tracing folder.
- Don't enable pipeline tracing for long periods of time. Pipeline tracing creates multiple message snapshot files that accumulate quickly. Always monitor available disk space when pipeline tracing is enabled.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Enable and configure pipeline tracing

Step 1: Use the Shell to configure the pipeline tracing sender address

Use the following syntax to configure the pipeline tracing sender address.

```
<Set-TransportService | Set-MailboxTransportService>
<ServerIdentity> -PipelineTracingSenderAddress <SMTPAddress
| "<>">
```

This example configures pipeline tracing to capture snapshots of all messages sent by the sender chris@contoso.com in the Transport service on the Mailbox server named Mailbox01.

```
Set-TransportService Mailbox01 -
PipelineTracingSenderAddress chris@contoso.com
```

This example configures pipeline tracing to capture snapshots of all the system-generated messages received by the Transport service on the Mailbox server named Mailbox02.

```
Set-TransportService Mailbox02 -
PipelineTracingSenderAddress "<>"
```

Caution:

Configuring pipeline tracing to capture all server-generated messages in a transport service may place a significant load on the server and may quickly consume available disk space. Always monitor available disk space when pipeline tracing is enabled.

Step 2: (Optional) Use the Shell to specify a custom pipeline tracing folder

The default pipeline tracing folder doesn't exist until after you enable pipeline tracing, and messages that meet the criteria you specify using the *PipelineTracingSenderAddress* parameter flow through the transport service on the server. For the Transport service on a Mailbox server, the default location is `%ExchangeInstallPath%TransportRoles\Logs\Hub\PipelineTracing`. For the Mailbox Transport service on a Mailbox server, the default location is `%ExchangeInstallPath%TransportRoles\Logs\Mailbox\PipelineTracing`. If you specify a custom path, the path must be on the local Exchange server.

Use the following syntax to configure the pipeline tracing folder.

```
<Set-TransportService | Set-MailboxTransportService>
<ServerIdentity> -PipelineTracingPath <LocalFilePath>
```

This example sets the pipeline tracing folder for the Transport service on the Mailbox server named Mailbox01 to D:\Hub\Pipeline Tracing.

```
Set-TransportService Mailbox01 -PipelineTracingPath "D:\Hub
\Pipeline Tracing"
```

Step 3: Use the Shell to enable pipeline tracing

By default, pipeline tracing is disabled on all Exchange servers. When you enable pipeline tracing, you are enabling pipeline tracing in the specified transport service on the specified Exchange server only. Before you enable pipeline tracing, you need to specify the sender address as described in Step 1.

Use the following syntax to enable pipeline tracing.

```
<Set-TransportService | Set-MailboxTransportService>
<ServerIdentity> -PipelineTracingEnabled $true
```

This example enables pipeline tracing in the Transport service on the Mailbox server named Mailbox01.

```
Set-TransportService Mailbox01 -PipelineTracingEnabled
$true
```

How do you know this worked?

To verify that you have successfully configured pipeline tracing, do the following:
1. Run the following command:

```
<Get-TransportService | Get-MailboxTransportService>
<ServerIdentity> | Format-List PipelineTracing*
```

2. Verify the values displayed are the values you configured.
3. Check the pipeline tracing folder for the Transport service or the Mailbox Transport service, and verify message snapshot files are being created in the folder.

Disable pipeline tracing

Because of the disk space and security concerns associated with pipeline tracing, pipeline tracing is a temporary action for diagnostic or troubleshooting purposes. Whenever you enable pipeline tracing, always remember to disable it when you are finished.

Use the following syntax to disable pipeline tracing.

```
<Set-TransportService | Set-MailboxTransportService>
<ServerIdentity> -PipelineTracingEnabled $false
```

This example disables pipeline tracing in the Transport service on the Mailbox server named Mailbox01.

```
Set-TransportService Mailbox01 -PipelineTracingEnabled
$false
```

How do you know this worked?

To verify that you have successfully disabled pipeline tracing, do the following:
1. Run the following command:

```
<Get-TransportService | Get-MailboxTransportService>
<ServerIdentity> | Format-List PipelineTracingEnabled
```

2. Verify the value of the *PipelineTracingEnabled* parameter is $false.
3. Check the pipeline tracing folder, and verify message snapshot files are no longer being created in the folder.

Protocol logging

Exchange Server 2013 > Mail flow > Transport logs >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-01-30*

Protocol logging records the SMTP conversations that occur between messaging servers as part of message delivery. These SMTP conversations occur on Send connectors and Receive connectors that exist in the Front End Transport service on Client Access servers, the Transport service on Mailbox servers, and the Mailbox Transport service on Mailbox servers. You can use protocol logging to diagnose mail flow problems.

By default, protocol logging is disabled on all Send connectors and Receive connectors. Protocol logging is enabled or disabled on each individual connector. Other protocol logging options are set for all the Receive connectors or all the Send connectors that exist in each individual transport service on the server. All the Receive connectors in a transport service share the same protocol log files and protocol log options. These protocol log files and protocol log options are separate from the Send connector protocol log files and protocol log options in the transport service on the same server.

The following options are available for the protocol logs of all Send connectors or all Receive connectors in each transport service on the Exchange server:
- Specify the location of the Send connector or the Receive connector protocol log files.
- Specify a maximum size for the Send connector or the Receive connector protocol log files. The

default size is 10 megabytes (MB).
- Specify a maximum size for the directory that contains the Send connector or Receive connector protocol log files. The default size is 250 MB.
- Specify a maximum age for the Send connector or Receive connector protocol log files. The default age is 30 days.

By default, Exchange uses circular logging to limit the protocol logs based on file size and file age to help control the hard disk space used by the log files.

A special Send connector named the intra-organization Send connector exists in the Transport service on every Mailbox server, and in the Front End Transport service on every Client Access server. This connector is implicitly created, invisible, and requires no management. The intra-organization Send connector is used by the following transport services:

- **Transport service on Mailbox servers**
  - Relays messages to the Transport service and the Mailbox Transport service on other Exchange 2013 Mailbox servers in the organization.
  - Relays messages to other Exchange 2007 or Exchange 2010 Hub Transport servers in the organization.
  - Relays messages to Edge Transport servers in the perimeter network.
- **Front End Transport service on Client Access servers** Relays messages to the Transport service on Exchange 2013 Mailbox servers in the organization.

An equivalent Send connector named the mailbox delivery Send connector exists in the Mailbox Transport service on every Mailbox server. This connector is also implicitly created, invisible, and requires no management. The mailbox delivery Send connector is used to relay messages to the Transport service and the Mailbox Transport service on other Mailbox servers in the organization.

By default, protocol logging for the mailbox delivery Send connector is also disabled. You can enable or disable protocol logging for the mailbox delivery Send connector by using the *MailboxDeliveryConnectorProtocolLoggingLevel* parameter on the **Set-MailboxTransportService** cmdlet. If you enable protocol logging for the mailbox delivery Send connector, logging occurs in the Send connector protocol logs for the Mailbox Transport service on the Mailbox server.

Contents

Structure of the protocol log files

By default, the protocol log files exist in the following locations:

- **Receive connector protocol log files for the Transport service on Mailbox servers** %ExchangeInstallPath%TransportRoles\Logs\Hub\ProtocolLog\SmtpReceive
- **Receive connector protocol log files for the Mailbox Transport service on Mailbox servers** %ExchangeInstallPath%TransportRoles\Logs\Mailbox\ProtocolLog\SmtpReceive
- **Receive connector protocol log files for the Front End Transport service on Client Access**

servers %ExchangeInstallPath%TransportRoles\Logs\FrontEnd\ProtocolLog\SmtpReceive

- **Send connector protocol log files for the Transport service on Mailbox servers** % ExchangeInstallPath%TransportRoles\Logs\Hub\ProtocolLog\SmtpSend
- **Send connector protocol log files for the Mailbox Transport service on Mailbox servers** % ExchangeInstallPath%TransportRoles\Logs\Mailbox\ProtocolLog\SmtpSend
- **Send connector protocol log files for the Front End Transport service on Client Access servers** %ExchangeInstallPath%TransportRoles\Logs\FrontEnd\ProtocolLog\SmtpSend

The naming convention for log files in each protocol log directory is *prefixyyyymmdd-nnnn*.log. The placeholders represent the following information:

- The placeholder *prefix* is SEND for Send connectors or RECV for Receive connectors.
- The placeholder *yyyymmdd* is the Coordinated Universal Time (UTC) date on which the log file was created. The placeholder *yyyy* = year, *mm* = month, and *dd* = day.
- The placeholder *nnnn* is an instance number that starts at the value of 1 for each day.

Information is written to the log file until the file size reaches its maximum specified value, and a new log file that has an incremented instance number is opened. This process is repeated throughout the day. Circular logging deletes the oldest log files when the protocol log directory reaches its maximum specified size, or when a log file reaches its maximum specified age.

The protocol log files are text files that contain data in the comma-separated value file (CSV) format. Each protocol log file has a header that contains the following information:

- **#Software** Name of the software that created the protocol log file. Typically, the value is Microsoft Exchange Server.
- **#Version** Version number of the software that created the protocol log file. Currently, the value is 15.0.0.0.
- **#Log-Type** Log type value of this field, which is either SMTP Receive Protocol Log or SMTP Send Protocol Log.
- **#Date** UTC date-time when the log file was created. The UTC date-time is represented in the ISO 8601 date-time format: *yyyy-mm-dd*T*hh:mm:ss.fff*Z, where *yyyy* = year, *mm* = month, *dd* = day, T indicates the beginning of the time component, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and Z signifies Zulu, which is another way to denote UTC.
- **#Fields** Comma-delimited field names used in the protocol log files.

Return to top

Information written to the protocol log

The protocol log stores each SMTP protocol event on a single line in the protocol log. The information stored on each line is organized by fields. These fields are separated by commas. The following table describes the fields used to classify each protocol.

Fields used to classify each protocol event

Field name	Description

date-time	UTC date-time of the protocol event. The UTC date-time is represented in the ISO 8601 date-time format: *yyyy-mm-dd*T*hh:mm:ss.fff*Z, where *yyyy* = year, *mm* = month, *dd* = day, T indicates the beginning of the time component, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and Z signifies Zulu, which is another way to denote UTC.
connector-id	Distinguished name (DN) of the connector associated with the SMTP event.
session-id	GUID that's unique for each SMTP session but is the same for each event associated with that SMTP session.
sequence-number	Counter that starts at 0 and is incremented for each event in the same SMTP session.
local-endpoint	Local endpoint of an SMTP session. This consists of an IP address and TCP port number formatted as <*IP address*>:<*port*>.
remote-endpoint	Remote endpoint of an SMTP session. This consists of an IP address and TCP port number formatted as <*IP address*>:<*port*>.
event	Single character that represents the protocol event. The possible values for the event are as follows: • **+** Connect • **-** Disconnect • **>** Send • **<** Receive • ***** Information

data	Text information associated with the SMTP event.
context	Additional contextual information that may be associated with the SMTP event.

A single SMTP conversation that represents the sending or receiving of a single email message generates multiple SMTP events. These SMTP events cause multiple lines to be written to the protocol log. Multiple SMTP conversations that represent the sending or receiving of multiple email messages can occur at the same time. This creates protocol log entries from different SMTP conversations that are interspersed. You can use the session-id and sequence-number fields to sort the protocol log entries by SMTP conversation.

Return to top

Configure protocol logging

Mail flow > Transport logs > Protocol logging >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-03-15*

Protocol logging records the SMTP conversations that occur on Send Connectors and Receive connectors as part of message delivery.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport Service", "Front End Transport service", "Mailbox Transport service", "Receive connectors" and "Send connectors" entries in the Mail flow permissions topic.
- You can use the Exchange admin center (EAC) to enable or disable protocol logging for Send connectors and Receive connectors in the Transport service on Mailbox servers, and for Receive connectors in the Front End Transport service on Client Access servers. You can also use the EAC to configure the protocol log paths for the Transport service only. For all other protocol logging options, you need to use the Shell.
- Protocol logging is enabled or disabled on each individual connector. All the Receive connectors on the Exchange server share the same protocol log files and protocol log options. These protocol log settings are separate from the Send connector protocol log files and protocol log options that are on the same server.

Caution:

Don't perform this procedure on an Edge Transport server that has been subscribed to the Exchange organization by using EdgeSync. Instead, make the changes in the Transport service on the Mailbox server. The changes are then replicated to the Edge Transport server next time EdgeSync synchronization occurs.

- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the EAC to configure protocol logging

To use the EAC to enable or disable protocol logging on a Send connector or a Receive connector in the Transport service on a Mailbox server, or on a Receive connector in the Front End Transport service on a Client Access server, do the following:

1. In the EAC, navigate to **Mail flow** > **Send connectors** or **Mail flow** > **Receive connectors**.
2. Select the connector you want to configure, and then click **Edit** .
3. On the **General** tab in the **Protocol logging level** section, select one of the following options:
   - **None** Protocol logging disabled on the connector.
   - **Verbose** Protocol logging is enabled on the connector.

When you are finished, click **Save**.

To use the EAC to configure the protocol log paths for the Send connectors and Receive connectors in the Transport service on a Mailbox server, do the following:

1. In the EAC, navigate to **Servers** > **Servers**.
2. Select the Mailbox server you want to configure, and then click **Edit** .
3. On the server properties page, click **Transport logs**.
4. In the **Protocol log** section, change any of the following settings:
   - **Send protocol log path** The value you specify must be on the local Exchange server. If the folder doesn't exist, it will be created for you when you click **Save**.
   - **Receive protocol log path** The value you specify must be on the local Exchange server. If the folder doesn't exist, it will be created for you when you click **Save**.

When you are finished, click **Save**.

How do you know this worked?

To verify that you have successfully used the EAC to configure the protocol log settings, do the following:

1. Browse to the location you specified for the Send connector or the Receive connector protocol

logs.
2. If you enabled protocol logging, verify a log file is created. If you disabled protocol logging, verify the latest log file is no longer being updated.

Use the Shell to enable or disable protocol logging on a Send connector or a Receive connector

To enable or disable protocol logging on a Send connector or a Receive connector, run the following command:

```
<Set-SendConnector |Set-ReceiveConnector>
<ConnectorIdentity> -ProtocolLoggingLevel <Verbose | None>
```

This example enables protocol logging for the Receive connector named Connection from Contoso.com.

```
Set-ReceiveConnector "Connection from Contoso.com" -
ProtocolLoggingLevel Verbose
```

How do you know this worked?

To verify that you have successfully enabled or disabled protocol logging, do the following:
1. In the Shell, run the following command:

```
<Get-SendConnector |Get-ReceiveConnector> | Format-List
Name,ProtocolLoggingLevel
```

2. Verify the values displayed are the values you configured.

Use the Shell to enable or disable protocol logging on the intra-organization Send connector

To enable or disable protocol logging on the implicit and invisible intra-organization Send connector that exists in the Transport service on a Mailbox server and in the Front End Transport service on a Client Access server, run the following command:

```
<Set-TransportService | Set-FrontEndTransportService> -
IntraOrgConnectorProtocolLoggingLevel <Verbose | None>
```

This example enables protocol logging on the intra-organization Send connector in the Transport service on a Mailbox server named Mailbox01.

```
Set-TransportService Mailbox01 -
```

```
IntraOrgConnectorProtocolLoggingLevel Verbose
```

How do you know this worked?

To verify that you have successfully enabled or disabled protocol logging on the intra-org Send connector, do the following:
1. In the Shell, run the following command:

```
<Get-TransportService | Get-FrontEndTransportService>
<ServerIdentity> | Format-List
IntraOrgConnectorProtocolLoggingLevel
```

2. Verify the value displayed is the value you configured.

Use the Shell to enable or disable protocol logging on the mailbox delivery Send connector

To enable or disable protocol logging on the implicit and invisible mailbox delivery Send connector that exists in the Mailbox Transport service on a Mailbox server, run the following command:

```
Set-MailboxTransportService -
MailboxDeliveryConnectorProtocolLoggingLevel <Verbose |
None>
```

This example enables protocol logging on the mailbox delivery Receive connector in the Mailbox Transport service on a Mailbox server named Mailbox01.

```
Set-MailboxTransportService Mailbox01 -
MailboxDeliveryConnectorProtocolLoggingLevel Verbose
```

How do you know this worked?

To verify that you have successfully enabled or disabled protocol logging on the mailbox delivery connector, do the following:
1. In the Shell, run the following command:

```
Get-MailboxTransportService <ServerIdentity> | Format-List
MailboxDeliveryConnectorProtocolLoggingLevel
```

2. Verify the value displayed is the value you configured.

Use the Shell to configure protocol logging settings

To configure the protocol log settings, run the following command:

```
<Set-TransportService | Set-MailboxTransportService | Set-
FrontEndTransportService> <ServerIdentity> -
ReceiveProtocolLogPath <LocalFilePath> -SendProtocolLogPath
<LocalFilePath> -ReceiveProtocolLogMaxFileSize <Size> -
SendProtocolLogMaxFileSize <Size> -
ReceiveProtocolLogMaxDirectorySize <Size> -
SendProtocolLogMaxDirectorySize <Size> -
ReceiveProtocolLogMaxAge <dd.hh:mm:ss> -
SendProtocolLogMaxAge <dd.hh:mm:ss>
```

This example sets the following protocol log settings in the Transport service on the Mailbox server named Mailbox01:

Sets the location of all Receive connector protocol logs to D:\Hub Receive SMTP Log and all Send connector protocol logs to D:\Hub Send SMTP Log. Note that if the folder doesn't exist, it will be created for you.

Sets the maximum size of a Receive connector protocol log file and a Send connector protocol log file to 20 MB.

Sets the maximum size of the Receive connector protocol log folder and the Send connector protocol log folder to 400 MB.

Sets the maximum age of a Receive connector protocol log file and a Send Connector protocol log file to 45 days.

```
Set-TransportService Mailbox01 -ReceiveProtocolLogPath "D:
\Hub Receive SMTP Log" -SendProtocolLogPath "D:\Hub Send
SMTP Log" -ReceiveProtocolLogMaxFileSize 20MB -
SendProtocolLogMaxFileSize 20MB -
ReceiveProtocolLogMaxDirectorySize 400MB -
SendProtocolLogMaxDirectorySize 400MB -
ReceiveProtocolLogMaxAge 45.00:00:00 -SendProtocolLogMaxAge
45.00:00:00
```

Note:

- To configure the protocol log settings in the Mailbox Transport service on a Mailbox server, use the **Set-MailboxTransportService** cmdlet. To configure the protocol log settings in the Front End Transport service on a Client Access server, use the **Set-**

FrontEndTransportService cmdlet.

- Setting the *SendProtocolLogPath* or *ReceiveProtocolLogPath* parameters to the value `$null` effectively disables protocol logging for all Send connectors or all Receive connectors on the server. However, setting either of these parameters to `$null` when protocol logging is enabled for any other connectors on the server, including the intra-organization Send connector or the mailbox delivery Send connector, event log errors are generated.
- Setting the *ReceiveProtocolLogMaxAge* or *SendProtocolLogMaxAge* parameters to the value `00:00:00` prevents the automatic removal of protocol log files because of their age.

How do you know this worked?

To verify that you have successfully configured the protocol log settings, do the following:
1. In the Shell, run the following command:

```
<Get-TransportService | Get-MailboxTransportService | Get-FrontEndTransportService> <ServerIdentity> | Format-List SendConnectorProtocolLog*,ReceiveConnectorProtocolLog*
```

2. Verify the values displayed are the values you configured.

Configure routing table logging

Exchange Server 2013 > Mail flow > Transport logs >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-22*

Routing table logging periodically records a snapshot of the routing table used by Microsoft Exchange Server 2013 to route messages to their destinations.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport service" and "Edge Transport server" entries in the Mail flow permissions topic.
- You can only use the Shell to perform this procedure.
- To configure the time interval for automatic recalculation of the routing table, you modify the EdgeTransport.exe.config XML application configuration file. Changes you save to this file are applied after you restart the Microsoft Exchange Transport service. When you restart this service,

mail flow on the server is temporarily interrupted.

- Any customized per-server settings you make in Exchange XML application configuration files, for example, web.config files on Client Access servers or the EdgeTransport.exe.config file on Mailbox servers, will be overwritten when you install an Exchange Cumulative Update (CU). Make sure that you save this information so you can easily re-configure your server after the install. You must re-configure these settings after you install an Exchange CU.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to configure routing table logging

Run the following command:

```
Set-TransportService <ServerIdentity> -
RoutingTableLogMaxAge <dd.hh:mm:ss> -
RoutingTableLogMaxDirectorySize <Size>  -
RoutingTableLogPath <LocalFilePath>
```

This example sets the following routing table log settings on the Mailbox server named Mailbox01:

- Sets the location of the routing table log files to D:\Routing Table Log. Note that if the folder doesn't exist, it will be created for you.
- Sets the maximum size of the routing table log folder to 70 MB.
- Sets the maximum age of a routing table log file to 45 days.

```
Set-TransportService Mailbox01 -RoutingTableLogPath "D:
\Routing Table Log" -RoutingTableLogMaxDirectorySize 70MB -
RoutingTableLogMaxAge 45.00:00:00
```

Note:

Setting the *RoutingTableLogMaxAge* parameter to the value `00:00:00` prevents the automatic removal of routing table log files because of their age.

How do you know this worked?

To verify that you have successfully configured routing table logging, do the following:

1. In the Shell, run the following command:

```
Get-TransportService <ServerIdentity> | Format-List
```

```
RoutingTableLog*
```

2. Verify the values displayed are the values you configured.

Use the Command Prompt to configure the interval for automatic recalculation of the routing table in the EdgeTransport.exe.config file

1. In a Command prompt window, open the EdgeTransport.exe.config application configuration file in Notepad by running the following command:

```
Notepad %ExchangeInstallPath%Bin\EdgeTransport.exe.config
```

2. Modify the following key in the `<appSettings>` section.

```
<add key="RoutingConfigReloadInterval" value="<hh:mm:ss>" /
>
```

For example, to change the interval for automatic recalculation of the routing table to 10 hours, use the following value:

```
<add key="RoutingConfigReloadInterval" value="10:00:00" />
```

3. When you are finished, save and close the EdgeTransport.exe.config file.
4. Restart the Microsoft Exchange Transport service by running the following command:

```
net stop MSExchangeTransport && net start
MSExchangeTransport
```

How do you know this worked?

To verify that you have successfully configured the interval for the automatic recalculation of the routing table, verify the routing table log is updated during the time interval you specified.

Note that the routing table will be recalculated and logged earlier than the value specified by the *RoutingConfigReloadInterval* key if any of the following conditions occur:

- A routing configuration change is detected. For example, a Send connector or a Receive connector is added, removed, or modified, or the 6 hour Kerberos token renewal occurs.
- The Microsoft Exchange Transport service is started.

Message tracking

Exchange Server 2013 > Mail flow >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-04-04*

In Microsoft Exchange Server 2013, the message tracking log is a detailed record of all message activity as messages are transferred to and from the Transport service on Mailbox servers, mailboxes on Mailbox servers, and Edge Transport servers. You can use message tracking logs for message forensics, mail flow analysis, reporting, and troubleshooting.

In Exchange 2013, you can use the **Set-TransportService** cmdlet or the **Set-MailboxServer** cmdlet for all message tracking configuration tasks, because the Exchange 2013 Mailbox server holds the Transport service and the mailboxes. You can use either of these cmdlets to make the following message tracking configuration changes:

- Enable or disable message tracking. The default is enabled.
- Specify the location of the message tracking log files.
- Specify a maximum size for the individual message tracking log files. The default is 10 MB.
- Specify a maximum size for the directory that contains the message tracking log files: The default is 1000 MB.
- Specify maximum age for the message tracking log files: The default is 30 days.
- Enable or disable message subject logging in the message tracking logs. The default is enabled.

Note:

You can also use the Exchange admin center (EAC) to enable or disable message tracking, and to specify the location of the message tracking log files.

By default, Exchange uses circular logging to limit the message tracking logs based on file size and file age to help control the hard disk space used by the message tracking log files.

Contents

Search the message tracking log

Message tracking logs contain vast amounts of data as messages move through an Exchange 2013 Mailbox server. When it comes to searching the message tracking logs, you have different options.

- **Get-MessageTrackingLog** Administrators can use this cmdlet to search the message tracking log for information about messages using a wide range of filter criteria. For more information,

see Search message tracking logs.

- **Delivery reports for administrators** Administrators can use the **Delivery reports** tab in the Exchange admin center (EAC) or the underlying **Search-MessageTrackingReport** and **Get-MesageTrackingReport** cmdlets to search the message tracking logs for information about messages sent by or received by a specific mailbox in the organization. For more information see Delivery reports for administrators.
- **Delivery reports for users** Users can use the **Delivery reports** tab in Outlook Web App to search the message tracking logs for information about messages sent to or sent by their own mailbox. For more information, see Delivery Reports for Users.

Return to top

Structure of the message tracking log files

By default, the message tracking log files exist in %ExchangeInstallPath%TransportRoles\Logs\MessageTracking.

The naming convention for log files in the message tracking log directory is `MSGTRK`*`yyyymmdd-nnnn`*`.log`, `MSGTRKMA`*`yyyymmdd-nnnn`*`.log`, `MSGTRKMD`*`yyyymmdd-nnnn`*`.log`, and `MSGTRKMS`*`yyyymmdd-nnnn`*`.log` . The different logs are used by the following services:

- **MSGTRK** These logs are associated with the Transport service.
- **MSGTRKMA** These logs are associated with the approvals and rejections used by moderated transport. For more information, see Managing message approval.
- **MSGTRKMD** These logs are associated with messages delivered to mailboxes by the Mailbox Transport Delivery service.
- **MSGTRKMS** These logs are associated with messages sent from mailboxes by the Mailbox Transport Submission service.

The placeholders in the log file names represent the following information:

- The placeholder *yyyymmdd* is the coordinated universal time (UTC) date on which the log file was created. *yyyy* = year, *mm* = month, and *dd* = day.
- The placeholder *nnnn* is an instance number that starts at the value of 1 daily for each message tracking log file name prefix.

Information is written to each log file until the file size reaches its maximum specified value for each log file. Then, a new log file that has an incremented instance number is opened. This process is repeated throughout the day. The log file rotation functionality deletes the oldest log files when either of the following conditions is true:

- A log file reaches its maximum specified age.
- The message tracking log directory reaches its maximum specified size.

Important:
The maximum size of the message tracking log directory is calculated as the total size of all log files that have the same name prefix. Other files that do not follow the name prefix convention are not counted in the total directory size calculation. Renaming old log files or copying other

files into the message tracking log directory could cause the directory to exceed its specified maximum size.
On Exchange 2013 Mailbox servers, the maximum size of the message tracking log directory is three times the specified value. Although the message tracking log files that are generated by the four different services have four different name prefixes, the amount and frequency of data written to the **MSGTRKMA** log files is negligible compared to the three other log file prefixes.

The message tracking log files are text files that contain data in the comma-separated value (CSV) format. Each message tracking log file has a header that contains the following information:

- **#Software:** Name of the software that created the message tracking log file. Typically, the value is Microsoft Exchange Server.
- **#Version:** Version number of the software that created the message tracking log file. Currently, the value is 15.0.0.0.
- **#Log-Type:** Log type value, which is Message Tracking Log.
- **#Date:** The UTC date-time when the log file was created. The UTC date-time is represented in the ISO 8601 date-time format: *yyyy-mm-dd*T*hh:mm:ss.fff*Z, where *yyyy* = year, *mm* = month, *dd* = day, T indicates the beginning of the time component, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and Z signifies Zulu, which is another way to denote UTC.
- **#Fields:** Comma-delimited field names used in the message tracking log files.

Return to top

Fields in the message tracking log files

The message tracking log stores each message event on a single line in the log. The message event information is organized by fields, and these fields are separated by commas. The field name is generally descriptive enough to determine the type of information that it contains. However, some fields may be blank, or the type of information that is stored in the field may change based on the message event type and the type of message tracking log file where the event was recorded. General descriptions of the fields that are used to classify each message tracking event are explained in the following table.

Field name	Description
date-time	The UTC date-time of the message tracking event. The UTC date-time is represented in the ISO 8601 date-time format: *yyyy-mm-dd*T*hh:mm:ss.fff*Z, where *yyyy* = year, *mm* = month, *dd* = day, T indicates the beginning of the time component, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and Z signifies Zulu, which is another way to denote UTC.

client-ip	The IPv4 or IPv6 address of the messaging server or messaging client that submitted the message.
client-hostname	The host name or FQDN of the messaging server or messaging client that submitted the message.
server-ip	The IPv4 or IPv6 address of the source or destination Exchange server.
server-hostname	The host name or FQDN of the destination server.
source-context	Extra information associated with the **source** field. For example, transport agent information.
connector-id	The name of the source or destination Send connector or Receive connector. For example, *ServerName**ConnectorName* or *ConnectorName*.
source	The Exchange transport component responsible for the message tracking event. The values found in this field are described in the Source values in the message tracking log section later in this topic.
event-id	The message event type. The event types are described in the Event types in the message tracking log section later in this topic.
internal-message-id	A message identifier assigned by the Exchange server currently processing the message. A specific message's value of **internal-message-id** is different in the message tracking log of every Exchange server that's involved in the transmission of the message. An example

	value is `73014444033`.
message-id	The value of the **Message-Id:** header field found in the message header. If the **Message-Id:** header field does not exist or is blank, an arbitrary value is assigned. This value is constant for the lifetime of the message. For messages created in Exchange, the value is in the format `<GUID@ServerFQDN>`, including the angle brackets (`< >`). For example, `<4867a3d78a50438bad95c0f6d072fca5@mailbox01.contoso.com>`. Other messaging systems may use different syntax or values.
network-message-id	A unique message ID value that persists across copies of the message that may be created due to bifurcation or distribution group expansion. An example value is `1341ac7b13fb42ab4d4408cf7f55890f`.
recipient-address	The email addresses of the message's recipients. Multiple email addresses are separated by the semicolon character (;).
recipient-status	This field contains the recipient status for each recipient separated by the semicolon character (;). The status values are presented for the recipients in the same order as the values in the **recipient-address** field. Example status values include `250 2.1.5 Recipient OK` or `550 4.4.7 QUEUE.Expired;<ErrorText>`.
total-bytes	The size of the message that includes attachments, in bytes.
recipient-count	The number of recipients in the message.

related-recipient-address	This field is used with **EXPAND**, **REDIRECT**, and **RESOLVE** events to display other recipient email addresses associated with the message.
reference	This field contains additional information for specific types of events. For example: **DSN** Contains the report link, which is the **Message-Id** value of the associated delivery status notification (DSN) if a DSN is generated subsequent to this event. If this is a DSN message, the **Reference** field contains the **Message-Id** value of the original message for which this DNS was generated. **EXPAND** The Reference field contains the **related-recipient-address** value of the related messages. **RECEIVE** The Reference field may contain the **Message-Id** value of the related message if the message was generated by other processes, for example, journaling or Inbox rules. **SEND** The Reference field contains the **Internal-Message-Id** value of any DSN messages. **THROTTLE** The Reference field contains the reason why the message was throttled. **TRANSFER** The Reference field contains the Internal-Message-Id of the message that is being forked. For messages generated by inbox rules, the **Reference** field contains the **Internal-Message-Id** value of the inbound message that caused the inbox rule to generate the outbound message.

	For other types of events, the **Reference** field may contain the **Internal-Message-Id** value for forked messages. For other types of events, the **Reference** field is usually blank.
message-subject	The message's subject found in the `Subject:` header field. The tracking of message subjects is controlled by the *MessageTrackingLogSubjectLoggingEnabled* parameter in the **Set-TransportService** or **Set-MailboxServer** cmdlets. By default, message subject tracking is enabled.
sender-address	The email address specified in the `Sender:` header field, or the `From:` header field if `Sender:` is not present.
return-path	The return email address specified by `MAIL FROM:` in the message envelope. Although this field is never empty, it can have the null sender address value represented as `<>`.
message-info	Additional information about the message. For example: • The message origination UTC date-time for **DELIVER** and **SEND** events. The origination date-time is the time when the message first entered the Exchange organization. The UTC date-time is represented in the ISO 8601 date-time format: *yyyy-mm-dd*T*hh:mm:ss.fff*Z, where *yyyy* = year, *mm* = month, *dd* = day, T indicates the beginning of the time component, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and Z

	signifies Zulu, which is another way to denote UTC. • Authentication errors. For example you may see the value `11a` and the type of authentication used when authentication errors occur.
directionality	The direction of the message. Example values include `Incoming`, `Undefined`, and `Originating`.
tenant-id	This field isn't used in on-premises Exchange 2013 organizations.
original-client-ip	The IPv4 or IPv6 address of the original client.
original-server-ip	The IPv4 or IPv6 address of the original server.
custom-data	This field contains data related to a specific event types. For example, the Transport Rule agent uses this field to record the GUID of the transport rule or DLP policy that acted on the message. For more information about these Transport Rule agent values, see the "Data logging" section in the DLP policy detection reports topic,

Return to top

Event types in the message tracking log

Various event types in the **event-id** field are used to classify the message events in the message tracking log. Some message events appear in only one type of message tracking log file, and some message events appear in all types of message tracking log files. The events types that are used to classify each message event are explained in the following table.

Event name	Description
AGENTINFO	This event is used by transport agents to log custom data.
BADMAIL	A message submitted by the Pickup directory or

	the Replay directory that can't be delivered or returned.
DEFER	Message delivery was delayed.
DELIVER	A message was delivered to a local mailbox.
DSN	A delivery status notification (DSN) was generated.
DUPLICATEDELIVER	A duplicate message was delivered to the recipient. Duplication may occur if a recipient is a member of multiple nested distribution groups. Duplicate messages are detected and removed by the information store.
DUPLICATEEXPAND	During the expansion of the distribution group, a duplicate recipient was detected.
DUPLICATEREDIRECT	An alternate recipient for the message was already a recipient.
EXPAND	A distribution group was expanded.
FAIL	Message delivery failed. Sources include **SMTP**, **DNS**, **QUEUE**, and **ROUTING**.
HADISCARD	A shadow message was discarded after the primary copy was delivered to the next hop. For more information, see Shadow redundancy.
HARECEIVE	A shadow message was received by the server in the local database availability group (DAG) or Active Directory site.
HAREDIRECT	A shadow message was created.
HAREDIRECTFAIL	A shadow message failed to be created. The details are stored in the **source-context** field.

INITMESSAGECREATED	A message was sent to a moderated recipient, so the message was sent to the arbitration mailbox for approval. For more information, see Managing message approval.
LOAD	A message was successfully loaded at boot.
MODERATOREXPIRE	A moderator for a moderated recipient never approved or rejected the message, so the message expired. For more information about moderated recipients, see Managing message approval.
MODERATORAPPROVE	A moderator for a moderated recipient approved the message, so the message was delivered to the moderated recipient.
MODERATORREJECT	A moderator for a moderated recipient rejected the message, so the message wasn't delivered to the moderated recipient.
MODERATORSALLNDR	All approval requests sent to all moderators of a moderated recipient were undeliverable, and resulted in non-delivery reports (NDRs).
NOTIFYMAPI	A message was detected in the Outbox of a mailbox on the local server.
NOTIFYSHADOW	A message was detected in the Outbox of a mailbox on the local server, and a shadow copy of the message needs to be created.
POISONMESSAGE	A message was put in the poison message queue or removed from the poison message queue.
PROCESS	The message was successfully processed.
RECEIVE	A message was received by the SMTP receive

	component of the transport service or from the Pickup or Replay directories (source: `SMTP`), or a message was submitted from a mailbox to the Mailbox Transport Submission service (source: `STOREDRIVER`).
REDIRECT	A message was redirected to an alternative recipient after an Active Directory lookup.
RESOLVE	A message's recipients were resolved to a different email address after an Active Directory lookup.
RESUBMIT	A message was automatically resubmitted from Safety Net. For more information, see Safety Net.
RESUBMITDEFER	A message resubmitted from Safety Net was deferred.
RESUBMITFAIL	A message resubmitted from Safety Net failed.
SEND	A message was sent by SMTP between transport services.
SUBMIT	The Mailbox Transport Submission service successfully transmitted the message to the Transport service. For **SUBMIT** events, the **source-context** property contains the following details: • **MDB** The mailbox database GUID. • **Mailbox** The mailbox GUID. • **Event** The event sequence number. • **MessageClass** The type of message. For example, `IPM.Note`. • **CreationTime** Date-time of the message submission. • **ClientType** For example, `User`, `OWA` ,or

	`ActiveSync`.
SUBMITDEFER	The message transmission from the Mailbox Transport Submission service to the Transport service was deferred.
SUBMITFAIL	The message transmission from the Mailbox Transport Submission service to the Transport service failed.
SUPPRESSED	The message transmission was suppressed.
THROTTLE	The message was throttled.
TRANSFER	Recipients were moved to a forked message because of content conversion, message recipient limits, or agents. Sources include **ROUTING** or **QUEUE**.

Return to top

Source values in the message tracking log

The values in the **source** field in the message tracking log indicate the transport component that's responsible for the message tracking event. The following table describes the values of the **source** field.

Source value	Description
ADMIN	The event source was human intervention. For example, an administrator used Queue Viewer to delete a message, or submitted message files using the Replay directory.
AGENT	The event source was a transport agent.
APPROVAL	The event source was the approval framework that's used with moderated recipients. For more information, see Managing message approval.

DNS	The event source was DNS.
DSN	The event source was a delivery status notification (DSN). For example, a non-delivery report (NDR).
GATEWAY	The event source was a Foreign connector. For more information, see Foreign connectors.
MAILBOXRULE	The event source was an Inbox rule. For more information, see Inbox rules.
ORAR	The event source was an Originator Requested Alternate Recipient (ORAR). You can enable or disable support for ORAR on Receive connectors using the *OrarEnabled* parameter on the **New-ReceiveConnector** or **Set-ReceiveConnector** cmdlets.
PICKUP	The event source was the Pickup directory. For more information, see Pickup directory and Replay directory.
POISONMESSAGE	The event source was the poison message identifier. For more information about poison messages and the poison message queue, see Queues
PUBLICFOLDER	The event source was a mail-enabled public folder.
QUEUE	The event source was a queue.
REDUNDANCY	The event source was Shadow Redundancy. For more information, see Shadow redundancy.
ROUTING	The event source was the routing resolution component of the categorizer in the Transport

	service.
SAFETYNET	The event source was Safety Net. For more information, see Safety Net.
SMTP	The message was submitted by the SMTP send or SMTP receive component of the transport service.
STOREDRIVER	The event source was a MAPI submission from a mailbox on the local server.

Return to top

Example entries in the message tracking log

An uneventful message sent between two users generates several entries in the message tracking log. You can see the results using the **Get-MessageTrackingLog** cmdlet. For more information, see Search message tracking logs.

This is a condensed example of the message tracking log entries created when the user chris@contoso.com successfully sends a test message to the user michelle@contoso.com. Both users have mailboxes on the same server.

```
EventId    Source      Sender            Recipients
     MessageSubject
-------    ------      ------            ----------
     --------------
NOTIFY     STOREDRIVER                   {}
RECEIVE    STOREDRIVER chris@contoso.com
{michelle@contoso.com} test
SUBMIT     STOREDRIVER chris@contoso.com
{michelle@contoso.com} test
HAREDIRECT SMTP        chris@contoso.com
{michelle@contoso.com} test
RECEIVE    SMTP        chris@contoso.com
{michelle@contoso.com} test
AGENT      AGENT       chris@contoso.com
{michelle@contoso.com} test
SEND       SMTP        chris@contoso.com
```

```
{michelle@contoso.com} test
DELIVER    STOREDRIVER chris@contoso.com
{michelle@contoso.com} test
```

Return to top

Security concerns for the message tracking log

No message content is stored in the message tracking log. By default, the subject line of an email message is stored in the message tracking log. You may want to disable message subject logging to comply with increased security or privacy requirements. Before you enable or disable message subject logging, make sure that you verify your organization's policy about revealing subject line information. For more information, see Configure message tracking.

Return to top

Configure message tracking

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-18*

Message tracking records the SMTP transport activity of all messages transferred to and from the Transport service or mailboxes on a Microsoft Exchange Server 2013 Mailbox server. You can use message tracking logs for message forensics, mail flow analysis, reporting, and troubleshooting.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport service" entries in the Mail flow permissions topic or the "Mailbox server configuration" entry in the Recipients Permissions topic.
- You can use the Exchange admin center (EAC) to enable or disable message tracking, or set the message tracking log path. For all other message tracking options, you need to use the Exchange Management Shell.
- On an Exchange 2013 Mailbox server, you can use either the **Set-TransportService** or the **Set-MailboxServer** cmdlet to configure the message tracking options. The procedures in this topic use the **Set-TransportService** cmdlet.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Use the EAC to configure message tracking on Mailbox servers

1. In the EAC, navigate to **Servers** > **Servers**.
2. Select the Mailbox server you want to configure, and then click **Edit** .
3. On the server properties page, click **Transport Logs**.
4. In the **Message tracking log** section, change any of the following:
   - **Enable message tracking log** To disable message tracking on the server, clear the check box. To enable message tracking on the server, select the check box.
   - **Message tracking log path** The value you specify must be on the local Exchange server. If the folder doesn't exist, it will be created for you when you click **Save**.
5. Click **Save**.

Use the Shell to configure message tracking

To configure message tracking, run the following command:

```
Set-TransportService <ServerIdentity> -
MessageTrackingLogEnabled <$true | $false> -
MessageTrackingLogMaxAge <dd.hh:mm:ss> -
MessageTrackingLogMaxDirectorySize <Size> -
MessageTrackingLogMaxFileSize <Size> -
MessageTrackingLogPath <LocalFilePath> -
MessageTrackingLogSubjectLoggingEnabled <$true|$false>
```

This example sets the following message tracking log settings on the Mailbox server named Mailbox01:

Sets the location of the message tracking log files to D:\Message Tracking Log. Note that if the folder doesn't exist, it will be created for you.

Sets the maximum size of a message tracking log file to 20 MB.

Sets the maximum size of the message tracking log directory to 1.5 GB.

Sets the maximum age of a message tracking log file to 45 days.

```
Set-TransportService Mailbox01 -MessageTrackingLogPath "D:
\Hub Message Tracking Log" -MessageTrackingLogMaxFileSize
20MB -MessageTrackingLogMaxDirectorySize 1.5GB -
MessageTrackingLogMaxAge 45.00:00:00
```

Note:

- Setting the *MessageTrackingLogPath* parameter to the value `$null`, effectively disables message tracking. However, if the value of the *MessageTrackingLogEnabled* parameter is `$true`, event log errors are generated.
- Setting the *MessageTrackingLogMaxAge* parameter to the value `00:00:00` prevents the automatic removal of message tracking log files because of their age.
- On Exchange 2013 Mailbox servers, the maximum size of the message tracking log directory is three times the value of the *MessageTrackingLogMaxDirectorySize* parameter. Although the message tracking log files that are generated by the four different services have four different name prefixes, the amount and frequency of data written to the **MSGTRKMA** log files is negligible compared to the three other log file prefixes. For more information, see the "Structure of the message tracking log files" section in the Message tracking topic.

This example disables message subject logging in the message tracking log on the Mailbox server named Mailbox01:

```
Set-TransportService Mailbox01 -
MessageTrackingLogSubjectLoggingEnabled $false
```

This example disables message tracking on the Mailbox server named Mailbox01:

```
Set-TransportService Mailbox01 -MessageTrackingLogEnabled
$false
```

How do you know this worked?

To verify that you have successfully configured message tracking, do the following:
1. In the Shell, run the following command:

```
Get-TransportService <ServerIdentity> | Format-List
MessageTrackingLog*
```

2. Verify that the values displayed are the values you configured.

Search message tracking logs

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-25*

In Microsoft Exchange Server 2013, the message tracking log is a detailed record of all message activity as messages are transferred to and from the Transport service on Mailbox servers, mailboxes on Mailbox servers, and Edge Transport servers.

You can use the **Get-MessageTrackingLog** cmdlet in the Exchange Management Shell to search for entries in the message tracking log by using specific search criteria.

What do you need to know before you begin?

- Estimated time to complete: 30 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Message tracking" entry in the Mail flow permissions topic.
- Searching the message tracking logs requires the Microsoft Exchange Transport Log Search service to be running. If you disable or stop this service, you can't search the message tracking logs or run delivery reports. However, stopping this service does not affect other features in Exchange.
- The field names displayed by the results from the **Get-MessageTrackingLog** cmdlet are similar to the actual field names used in the message tracking logs. The biggest differences are:
  - The dashes are removed from the field names. For example **internal-message-id** is displayed as `InternalMessageId`.
  - The **date-time** field is displayed as `Timestamp`.
  - The **recipient-address** field is displayed as `Recipients`.
  - The **sender-address** field is displayed as `Sender`.
- The **date-time** field in the message tracking log stores information in Coordinated Universal Time (UTC). However, you should enter your date-time search criteria for the *Start* or *End* parameters in the regional date-time format of the computer that you are using to perform the search.
- You can't copy the message tracking log files from another Exchange server and then search them by using the **Get-MessageTrackingLog** cmdlet. Also, if you manually save an existing message tracking log file, the change in the file's date-time stamp breaks the query logic that Exchange uses to search the message tracking logs.
- The Exchange 2013 **Get-MessageTrackingLog** cmdlet is able to search the message tracking logs on Exchange 2007 and Exchange 2010 servers in the same Active Directory site.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see

Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to search the message tracking logs

To search the message tracking log entries for specific events, use the following syntax.

```
Get-MessageTrackingLog [-Server <ServerIdentity.] [-
ResultSize <Integer> | Unlimited] [-Start <DateTime>] [-End
<DateTime>] [-EventId <EventId>] [-InternalMessageId
<InternalMessageId>] [-MessageId <MessageId>] [-
MessageSubject <Subject>] [-Recipients
<RecipientAddress1,RecipientAddress2...>] [-Reference
<Reference>] [-Sender <SenderAddress>]
```

To view the 1000 most recent message tracking log entries on the server, run the following command:

```
Get-MessageTrackingLog
```

This example searches the message tracking logs on the local server for all entries from 3/28/2013 8:00 AM to 3/28/2013 5:00 PM for all **FAIL** events where the message sender was pat@contoso.com.

```
Get-MessageTrackingLog -ResultSize Unlimited -Start
"3/28/2013 8:00AM" -End "3/28/2013 5:00PM" -EventId "Fail"
-Sender "pat@contoso.com"
```

Use the Shell to control the output of a message tracking log search

Use the following syntax.

```
Get-MessageTrackingLog <SearchFilters> | <Format-Table |
Format-List> [<FieldNames>] [<OutputFileOptions>]
```

This example searches the message tracking logs using the following search criteria:

- Return results for the first 1,000 **Send** events.
- Display the results in the list format.
- Display only those field names that begin with `Send` or `Recipient`.
- Write the output to a new file named `D:\Send Search.txt`

```
Get-MessageTrackingLog -EventId Send | Format-List
Send*,Recipient* > "D:\Send Search.txt"
```

Use the Shell to search the message tracking logs for message entries on multiple servers

Typically, the value in the **MessageID:** header field remains constant as the message travels throughout the Exchange organization. This property is named **InternetMessageId** in queue viewing utilities, and **MessageId** in the message tracking log viewing utilities. After you have determined the `MessageID:` value of a specific message, you can search for information about that message in the message tracking logs on every Mailbox server in your Exchange organization.

To search all message tracking log entries for a specific message across all Mailbox servers, use the following syntax.

```
Get-ExchangeServer | where {$_.isHubTransportServer -eq
$true -or $_.isMailboxServer -eq $true} | Get-
MessageTrackingLog -MessageId <MessageID> | Select-Object
<CommaSeparatedFieldNames> | Sort-Object -Property
<FieldName>
```

This example searches the message tracking logs on all Exchange 2013 Mailbox servers using the following search criteria:

- Find any entries related to a message that has a **MessageID:** value of `<ba18339e-8151-4ff3-aeea-87ccf5fc9796@mailbox01.contoso.com>`. Note that you can omit the angle bracket characters (< >). If you don't, you need to enclose the entire **MessageID:** value in quotation marks.
- For each entry, display the fields **date-time**, **server-hostname**, **client-hostname**, **source**, **event-id**, and **recipient-address**.
- Sort the results by the **date-time** field.

```
Get-ExchangeServer | where {$_.isHubTransportServer -eq
$true -or $_.isMailboxServer -eq $true} | Get-
MessageTrackingLog -MessageId ba18339e-8151-4ff3-aeea-
87ccf5fc9796@mailbox01.contoso.com | Select-Object
Timestamp,ServerHostname,ClientHostname,Source,EventId,Reci
pients | Sort-Object -Property Timestamp
```

Use the EAC to search the message tracking logs

You can use the Delivery Reports for administrators feature in the Exchange admin center (EAC) to search the message tracking logs for information about messages sent by or received by a specific mailbox in your organization. For more information see Track messages with delivery reports.

Delivery reports for administrators

Exchange Server 2013 > Mail flow >

Topic Last Modified: *2013-02-18*

With delivery reports for administrators, you can track delivery information about messages sent by or received from any specific mailbox in your organization. Specifically, delivery reports for administrators uses the Exchange admin center (EAC) to perform a targeted search of the message tracking logs. The search is always scoped to a specific mailbox. You can search for messages sent by the mailbox, or sent to the mailbox, and you can filter the search results by the message subject.

The content of the message body isn't returned in a delivery report, but the subject line is displayed in the results. If you want to search the mailboxes in your organization for specific email messages based on message content, see In-Place eDiscovery.

You may find delivery report searches useful in the following situations:

- A manager gives a poor review for a trainee because the trainee didn't turn in an assignment on time. The trainee insists he sent a message with the assignment attached. The manager asks you to verify the status of the message.
- A security bulletin has been sent to users asking that they reply immediately, but no one has replied. Are they ignoring the message or did they just not receive it?
- Users complain that no one is receiving their messages. They check delivery status for their mail but can't figure out what is going on. This may be because a rule is being applied to messages at the organization level.

After you create a delivery report search, the resulting delivery report will show the following information: Who the message was sent from and to, the subject line, and when the message was sent. The delivery report also shows message delivery status and reasons why delivery may be delayed or failed.

More about delivery reports

- Here's how to create a new delivery report: Track messages with delivery reports.
- On-premises Exchange organizations can use the Exchange Management Shell to query the message tracking logs directly. For more information, see Search message tracking logs.

- Users can track their own messages. For more information, see Delivery Reports for Users.
- If your organization contains a previous version of Exchange, you need to consider how the delivery reports feature in Exchange 2013 works across Exchange versions.
  - Exchange 2013 delivery reports can track messages across Exchange 2010 servers in the same Active Directory site.
  - Exchange 2013 delivery reports can't track messages across Exchange 2007 servers in the same Active Directory site. The delivery reports feature uses a remote procedure call and a web service interface that doesn't exist in Exchange 2007.

Track messages with delivery reports

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-13*

Delivery Reports is a message tracking tool in the Exchange Administration Center (EAC) that you can use to search for delivery status on email messages sent to or from users in your organization's address book, with a certain subject. You can track delivery information about messages sent by or received from any specific mailbox in your organization. The content of the message body isn't returned in a delivery report, but the subject line is displayed in the results. You can track messages for up to 14 days after they were sent or received.

Note:

Delivery Reports tracks messages sent by people using the Microsoft Outlook or Outlook Web App email clients. It doesn't track messages sent from POP or IMAP email clients, such as Windows Mail, Outlook Express, or Mozilla Thunderbird.

What do you need to know before you begin?

- Estimated time to complete each procedure: Time to complete will vary based on the scope of your search.
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Message tracking" entry in the Mail flow permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.
- Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection..

What do you want to do?

Use the EAC to track messages

1. In the EAC, navigate to **Mail Flow** > **Delivery Reports**.
2. Enter the following information:
   - *** Mailbox to search:** Click **Browse** to select the mailbox from the address book and then click **OK**. Selecting the mailbox to search is required.
   - Select one of the following:
     - **Search for messages sent to** Use this option to search for messages sent to specific users. Click **Select users** and then pick users from the address book by selecting a user from the list and clicking **Add**. You can select more than one user here. When you're finished selecting users, click **OK** to return to the **Delivery Reports** page. If you select this option, you can also leave the field blank to find messages sent to anyone.
     - **Search for messages received from** Use this option to search for messages received from a specific user. Again, just select the user from the address book and click **OK** to return to the **Delivery Reports** page. If you select this option, you have to specify a sender.
   - **Search for these words in the subject line** Enter subject line information here, or leave it blank to expand your search.
3. When you are finished, click **Search**. If you want to start over, click **Clear**.

Use the EAC to review a delivery report

To view delivery information, select a message in the **Search results** pane and click **Details**.

The delivery report shows delivery status and detailed delivery information for the message you have selected from the **Search results** pane. At the top of the report, you'll see the following fields:

- **Subject** The subject line of the message appears as the heading of the report.
- **From** Alias, display name, or email address of the person who sent the message.
- **To** Alias, display name, or email address for each recipient of the message.
- **Sent** Date and time the message was sent.

Summary to date section

This section appears in the delivery report if a message was sent to more than one person or recipient. The top of this section tells you the total number of recipients that the message was sent to and gives brief delivery information for each recipient.

- **Summary to date** Displays total number of recipients, and if there are messages Pending, Delivered, or Unsuccessful. Click the hyperlinks to sort by status.
- **Search box** The search box is useful if you sent the message to a group of more than 30 recipients. In the search box, type an email address that you want to get delivery information about and click the magnifying glass.
- **To** Shows the email address of the recipient.

- **Status** This column displays the status of the message for each recipient.

Detailed report information

This section contains detailed delivery information for a message sent to the recipient you select in the Summary to date section.

- **Delivery Report for** The email address of the selected recipient is shown here.
- **Submitted** Date and time that the message was submitted for delivery by the system.

Depending on the delivery status of the message, you may see a variety of status states, including:

- **Delivered** Indicates successful delivery.
- **Deferred** Indicates that a message is delayed.
- **Pending** If message delivery is pending because a message meets the criteria for an organization-wide rule or policy or because it's subject to message approval, the status message explains what action a rule is performing or that the message must be approved by a moderator before delivery.
- **Moderator** The status indicates whether the message was approved or rejected by the moderator.
- **Groups Expanded** If a message was sent to a group, the individual users are shown in the **Summary to date** section so you can see the delivery status for each recipient. If you need to remove or add a user to a group during a delivery report investigation, you can modify a group by clicking **Edit Groups**.
- **Failed** Shows the date, time, and reason for a message delivery failure. For example, an organization-wide rule may be blocking message delivery or the message couldn't be delivered.

When you're done reviewing the report, click **Close**. Delivery reports aren't saved, but you can re-run a report at any time. Remember there is a two-week search window.

How do you know this worked?

If your search was successful, messages that fit the search criteria are listed in the **Search results** pane. To view the delivery information for a specific message, select it and then click **Details**. If no messages are displayed in the **Search results** pane, change the search criteria and then re-run the search.

Content conversion

Exchange Server 2013 > Mail flow >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-16*

Content conversion is the process of correctly formatting a message for each recipient. The decision to perform content conversion on a message depends on the destination and format of the message being processed. In Microsoft Exchange Server 2013, there are two different kinds of content conversion:

- **Message conversion for external recipients** This type of content conversion includes the Transport Neutral Encapsulation Format (TNEF) conversion options and message encoding options for external recipients. Messages sent to recipients inside the Exchange organization don't require this type of content conversion. This type of content conversion is handled by the categorizer in the Transport service on Mailbox server. Categorization on each message happens after a newly arrived message is put in the Submission queue. In addition to recipient resolution and routing resolution, content conversion is performed on the message before the message is put in a delivery queue. If a single message contains multiple recipients, the categorizer determines the appropriate encoding for each message recipient. Content conversion tracing doesn't capture any content conversion failures that the categorizer encounters as it converts messages sent to external recipients.
- **MAPI conversion for internal recipients** This type of content conversion is handled by the Mailbox Transport service. The Mailbox Transport service exists on Mailbox servers to transmit messages between mailbox databases on the local server, and the Transport service on Mailbox servers. Specifically, the Mailbox Transport Submission service transmits messages from the sender's Outbox to the Transport service on a Mailbox server. The Mailbox Transport Delivery service transmits messages from the Transport service on a Mailbox server to the recipient's Inbox. The Mailbox Transport Submission service converts all outgoing messages from MAPI and the Mailbox Transport Delivery service converts all incoming messages to MAPI. Content conversion tracing captures these MAPI conversion failures. For more information, see Content conversion tracing.

This topic explains the message conversion options for external recipients.

Contents

Exchange and Outlook message formats

The following list describes the basic message formats available in Exchange and Microsoft Outlook:

- **Plain text** A plain text message uses only US-ASCII text as described in RFC 2822. The message can't contain different fonts or other text formatting. The following two formats can be used for a plain text message:
  - The message headers and the message body are composed of US-ASCII text. Attachments must be encoded by using *Uuencode*. Uuencode represents Unix-to-Unix encoding and defines an

encoding algorithm to store binary attachments in the body of an email message by using US-ASCII text characters.
    - The message is MIME-encoded with a Content-Type value of text/plain, and a Content-Transfer-Encoding value of 7bit for the text parts of a multipart message. Any message attachments are encoded by using Quoted-printable or Base64 encoding. By default, when you compose and send a plain text message in Outlook, the message is MIME-encoded with a Content-Type value of text/plain.
- **HTML** An HTML message supports text formatting, background images, tables, bullet points, and other graphical elements. By definition, an HTML-formatted message must be MIME-encoded to preserve these formatting elements.
- **Rich text format (RTF)** RTF supports text formatting and other graphical elements. RTF is synonymous with TNEF. TNEF and RTF can be used interchangeably. The rich text message format is completely different from the rich text document format available in Microsoft Word.

Only Outlook and a few other MAPI email clients understand RTF messages.

- **TNEF** The Transport Neutral Encapsulation Format is a Microsoft-specific format for encapsulating MAPI message properties. A TNEF message contains a plain text version of the message and an attachment that packages the original formatted version of the message. Typically, this attachment is named Winmail.dat. The Winmail.dat attachment includes the following information:
    - Original formatted version of the message, including, for example, fonts, text sizes, and text colors
    - OLE objects, including, for example, embedded pictures or embedded Microsoft Office documents
    - Special Outlook features, including, for example, custom forms, voting buttons, or meeting requests
    - Regular message attachments that were in the original message

The resulting plain text message can be represented in the following formats:

- RFC 2822-compliant message composed of only US-ASCII text with a Winmail.dat attachment encoded in Uuencode
- Multipart MIME-encoded message that has a Winmail.dat attachment

A MAPI-compliant email client that fully understands TNEF, such as Outlook, processes the Winmail.dat attachment and displays the original message content without ever displaying the Winmail.dat attachment. An email client that doesn't understand TNEF may present a TNEF message in any of the following ways:

- The plain text version of the message is displayed, and the message contains an attachment named Winmail.dat, Win.dat, or some other generic name such as Att*nnnnn*.dat or Att*nnnnn*.eml where the *nnnnn* placeholder represents a random number.
- The plain text version of the message is displayed. The TNEF attachment is ignored or removed. The result is a plain text message.
- Messaging servers that understand TNEF can be configured to remove TNEF attachments from incoming messages. The result is a plain text message. Moreover, some email clients such as Microsoft Outlook Express may not understand TNEF, but recognize and ignore TNEF

attachments. The result is a plain text message.

There are third-party utilities that can help convert Winmail.dat attachments.

TNEF is understood by all versions of Exchange since Exchange Server version 5.5.

- **Summary Transport Neutral Encapsulation Format (STNEF)** STNEF is equivalent to TNEF. However, STNEF messages are encoded differently than TNEF messages. Specifically, STNEF messages are always MIME-encoded and always have a Content-Transfer-Encoding value of Binary. Therefore, there's no plain text representation of the message, and there's no distinct Winmail.dat attachment contained in the body of the message. The whole message is represented by using only binary data. Messages that have a Content-Transfer-Encoding value of Binary can only be transferred between SMTP messaging servers that support and advertise the BINARYMIME and CHUNKING SMTP extensions as defined in RFC 3030. The messages are always transferred between SMTP messaging by using the BDAT command, instead of the standard DATA command.

STNEF is understood by all versions of Exchange since Exchange 2000. STNEF is automatically used for all messages transferred between Exchange servers in the organization since native mode Exchange Server 2003.

Exchange never sends STNEF messages to external recipients. Only TNEF messages can be sent to recipients outside the Exchange organization.

Return to top

Content conversion options for external recipients

The content conversion options that you can set in an Exchange organization for external recipients can be described in the following categories:

- **TNEF conversion options** These conversion options specify whether TNEF should be preserved or removed from messages that leave the Exchange organization.
- **Message encoding options** These options specify message encoding options, such as MIME and non-MIME character sets, message encoding, and attachment formats.

These conversion and encoding options are independent of one another. For example, whether TNEF messages can leave the Exchange organization isn't related to the MIME encoding settings or plain text encoding settings of those messages.

You can specify the content conversion at various levels of the Exchange organization as described in the following list:

- **Remote domain settings** Remote domains define the settings for outgoing message transfers between the Exchange organization and external domains.. Even if you don't create remote domain entries for specific domains, there's a predefined remote domain named Default that applies to all remote address spaces (*).
- **Mail user and mail contact settings** Mail users and mail contacts are similar because both have external email addresses and contain information about people outside the Exchange organization. The main difference is mail users have accounts that can be used to log on to the

Active Directory domain and access resources in the organization.

- **Outlook settings** In Outlook, you can set the message formatting and encoding options described in the following list:
  - **Message format** You can set the default message format for all messages. You can override the default message format as you compose a specific message.
  - **Internet message format** You can control whether TNEF messages are sent to remote recipients or whether they are first converted to a more compatible format. You can also specify various message encoding options for messages sent to remote recipients. These settings don't apply to messages sent to recipients in the Exchange organization.
  - **Internet recipient message format** You can control whether TNEF messages are sent to specific recipients or whether they are first converted to a more compatible format. You can set the conversion options for specific contacts in your Contacts folder, and you can override the conversion options for a specific recipient in the To, Cc, or Bcc fields as you compose a message. These conversion options aren't available for recipients in the Exchange organization.
  - **Internet recipient message encoding options** You can control the MIME or plain text encoding options for specific contacts in your Contacts folder, and you can override the conversion options for a specific recipient in the To, Cc, or Bcc fields as you compose a message. These conversion options aren't available for recipients in the Exchange organization.
  - **International options** You can control the character sets used in messages.

TNEF conversion options

You can specify the TNEF conversion options at the following levels:

- Remote domain settings
- Mail user and mail contact settings
- Outlook settings, including:
  - Message format
  - Internet message format
  - Internet recipient message format

Message encoding options

You can specify the message encoding options at the following levels:

- Remote domain settings
- Mail user and mail contact settings
- Outlook settings, including:
  - Message format
  - Internet message
  - Internet recipient message format
  - Message character set encoding options

For detailed information, see Message encoding options.

Return to top

Understanding the structure of email messages

To better understand the content conversion options for external recipients, you need to understand the structure of email messages. An SMTP message is based on plain 7-bit US-ASCII text to compose and send email messages. A standard SMTP message consists of the following elements:

- **Message envelope** The message envelope is defined in RFC 2821. The message envelope contains information required to transmit and deliver the message. Recipients never see the message envelope, because it's generated by the message transmission process and isn't actually part of the message contents.
- **Message contents** The message contents are defined in RFC 2822. The message contents consist of the following elements:
  - **Message header** The message header is a collection of header fields. Header fields consist of a field name, followed by a colon (:) character, followed by a field body, and ended by a carriage return/line feed (CR/LF) character combination.

A field name must be composed of printable US-ASCII text characters except the colon (:) character. Specifically, ASCII characters that have values from 33 through 57 and 59 through 126 are permitted.

A field body may be composed of any US-ASCII characters, except for the carriage return (CR) character and the line feed (LF) character. However, a field body may contain the CR/LF character combination when used in *header folding*. Header folding is the separation of a single header field body into multiple lines as described in section 2.2.3 of RFC 2822. Other field body syntax requirements are described in sections 3 and 4 of RFC 2822.

  - **Message body** The message body is a collection of lines of US-ASCII text characters that appears after the message header. The message header and the message body are separated by a blank line that ends with the CR/LF character combination. The message body is optional. Any line of text in the message body must be less than 998 characters. The CR and LF characters can only appear together to indicate the end of a line.

When SMTP messages contain elements that aren't plain US-ASCII text, the message must be encoded to preserve those elements. The MIME standard defines a method of encoding content in messages that isn't text. MIME allows for text in other character sets, attachments without text, multipart message bodies, and header fields in other character sets. MIME is defined in RFC 2045, RFC 2046, RFC 2047, RFC 2048, and RFC 2077. MIME defines a collection of header fields that specifies additional message attributes. The following table describes some important MIME header fields.

Important MIME header fields

Header field name	Default value	Description
MIME-Version	1.0	This header field is the first MIME header field that appears in a

		MIME-formatted message. This header field appears after the other standard RFC 2822 header fields, but before any other MIME header fields. MIME-aware email clients use this header field to identify a MIME-encoded message. When this header field is absent, MIME-aware email clients identify the message as plain text.
Content-Type	text/plain	This header field identifies the media type of the message content as described in RFC 2046. A media type consists of a type, a subtype, and one or more optional parameters, such as a *charset*= parameter that defines the MIME character encoding. Types that begin with "x-" aren't standard. Subtypes that begin with "vnd." are vendor-specific. The Internet Assigned Numbers Authority (IANA) maintains a list of registered media types. For more information, see MIME Media Types. The *multipart* media type allows for multiple message parts in the same message by using sections defined by different media types. Some Content-Type field values include text/plain, text/html,

		multipart/mixed, and multipart/alternative.
Content-Transfer-Encoding	7bit	This header field can describe the following information about a message: • The encoding algorithm used to transform any non-US-ASCII text or binary data that exists in the message body. • An indicator that describes the current condition of the message body. There can be multiple values of the Content-Transfer-Encoding header field in a MIME message. When the Content-Transfer-Encoding header field appears in the message header, it applies to the whole body of the message. When the Content-Transfer-Encoding header field appears in one of the parts of a multipart message, it applies only to that part of the message. When an encoding algorithm is applied to the message body data, the message body data is transformed into plain US-ASCII text. This transformation allows the message to travel through older SMTP messaging servers that only support messages in US-ASCII text. The values of the Content-

		Transfer-Encoding header field that indicate an encoding algorithm was used on the message body are as follows: • **Quoted-printable** This encoding algorithm uses printable US-ASCII characters to encode the message body data. If the original message text is mostly US-ASCII text, Quoted-printable encoding gives somewhat readable and compact results. All printable US-ASCII text characters except the equal sign (=) character can be represented without encoding. • **Base64** This encoding algorithm is based primarily on the privacy-enhanced mail (PEM) standard defined in RFC 1421. Base64 encoding uses the 64-character alphabet encoding algorithm and output padding characters defined by PEM to encode the message body data. A Base64 encoded message is typically 33 percent larger than the original message. Base64 encoding creates a predictable increase in message size and is optimal for binary data and non-US-ASCII text. Typically, you won't see multiple

		encoding algorithms used in the same message. When no encoding algorithm has been used on the message body, the Content-Transfer-Encoding header field merely identifies the current condition of the message body data. The following values of the Content-Transfer-Encoding header field indicate that no encoding algorithms were used on the message body: • **7bit** This value indicates that the message body data is already in the RFC 2822 format. Specifically, this means that the following conditions must be true: ○ All lines of text must be less than 998 characters long. ○ All characters must be US-ASCII text that have character values from 1 through 127. ○ The CR and LF characters can only be used together to indicate the end of a line of text. The whole message body may be 7bit, or part of the message body in a multipart message may be 7bit. If the multipart message contains other parts that have any binary data or non-US-ASCII text, that part of the message must be encoded using the Quoted-

		printable or Base64 encoding algorithms. Messages that have 7bit bodies can travel between SMTP messaging servers by using the standard DATA command. • **8bit** This value indicates that the message body data contains non-US-ASCII characters. Specifically, this means that the following conditions must be true: ○ All lines of text must be less than 998 characters long. ○ One or more characters in the message body have values larger than 127. ○ The CR and LF characters can only be used together to indicate the end of a line of text. The whole message body may be 8bit, or part of the message body in a multipart message may be 8bit. If the multipart message contains other parts that have binary data, that part of the message must be encoded using the Quoted-printable or Base64 encoding algorithms. Messages that have 8bit bodies can only travel between SMTP messaging servers that support the 8BITMIME SMTP extension as defined in RFC 1652, such as servers running Exchange 2000 Server or newer versions.

		Specifically, this means that the following conditions must be true: ○ The 8BITMIME keyword must be advertised in the server's EHLO response. ○ Messages are still transferred by using the SMTP standard DATA command. However, the BODY=8BITMIME parameter must be added to the end of the MAIL FROM command. • **Binary** This value indicates that the message body contains non-US-ASCII text or binary data. Specifically, this means that the following conditions are true: ○ Any sequence of characters is allowed. ○ There is no line length limitation. ○ Binary message elements don't require encoding. Messages that have Binary bodies can only travel between SMTP messaging servers that support the BINARYMIME SMTP extension as defined in RFC 3030, such as servers running Exchange 2000 Server or newer versions. Specifically, this means that the following conditions must be true: ○ The BINARYMIME keyword must be advertised in the server's EHLO response. ○ The BINARYMIME SMTP extension can only be used with the CHUNKING SMTP extension. *Chunking* enables

		large message bodies to be sent in multiple, smaller chunks. Chunking is also defined in RFC 3030. The CHUNKING keyword must also be advertised in the server's EHLO response. ○ Messages are transferred using the BDAT command instead of the standard DATA command. ○ The *BODY=BINARYMIME* parameter must be added to the end of the MAIL FROM command when the message has a message body. The values 7bit, 8bit, and Binary never exist together in the same multipart message. The values are mutually exclusive. The Quoted-printable or Base64 values may appear in a 7bit or 8bit multipart message body, but never in a Binary message body. If a multipart message body contains different parts composed of 7bit and 8bit content, the whole message is classified as 8bit. If a multipart message body contains different parts composed of 7bit, 8bit, and Binary content, the whole message is classified as Binary.
Content-Disposition	Attachment	This header field instructs a MIME-enabled email client on how it should display an attached file, and

		is described in RFC 2183. The values of this field may be Inline or Attachment. When the value of this field is Inline, the attachment is displayed in the message body. When the value of this field is Attachment, the attached file appears as a regular attachment separate from the message body. Other parameters are available when the value is Attachment, such as Filename, Creation-date, and Size.

Return to top

Configure content transfer encoding

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2012-10-03*

Content transfer encoding defines encoding methods for transforming binary email message data into the US-ASCII plain text format. This transformation allows the message to travel through older SMTP messaging servers that only support messages in US-ASCII text. Content transfer encoding is defined in RFC 2045. The transfer encoding method is stored in the **Content-Transfer-Encoding** header field in the message. In Microsoft Exchange Server 2013, the following content transfer encoding methods are available:

- **7-bit** This value indicates that the message body data is already in the US ASCII plain text format, and no message encoding has been done to the message.
- **Quoted-printable (QP)** This encoding method uses printable US-ASCII characters to encode the message body data. If the original message text is mostly US-ASCII text, QP encoding gives somewhat readable and compact results. By default, Exchange 2013 uses QP for encoding binary message data.
- **Base64** This encoding method is based primarily on the privacy-enhanced mail (PEM) standard defined in RFC 1421. Base64 encoding uses the 64-character alphabet encoding method and

output padding characters defined by PEM to encode the message body data. Base64 encoding creates a predictable increase in message size and is optimal for binary data and non-US-ASCII text.

You configure the transfer encoding method using the *ByteEncoderTypeFor7BitCharsets* parameter on the **Set-OrganizationConfig** and **Set-RemoteDomain** cmdlets. The content transfer encoding settings you configure with **Set-OrganizationConfig** apply to all messages in the Exchange organization. The content transfer encoding settings you configure with **Set-RemoteDomain** apply only to message sent to external recipients in the remote domain.

The following table lists the values that you can use to set the transfer encoding method.

Parameter in Set-OrganizationConfig	Parameter in Set-RemoteDomain	Description
0	`Use7Bit`	Always use 7-bit encoding for HTML and for plain text. This is the default value.
1	`UseQP`	Always use QP encoding for HTML and for plain text.
2	`UseBase64`	Always use Base64 encoding for HTML and for plain text.
5	`UseQPHtmlDetectTextPlain`	Use QP encoding for HTML and for plain text unless line wrapping is enabled in plain text. If line wrapping is enabled, use 7-bit encoding for plain text.
6	`UseBase64HtmlDetectTextPlain`	Use Base64 encoding for HTML and for plain text, unless line wrapping is enabled in plain text. If line wrapping is enabled in plain text, use Base64 encoding for HTML, and use 7-bit encoding for plain text.
13	`UseQPHtml7BitTextPlain`	Always use QP encoding for

		HTML. Always use 7-bit encoding for plain text.
14	`UseBase64Html7BitTextPlain`	Always use Base64 encoding for HTML. Always use 7-bit encoding for plain text.

For more details about **Content-Transfer-Encoding** header field, see the "Understanding the structure of email messages" section in Content conversion.

For more information about remote domains, see Remote domains.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Transport service" entry in the Mail flow permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to configure the content transfer encoding method for the organization

To configure the content transfer encoding method for the organization, run the following command:

```
Set-OrganizationConfig -ByteEncoderTypeFor7BitCharsets <Integer>
```

For example, to set the content transfer encoding method to Base64, run the following command:

```
Set-OrganizationConfig -ByteEncoderTypeFor7BitCharsets 2
```

Use the Shell to configure the content transfer encoding

method for a remote domain

To configure the content transfer encoding method for all the recipients in a remote domain, run the following command:

```
Set-RemoteDomain -ByteEncoderTypeFor7BitCharsets <Value>
```

For example, to set the content transfer encoding method to Base64, run the following command:

```
Set- RemoteDomain -ByteEncoderTypeFor7BitCharsets UseBase64
```

How do you know this worked?

To verify that you have successfully configured the method for content transfer encoding, do the following:

1. Send a test message that contains a mixture of US-ASCII text and binary data or non-US-ASCII text to an internal or external test account. Use an internal account to test organization settings, and an external account in the remote domain to test remote domain settings.
2. In an email client, view the **Content-Transfer-Encoding** header field in the message, and verify the content transfer encoding method that was used on the message matches the method you configured.

Message encoding options

Exchange Server 2013 > Mail flow > Content conversion >

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-07-28*

The message encoding options that are available in Exchange specify message characteristics, such as MIME and non-MIME character sets, binary encoding, and attachment formats. You can specify message encoding options in the following locations:

- Remote domain settings
- Mail user and mail contact settings
- Microsoft Outlook settings
  - Message format
  - Internet message format
  - Internet recipient message format
  - Message character set encoding options

Content

Message encoding options for messages sent to remote domains

When you configure message encoding options for a remote domain, the specific settings are applied for all messages sent to that domain. For remote domains in your organization, you have the following configuration options for message encoding.

Setting	Available in EAC in Exchange Online Dedicated	Available in the Shell
MIME character set The character set that you specify will only be used for MIME messages that don't have their own character set specified. Setting this parameter won't overwrite character sets that are already specified in the outgoing mail. **Non-MIME character set** This setting is used if either of the following conditions are true: • Incoming messages from a remote domain are missing the value of the *charset*= setting in the MIME Content-Type: header field. • Outgoing messages to a remote domain are missing the value of	Yes	Yes

the MIME character set.		
Content type You can specify the content type for MIME messages sent to the recipients in the remote domain. You can use of the following settings: • **MimeHtmlText** All messages are converted to MIME messages that use HTML formatting, unless the original message is a text message. If the original message is a text message, the outgoing message will be a MIME message that uses text formatting. This is the default setting. • **MimeText** All messages are converted to MIME messages that use text formatting. • **MimeHtml** All messages are converted to MIME messages that use HTML formatting.	No	Yes
Line wrap size You can specify the maximum number of characters that can exist on a single line of text in the body of the e-mail message. Older email client applications may prefer 78 characters per line. This option is only available by using the Shell.	No	Yes

Return to top

Message encoding options for mail users and mail contacts

When you configure message encoding options for a mail contact or a mail user, that option is applied to all messages sent to that specific recipient. For mail contacts and mail users in your organization, you have the following configuration options for message encoding:

- **UsePreferMessageFormat** This parameter specifies whether the message format settings configured for the mail contact override the global settings configured for the remote domain. If you disable this setting, Exchange ignores other message encoding options for this recipient and the message encoding is determined by the configuration of the remote domain or the settings configured by the message sender.
- **MessageFormat** This parameter specifies the message format. You can either specify Text or Mime as the message format. The value of this setting is dependent on the *MessageBodyFormat* parameter. If the message body format is Html or TextAndHtml, you must set this parameter to Mime.
- **MessageBodyFormat** This parameter specifies the message body format. You can specify Text, Html, or TextAndHtml. The value of this setting is dependent on the *MessageFormat* parameter. If the message format is Text, you must also set this parameter to Text.
- **MacAttachmentFormat** This parameter specifies the Apple Macintosh operating system attachment format for messages. You can specify BinHex, UuEncode, AppleSingle, or AppleDouble. The value of this setting is dependent on the *MessageFormat* parameter. If the message format is set to Text, you must set this parameter to either BinHex or UuEncode. If the message format is set to Mime, you must set this parameter to BinHex, AppleSingle or AppleDouble.

You need to use these parameters in the Exchange Management Shell to set the message encoding options for mail users and mail contacts. For more information, see the following topics:

- Enable-MailContact
- New-MailContact
- Set-MailContact
- Enable-MailUser
- New-MailUser
- Set-MailUser

Return to top

Message encoding options available in Outlook

As a sender, you can specify message encoding options in Outlook at any of the following stages:

- By configuring the default message format to be either plain text or HTML.
- By setting the message format as you're composing it to either plain text or HTML using the **Format** area in the **Options** tab.
- By configuring the message encoding options for messages that are sent to all recipients outside

the Exchange organization. These options are called *Internet message format* options. The options only apply to remote recipients, and not to recipients in the Exchange organization.

- By configuring the message encoding options for messages that are sent to specific recipients outside the Exchange organization. These options are called *Internet recipient message format* options. The options only apply to remote recipients in your Contacts folder, and not to recipients in the Exchange organization.

By default, Outlook uses automatic character set message encoding by scanning the whole text of the outgoing message to determine the appropriate encoding to use for the message. This setting applies to messages that you send to Internet recipients and recipients in the Exchange organization. However, you can bypass this and specify a preferred encoding for outgoing messages.

Return to top

Message encoding options available in Outlook Web App

As a sender, you can specify message encoding options in Outlook Web App at any of the following stages:

- By configuring the default message format to be either plain text or HTMLin the **Message format** section of the **Settings** >**Options** > **Settings** page.
- By setting the message format as you're composing it to either plain text or HTML by using the **More options** (...) menu, and selecting **Switch to plain text** or **Switch to HTML**.

Return to top

Order of precedence for message encoding options

Exchange uses the order of precedence as described in the following list to determine the message encoding options for outgoing messages sent to recipients outside the Exchange organization:

1. Remote domain settings
2. Outlook or Outlook Web App settings
3. Mail user or mail contact settings

The list specifies the order of precedence from lowest to highest. A setting made at a higher level may override a setting made at a lower level.

The following table describes the order of precedence from lowest priority to highest priority for message character set encoding options.

Order of precedence from lowest priority to highest priority for message character set encoding options

Source	Parameter	Values
Remote domain entry setting,	*CharacterSet*	Specified

using the EAC or **Set-RemoteDomain**		
Remote domain entry setting, using the EAC or **Set-RemoteDomain**	*NonMimeCharacterSet*	Specified
Outlook setting	Message character set encoding	• Auto-select • Specified

When you set the non-MIME character set for a remote domain, the character set is assigned to the following types of messages:

- Outgoing messages to a configured remote domain that don't contain a specified character set.
- Incoming messages from a configured remote domain that don't contain a specified character set.

The value of the Windows ANSI code page for the transport server is used to assign a character set to the following types of messages:

- Internal messages that don't contain a specified character set.
- Internal messages that contain a specified character set, but don't contain a specified server code page.

If a message contains a specified but invalid character set, the transport server tries to replace the invalid character set with a valid character set.

The following table describes the order of precedence from lowest priority to highest priority for plain text message encoding options.

Order of precedence from lowest priority to highest priority for plain text message encoding options

Source	Parameter	Values
Set-RemoteDomain	*LineWrapSize*	• From 0 through 132 • unlimited
Outlook settings	Message format	Plain text
Outlook settings	Internet message format	Plain text options: • Encode attachments in UuEncode format when you send a plain text message • Automatically wrap text at *nn* characters

Outlook settings	Internet recipient message format	Plain text format: • Encode attachments in UuEncode attachment format • Use BinHex Mac attachment format
Set-MailUser **Set-MailContact**	*UsePreferMessageFormat*	• `$true` • `$false` If the value is `$false` or if the recipient isn't defined as a mail user or mail contact in the Exchange organization, the mail user or mail contact settings are ignored.
Set-MailUser **Set-MailContact**	*MessageFormat*	Text
Set-MailUser **Set-MailContact**	*MessageBodyFormat*	Text
Set-MailUser **Set-MailContact**	*MacAttachmentFormat*	• BinHex • UuEncode

The following table describes the order of precedence from lowest priority to highest priority for MIME message encoding options.

Order of precedence from lowest priority to highest priority for MIME message encoding options

Source	Parameter	Values
Set-RemoteDomain	*ContentType*	• `MimeHtmlText` • `MimeText` • `MimeHtml`
Outlook or Outlook Web App settings	Message format	• Plain text • HTML
Outlook settings	Internet recipient message format	MIME message format • Plain text • Include both plain text and

		HTML • HTML

Set-MailUser
Set-MailContact
	UsePreferMessageFormat	`$true`
		`$false`
		If the value is `$false` or if the recipient isn't defined as a mail user or mail contact in the Exchange organization, the mail user or mail contact settings are ignored.

Set-MailUser **Set-MailContact**	*MessageFormat*	• Text • Mime
Set-MailUser **Set-MailContact**	*MessageBodyFormat*	• `Text` • `Html` • `TextAndHtml`
Set-MailUser **Set-MailContact**	*MacAttachmentFormat*	• BinHex • AppleSingle • AppleDouble

Change the message format in Outlook

TNEF conversion options

Applies to: *Exchange Server 2013, Exchange Online*

Topic Last Modified: *2014-07-28*

You can specify whether Transport Neutral Encapsulation Format (TNEF) should be preserved or removed from messages that leave the Exchange organization. TNEF, also known as Outlook Rich Text Format or Exchange Rich Text Format, is a Microsoft-specific format for encapsulating MAPI message properties. All versions of Microsoft Outlook fully understand TNEF. Outlook Web App translates TNEF into MAPI and displays the formatted messages. However, other email clients that don't understand TNEF typically display TNEF formatted messages as plain text messages with Winmail.dat or Win.dat attachments.

Contents

TNEF conversion options for remote domains

When you configure TNEF conversion options for a remote domain, those TNEF conversion options are applied to all messages sent to that domain.

- For Exchange Online Dedicated, you use the Exchange admin center (EAC) to set TNEF conversion options for a remote domain at **Mail flow** > **Remote domains** > **Edit** (✎) > **Use Exchange rich-text format**.
- For Exchange Online and Exchange 2013, you use the *TnefEnabled* parameter on the **Set-RemoteDomain** cmdlet to set TNEF conversion options for a remote domain.

For remote domains in your organization, you have the following configuration options for TNEF conversion:

Setting	In the EAC	In the Shell
Use TNEF for all messages sent to the remote domain.	**Always**	`$true`
Never use TNEF for any messages sent to the remote domain.	**Never**	`$false`
TNEF messages aren't specifically allowed or	**Follow user settings**	`$null` (blank)

prevented for recipients in the remote domain. Whether TNEF messages are sent to recipients in the remote domain depends on the specific setting on the mail contact or mail user, or the setting specified by the sender in Outlook. This is the default value.		

For more information about remote domains, see Remote domains or **Remote domains in Exchange Online**.

Return to top

TNEF conversion options for mail users and mail contacts

When you configure TNEF conversion options for a mail contact or a mail user, those TNEF conversion options are applied to all messages sent to that specific recipient. You use the *UseMapiRichTextFormat* parameter on the **Set-MailUser** and **Set-MailContact** cmdlets to configure the TNEF conversion options for mail users and mail contacts.

For mail users and mail contacts in your organization, you have the following configuration options for TNEF conversion:

- **Always** TNEF is used for all messages sent to the recipient. The corresponding value for the *UseMapiRichTextFormat* parameter is `Always`.
- **Never** TNEF is never used for any messages sent to the recipient. The corresponding value for the *UseMapiRichTextFormat* parameter is `Never`.
- **Use default settings** TNEF messages aren't specifically allowed or prevented for the mail user or mail contact. Whether TNEF messages are sent to the recipient depends on the specific setting for the corresponding remote domain or the setting specified by the sender in Outlook. The corresponding value for the *UseMapiRichTextFormat* parameter is `UseDefaultSettings`. This is the default setting.

Return to top

TNEF conversion options in Outlook

Senders can control the default TNEF message conversion options for TNEF messages sent to all recipients outside the Exchange organization. These options are called *Internet message format* options. The options only apply to remote recipients, and not to recipients in the Exchange

organization.

Note:

The following options define how messages containing Outlook rich text are handled when sent to external recipients. If the message format you're using is HTML or plain text, these settings don't apply.

You have the following TNEF conversion options in Outlook:

- **Convert to HTML format** This is the default option. Any TNEF messages sent to remote recipients are converted to HTML. Any formatting in the message should closely resemble the original message. MIME-encoded HTML messages are supported by many, but not all, email clients.
- **Convert to Plain Text format** Any TNEF messages sent to remote recipients are converted to plain text. Any formatting in the message is lost.
- **Send using Outlook Rich Text Format** Any TNEF messages sent to remote recipients remain TNEF messages.

You can configure these options in the following locations in Outlook:

- **Outlook 2010 or Outlook 2013** **File** > **Options** > **Mail** > **Message format**.
- **Outlook 2007** **Tools** > **Options** > **Mail Format** > **Internet Format**.

Senders can also control the default TNEF message conversion options for TNEF messages sent to specific recipients outside the Exchange organization. These options are called *Internet recipient message format* options. The options only apply to remote recipients stored in your Contacts folder, and not to recipients in the Exchange organization. You have the following TNEF conversion options for remote recipients in your Contacts folder:

- **Let Outlook decide the best sending format** This is the default setting. This setting forces Outlook to use the TNEF conversion option that's specified by the default Internet format. The possible values are **Convert to HTML format**, **Convert to Plain Text format**, or **Send using Outlook Rich Text Format**. Therefore, the TNEF message may be left as TNEF, converted to HTML, or converted to plain text. If you want to make sure that the TNEF message remains TNEF for this recipient, you should change this setting from **Let Outlook decide the best sending format** to **Send using Outlook Rich Text format**.
- **Send Plain Text only** Any TNEF messages sent to the recipient are converted to plain text. Any formatting in the message is lost.
- **Send using Outlook Rich Text format** Any TNEF messages sent to remote recipients remain TNEF messages.

You can configure these options for a contact in the following locations in Outlook:

- **Outlook 2010 or Outlook 2013** Open the contact card, double-click the email address, click the **View more options for interacting with this person** icon, and select **Outlook properties**. In the **E-mail Properties** dialog box, select **Internet format**.
- **Outlook 2007** Open the contact card, double-click the **E-mail** field and select **Internet format**.

Return to top

Order of precedence for TNEF conversion options

Exchange uses the order of precedence as described in the following list to determine the TNEF conversion options for outgoing messages sent to recipients outside the Exchange organization:

1. Remote domain settings
2. Mail user or mail contact settings
3. Outlook settings

The list specifies the order of precedence from highest to lowest. The TNEF setting on the remote domain overrides the TNEF settings on the mail user, mail contact or in Outlook. For example, suppose you send a Rich Text message in Outlook, but the recipient is in a domain where the remote domain setting specifically doesn't allow TNEF-formatted messages. The message received by the recipient will be plain text or HTML, but not TNEF.

Also, Exchange never sends Summary Transport Neutral Encoding Format (STNEF) messages to external recipients. Only TNEF messages can be sent to recipients outside the Exchange organization.

Content conversion tracing

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-25*

Content conversion tracing captures failures in the MAPI content conversion that's performed by the Mailbox Transport service on inbound and outbound messages on a Microsoft Exchange Server 2013 Mailbox server.

The Mailbox Transport service on a Mailbox server is responsible for the content conversion of messages sent to and from mailbox recipients. Specifically, the Mailbox Transport Submission service converts outbound messages from mailbox users from MAPI to MIME. The Mailbox Transport Delivery service converts inbound messages for mailbox users from MIME to MAPI. Content conversion tracing is responsible for capturing these MAPI conversion failures.

The categorizer in the Transport service on a Mailbox server is responsible for the content conversion of all messages sent to external recipients. Content conversion tracing doesn't capture any content conversion failures that the categorizer in the Transport service encounters as it converts messages sent to external recipients.

Contents

Configure content conversion tracing

Content conversion tracing is controlled by the following parameters in the **Set-TransportService** and **Set-MailboxTransportService** cmdlets in the Exchange Management Shell:

- *ContentConversionTracingEnabled* This parameter enables or disables content conversion tracing in the Transport service on the Mailbox server, or in the Mailbox Transport service on the Mailbox server. Valid values for this parameter are `$true` and `$false`. The default value is `$false`. If your Exchange organization contains multiple Mailbox servers, you must enable content conversion tracing on each Mailbox server.
- *PipelineTracingPath* Although this parameter is associated with pipeline tracing, it also specifies the root location of the content conversion tracing files. The default location in the Transport service is `%ExchangeInstallPath%TransportRoles\Logs\Hub\PipelineTracing`. The default location in the Mailbox Transport service is `%ExchangeInstallPath%TransportRoles\Logs\Mailbox\PipelineTracing`.The path must be local to the Exchange computer.

Content conversion creates a folder named `ContentConversionTracing` in the path specified by the *PipelineTracingPath* parameter. In the `ContentConversionTracing` folder, content conversion creates two subfolders: `InboundFailures` and `OutboundFailures`. The `InboundFailures` folder contains the information from inbound message content conversion failures. The `OutboundFailures` folder contains the information from outbound message content conversion failures.

The maximum size for all the files in the `InboundFailures` folder or the `OutboundFailures` folder is 128 megabytes (MB). Content conversion tracing doesn't use circular logging to remove old files based on the age or size of the files. As soon as the maximum size for a folder is reached, content conversion tracing stops writing information to the folder. If you want to make sure that the maximum folder size limits aren't exceeded, you can create a scheduled task that periodically moves the content conversion tracing files to a different location.

The permissions required on the folders and subfolders used in content conversion tracing are as follows:

- Administrators: Full Control
- Network Service: Full Control
- System: Full Control

Caution:
Content conversion tracing copies the complete contents of email messages. To avoid the unwanted disclosure of confidential information, you need to set appropriate security permissions on the location of the content conversion tracing files.

Return to top

How content conversion tracing works

When the content conversion of an inbound message fails, a delivery status notification (DSN) that has the status code 5.6.0 is sent to the message sender. If content conversion tracing is enabled, the failure information is recorded at the time that the 5.6.0 DSN message is generated. Each content conversion error generates two separate files.

A content conversion error that occurs when an inbound message is converted from MIME to MAPI generates the following two files in the InboundFailures folder:

- **<GUID>.eml** This file contains the failed message in text format.
- **<GUID>.txt** This file contains the exception description, conversion results, conversion options, and message size limits imposed on all messages by the Mailbox Transport service.

A content conversion error that occurs when an outbound message is converted from MAPI to MIME generates the following two files in the OutboundFailures folder:

- **<GUID>.msg** This file contains the failed message in the Microsoft Outlook message format.
- **<GUID>.txt** This file contains the exception description, conversion results, conversion options, and message size limits imposed on all messages by the store driver.

The placeholder *<GUID>* is the same in both file names. Each content conversion error generates a different GUID that's used in the file names of the corresponding message and text files. An example of a GUID that's used in the file names is `038b930e-61fd-4bfd-b9b4-0374c18b73f7`.

Return to top

Considerations for content conversion tracing

You can leave content conversion tracing enabled for proactive monitoring. Or, you can enable content conversion tracing to troubleshoot a specific failure event. You can usually reproduce inbound content conversion failures by asking the recipient of the 5.6.0 DSN message to resend the original message.

Inbound content conversion failures are the most common. Some of the reasons for inbound content conversion errors include the following:

- **Violations of message size limits** These message size limits are imposed by the Mailbox Transport service to help prevent denial of service attacks (DoS). These message limits are listed in the *<GUID>*.txt file. These message limits include the following:
  - **MaxMimeTextHeaderLength** This limit specifies the maximum number of text characters that can be used in a MIME header. The value is 2000.
  - **MaxMimeSubjectLength** This limit specifies the maximum number of text characters that can be used in the subject line. The value is 255.
  - **MSize** This limit specifies the maximum message size. The value is 2147483647 bytes.
  - **MaxMimeRecipients** This limit specifies the total number of recipients allowed in the To, Cc, and Bcc fields. The value is 12288.

- **MaxRecipientPropertyLength** This limit specifies the maximum number of text characters that can be used in a recipient description. The value is 1000.
- **MaxBodyPartsTotal** This limit specifies the maximum number of message parts that can be used in a MIME multipart message. The value is 250.
- **MaxEmbeddedMessageDepth** This limit specifies the maximum number of forwarded messages that can exist in a message. The value is 30.

For more information about configurable message size limits used in the Transport service on Mailbox servers or on Edge Transport servers, see Message size limits.

- **Failure to convert an inbound iCalendar message to a meeting request** RFC 2445 defines iCalendar as a standard for calendar data exchange. Specific causes of the conversion failure include the following:
  - Incorrect use of iCalendar by the sending agent.
  - Constructs of iCalendar that can't be supported by the Outlook or Exchange calendar schema.

Conversion failures of iCalendar don't result in the sender receiving a 5.6.0 DSN message. Instead, the message is delivered with an attached .ics file that contains the iCalendar message body.

- **Failures caused by badly formatted MIME messages** Unsolicited commercial email or spam messages may have formatting errors in the message header, such as unmatched quotation marks in recipient descriptions. A much smaller number of failures caused by badly formatted MIME messages are considered bugs.

Outbound content conversion failures are much less common than inbound failures. When outbound failures occur, they are usually caused by Exchange code bugs or corrupted message content.

DSNs and NDRs

Exchange Server 2013 > Mail flow >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-15*

This topic describes how to read and interpret non-delivery report (NDR) delivery status notification (DSN) messages in Microsoft Exchange Server 2013.

Contents

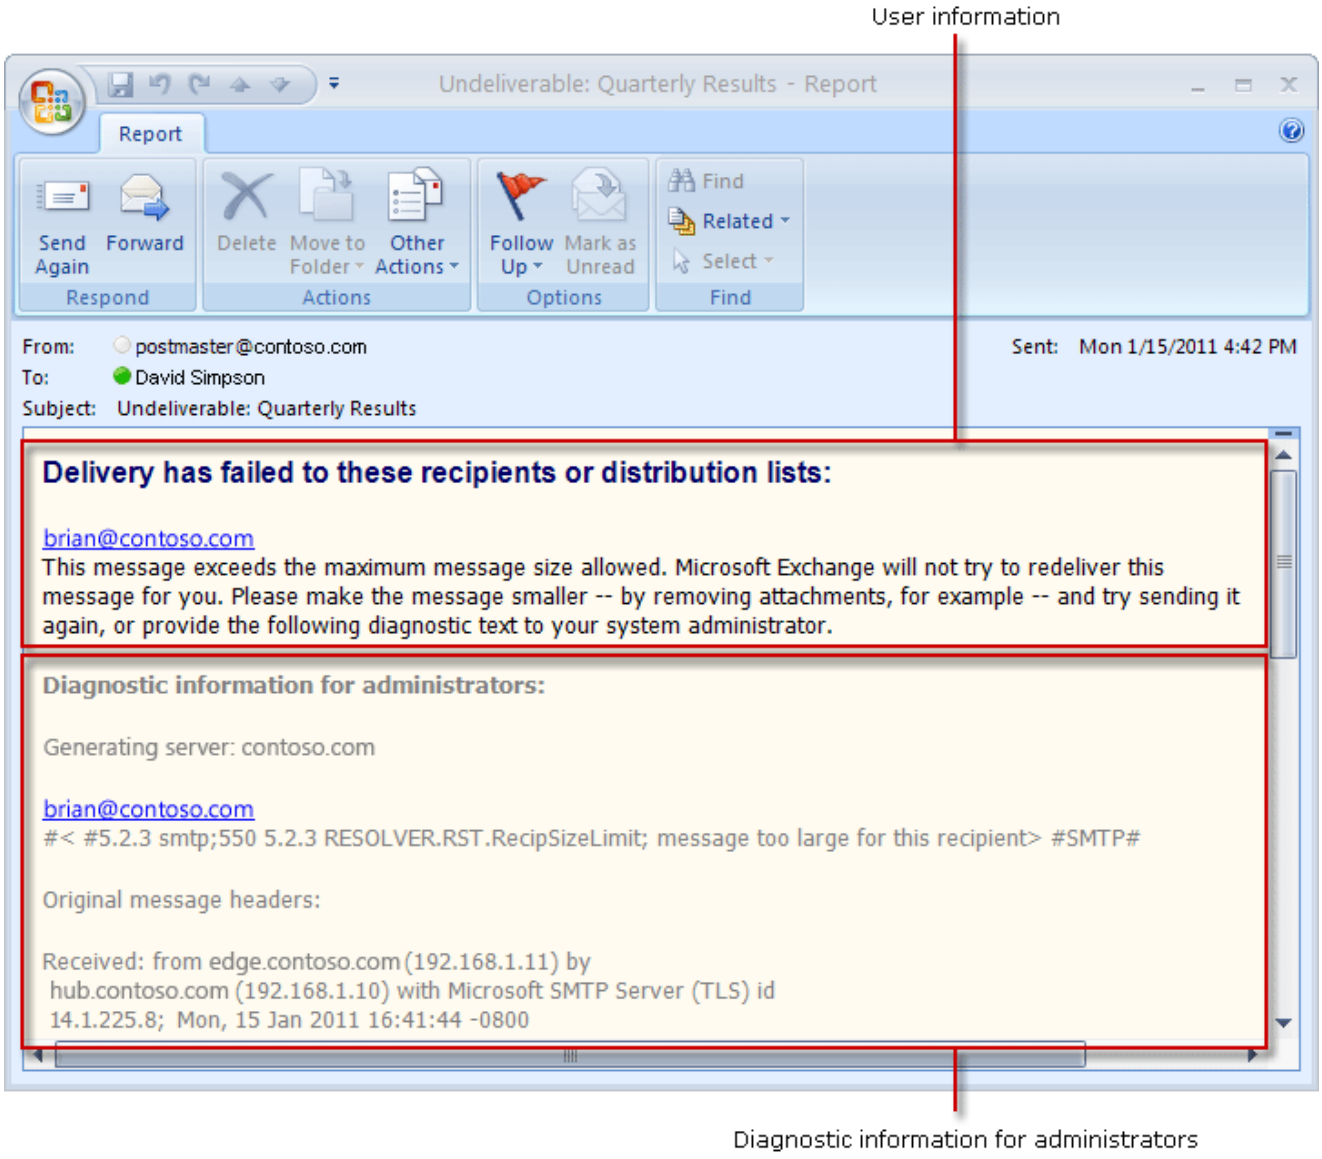
NDR sections

In Exchange 2013, NDRs are designed to be easy to read and understand by both end-users and administrators. Information that is displayed in an NDR is separated into the following two areas:

- A user information section
- A **Diagnostic information for administrators** section

The information in each section is targeted to the readers of that section. The user information section appears first and contains feedback to help the user understand in nontechnical terms why the delivery of the message failed. The **Diagnostic information for administrators** section provides deeper technical information such as the original message headers, to help email administrators troubleshoot a delivery issue that may exist. The following figure shows the user information section and **Diagnostic information for administrators** section of an NDR.

NDR Sections



User information section

The user information section of an NDR generated by Exchange contains information that you want to communicate to an end-user who has sent a message that is later returned with an NDR. The text that is displayed in this section is inserted by the Exchange server that generated the NDR.

The text in the user information section is designed to help end-users determine why the message was rejected and how to resend the message successfully if the message should be resent. When applicable, the fully qualified domain name (FQDN) of the server that rejected the message is included in the user information section. If delivery fails to more than one recipient, the email address of each recipient is listed and the reason for the failure is included in the space below the recipient's email address.

You can modify the text in the user information section by using the **New-SystemMessage** cmdlet. By creating a custom message, you can provide specific information to end-users, such as a telephone number to use to contact the helpdesk department or a hyperlink to use to obtain self-service support.

Return to top

Diagnostic information for administrators

The **Diagnostic information for administrators** section contains more detailed information about the specific error that occurred during delivery of the message, the server that generated the NDR, and the server that rejected the message. The following fields are present in most NDRs and are visible in the "NDR sections" figure earlier in this topic:

- **Generating server** The generating server is the SMTP server that created the NDR. The generating server takes the enhanced status code that is explained later in this topic. This code creates an easy-to-read NDR. If no remote server is listed below the email address of the sender in the **Diagnostic information for administrators** section, the generating server is also the server that rejected the original email message. If message delivery fails when the message is sent to another recipient in the Exchange organization, the same server typically rejects the original message and generates the NDR.
- **Rejected recipient** The rejected recipient is the email address of the recipient to which delivery of the original message failed. If delivery to more than one recipient has failed, the email address for each recipient is listed. The rejected recipient field also contains the following sub-fields for each email address listed:
  - **Remote server** The remote server field contains the FQDN of the server that rejects delivery of the message during the SMTP conversation. The remote server field is only populated when delivery has been attempted to a remote server, and that delivery attempt has been rejected before the receiving server successfully acknowledges the message after the message body is sent. If the original message is successfully acknowledged by the receiving server and is then rejected because of content restrictions, for example, the remote server field is not populated.
  - **Enhanced status code** The enhanced status code is the code returned by the server that rejected the original message. The enhanced status code indicates why the original message was rejected. The enhanced status code is not rewritten by Exchange but is used to determine

what text to display in the user information section. The enhanced status codes you're most likely to encounter are listed in "Common Enhanced Status Codes" later in this topic. For a detailed list of enhanced status codes, see RFC 3463.

  - **SMTP response** The SMTP response is the machine readable text returned by the server that rejected the original message. The SMTP response typically contains a short string that provides an explanation of the enhanced status code that is also returned. The SMTP response is not rewritten by Exchange. Additionally, this response is always presented in US-ASCII format.

- **Original message headers** The original message headers section contains the message headers of the rejected message. These headers can provide useful diagnostic information, such as information that can help you determine the path that the message took before it was rejected or whether the **To** field matches the email address that is specified in the rejected recipient field.

Return to top

Examples of NDR messages

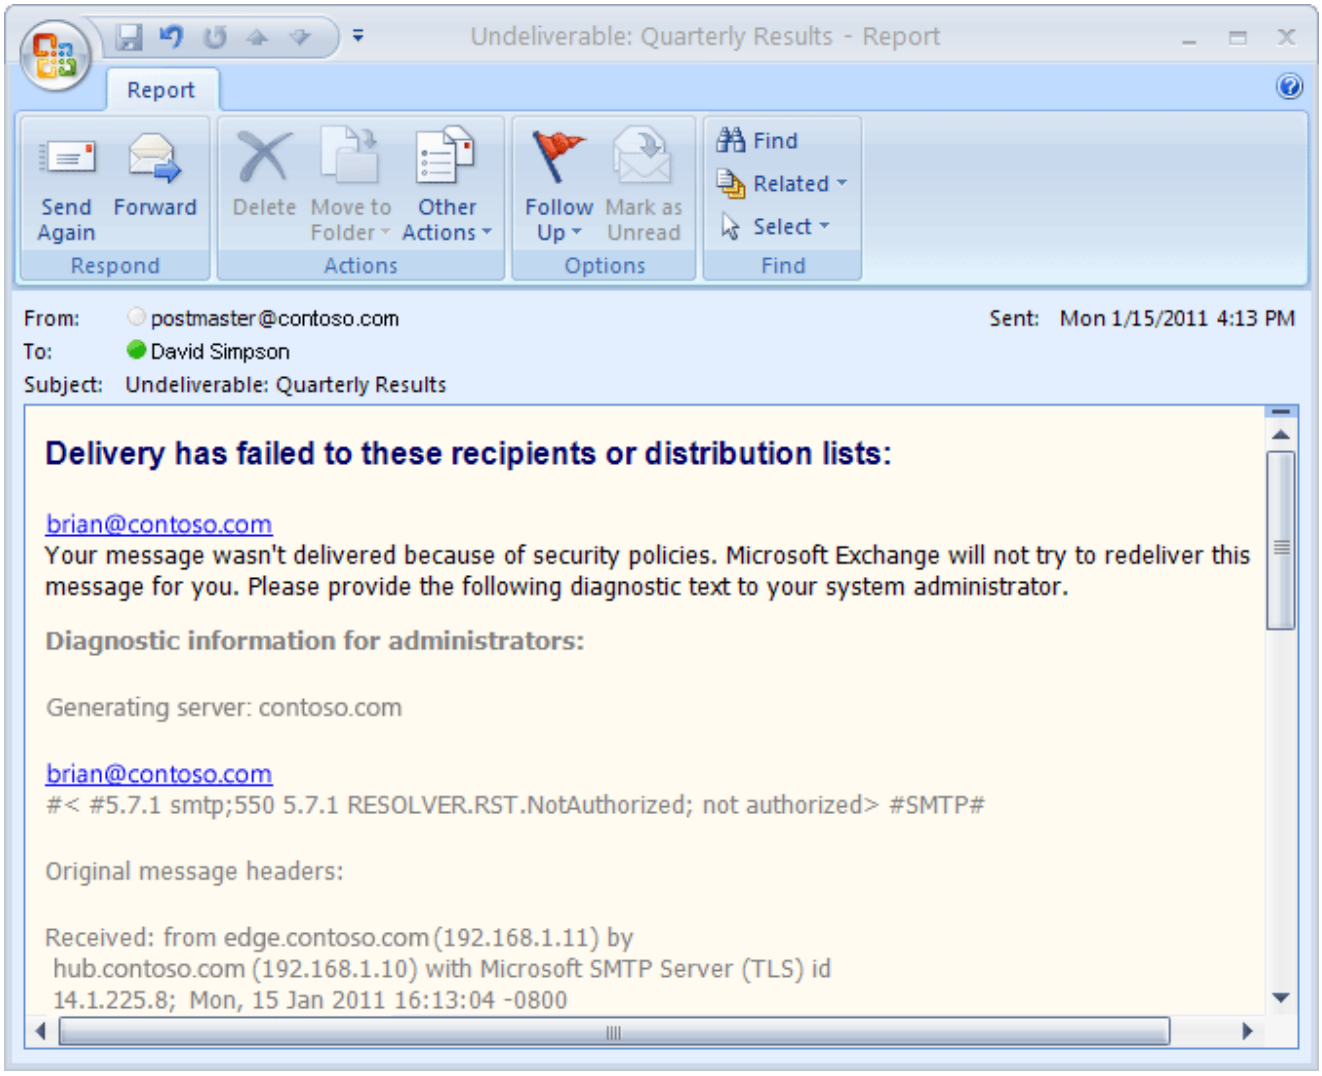
The following sections provide examples of two ways that NDR messages can be generated:

- By the same server
- By different servers

NDR generated and original message rejected by the same server

The following example shows what happens when a remote email organization accepts delivery of an email message through an Edge Transport server, and then rejects that message because of a policy restriction on the recipient's mailbox. In this case, the sender is not allowed to send messages to the recipient. Edge Transport servers do not perform message size validation so the Edge Transport server in this example accepts the message because it has a valid recipient address and the message does not violate another content restrictions. Because the remote email organization accepts the whole message, including the message contents, the remote email organization is responsible for rejecting the message and for generating the NDR message to be sent to the sender.

NDR generated and message rejected by the same server



Also, messages that are rejected when they are sent to recipients that are part of the same Exchange organization are typically rejected by the same email server that generates the NDR message. Messages sent to local recipients can be rejected for various reasons, such as mailboxes that have exceeded their quota, lack of authorization to send messages to the recipient address, or hardware failures that result in an extended loss of connectivity to other servers in the organization.

In both situations, no remote server is included under the email address of the recipients listed in the NDR message.

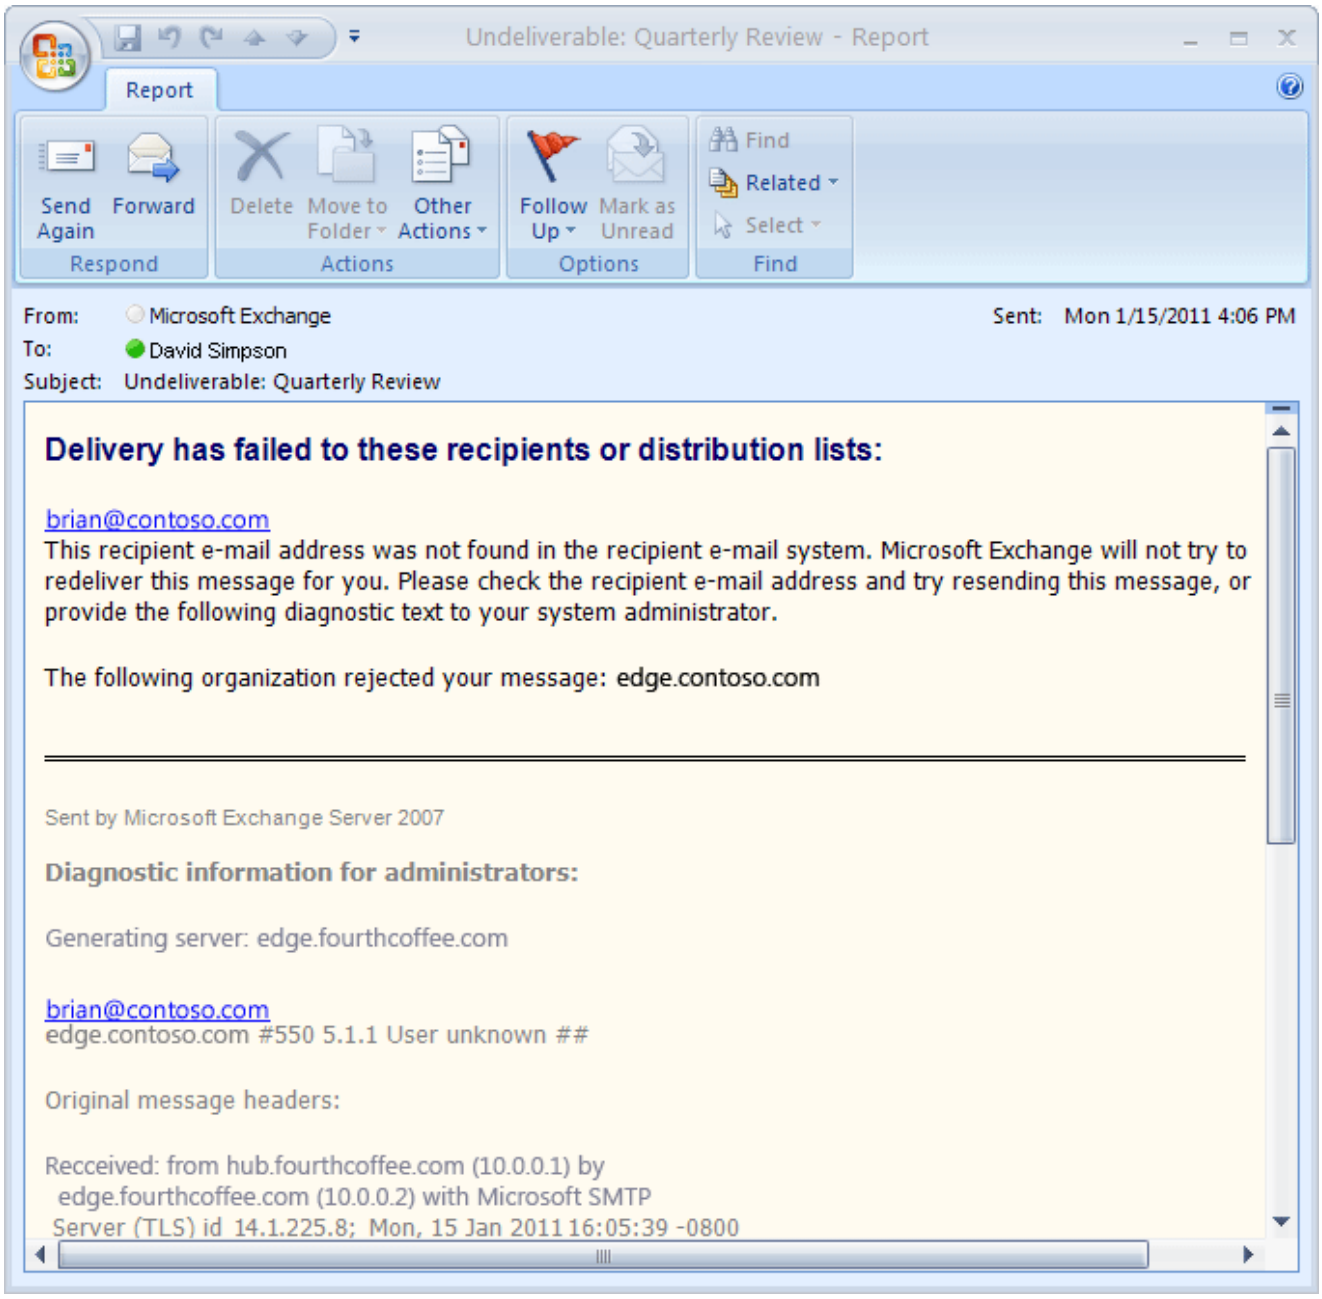
Return to top

NDR generated and original message rejected by different servers

The following example shows what happens when a remote email organization rejects delivery of an email message before it ever accepts the message. In this example, the remote server rejects the message and returns an enhanced status code to the local sending server because the specified recipient does not exist. The rejection happens before the receiving server ever acknowledges the message. Because the receiving server doesn't successfully acknowledge the message, the receiving server is not responsible for the message. Therefore, the local sending server generates the NDR

message and sends it to the sender of the original message.

NDR generated and message rejected by different servers



Return to top

Common enhanced status codes

The following table contains a list of the enhanced status codes that are returned in NDRs for the most common message delivery failures.

Enhanced status code	Description	Possible cause	Additional information
4.3.1	`Insufficient system resources`	An out-of-memory error occurred. A resource problem, such as a full	Ensure that your Exchange server has

		disk, can cause this problem. Instead of getting a disk full error, you might be getting an out-of-memory error.	enough disk storage.
4.3.2	`System not accepting network messages`	This NDR is generated when a queue has been frozen.	You can resolve this condition by unfreezing the queue.
4.4.1	`Connection timed out`	The destination server is not responding. Transient network conditions can cause this error. The Exchange server tries automatically to connect to the server again and deliver the mail. If delivery fails after multiple attempts, an NDR with a permanent failure code is generated.	Monitor the situation. This may be a transient problem that may correct itself.
4.4.2	`Connection dropped`	A connection dropped between the servers. Transient network conditions or a server that is experiencing problems can cause this error. The sending server will retry delivery of the message for a specific time period, and then	Monitor the situation as the server retries delivery. This may be a transient problem that may correct itself. This situation can also occur when the message size limit for the connection is reached, or if the message

		generate further status reports.	submission rate for the client IP address has exceeded the configured limit.
4.4.7	`Message expired`	The message in the queue has expired. The sending server tried to relay or deliver the message, but the action was not completed before the message expiration time occurred. This message can also indicate that a message header limit has been reached on a remote server, or some other protocol time-out occurred while communicating with the remote server.	This message usually indicates an issue on the receiving server. Check the validity of the recipient address, and determine if the receiving server is configured correctly to receive messages. You may have to reduce the number of recipients in the message header for the host about which you are receiving this error. If you send the message again, it is placed in the queue again. If the receiving server is available, the message is delivered.
5.0.0	`HELO / EHLO requires domain address`	This situation is a permanent failure. Possible causes include: • There is no route for the given address space; for example, an SMTP connector is configured, but this	Some potential resolutions include: • On one or more SMTP connectors, add an asterisk (*****) value as the SMTP address space. • Verify that DNS is working.

		address does not match. • DNS returned an authoritative host that was not found for the domain. • An SMTP error occurred.	
5.1.0	`Sender denied`	This NDR is caused by a general failure (bad address failure). An email address or another attribute could not be found in Active Directory. Contact entries without the **targetAddress** attribute set can cause this problem. Another possible cause could be that the **homeMDB** attribute of a user could not be determined. The **homeMDB** attribute corresponds to the Exchange server on which the user's mailbox resides. Another common cause of this NDR is if you used Microsoft Outlook to save your email message as a file, and then someone opened the	Either the recipient address is incorrectly formatted, or the recipient could not be correctly resolved. The first step in resolving this error is to check the recipient address and send the message again.

		message offline and replied to the message. The message property only preserves the **legacyExchangeDN** attribute when Outlook delivers the message, and therefore the lookup could fail.	
5.1.1	`Bad destination mailbox address`	This failure may be caused by the following conditions: • The recipient email address was entered incorrectly by the sender. • No recipient exists in the destination email system. • The recipient mailbox has been moved and the Outlook recipient cache on the sender's computer has not updated. • An invalid legacy domain name (DN) exists for the recipient mailbox Active Directory.	This error typically occurs when the sender of the message incorrectly enters the email address of the recipient. The sender should check the recipient's email address and send again. This error can also occur if the recipient email address was correct in the past but has changed or has been removed from the destination email system. If the sender of the message is in the same Exchange organization as the recipient, and the recipient mailbox still exists, determine whether the recipient mailbox has been relocated to a new email server. If this is the

			case, Outlook may not have updated the recipient cache correctly. Instruct the sender to remove the recipient address from sender's Outlook recipient cache and then create a new message. Resending the original message will result in the same failure. Other issues may cause this error, such as an invalid legacy distinguished name (DN) in Active Directory. Examine and correct the legacy DN of the recipient's mailbox. Then instruct the sender to remove the recipient address from sender's Outlook recipient cache and then create a new message. Resending the original message will result in the same failure.
5.1.2	`Invalid X.400 address`	The recipient has a non-SMTP address that can't be matched to a destination. The address does not appear to be	Verify that the recipient's address was entered correctly. If the recipient's address is in a non-SMTP email system that you

		local, and there are no connectors configured with address spaces that contain the recipient's address.	specifically want to provide mail delivery to, you will need to add the appropriate type of connector to your topology and configure it to provide service to the recipient's email system.
5.1.3	`Invalid recipient address`	This message indicates that the recipient address appears incorrectly on the message.	Either the recipient address is formatted incorrectly, or the recipient could not be correctly resolved. The first step in resolving this error is to check the recipient address and send the message again. Also, examine the SMTP recipient policy and ensure that each mail domain for which you want to accept mail appears correctly.
5.1.4	`Destination mailbox address ambiguous`	Two or more recipients in the Exchange organization have the same address.	This error typically occurs because of a misconfiguration in Active Directory. Possibly because of replication problems, two recipient objects in Active Directory have the same SMTP address or

			Exchange Server (EX) address.
5.1.7	`Invalid address`	The sender has a malformed or missing SMTP address, the **mail** attribute in the directory service. The mail item cannot be delivered without a valid **mail** attribute.	Check the sender directory structure, and determine if the **mail** attribute exists.
5.2.1	`Mailbox cannot be accessed`	The mailbox cannot be accessed. The mailbox may be offline, disabled, or the message has been quarantined by a rule.	Check to see if the recipient database is online, the recipient mailbox is disabled, or the message has been quarantined.
5.2.2	`Mailbox full`	The recipient's mailbox has exceeded its storage quota and is no longer able to accept new messages.	This error occurs when the recipient's mailbox has exceeded its storage quota. The recipient must reduce the size of the mailbox or the administrator must increase the storage quota before delivery can be successful.
5.2.3	`Message too large`	The message is too large, and the local quota is exceeded. For example, a remote Exchange user might have a restriction	Send the message again without attachments, or set the server or the client-side limit to allow a larger message size limit.

		on the maximum size of an incoming message.	
5.2.4	`Mailing list expansion problem`	The recipient is a misconfigured dynamic distribution list. Either the filter string or the base DN of the dynamic distribution list is invalid.	Set the categorizer event logging level to at least the minimum level, and send another message to the dynamic distribution list. Check the application event log for a 6025 event or a 6026 event detailing which attribute is misconfigured on the dynamic distribution list object.
5.3.3	`Unrecognized command`	When the Exchange remote server reaches capacity of its disk storage to hold mail, it could respond with this NDR. This error usually occurs when the sending server is sending mail with an ESMTP BDAT command. This error also indicates a possible SMTP protocol error.	Ensure that the remote server has enough storage capacity to hold mail. Check the SMTP log.
5.3.4	`Message too big for system`	The message exceeds a size limit configured on a transport or mailbox database and can't be accepted. This failure can	This error occurs when the size of the message that was sent by the sender exceeds the maximum allowed

		be generated by either the sending email system or the recipient email system.	message size when passing through a transport component or mailbox database. The sender must reduce the size of the message for the message to be successfully delivered. For more information about how to configure message size limits, see Message size limits.
5.3.5	`System incorrectly configured`	A mail-looping situation was detected, which means that the server is configured to loop mail back to itself.	Check the configuration of the server's connectors for loops, and ensure that each connector is defined by a unique incoming port. If there are multiple virtual servers, ensure that none are set to "All Unassigned."
5.4.4	`Invalid arguments`	This NDR occurs if no route exists for message delivery, or if the categorizer could not determine the next-hop destination.	Check that the domain name specified is valid, and that a mail exchanger (MX) record exists.
5.4.6	`Routing loop detected`	A configuration error has caused an email loop. By default, after 20	This error occurs when the delivery of a message generates another

		iterations of an email loop, Exchange interrupts the loop and generates an NDR to the sender of the message.	message in response. That message then generates a third message, and the process is repeated, creating a loop. To help protect against exhausting system resources, Exchange interrupts the mail loop after 20 iterations. Mail loops are typically created because of a configuration error on the sending mail server, the receiving mail server, or both. Check the mailbox rules configuration of the recipient and sender to determine whether automatic message forwarding is enabled.
5.5.2	`Send hello first`	A generic SMTP error occurs when SMTP commands are sent out of sequence. For example, a server attempts to send an AUTH (authorization) command before identifying itself with an EHLO command.	View the SMTP Log or a Netmon trace, and ensure that there is adequate disk storage and virtual memory available.

		It is possible that this error can also occur when the system disk is full.	
5.5.3	`Too many recipients`	The combined total of recipients on the To, Cc, and Bcc lines of the message exceeds the total number of recipients allowed in a single message.	This error occurs when the sender has included too many recipients on the message. The sender must reduce the number of recipient addresses in the message or the maximum number of recipients must be increased to allow the message to be successfully delivered.
5.5.4	`Invalid domain name`	The message contains either an invalid sender or an incorrect recipient address format. One possible cause is that the recipient address format might contain characters that are not conforming to Internet standards.	Check the recipient address for nonstandard characters.
5.5.6	`Invalid message content`	This message indicates a possible protocol error.	Check Event Log for possible failures.
5.7.1	`Delivery not authorized`	The sender of the message is not allowed to send messages to the	This error occurs when the sender tries to send a message to a recipient

		recipient.	but the sender is not authorized to do this. This frequently occurs when a sender tries to send messages to a distribution group that has been configured to accept messages only from members of that distribution group or other authorized senders. The sender must request permission to send messages to the recipient. This error can also occur if an Exchange transport rule rejects a message because the message matched conditions that are configured on the transport rule.
5.7.1	`Unable to relay`	The sending email system is not allowed to send a message to an email system where that email system is not the final destination of the message.	This error occurs when the sending email system tries to send an anonymous message to a receiving email system, and the receiving email system does not accept messages for the domain or domains specified in one or more of the

			recipients. The following are the most common reasons for this error: • A third party tries to use a receiving email system to send spam, and the receiving email system rejects the attempt. By the nature of spam, the sender's email address may have been forged and the resulting NDR could have been sent to the unsuspecting sender's email address. It is difficult to avoid this situation. • An MX record for a domain points to a receiving email system where that domain is not accepted. The administrator responsible for the specific domain name must correct the MX record or configure the receiving email system to accept messages sent to that domain, or both. • A sending email system

			or client that should use the receiving email system to relay messages does not have the correct permissions to do this.
5.7.1	`Client was not authenticated`	The sending email system did not authenticate with the receiving email system. The receiving email system requires authentication before message submission.	This error occurs when the receiving server must be authenticated before message submission, and the sending email system has not authenticated with the receiving email system. The sending email system administrator must configure the sending email system to authenticate with the receiving email system for delivery to be successful. This error can also occur if you try to accept anonymous messages from the Internet on a Mailbox server that has not been configured to do this.
5.7.3	`Not Authorized`	The sender prohibited reassignment to the alternate recipient.

Manage DSN messages

Exchange Server 2013 > Mail flow > DSNs and NDRs >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-02-20*

Microsoft Exchange Server 2013 uses delivery status notifications (DSN) to provide non-delivery reports (NDRs) and other status messages to message senders. You can use the built-in DSNs, or you can create custom DSN messages to meet the needs of your organization.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "DSNs" entry in the Mail flow permissions topic.
- You can't remove a built-in DSN message that's included with Exchange. To change a built-in DSN message, you need to create a custom DSN message for the DSN code that you want to customize. When you remove a custom DSN message, the DSN code associated with that message reverts to the built-in DSN message that's included with Exchange.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Use the Shell to view built-in and custom DSN messages

To view a summary list of all built-in DSN messages included with Exchange 2013, run the following command:

```
Get-SystemMessage -Original
```

To view a summary list of all custom DSN messages in your organization, run the following command:

```
Get-SystemMessage
```

To view detailed information for the custom DSN message for DSN code 5.1.2 that's sent to internal

senders in English, run the following command:

```
Get-SystemMessage En\Internal\5.1.2 | Format-List
```

Use the Shell to create a custom DSN message

Run the following command:

```
New-SystemMessage -Internal <$true | $false> -Language
<Locale> -DSNCode <x.y.z> -Text "<DSN text>"
```

This example creates a custom plain text DSN message for the DSN code 5.1.2 that's sent to internal senders in English.

```
New-SystemMessage -Internal $true -Language En -DSNCode
5.1.2 -Text "You tried to send a message to a disabled
mailbox that's no longer accepting messages. Please contact
the Help Desk at extension 123 for assistance."
```

This example creates a custom plain text DSN message for the DSN code 5.1.2 that's sent to external senders in English.

```
New-SystemMessage -Internal $false -Language En -DSNCode
5.1.2 -Text "You tried to send a message to a disabled
mailbox that's no longer accepting messages. Please contact
your System Administrator for more information."
```

This example creates a custom HTML DSN message for the DSN code 5.1.2 that's sent to internal senders in English.

```
New-SystemMessage -DSNCode 5.1.2 -Internal $true -Language
En -Text 'You tried to send a message to a <B>disabled</B>
mailbox. Please visit <A HREF="http://
it.contoso.com">Internal Support</A> or contact
&quot;InfoSec&quot; for more information.'
```

How do you know this worked?

To verify that you have successfully created a custom DNS message, do the following:
1. Run the following command:

```
Get-SystemMessge -DSNCode <x.y.z> | Format-List
Name,Internal,Text,Language
```

2. Verify the values you see are the values you configured.
3. Send a test message that will generate the custom DSN you configured.

Use the Shell to change the text of a custom DSN message

To change the text of a custom DSN message the following command:

```
Set-SystemMessage <Locale>\<Internal | External>\<DSNcode>
-Text "<DSN text>"
```

This example changes the text assigned to the custom DSN message for DSN code 5.1.2 that's sent to internal senders in English.

```
Set-SystemMessage En\Internal\5.1.2 -Text "The mailbox you
tried to send an e-mail message to is disabled and is no
longer accepting messages. Please contact the Help Desk at
extension 123 for assistance."
```

How do you know this worked?

To verify that you have successfully changed the text of a custom DNS message, do the following:
1. Run the following command: `Get-SystemMessage`.

```
Set-SystemMessage <Locale>\<Internal | External>\<DSNcode>
| Format-List -Text
```

2. Verify the value displayed is the value you configured.

Use the Shell to remove a custom DSN message

Run the following command:

```
Remove-SystemMessage <Local>\<Internal | External>
\<DSNcode>
```

This example removes the custom DSN message for the DSN code 5.1.2 that's sent to internal senders in English.

```
Remove-SystemMessage En\Internal\5.1.2
```

How do you know this worked?

To verify that you have successfully removed a custom DNS message, do the following:
1. Run the command: `Get-SystemMessage`.
2. Verify a DSN for the locale, internal or external recipients, and DSN code you deleted isn't listed.

Forward copies of DSN messages to the Exchange recipient mailbox

You can specify a list of DSN codes that you want to monitor by having the DSN messages copied to the mailbox of the Exchange recipient. However, by default, no mailbox is assigned to the Exchange recipient, so any messages sent to the Exchange recipient are discarded. To send copies of DSN messages to the Exchange recipient mailbox, you need to assign a mailbox to the Exchange recipient, and then specific the DSN codes you want to monitor. By default, the following DSN codes are monitored: `5.4.8`, `5.4.6`, `5.4.4`, `5.2.4`, `5.2.0`, and `5.1.4`.

Step 1: Use the Shell to assign a mailbox to the Exchange recipient

To assign a mailbox to the Exchange recipient, perform the following steps:

1. Due to the potentially high volume of email, consider creating a dedicated mailbox and Active Directory user account for the Exchange recipient. For more information, see Create user mailboxes. Otherwise, identify the existing mailbox you want to associate with the Exchange recipient.
2. Run the following command:

```
Set-OrganizationConfig -
MicrosoftExchangeRecipientReplyRecipient <MailboxIdentity>
```

For example, to assign the existing mailbox named "Contoso System Mailbox" to the Exchange recipient, run the following command:

```
Set-OrganizationConfig -
MicrosoftExchangeRecipientReplyRecipient "Contoso System
Mailbox"
```

Step 2: Specify the DSN codes you want to monitor

Use the EAC to specify the DSN codes

1. In the EAC, navigate to **Mail flow** > **Receive connectors** > **More options** ··· > **Organization transport settings** > **Delivery**.
2. In the **DNS codes** section, type the DSN codes you want to monitor using the format *<x.y.z>*, and click **Add** +. Select an existing entry and click **Edit** ✎ to modify it, or click **Remove** − to remove it. When you are finished, click **Save**.

Use the Shell to specify the DSN codes

To replace the existing values, run the following command:

```
Set-TransportConfig -GenerateCopyOfDSNFor
```

```
<x.y.z>,<x.y.z>...
```

This example configures the Exchange organization to forward all DSN messages that have the DSN codes 5.7.1, 5.7.2, and 5.7.3 to the Exchange recipient.

```
Set-TransportConfig -GenerateCopyOfDSNFor 5.7.1,5.7.2,5.7.3
```

To add or remove entries without modifying any existing values, run the following command:

```
Set-TransportConfig -GenerateCopyOfDSNFor
@{Add="<x.y.z>","<x.y.z>"...;
Remove="<x.y.z>","<x.y.z>"...}
```

This example adds the DSN code 5.7.5 and removes the DSN code 5.7.1 from the existing list of DSN messages that are forwarded to the Exchange recipient.

```
Set-TransportConfig -GenerateCopyOfDSNFor @{Add="5.7.5";
Remove="5.7.1"}
```

How do you know this worked?

To verify that you successfully configured copies of DNS messages to be sent to the mailbox of the Exchange recipient, monitor the mailbox that's associated with the Exchange recipient, and verify the DSN messages contain the DSN codes you specified.

DSN message identity

Exchange Server 2013 > Mail flow > DSNs and NDRs >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-25*

You can identify a customized delivery status notification (DSN) message based on its syntax. The identity is the customized DSN message's GUID or a string that consists of the following values:

- **Locale** This variable specifies the locale of the language that the DSN message is displayed in. For a list of locale codes that you can use with the **New-SystemMessage** command, see Supported languages for system messages.
- **Internal or External** This variable specifies whether the DSN message is sent only to senders who are part of the internal Microsoft Exchange Server 2013 organization or also to senders outside the Exchange organization. You can use the Internal option when you want to include a specific e-mail contact or resolution in DSN messages sent to internal senders, but don't want to expose that information to senders outside your organization.
- **DSN code** This variable specifies the DSN code of the customized DSN message.

The syntax of the DSN message identity is `<Locale>\<Internal or External>\<DSN code>`.

For each DSN code, you can create more than one customized DSN message, which can target internal senders or external senders, and different locales. For example, the following table shows some of the possible configurations for the DSN code 5.1.2 and the corresponding DSN message identities.

Example DSN configurations and identities

DSN configuration	DSN identity
Display DSN messages to internal senders with an English (en) locale	En\Internal\5.1.2
Display DSN messages to external senders with an English (en) locale	En\External\5.1.2
Display DSN messages to internal senders with a Japanese (ja) locale	Ja\Internal\5.1.2
Display DSN messages to external senders with a Japanese (ja) locale	Ja\External\5.1.2

DSN message text

Exchange Server 2013 > Mail flow > DSNs and NDRs >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-09-25*

You can include text in a customized delivery status notification (DSN) message in Microsoft Exchange Server 2013, and you can format that text in HTML.

You can include any information that you want to display to the recipient of the DSN message. For example, you can include a detailed description of the DSN, contact information for your help desk, and a link to your support department's Web site. Each DSN message can contain a maximum of 512 characters.

Because DSN messages can be displayed in HTML, you can embed HTML formatting tags in the DSN text. For example, if you want to make some text in your DSN message bold, enclose the text in <B> and </B> HTML tags. The following table provides some examples of valid HTML tags that can be used in DSN message text.

Valid HTML tags for use in DSN messages

HTML tag	Description
<B>	Bold begin
</B>	Bold end
<A HREF="url">	Hyperlink begin
</A>	Hyperlink end
 	Link break
<EM>	Italic begin
</EM>	Italic end
<P>	Paragraph begin
</P>	Paragraph end

Note:

By default, Exchange sends HTML DSN messages, but you can configure whether Exchange sends HTML DSN messages to internal senders, external senders, or both. To configure this behavior, modify the *InternalDsnSendHtml* parameter and the *ExternalDsnSendHtml* parameter with the **Set-TransportService** command.
If the *InternalDsnSendHtml* parameter is set to `$false`, Exchange suppresses HTML tags in DSN messages sent to internal senders. If the *ExternalDsnSendHtml* parameter is set to `$false`, Exchange suppresses HTML tags in DSN messages sent to external senders.

The following characters that Exchange uses in DSN message text have special meanings:

- Greater than sign (>)
- Less than sign (<)
- Ampersand (&)
- Quotation marks (")

These characters are used to determine where HTML tags begin and end, and where text that should be displayed to senders starts and stops. If you want to display these characters in your DSN messages, you must use the escape codes in the following table.

For example, if you want to display the message `"Please contact the Help Desk at <1234>."`, you must add `"Please contact the Help Desk at <1234>."` to the DSN message text.

DSN message character escape codes

Escape code	Character

&lt;	<
&gt;	>
&quot;	"
&amp;	&

Important:
If you include an HTML tag in your DSN message text that contains quotation marks ("), such as `<A HREF="url">`, you must use single quotation marks (') around the whole DSN message text. You will receive an error message if you use double quotation marks around the whole DSN message text and around an HTML tag.

Supported languages for system messages

Exchange Server 2013 > Mail flow > DSNs and NDRs >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-04-25*

The following table lists the supported language codes you can use with the **New-SystemMessage** cmdlet.

Language code	Language
af	Afrikaans
am-ET	Amharic (Ethiopia)
ar	Arabic
as-IN	Assamese (India)
bg	Bulgarian
bn-BD	Bengali (Bangladesh)
bn-IN	Bengali (India)

bs-Cyrl-BA	Bosnian (Cyrillic, Bosnia and Herzegovina)
bs-Latn-BA	Bosnian (Latin, Bosnia and Herzegovina)
ca	Catalan
cs	Czech
cy-GB	Welsh (Great Britain)
da	Danish
de	German
el	Greek
en	English
es	Spanish
et	Estonian
eu	Basque
fa	Persian
fi	Finnish

Message size limits

Exchange Server 2013 > Mail flow >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-01-30*

You can apply limits to messages that move through the Microsoft Exchange Server 2013 organization. You can restrict the total size of a message or the size of the individual components of a message, such as the message header, the message attachments, and the number of recipients. You can apply limits globally for the whole Exchange organization, or specifically to a connector or user object.

As you plan the message size limits for your Exchange organization, consider the following questions:

- What size limits should I impose on all incoming messages?
- What size limits should I impose on all outgoing messages?
- What is the mailbox quota for my Exchange organization?
- How do the message size limits that I have chosen relate to the mailbox quota size?
- Are there users in my Exchange organization who must send or receive messages that are larger than the specified allowed size?
- Does my Exchange network topology include other messaging systems or distinctly separate business units that have different message size limits?

This topic provides guidance to help you answer these questions.

Contents

Types of message size limits

Following are the basic categories of the size limits available for individual messages:

- **Message header size limits** These limits apply to the total size of all message header fields that

are present in a message. The size of the message body or attachments isn't considered. Because the header fields are plain text, the size of the header is determined by the number of characters in each header field and by the total number of header fields. Each character of text consumes 1 byte.

Note:

Some third-party firewalls or proxy servers apply their own message header size limits. These third-party firewalls or proxy servers may have difficulty processing messages that contain attachment file names that are greater than 50 characters or attachment file names that contain non-US-ASCII characters.

- **Message size limits** These limits apply to the total size of a message, which includes the message header, the message body, and any attachments. Message size limits may be imposed on incoming messages or outgoing messages. For internal message flow, Exchange uses the custom `X-MS-Exchange-Organization-OriginalSize:` message header to record the original message size of the message as it enters the Exchange organization. Whenever the message is checked against the specified message size limits, the lower value of the current message size or the original message size header is used. The size of the message can change because of content conversion, encoding, and agent processing.
- **Attachment size limits** These limits apply to the maximum allowed size of a single attachment within a message. The message may contain many attachments that greatly increase the overall size of the message. However, an attachment size limit applies to the size of an individual attachment only.
- **Recipient limits** These limits apply to the total number of message recipients. When a message is first composed, the recipients exist in the `To:`, `Cc:`, and `Bcc:` header fields. When the message is submitted for delivery, the message recipients are converted into `RCPT TO:` entries in the message envelope. A distribution group is counted as a single recipient during message submission.

Return to top

Scope of limits

Following are the basic categories for the scope of the limits available for individual messages:

- **Organizational limits** These limits apply to all Exchange 2013 Mailbox servers and Exchange 2010 and Exchange 2007 Hub Transport servers that exist in the organization. If you have an Edge Transport server installed in the perimeter network, the specified limits apply to the specific server.
- **Connector limits** These limits apply to any messages that use the specified Send connector, Receive connector, Delivery Agent connector, or Foreign connector for message delivery. Send connectors are defined in the Transport service on Mailbox servers and on Edge Transport servers. Receive connectors are defined in the Transport service on Mailbox servers, in the Front End Transport service on Client Access servers, and on Edge Transport servers.
- **Active Directory site links** The Transport service on Mailbox servers use Active Directory sites and the costs that are assigned to the Active Directory IP site links as one of the factors to

determine the least-cost routing path between Mailbox servers in the organization. You can assign specific message size limits to the Active Directory site links in your organization.

- **Server limits** These limits apply to a specific Mailbox server or Edge Transport server. You can set the specified message limits independently on each Mailbox server or Edge Transport server.

In Outlook Web App, the maximum HTTP request size limit setting on the Client Access servers also controls the size of messages that Outlook Web App users can send.

- **User limits** These limits apply to a specific user object, such as a mailbox, contact, distribution group, or public folder.

The following tables show the message limits, including information about how to configure the limits in the Exchange Management Shell or the Exchange Administrator Center (EAC).

Organizational limits

Size limit	Default value	Shell configuration	EAC configuration
Maximum size for messages received	10 MB	Cmdlet: **Set-TransportConfig** Parameter: *MaxReceiveSize*	**Mail flow** > **Receive connectors** > **More options** ··· > **Organization transport settings** > **Limits** tab > **Maximum receive message size**
Maximum size for messages sent	10 MB	Cmdlet: **Set-TransportConfig** Parameter: *MaxSendSize*	**Mail flow** > **Receive connectors** > **More options** ··· > **Organization transport settings** > **Limits** tab > **Maximum send message size**
Maximum number of recipients per message **Note:**	500	Cmdlet: **Set-TransportConfig** Parameter: *MaxRecipientEnvelopeLimit*	**Mail flow** > **Receive connectors** > **More options** ··· > **Organization transport settings** > **Limits** tab > **Maximum number of recipients**

Maximum attachment size in Transport rules that apply to all Mailbox servers in the organization	Not configured	Cmdlets: **New-TransportRule**, **Set-TransportRule** Parameter: *AttachmentSizeOver*	**Mail flow** > **Rules** > **Add +** or **Edit** . Use the predicate **Apply this rule if** > **Any attachment** > **is greater than or equal to** Use the predicate **Apply this rule if** > **The message** > **size is greater than or equal to**
Maximum message size in Transport rules that apply to all Mailbox servers in the organization		Cmdlets: **New-TransportRule**, **Set-TransportRule** Parameter: *MessageSizeOver*	**Mail flow** > **Rules** > **Add +** or **Edit** . Use the predicate **Apply this rule if** > **The message** > **size is greater than or equal to**

Maximum message	Unlimited	Cmdlets:	For mailboxes:

size that can be sent by this recipient		**Set-DistributionGroup** **Set-DynamicDistributionGroup** **Set-Mailbox** **Set-MailContact** **Set-MailUser** **Set-MailPublicFolder** **Set-RemoteMailbox** Parameter: *MaxSendSize*	**Recipients** > **Mailboxes** > **Edit** > **Mailbox features** > **Mail flow** > **Message size restrictions** > **View details** > **Sent messages** **Note:** This setting isn't configurable using the EAC for other recipient types.
Maximum message size that can be sent to this recipient	Unlimited For site mailbox provisioning policies: 36 MB	Cmdlets: **Set-DistributionGroup** **Set-DynamicDistributionGroup** **Set-Mailbox** **Set-MailContact** **Set-MailUser** **Set-MailPublicFolder** **New-SiteMailboxProvisioningPolicy** **Set-SiteMailboxProvisioningPolicy**	For mailboxes: **Recipients** > **Mailboxes** > **Edit** > **Mailbox features** > **Mail flow** > **Message size restrictions** > **View details** > **Received messages** **Note:** This setting isn't configurable using the EAC for other recipient types.

		Parameter: *MaxReceiveSize*	
Maximum number of recipients per message sent by this recipient	Unlimited	Cmdlets: **Set-Mailbox**, **Set-MailUser** Parameter: *RecipientLimits*	N/A

Return to top

Order of precedence for message size limits

You can set different message size limits at different levels in the Exchange organization. As a message is routed through your Transport infrastructure, it may be subjected to several different message size restrictions. You should plan your message size restrictions in a way that makes sure that messages in the transport pipeline are rejected as early as possible if they violate message size limits. Generally speaking, you should set more restrictive limits at the points where messages enter your infrastructure. For example, any message size restrictions on your Receive connectors that receive messages from the Internet should be less than or equal to the message size restrictions you configure for your internal Exchange organization. It would be a waste of system resources for the Exchange server to accept and process a message from the Internet that would be rejected by the Transport service on your Mailbox servers. Make sure that your organization, server, and connector limits are configured in a way that minimizes any unnecessary processing of messages.

One exception to this approach is the user limits. User level limits take precedence over other message size restrictions. Therefore, you can configure a user to exceed the default message size limits for your organization. For example, you can allow a specific group of user mailboxes to send larger messages than the rest of the organization by configuring custom send and receive limits for those mailboxes.

The exceptions for the user limits only apply to message exchanges between authenticated users. If a message is sent to or received by a recipient on the Internet, the organizational limits will be applied. For example, assume that you have an organizational message size restriction of 10 MB, but you have configured the users in your marketing department to send and receive messages up to 50 MB. These users will be able to exchange large messages with each other, but they still won't be able to receive large messages from Internet users because such messages will be coming from unauthenticated senders.

Return to top

Messages exempt from size limits

The following list shows the types of messages generated by a Mailbox server or an Edge Transport server and exempted from all message size limits:

- System messages
- Agent-generated message
- Delivery status notification (DSN) messages
- Journal report messages
- Quarantined messages

However, these messages are still subject to the organizational value for maximum number of recipients in a message.

Return to top

Message throttling

Applies to: *Exchange Server 2013*

Topic Last Modified: *2012-10-17*

Message throttling refers to a group of limits that are set on the number of messages and connections that can be processed by a Microsoft Exchange Server 2013 computer. These limits prevent the accidental or intentional exhaustion of system resources on the Exchange server.

Contents

Message throttling scope

Message throttling involves a variety of limits on message processing rates, SMTP connection rates, and SMTP session time-out values. These limits work together to protect an Exchange server from being overwhelmed by accepting and delivering messages. Although a large backlog of messages

and connections may be waiting to be processed, the message throttling limits enable the Exchange server to process the messages and connections in an orderly manner.

In addition to message throttling, you can also put size limits on the individual components of messages, such as the number of recipients, the size of the message header, or the size of individual attachments. For more information about message size limits, see Message size limits.

Another feature that helps avoid overwhelming the system resources of an Exchange transport server is *back pressure*. Back pressure is a system resource monitoring feature in the Transport service on Mailbox servers and on Edge Transport servers. When a monitored system resource, such as hard disk utilization or memory utilization, exceeds the specified threshold, the server reduces the rate at which it accepts new connections and messages, and focuses on delivering existing messages. When the utilization of the monitored system resources returns to normal levels, the server slowly increases the rate at which it accepts new connections and then establishes a normal level.

Return to top

Message cost and mail flow throttling

To provide more consistent message throughput and predictable message delivery latency, Exchange 2013 establishes an accumulated cost for messages. This quality of service (QoS) feature was added in Microsoft Exchange Server 2010 SP1This cost is based on the following criteria:

- Message size
- Number of recipients
- Frequency of transmission

Exchange 2013 transport servers track the average delivery cost of messages that are sent by individual users. By using message costs, Exchange 2013 provides a group of settings that can control the effect that a user or connection has on an Exchange organization. This group of settings is known as a *throttling policy*. When a user repeatedly sends costly messages, such as messages that have large attachments or messages that are sent to many recipients, the Exchange 2013-based transport servers use a throttling policy to assign a lower priority to higher-cost messages from the user while continuing to deliver lower-cost messages. This new behavior adds a "quality of service" aspect to the message throttling functionality in Exchange 2013.

Note:

Message throttling doesn't affect the message priority from a user's perspective. Messages still retain the original priority set by the user. For example, messages retain a setting of Important or Urgent, and so on.

To support this functionality, Exchange 2013 uses the following mechanisms:

- **Internal prioritization agent** This agent is triggered on the **OnResolvedMessage** event and assigns a lower priority to messages from the same sender that have a high accumulated cost. This cost is measured over a period of one minute and affects messages that have more than 500 recipients or that are larger than 1 megabyte (MB).

- **Quota-based priority queuing for the MapiDelivery queue type** This mechanism causes Exchange to deliver messages in a normal-priority queue more frequently than messages in a low-priority queue. By default, the normal-to-low message ratio is 20:1. However, new messages from a lower priority queue are never delivered sooner than new items from a higher priority queue. For example, consider the following scenario:
  1. Twenty normal priority messages are delivered. By default, the next delivered message is a lower priority message.
  2. Two new messages are received by the transport server: One message from a higher priority queue and one message from a lower priority queue.

In this scenario, the message from the higher priority queue is delivered first. Then, the message from the lower priority queue is delivered.

- **Throttle concurrent connections based on messaging database health** This mechanism monitors the health of the Exchange messaging database (MDB) health and throttles concurrent connections to Exchange transport servers based on an assigned Health Measure value. The MDB is monitored by the Resource Health Monitor API in the Transport service on the Mailbox server and is assigned a health value from -1 through 100. This value is based on the RPC performance statistics that are included with each RPC response from the Store.exe process in the Mailbox Transport service. The Resource Health framework uses both the **Requests/Second** rate performance counter and the **Average RPC Latency** performance counter to calculate a health value for the database. To help maintain a consistent interactive user experience, Exchange reduces the number of concurrent connections as the health value decreases. The following health value ranges are available:
  1. **-1:** This value indicates that the MDB health state is unknown. This value is assigned when the database starts. In this scenario, the database is considered healthy.
  2. **0:** This value is assigned if the database is in an unhealthy state. In this state, the database should not be contacted.
  3. **1 through 99:** These values represent a fair health state. A lower value represents a less healthy database.
  4. **100:** This value represents a healthy database.

The Microsoft Exchange Throttling service provides the framework for mail flow throttling. The Microsoft Exchange Throttling service keeps track of mail flow throttling settings for a specific user and caches the throttling information in memory. Mail flow throttling settings are also known as a *budget*. Restarting the Microsoft Exchange Throttling service also resets mail flow throttling budgets.

You can use the throttling policy cmdlets that are available in Exchange 2013 to configure individual budget settings for a throttling policy. A budget is the amount of access that a user or application may have for a specific setting. A budget represents how many connections a user may have or how much activity a user may be permitted for each one-minute period. For example, a budget may be configured to set the amount of time that a user may spend using a specific feature in Exchange, such as ActiveSync, Outlook Web App, or Exchange Web Services. This threshold is stored in a throttling policy and defines the budget.

Time settings for a budget are set as a percentage of one minute. Therefore, a threshold of 100 percent represents 60 seconds. For example, assume that you want to specify Outlook Web App policy settings that limit the amount of time during which a user may run Outlook Web App code on a Client Access server and the amount of time the user may communicate with the Client Access server to 600 milliseconds over a one-minute period. To accomplish this, you need to set the value to 1 percent of one minute (600 milliseconds) for both of the following parameters:

- **OWAPercentTimeInCAS:** 1
- **OWAPercentTimeInMailboxRPC:** 1

A user who has this policy applied has a budget of OWAPercentTimeInCAS of 600 milliseconds and of OWAPercentageTimeInMailboxRPC of 600 milliseconds. In this scenario, when the user is logged into Outlook Web App, the user can run Client Access code for up to 600 milliseconds. After the 600 millisecond-period, the connection is considered over budget and the Exchange server doesn't allow any further Outlook Web App action until one minute after the budget limit is reached. After the one-minute period, the user can run Outlook Web App client access code for another 600 milliseconds.

Return to top

Message throttling on servers

You can set the message throttling options at the following locations:

- In the transport service
- On a Send connector
- On a Receive connector

You can set all the message throttling options that are available in the Transport service on Mailbox servers, in the Mailbox Transport service on Mailbox servers, or in the Front End Transport service on Client Access servers using the Exchange Management Shell. You can also set some of the same options by configuring the transport server properties in the Exchange Administration Center (EAC).

The following table shows the message throttling options that are available on transport servers.

Message throttling options on transport servers

Source	Parameter	Default value	Description
Set-TransportService **Set-MailboxTransportService**	*MaxConcurrentMailboxDeliveries*	20	This parameter specifies the maximum number of delivery threads that the transport service can have open at the same time to deliver

			messages to mailboxes. The valid input range for this parameter is from 1 through 256. We recommend that you don't modify the default value unless Microsoft Customer Service and Support advises you to do this.
Set-TransportService **Set-MailboxTransportService**	*MaxConcurrentMailboxSubmissions*	20	This parameter specifies the maximum number of submission threads that the transport service can have open at the same time to send messages from mailboxes. The valid input range for this parameter is from 1 through 256.
Set-TransportService	*MaxConnectionRatePerMinute*	1200	This parameter specifies the maximum rate that connections are allowed to be opened with the transport service. If many connections are attempted with the transport service at the same time, the *MaxConnectionRatePer*

			Minute parameter limits the rate that the connections are opened so that the server's resources aren't overwhelmed.
Set-TransportService or Transport server properties	*MaxOutboundConnections*	1000	This parameter specifies the maximum number of outbound connections that can be open at a time. If you enter a value of `unlimited`, no limit is imposed on the number of outbound connections. The value of this parameter must be greater than or equal to the value of the *MaxPerDomainOutboundConnections* parameter. This value can also be configured using the EAC at **Servers** > **Servers** > **Properties** > **Transport limits** > **Outbound connection restrictions**.
Set-TransportService	*MaxPerDomainOutbou*	20	This parameter

or Transport server properties	*ndConnections*		specifies the maximum number of concurrent connections to any single domain. If you enter a value of `unlimited`, no limit is imposed on the number of outbound connections per domain. The value of this parameter must be greater than or equal to the value of the *MaxOutboundConnections* parameter. This value can also be configured using the EAC at **Servers** > **Servers** > **Properties** > **Transport limits** > **Outbound connection restrictions**.
Set-TransportService	*PickupDirectoryMaxMessagesPerMinute*	100	This parameter specifies the maximum number of messages processed per minute by the Pickup directory and by the Replay directory. Each directory can independently process

			message files at the rate specified by this parameter.

Return to top

Message throttling on Send connectors

The following table shows the message throttling option that's available on Send connectors. You need to use the Exchange Management Shell to configure this option.

Message throttling option available on Send connectors

Source	Parameter	Default value	Description
Set-SendConnector	*ConnectionInactivityTimeOut*	10 minutes	This parameter specifies the maximum time that an open SMTP connection with a destination messaging server can remain idle before the connection is closed.

Return to top

Message throttling on Receive connectors

The following table shows the message throttling options that are available on Receive connectors that are configured in the Transport service on a Mailbox server or on an Edge Transport server. You need to use the Exchange Management Shell to configure these options.

Message throttling options available on Receive connectors

Source	Parameter	Default value	Description
Set-ReceiveConnector	*ConnectionInactivityTimeOut*	5 minutes in the Transport service on Mailbox servers 5 minutes in the Front End Transport service	This parameter specifies the maximum time that an open SMTP connection with a source messaging

		on Client Access servers. 1 minute on Edge Transport servers.	server can remain idle before the connection is closed. The value of this parameter must be smaller than the value specified by the *ConnectionTimeout* parameter.
Set-ReceiveConnector	*ConnectionTimeOut*	10 minutes in the Transport service on Mailbox servers 10 minutes in the Front End Transport service on Client Access servers. 5 minutes on Edge Transport servers.	This parameter specifies the maximum time that an SMTP connection with a source messaging server can remain open, even if the source messaging server is transmitting data. The value of this parameter must be larger than the value specified by the *ConnectionInactivityTimeout* parameter.
Set-ReceiveConnector	*MaxInboundConnection*	5000	This parameter specifies the maximum number of inbound SMTP connections that this Receive connector allows at the same time.
Set-ReceiveConnector	*MaxInboundConnectionPercentagePerSource*	100 percent on the Default Receive connector in the	This parameter specifies the maximum

		Transport service on a mailbox server 2 percent on the other Receive connectors in the Transport service on Mailbox servers, and in the Front End Transport service on Client Access servers.	number of SMTP connections that a Receive connector allows at the same time from a single source messaging server. The value is expressed as the percentage of available remaining connections on a Receive connector. The maximum number of connections that are permitted by the Receive connector is defined by the *MaxInboundConnection* parameter.
Set-ReceiveConnector	*MaxInboundConnectionPerSource*	**unlimited** on the Default Receive connector in the Transport service on a mailbox server 20 on the other Receive connectors in the Transport service on Mailbox servers, and in the Front End Transport service on Client Access servers.	This parameter specifies the maximum number of SMTP connections that a Receive connector allows at the same time from a single source messaging server.
Set-ReceiveConnector	*MaxProtocolErrors*	5	This parameter specifies the maximum

			number of SMTP protocol errors that a Receive connector allows before the Receive connector closes the connection with the source messaging server.
Set-ReceiveConnector	*TarpitInterval*	5 seconds	This parameter specifies the delay that's used in *tarpitting*. Tarpitting is the practice of artificially delaying SMTP responses for specific SMTP communication patterns that indicate a directory harvest attack or other unwelcome messages. A *directory harvest attack* is an attempt to collect valid e-mail addresses from a particular organization to use as a target for unsolicited commercial e-mail. The delay that's specified by the *TarpitInterval* parameter only applies to anonymous

			connections.

Return to top

Message throttling policies

In Exchange 2013, each mailbox has a *ThrottlingPolicy* setting. The default value for this setting is blank (`$null`). You can use the *ThrottlingPolicy* paramenter on the **Set-Mailbox** cmdlet to configure a throttling policy for a mailbox.

A default throttling policy exists to provide a default set budget configuration for users who connect to Exchange. To configure customized budget settings for one or more users, create a new throttling policy. Then, apply the policy to the appropriate user or group.

Important:
We recommend that you don't modify the default throttling policy.

You can set all the message throttling options that are available on Mailbox servers in the Exchange Management Shell. The following cmdlets are available to manage throttling policies:

- **Get-ThrottlingPolicy**
- **Remove-ThrottlingPolicy**
- **New-ThrottlingPolicy**
- **Set-ThrottlingPolicy**

You can use the **New-ThrottlingPolicy** and **Set-ThrottlingPolicy** cmdlets to configure how much activity a user can perform against Exchange over a specific connection or time period. These settings make up a user's budget. You can establish throttling policies to control access to the following Exchange features:

- Exchange ActiveSync
- Exchange Web Services
- Outlook Web App
- Unified Messaging
- IMAP4
- POP3
- Outlook client connections (MAPI or RPC connections)
- Mail flow settings
- PowerShell commands
- CPU usages

Back pressure

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-03-20*

Back pressure is a system resource monitoring feature of the Microsoft Exchange Transport service that exists on Microsoft Exchange 2013 Mailbox servers and Edge Transport servers.

Exchange can detect when vital resources, such as available hard drive space and memory, are under pressure, and take action in an attempt to prevent service unavailability. Back pressure prevents the system resources from being completely overwhelmed, and the Exchange server tries to process the existing messages before accepting any new messages. When utilization of the system resource returns to a normal level, the Exchange server gradually resumes normal operation and starts accepting new messages again.

In Exchange 2013, when the Transport service on a Mailbox server or an Edge Transport server is under resource pressure, incoming connections are accepted, but incoming messages over those connections are either accepted at a slower rate or are rejected. When an SMTP host attempts to connect to an Exchange server that's under resource pressure, the connection will succeed. However, when the host issues the **MAIL FROM** command to submit a message, depending on the resource that's under pressure, the Transport service either delays the acknowledgement of the **MAIL FROM** command or rejects the connection.

Contents

Resources monitored

The following system resources are monitored as part of the back pressure feature:

- Free space on the hard drive that stores the message queue database.
- Free space on the hard drive that stores the message queue database transaction logs.
- The number of uncommitted message queue database transactions that exist in memory.
- The memory that's used by the EdgeTransport.exe process.
- The memory that's used by all other processes.
- The number of messages in the Submission queue.

For each monitored system resource on a Mailbox server or Edge Transport server, the following three levels of resource utilization are applied:

- **Normal** The resource isn't overused. The server accepts new connections and messages.
- **Medium** The resource is slightly overused. Back pressure is applied to the server in a limited

manner. Mail from senders in the authoritative domain can flow. However, depending on the specific resource under pressure, the server uses tarpitting to delay server response or rejects incoming **MAIL FROM** commands from other sources.

- **High** The resource is severely overused. Full back pressure is applied. All message flow stops, and the server rejects all new incoming **MAIL FROM** commands.

The following sections explain how Exchange handles the situation when a specific resource is under pressure.

Free hard drive space for the message queue database

By default, the message queue database is stored at %ExchangeInstallPath%TransportRoles\data\Queue. Exchange monitors the hard drive space utilization for this location. The high level of hard drive space utilization is calculated by using the following formula:

100 * (*hard disk size* - *fixed constant*) / *hard drive size*

The value of *fixed constant* is 500 megabytes (MB).

The results of this formula are expressed as a percentage of the total hard drive space that's being used. The results of the formula are always rounded down to the nearest integer. By default, the medium level of hard drive utilization is 2 percent less than the high level. By default, the normal level of hard drive utilization is 4 percent less than the high level.

Return to top

Free hard drive space for the message queue database transaction logs

By default, the message queue database transaction logs are stored at %ExchangeInstallPath%TransportRoles\data\Queue. Exchange monitors the hard drive space utilization for this location. The %ExchangeInstallPath%Bin\EdgeTransport.exe.config application configuration file contains a *DatabaseCheckPointDepthMax* key that has a default value of 384 MB. This key controls the total allowed size of all uncommitted transaction logs that exist on the hard drive. This key is used in the formula that calculates hard drive utilization.

Note:

The value of the *DatabaseCheckPointDepthMax* key applies to all transport-related Extensible Storage Engine (ESE) databases that exist on the Mailbox server or Edge Transport server. This would include the message queue database and the IP filter database.

By default, the high level of disk utilization is calculated by using the following formula:

100 * (*hard drive size* - Min(5 GB, 3**DatabaseCheckPointDepthMax*)) / *hard drive size*

The results of the formula are always rounded down to the nearest integer. By default, the medium level of hard drive utilization is 2 percent less than the high level. The normal level of hard drive

utilization is 4 percent less than the high level.

Return to top

Number of uncommitted message queue database transactions in memory

A list of changes that are made to the message queue database is kept in memory until those changes can be committed to a transaction log. Then the list is committed to the message queue database itself. These outstanding message queue database transactions that are kept in memory are known as *version buckets*. The number of version buckets may increase to unacceptably high levels because of an unexpectedly high volume of incoming messages, spam attacks, problems with the message queue database integrity, or hard drive performance.

When Exchange starts receiving messages, these messages are grouped together in batches and then prepared as version buckets. If an incoming message has a large attachment, it can be separated into multiple batches. These batches that are being processed are known as *batch points*. The number of outstanding batch points can exceed the set thresholds, especially when there's an unexpectedly high volume of incoming messages with large attachments.

When version buckets or batch points are under pressure, the Exchange server will start throttling incoming connections by delaying acknowledgement to incoming messages. Exchange will reduce the rate of inbound message flow by tarpitting, which introduces a delay to the **MAIL FROM** commands. If the resource pressure condition continues, Exchange will gradually increase the tarpitting delay. After the resource utilization returns to normal, Exchange will gradually start reducing the acknowledgement delay and ease into normal operation. By default, Exchange will start delaying message acknowledgements 10 seconds when under resource pressure. If the resources continue to be under pressure, the delay is increased in 5-second increments up to 55 seconds.

Exchange keeps a history of version bucket and batch point resource utilization. If the resource utilization doesn't go down to normal level for a specific number of polling intervals, known as the history depth, Exchange will stop the tarpitting delay and start rejecting incoming messages until the resource utilization goes back to normal. By default, the history depths for version buckets and batch points are in 10 and 300 polling intervals respectively.

Return to top

Memory used by the EdgeTransport.exe process

By default, the high level of memory utilization by the EdgeTransport.exe process is calculated by using the following formula:

75 percent of the total physical memory or 1 terabyte, whichever is less

This calculation doesn't include virtual memory that's available on the hard drive in the paging file, or the memory that's used by other processes. The results of this formula are expressed as a percentage of the total memory that's used by the EdgeTransport.exe process. The results of the formula are always rounded down to the nearest integer.

By default, the medium level of memory utilization by the EdgeTransport.exe file is calculated as 73 percent of the total physical memory or 2 percent less than the value of the high level, whichever is less. By default, the normal level of memory utilization by the EdgeTransport.exe file is calculated as 71 percent of the total physical memory or 4 percent less than the value of the high level, whichever is less.

If the memory utilization of the EdgeTransport.exe process is higher than the specified normal level, *garbage collection* is forced. Garbage collection is a process that checks for unused objects that exist in memory, and reclaims the memory that's used by those unused objects.

Exchange keeps a history of the memory utilization of the EdgeTransport.exe process. If the utilization doesn't go down to normal level for a specific number of polling intervals, known as the history depth, Exchange will start rejecting incoming messages until the resource utilization goes back to normal. By default, the history depth for EdgeTransport.exe memory utilization is 30 polling intervals.

Return to top

Memory used by all processes

By default, the high level of memory utilization by all processes is 94 percent of total physical memory. This value doesn't include virtual memory that's available on the hard drive in the paging file.

When the specified memory utilization level is reached, *message dehydration* occurs. Message dehydration is the act of removing unnecessary elements of queued messages that are cached in memory. Complete messages are cached in memory for enhanced performance. Removal of the MIME content of queued messages from memory reduces the memory that's used at the expense of higher latency because the messages are read directly from the message queue database. By default, message dehydration is enabled.

Return to top

Number of messages in the Submission queue

The Submission queue is associated with the Transport service on Exchange 2013 Mailbox servers and on Edge Transport servers. The categorizer processes each message in the Submission queue. This categorization results in the message being put in a delivery queue. For more information, see Mail flow and Queues. A large number of messages in the Submission queue indicates the categorizer is having difficulty processing messages.

When the Submission queue is under pressure, the Exchange server will start throttling incoming connections by delaying acknowledgement to incoming messages. Exchange will reduce the rate of inbound message flow by tarpitting, which introduces a delay to the **MAIL FROM** commands. If the Submission queue pressure condition continues, Exchange will gradually increase the tarpitting delay. After the Submission queue utilization returns to normal, Exchange will gradually start reducing the acknowledgement delay and ease into normal operation. By default, Exchange will start delaying message acknowledgements 10 seconds when under Submission queue pressure. If the Submission queue continues to be under pressure, the delay is increased in 5-second increments up to 55 seconds.

Exchange keeps a history of Submission queue utilization. If the Submission queue utilization doesn't go down to normal level for a specific number of polling intervals, known as the history depth, Exchange will stop the tarpitting delay and start rejecting incoming messages until the Submission utilization goes back to normal. By default, the history depth for the Submission queue is in 300 polling intervals.

Actions taken by Exchange Transport when under resource pressure

The following table summarizes the actions taken by Exchange transport when a specific resource is under pressure.

Back pressure actions taken by Mailbox and Edge Transport servers when responding to resource pressure

Resource under pressure	Utilization level	Actions taken
Hard drive space for message queue database	Medium	• Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories
Hard drive space for message queue database	High	• Reject incoming messages from other Exchange servers • Reject message submissions from mailbox databases by the Mailbox Transport Submission service on Mailbox servers • Reject incoming messages from non-Exchange servers

		• Reject message submissions from Pickup and Replay directories
Hard drive space for message queue database transaction logs	Medium	• Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories
Hard drive space for message queue database transaction logs	High	• Reject incoming messages from other Exchange servers • Reject message submissions from mailbox databases by the Mailbox Transport Submission service on Mailbox servers • Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories
Version buckets	Medium	Introduce or increment the tarpitting delay to incoming messages. If normal level isn't reached for the entire version bucket history depth, take the following actions: • Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories
Version buckets	High	Introduce or increment the tarpitting delay to incoming messages. If normal level isn't

		reached for the entire version bucket history depth, take the following actions: • Reject incoming messages from other Exchange servers • Reject message submissions from mailbox databases by the Mailbox Transport Submission service on Mailbox servers • Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories
Batch point	Medium	Introduce or increment the tarpitting delay to incoming messages. If normal level isn't reached for the entire batch point history depth, take the following actions: • Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories
Batch point	High	Introduce or increment the tarpitting delay to incoming messages. If normal level isn't reached for the entire batch point history depth, take the following actions: • Reject incoming messages from other Exchange servers

		• Reject message submissions from mailbox databases by the Mailbox Transport Submission service on Mailbox servers • Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories
Memory used by EdgeTransport.exe process	Medium	• Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories • Force garbage collection
Memory used by EdgeTransport.exe process	High	• Reject incoming messages from other Exchange servers • Reject message submissions from mailbox databases by the Mailbox Transport Submission service on Mailbox servers • Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories
Memory used by all processes	Medium	• Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories • Force garbage collection
Memory used by all processes	High	• Reject incoming messages from other Exchange servers

		• Reject message submissions from mailbox databases by the Mailbox Transport Submission service on Mailbox servers • Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories • Flush enhanced DNS cache from memory • Start message dehydration
Number of messages in the Submission queue	Medium	Introduce or increment the tarpitting delay to incoming messages. If normal level isn't reached for the entire Submission queue history depth, take the following actions: • Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories • Force garbage collection
Number of messages in the Submission queue	High	Introduce or increment the tarpitting delay to incoming messages. If normal level isn't reached for the entire Submission queue history depth, take the following actions: • Reject incoming messages from other Exchange servers • Reject message submissions

		from mailbox databases by the Mailbox Transport Submissions service on Mailbox servers • Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories • Flush enhanced DNS cache from memory • Start message dehydration

Return to top

Back pressure configuration options in the EdgeTransport.exe.config file

All configuration options for back pressure are available in the %ExchangeInstallPath%Bin\EdgeTransport.exe.config XML application configuration file.

Caution:

These settings are listed as a reference only. We strongly discourage any modifications to the back pressure settings in the EdgeTransport.exe.config file. Modifications to the back pressure settings may result in poor performance or data loss. We recommend that you investigate and correct the root cause of any back pressure events that you may encounter.

Back pressure configuration options

Key name	Default value
EnableResourceMonitoring	true
ResourceMonitoringInterval	`00:00:02` (2 seconds)

Return to top

Back pressure logging information

The following list describes the event log entries that are generated by specific back pressure

events in Exchange:

- **Event log entry for an increase in any resource utilization level**

Event Type: Error

Event Source: MSExchangeTransport

Event Category: Resource Manager

Event ID: 15004

Description: Resource pressure increased from *Previous Utilization Level* to *Current Utilization Level*.

- **Event log entry for a decrease in any resource utilization level**

Event Type: Information

Event Source: MSExchangeTransport

Event Category: Resource Manager

Event ID: 15005

Description: Resource pressure decreased from *Previous Utilization Level* to *Current Utilization Level*.

- **Event log entry for critically low available disk space**

Event Type: Error

Event Source: MSExchangeTransport

Event Category: Resource Manager

Event ID: 15006

Description: The Microsoft Exchange Transport service is rejecting messages because available disk space is below the configured threshold. Administrative action may be required to free disk space for the service to continue operations.

- **Event log entry for critically low available memory**

Event Type: Error

Event Source: MSExchangeTransport

Event Category: Resource Manager

Event ID: 15007

Description: The Microsoft Exchange Transport service is rejecting message submissions because the service continues to consume more memory than the configured threshold. This may require that this service be restarted to continue normal operation.

Return to top

Queues

Exchange Server 2013 > Mail flow >

Topic Last Modified: *2014-01-31*

A *queue* is a temporary holding location for messages that are waiting to enter the next stage of

processing or delivery to a destination. Each queue represents a logical set of messages that the Exchange server processes in a specific order. In Microsoft Exchange Server 2013, queues hold messages before, during and after delivery. Queues exist on Mailbox servers and Edge Transport servers. Mailbox servers and Edge Transport servers are called *transport servers* throughout this topic.

Like the previous versions of Exchange, Exchange 2013 uses a single Extensible Storage Engine (ESE) database for queue storage.

You can manage queues and the messages in queues using the Exchange Management Shell and Queue Viewer in the Exchange Toolbox. You can use these interfaces to view the status and contents of queues and detailed message properties. You can also use these interfaces to perform actions that modify queues or the messages in the queues.

Contents

Types of queues

The following types of queues are used in Exchange 2013:

- **Persistent queues** *Perisistent queues* are queues that exist on every transport server in every Exchange organization. Like previous versions of Exchange, there are three persistent queues in Exchange 2013:
  - **Submission queue** The Submission queue is used by the categorizer to gather all messages that have to be resolved, routed, and processed by transport agents on the transport server. All messages that are received by a transport server enter processing in the Submission queue. On Mailbox servers, messages are submitted through a Receive connector, the Pickup or Replay directories, or the Mailbox Transport Submission service. On Edge Transport servers, messages are typically submitted through a Receive connector, but the Pickup and Replay directories are also available.

The categorizer retrieves messages from this queue and, among other things, determines the location of the recipient and the route to that location. After categorization, the message is moved to a delivery queue or to the Unreachable queue. Each transport server has only one Submission queue. Messages that are in the Submission queue can't be in other queues at the same time. For

more information about the categorizer and the transport pipeline, see Mail flow.

- **Unreachable queue** The Unreachable queue contains messages that can't be routed to their destinations. Typically, an unreachable destination is caused by configuration changes that have modified the routing path for delivery. Regardless of destination, all messages that have unreachable recipients reside in this queue. Each transport server has only one Unreachable queue.

Messages in the Unreachable queue are automatically resubmitted when a routing change is detected. So, after the condition or configuration error caused the messages to enter the Unreachable queue is repaired, you don't need to take additional action to move the messages out of the Unreachable queue for delivery.

The Unreachable queue is typically empty. If the Unreachable queue contains no messages it doesn't appear in Queue Viewer or **Get-Queue** results.

- **Poison message queue** The poison message queue is a special queue that's used to isolate messages that are determined to be harmful to the Exchange 2013 system after a transport server or service failure. The messages may be genuinely harmful in their content and format. Alternatively, they may be the results of a poorly written agent that has caused the Exchange server to fail when it processed the supposedly bad messages.

The poison message queue is typically empty. If the poison message queue contains no messages it doesn't appear in Queue Viewer or **Get-Queue** results. The messages in the poison message queue are never automatically resumed or expired. Messages remain in the poison message queue until they're manually resumed or removed by an administrator.

- **Delivery queues** Delivery queues hold messages that are being delivered to any local or remote destinations by using SMTP. All messages are transmitted between Exchange servers by using SMTP. Non-SMTP destinations also use delivery queues if the destination is serviced by a Delivery Agent connector. . Each delivery queue contains messages that are being routed to the same destination. It's practically inevitable that multiple delivery queues will exist on a transport server. Delivery queues are dynamically created when they're required and are automatically deleted when the queue is empty and the expiration time has passed. The queue expiration time is controlled by the *QueueMaxIdleTime* parameter on the **Set-TransportService** cmdlet. The default value is three minutes.
- **Shadow queues** Shadow queues hold redundant copies of a message while the message is in transit. For more information, see Shadow redundancy.
- **Safety Net** Safety Net retains copies of messages that were successfully delivered by the transport server. Although it's not accessible by queue management tools, Safety Net is just another queue in the queue database. For more information, see Safety Net.

Return to top

Queue database files

All the different queues are stored in a single ESE database. By default, this queue database is located on the transport server at `%ExchangeInstallPath%TransportRoles\data\Queue`.

Like any ESE database, the queue database uses log files to accept, track, and maintain data. To enhance performance, all message transactions are written first to log files and memory, and then to the database file. The checkpoint file tracks the transaction log entries that have been committed to the database. During an ordinary shutdown of the Microsoft Exchange Transport service, uncommitted database changes that are found in the transaction logs are always committed to the database.

Circular logging is used for the queue database. This means that the history of committed transactions that are found in the transaction logs isn't maintained. Any transaction logs that are older than the current checkpoint are immediately and automatically deleted. Therefore, the transaction logs can't be replayed for queue database recovery from backup.

Exchange 2013 uses *generation tables* for storage and clean-up of messages in the queue database. Instead of processing and deleting individual message records from one large table, the queue database stores messages in time-based tables, and only deletes the entire table after all the messages in the table have been successfully processed. For example, all messages queued from 1:00 PM to 2:00 PM, regardless of the queue or destination, are stored in the `1p-2p_msgs` table. At 2:00 PM, new messages are stored in the `2p-3p_msgs` table. At 4:00 PM, a new table named `4p-5p_msgs` is created, and the entire `1p-2p_msgs` table is deleted, but only if all messages in the table have been successfully processed. This approach of deleting entire messages tables instead of individual messages helps improves the I/O performance of the drive that holds the queue database.

The following table lists the files that constitute the queue database.

Files that constitute the queue database

File	Description
Mail.que	This queue database file stores all the queued messages.
Tmp.edb	This temporary database file is used to verify the queue database schema on startup.
Trn*.log	This transaction log records all changes to the queue database. Changes to the database are first written to the transaction log and then committed to the database. Trn.log is the current active transaction log file. Trntmp.log is the next provisioned transaction log file that's created in advance. If the existing Trn.log transaction log file reaches its maximum size,

	Trn.log is renamed to Trn*nnnn*.log, where *nnnn* is a sequence number. Trntmp.log is then renamed Trn.log and becomes the current active transaction log file.
Trn.chk	This checkpoint file tracks the transaction log entries that have been committed to the database. This file is always in the same location as the mail.que file.
Trnres00001.jrs Trnres00002.jrs	These reserve transaction log files act as placeholders. They're only used when the hard disk that contains the transaction log runs out of space to stop the queue database cleanly.

Return to top

Options for configuring the queue database

You configure the queue database by adding or modifying keys in the `%ExchangeInstallPath%Bin\EdgeTransport.exe.config` XML application configuration file. This file is associated with the Microsoft Exchange Transport service. Changes you make to the EdgeTransport.exe.config file take effect after you restart the Microsoft Exchange Transport service.

The `<appSettings>` section of the EdgeTransport.exe.config file is where you can add new keys or modify existing keys. If a specific key doesn't exist, you can add it manually to change its value.

The keys for the queue database that are available in the EdgeTransport.exe.config file are described in the following table.

Message queue database keys that are available in the EdgeTransport.exe.config file

Key	Default value	Description
QueueDatabaseBatchSize	40	This key specifies the number of database I/O operations that can be grouped together before they're executed. By default, this key doesn't exist in the EdgeTransport.exe.config file.

QueueDatabaseBatchTimeout	100	This key specifies the maximum time in milliseconds that the database will wait for multiple database I/O operations to group before it executes them. The database I/O operations are executed without waiting for any more if the following conditions are true: • The number of database I/O operations that's specified by the *QueueDatabaseBatchSize* key hasn't been reached. • The time specified by the *QueueDatabaseBatchTimeout* key has passed. By default, this key doesn't exist in the EdgeTransport.exe.config file.
QueueDatabaseMaxConnections	4	This key specifies the number of ESE database connections that can be open.
QueueDatabaseLoggingBufferSize	5 MB	This key specifies the memory that's used to cache the transaction records before they're written to the transaction log file.
QueueDatabaseLoggingFileSize	5 MB	This key specifies the maximum size of a transaction log file. When the maximum log file size is reached, a new log file is opened.
QueueDatabaseLoggingPath	`%ExchangeInstallPath%TransportRoles\data\Queue`	This key specifies the default directory for the queue database

		log files. For instructions on how to change the location of the queue database, see Change the location of the queue database.
QueueDatabaseMaxBackgroundCleanupTasks	32	This key specifies the maximum number of background cleanup work items that can be queued to the database engine thread pool at any time.
QueueDatabaseOnlineDefragEnabled	True	The key enables or disables scheduled online defragmentation of the mail queue database. By default, this key doesn't exist in the EdgeTransport.exe.config file.
QueueDatabaseOnlineDefragSchedule	`1:00:00` or 1:00 A.M.	This key specifies the time of day in 24 hour format to start the online defragmentation of the mail queue database. To specify a value, enter the value as a time: *hh:mm:ss*, where *h* = hours, *m* = minutes, and *s* = seconds.
QueueDatabaseOnlineDefragTimeToRun	`3:00:00` or 3 hours	This key specifies the length of time the online defragmentation task is allowed to run. Even if the defragmentation task doesn't finish in the time specified, the queue database is left in a consistent state. To specify a value, enter the value as a time span: *hh:mm:ss*, where *h* = hours,

		m = minutes, and *s* = seconds.
QueueDatabasePath	`%ExchangeInstallPath%TransportRoles\data\Queue`	This key specifies the default directory for the queue database files. For instructions on how to change the location of the queue database, see Change the location of the queue database.

Note:

Any customized per-server settings you make in Exchange XML application configuration files, for example, web.config files on Client Access servers or the EdgeTransport.exe.config file on Mailbox servers, will be overwritten when you install an Exchange Cumulative Update (CU). Make sure that you save this information so you can easily re-configure your server after the install. You must re-configure these settings after you install an Exchange CU.

Return to top

Queue properties

A queue has many properties that describe the purpose and status of the queue. Some queue properties are applied to the queue when the queue is created, and don't change. Other properties contain status size, time, or other indicators that are updated frequently.

Return to top

NextHopSolutionKey

The routing component of the categorizer in the Microsoft Exchange Transport service selects the destination for a message, and this destination is used to create the delivery queue. The destination is stamped on every recipient as the **NextHopSolutionKey** attribute. Every unique value of the **NextHopSolutionKey** attribute corresponds to a separate delivery queue.

The **NextHopSolutionKey** attribute contains the following fields:

- **DeliveryType** The value of this field represents the results of the categorization of the message, and how the Transport service intends to transmit the message to the next hop, which could be the ultimate destination of the message, or an intermediate hop along the way. The Transport service uses a predefined list of values for **DeliveryType** based on the target routing destination or delivery group.
- **NextHopDomain** This field uses specific values based on the value of the **DeliveryType** field. For delivery queues, the value of this field is effectively the name of the queue. The value of **NextHopDomain** isn't always a domain name. For example, the value could be the name of the

target Active Directory site or database availability group (DAG). Think of this field as the next hop name, where the value is the name of the routing destination or the target delivery group.

- **NextHopConnector** This field uses specific values based on the value of the **DeliveryType** field. The value is always expressed as a GUID. If this field isn't used, the value is a GUID with all zeroes. The value of **NextHopConnector** isn't always the GUID of a connector. For example, the value could be the GUID of the target Active Directory site or DAG. Think of this field as the next hop GUID, where the value is the GUID of the routing destination or the target delivery group.

Exchange 2013 also adds the **NextHopCategory** property to the queue based on the value of **DeliveryType**. The value of **NextHopCategory** is `External` or `Internal`. The value `External` indicates the next hop of the queue is outside the Exchange organization. The value `Internal` indicates the next hop of the queue is inside the Exchange organization. Note that a message for an external recipient may require one or more internal hops before the message is delivered externally.

The values of **DeliveryType**, **NextHopCategory**, **NextHopDomain** and **NextHopConnector** are described in the following table.

Delivery Type in Queue Viewer	DeliveryType in the Shell	Description	NextHopCategory	NextHopDomain	NextHopConnector
Delivery Agent	**DeliveryAgent**	The queue holds messages for delivery to recipients in a non-SMTP address space. The messages are delivered by using a Delivery Agent connector that's configured on the local server.	External	This value is the destination address space that's configured on the Delivery Agent connector.	This value is he GUID of the Delivery Agent connector. For example, `4520e633-d83d-411a-bbe4-6a84648674ee`.
DnsConnectorDelivery	**DnsConnectorDelivery**	The queue holds messages for delivery to recipients in an SMTP address	External	This value is the destination address space that's configured on the Send	This value is the GUID of the Send connector. For example,

		space. The messages are delivered by using a Send connector that's configured on the local server. The Send connector is configured to use DNS routing.		connector. For example, `contoso.com`.	`4520e633-d83d-411a-bbe4-6a84648674ee`.
NonSmtpGatewayDelivery	**NonSmtpGatewayDelivery**	The queue holds messages for delivery to recipients in a non-SMTP address space. The messages are delivered by using a Foreign connector that's configured on the local server.	External	This value is the destination address space that's configured on the Foreign connector.	This value is the GUID of the Foreign connector. For example, `4520e633-d83d-411a-bbe4-6a84648674ee`.
SmartHostConnectorDelivery	**SmartHostConnectorDelivery**	The queue holds messages for delivery to recipients in an SMTP address space. The messages are delivered by using a Send connector that's	External	This value is the list of smart hosts that are configured on the Send connector. Smart hosts can be configured as FQDNs, IP addresses or both. The values	This value is the GUID of the Send connector. For example, `4520e633-d83d-411a-bbe4-6a84648674ee`.

		configured on the local server. The Send connector is configured to use smart host routing.		can be one of the following: • **FQDN** The syntax is `<FQDN1,FQDN2,...>`. For example, `smarthost01.contoso.com` or `smarthost01.contoso.com,smarthost02.fabrikam.com`. • **IP address** The syntax is `<[IPAddress1],[IPAddress2],...>`. For example, `[10.10.10.100]` or `[10.10.10.100],[10.10.10.101]`. • **FQDN and IP address** The syntax is `<[IPAddress1],FQDN1,...>`, and depends on how the smart hosts are listed on the Send connector. For example, `[172.17.17.7],relay.tailspintoys.com` or	

				`mail.contoso.com, [192.168.1.50]`.	
SMTP Delivery to Mailbox	**SmtpDeliveryToMailbox**	The queue holds messages for delivery to Exchange 2013 mailbox recipients. The destination mailbox database is in one of the following locations: • The local Exchange 2013 Mailbox server. • An Exchange 2013 Mailbox server in the same DAG. • An Exchange 2013 Mailbox server in the same Active Directory site in non-DAG environments.	Internal	This value is the name of the destination mailbox database. For example, `Mailbox Database 0471695037`.	This value is the GUID of the target mailbox database. For example, `6dcb5a1e-0a88-4fc9-b8f9-634c34b1a123`.
SMTP Relay to Send Connector Source Servers	**SmtpRelayToConnectorSourceServers**	The queue holds messages for delivery to SMTP or non-SMTP recipients. The	Internal	This value is the name of the destination Send connector, Delivery Agent	This value is the GUID of the destination Send

		messages are delivered by using a Send connector, Delivery Agent connector, or Foreign connector that's configured on a remote transport server. The remote transport server could be an Exchange 2013 Mailbox server, or an Exchange 2007 or Exchange 2010 Hub Transport server from a previous version of Exchange. The remote server could be located in the local Active Directory site, or in a remote Active Directory site.		connector, or Foreign connector. For example, `Contoso.com Send Connector`.	connector, Delivery Agent connector, or Foreign connector. For example, `4520e633-d83d-411a-bbe4-6a84648674ee`.
SMTP Relay to Database Availability Group	**SmtpRelayToDag**	The queue holds messages for delivery to Exchange 2013 mailbox	Internal	This value is the name of the destination DAG. For example, `DAG1`.	This value is the GUID of the destination DAG. For

		recipients, where the destination mailbox database is located in a remote DAG. The remote DAG could be in the local Active Directory site, or a remote Active Directory site.			example, `6dcb5a1e-0a88-4fc9-b8f9-634c34b1a123`
SMTP Relay to Mailbox Delivery Group	**SmtpRelayToMailboxDeliveryGroup**	The queue holds messages for delivery to legacy mailbox recipients, where the destination mailbox is on an Exchange 2007 or Exchange 2010 Mailbox server. The message is related to a Hub Transport server that's running the same version of Exchange as the destination mailbox. The destination Hub Transport server could be in the	Internal	The queue name uses the syntax: `Site:<ADSiteName>;Version:<ExchangeVersion>`, where *<ADSiteName>* is the name of the destination Active Directory site, and *<ExchangeVersion>* is the version of Exchange on the Mailbox server.	This value is blank.

		local Active Directory site, or a remote Active Directory site.			
SMTP Relay to Remote Active Directory Site	**SmtpRelayToRemoteActiveDirectorySite**	The queue holds messages for delivery to a remote destination, and the routing topology requires the message to be routed through a specific Active Directory site. The site is an intermediate hop on the way to the final destination. This situation occurs under the following circumstances: • The message needs to be routed through a hub site. • The message requires delivery through a Send connector that's configured on	Internal	This value is the target Active Directory site name. For example, `NorthAmericanSite`.	This value is the GUID of the target Active Directory site. For example, `bfd6c3df-5b65-8bfb-53f1f2c0d55c`.

		an Edge Transport server that's subscribed to a remote Active Directory site.			
SMTP Relay to Specified Exchange Servers	**SmtpRelayToServers**	The queue holds messages for delivery to a distribution group that's configured for a specific expansion server. The expansion could be an Exchange 2013 Mailbox server, or an Exchange 2007 or Exchange 2010 Hub Transport server. The server could be in the local Active Directory site, or in a remote Active Directory site.	Internal	This value is the FQDN of the target expansion server. For example, `mailbox01.contoso.com`.	This value is `00000000-0000-0000-0000-000000000000`.
SMTP Relay in Active Directory Site to Edge Transport Server	**SmtpRelayWithinAdSiteToEdge**	The queue holds messages for delivery to an SMTP address space. The messages are	Internal	This value is the name of the Send connector that sends outbound Internet mail from the organization	This value is the GUID of the Send connector. For example, `4520e633-d83d-411a-bbe4-`

		delivered by using a Send connector that's configured on an Edge Transport server that's subscribed to the local Active Directory site.		to the Internet. This Send connector is automatically created by the Edge subscription, and is named `EdgeSync - <ADSiteName> to Internet`. *<ADSiteName>* is the name of the local Active Directory site to which the Edge Transport server is subscribed.	`6a84648674ee.`
Heartbeat	**Heartbeat**	This value is reserved for internal Microsoft use. For more information about heartbeat, see Shadow redundancy.	n/a	n/a	n/a
Shadow Redundancy	**ShadowRedundancy**	The queue holds messages in a shadow queue. A shadow queue holds redundant copies messages in transit in case the primary	Internal	This value is the FQDN of the primary server for which the shadow queue is holding redundant copies of the primary messages. For	This value is `00000000-0000-0000-0000-000000000000.`

		messages aren't successfully delivered. For more information, see Shadow redundancy.		example, `mailbox01.contoso.com`.	
Undefined	**Undefined**	This value is used only on the Submission queue and the poison message queue.	Internal	For the Submission queue, this value is `Submisssion`. For the poison message queue, this value is `Poison Message`.	This value is `00000000-0000-0000-0000-000000000000`.
Undreachable	**Unreachable**	This value is used only on the Unreachable queue.	Internal	This value is `Unreachable Domain`.	This value is `00000000-0000-0000-0000-000000000000`.

Note that Exchange 2013 supports legacy values of **DeliveryType** for backwards compatibility with previous versions of Exchange. These values are available in Queue Viewer and the Shell, but they aren't used by Exchange 2013. These legacy **DeliveryType** values are:

- **MapiDelivery** The queue holds messages for delivery by an Exchange 2007 or Exchange 2010 Hub Transport server to a mailbox on an Exchange 2007 or Exchange 2010 Mailbox server in the local Active Directory site.
- **SmtpRelayWithinAdSite** The queue holds messages for delivery by an Exchange 2007 or Exchange 2010 Hub Transport server to another Hub Transport server in the same Active Directory site. The destination Hub Transport server can be the source server for a connector, or a distribution group expansion server.
- **SmtpRelaytoTiRg** The queue holds messages for delivery by an Exchange 2007 or Exchange 2010 Hub Transport server to an Exchange Server 2003 routing group. The destination server can be the source server for a connector, a distribution group expansion server, or an Exchange 2003 bridgehead server.

Return to top

IncomingRate, OutgoingRate, and Velocity

Exchange 2013 measures the rate of messages entering and leaving a queue and stores these values in queue properties. You can use these rates as an indicator of queue and transport server health. The properties are:

- **IncomingRate** This property is the rate that messages are entering the queue.

This value is calculated from the number of messages entering the queue every 5 seconds averaged over the last 60 seconds. The formula can be expressed as `(i1+i2+i3+i4+i5+i6)/6`, where i*n* = the number of incoming messages in 5 seconds.

- **OutgoingRate** This property is the rate that messages are leaving the queue.

This value is calculated from the number of messages leaving the queue every 5 seconds averaged over the last 60 seconds. The formula can be expressed as `(o1+o2+o3+o4+o5+o6)/6`, where o*n* = the number of outgoing messages in 5 seconds.

- **Velocity** This property is the drain rate of the queue, and is calculated by subtracting the value of **IncomingRate** from the value of **OutgoingRate**.

If the value of **Velocity** is greater than 0, messages are leaving the queue faster than they are entering the queue.

If the value of **Velocity** is equals 0, messages are leaving the queue as fast as they are entering the queue. This is also the value you'll see when the queue is inactive.

If the value of **Velocity** is less than 0, messages are entering the queue faster than they are leaving the queue.

At a basic level, a positive value of **Velocity** indicates a healthy queue that's efficiently draining, and a negative value of **Velocity** indicates a queue that isn't efficiently draining. However, you also need to consider the values of the **IncomingRate**, **OutgoingRate**, and **MessageCount** properties, as well as the magnitude of the **Velocity** value for the queue. For example, a queue that has a large negative value of **Velocity**, a large **MessageCount** value, a small **OutgoingRate** value, and a large **IncominRate** value are accurate indicators that the queue isn't draining properly. However, a queue with a negative **Velocity** value that's very close to zero that also has very small values for **IncomingRate**, **OutgoingRate**, and **MessageCount** doesn't indicate a problem with the queue.

Return to top

Queue status

The current status of a queue is stored in the **Status** property of the queue. A queue can have one of the following status values:

- **Active** The queue is actively transmitting messages.
- **Connecting** The queue is in the process of connecting to the next hop.
- **Ready** The queue recently transmitted messages, but the queue is now empty.
- **Retry** The last automatic or manual connection attempt failed, and the queue is waiting to retry the connection.

- **Suspended** The queue has been manually suspended by an administrator to prevent message delivery. New messages can enter the queue, and messages that are in the act of being transmitted to the next hop will finish delivery and leave the queue. Otherwise, messages won't leave the queue until the queue is manually resumed by an administrator. Note that suspending a queue doesn't change the status of the individual messages in the queue.

You can suspend a queue that has a status of Active or Retry. You can also suspend the Unreachable queue and the Submission queue.

If you suspend the Unreachable queue, messages won't be automatically resubmitted to the categorizer when configuration updates are detected. To automatically resubmit these messages, you need to manually resume the Unreachable queue. If you suspend the Submission queue, messages won't be picked up by the categorizer until the queue is resumed.

Return to top

Other queue properties

There are other queue properties that are self-explanatory. You use most of the queue properties as filter options. By specifying filter criteria, you can quickly locate queues and take action on them. For a complete description of the filterable queue properties, see Queue filters.

An important queue property that's also worth mentioning here is the **MessageCount** property that shows how many messages are in a queue. This property is an important indicator of queue health. For example, a delivery queue that contains a large number of messages that continues to grow and never decreases could indicate a routing or transport pipeline issue that requires your attention.

Return to top

Message properties

A message in a queue has many properties. Many of the properties reflect the information that was used to create the message. Some of the messages status and information properties are heavily influenced by corresponding properties on the queue. However, an individual message may have a different value than the corresponding property of the queue. Other properties contains status, time, or other indicators that are updated frequently.

Return to top

Message status

The current status of a message is stored in the **Status** property of the message. A message can have one of the following status values:

- **Active** If the message is in a delivery queue, the message is being delivered to its destination. If the message is in the Submission queue, the message is being processed by the categorizer.

- **Locked** This value is reserved for internal Microsoft use, and isn't used in on-premises Exchange organizations.
- **PendingRemove** The message was deleted by the administrator, but the message was already in the act of being transmitted to the next hop. The message will be deleted if the delivery ends in an error that causes the message to reenter the queue. Otherwise, delivery will continue.
- **PendingSuspend** The message was suspended by the administrator, but the message was already in the act of being transmitted to the next hop.. The message will be suspended if the delivery ends in an error that causes the message to reenter the queue. Otherwise, delivery will continue.
- **Ready** The message is waiting in the queue and is ready to be processed.
- **Retry** The last automatic or manual connection attempt for the queue in which this message is located failed. The message is waiting for the next automatic queue connection retry.
- **Suspended** The message was manually suspended by the administrator. All messages in the poison message queue are in a permanently suspended state.

Return to top

Other message properties

There are other message properties that are self-explanatory. You can use most of the message properties as filter options. By specifying filter criteria, you can quickly locate messages and take action on them. For a complete description of the filterable message properties, see Message filters.

Return to top

Manage queues and messages in queues

Queue Viewer and virtually all of the queue and message management cmdlets are restricted to a single Exchange server. You can view or operate on individual queues or messages, or multiple queues or messages, but only on a specific server.

Exchange 2013 introduces the **Get-QueueDigest** cmdlet that provides a high-level, aggregate view of the state of queues on all servers within a specific scope, for example, a DAG, an Active Directory site, a list of servers, or the entire Active Directory forest. Note that queues on a subscribed Edge Transport server in the perimeter network aren't included in the results. Also, **Get-QueueDigest** is available on an Edge Transport server, but the results are restricted to queues on the Edge Transport server.

Note:
By default, the **Get-QueueDigest** cmdlet displays delivery queues that contain ten or more messages, and the results are between one and two minutes old. For instructions on how to change these default values, see Configure Get-QueueDigest.

The following table describes the management tasks you can perform on queues or messages in

queues.

Task	Description	Tool to use	Instructions
View and filter queues on a server	This action displays one or more queues on a transport server. You can use the results to take action on the queues.	Queue Viewer or the **Get-Queue** cmdlet.	Manage queues
View and filter queues on specific servers in specific DAGs, specific Active Directory sites, or in the whole Active Directory forest.	This action displays a summary view of queues across a defined scope (servers, DAGs, Active Directory sites, or the entire Active Directory forest).	**Get-QueueDigest** cmdlet only	Manage queues
Suspend queues	This action temporarily prevents delivery of messages that are currently in the queue. The queue continues to accept new messages, but no messages leave the queue.	Queue Viewer or the **Suspend-Queue** cmdlet.	Manage queues
Resume queues	This action reverses the effect of the suspend queue action and enables delivery of queued messages to resume.	Queue Viewer or the **Resume-Queue** cmdlet.	Manage queues
Retry queues	This action immediately tries to	Queue Viewer or the **Retry-Queue** cmdlet.	Manage queues

	connect to the next hop. Without manual intervention, when the connection to the next hop fails, the connection is attempted a specific number of times after a specific time interval between each attempt. Whether the connection attempt is manual or automatic, any connection attempt resets the next retry time. For more information, see Message retry, resubmit, and expiration intervals.		
Resubmit messages in queues	This action causes the messages in the queue to be resubmitted to the Submission queue and to go back through the categorization process.	**Retry-Queue** with the *Resubmit* parameter Note that you can use Queue Viewer to resubmit messages, but only from the poison message queue. To resubmit a message in poison message, you resume the message in Queue Viewer, or by using the **Resume-**	Manage queues

		Message cmdlet.	
Suspend messages in queues	This action temporarily prevents delivery of a message. You can use the suspend message action to prevent delivery of a message to all the recipients in a specific queue or to all recipients in all queues.	Queue Viewer or the **Suspend-Message** cmdlet.	Manage messages in queues
Resume messages in queues	This action reverses the effect of the suspend message action and enables delivery of queued messages to resume. You can use the resume message action to resume delivery of a message to all the recipients in a specific queue or to all recipients in all queues.	Queue Viewer or the **Resume-Message** cmdlet.	Manage messages in queues
Remove messages from queues	This action permanently prevents delivery of a message. You can use the remove message action to prevent delivery of a message to any recipients in a specified queue or to	Queue Viewer or the **Remove-Message** cmdlet.	Manage messages in queues

	all recipients in all queues. You can also configure the remove message action to send a non-delivery report (NDR) to the sender when the message is removed.		
Export messages from queues	This action copies a message to the file path that you specify. The messages aren't deleted from the queue, but a copy of the message is saved to a file location. This enables administrators or officials in an organization to later examine the messages. Before you export a message, you need to suspend the message in the queue so that typical delivery doesn't continue during the export process.	**Export-Message** cmdlet only.	Export messages from queues

Manage queues

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-01-31*

In Microsoft Exchange Server 2013, you can use the Queue Viewer in the Exchange Toolbox or the Exchange Management Shell to manage queues. For more information about using the queue management cmdlets in the Exchange Management Shell, see Use the Exchange Management Shell to manage queues.

What do you need to know before you begin?

- Estimated time to complete each procedure: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Queues" entry in the Mail flow permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

View queues

Use Queue Viewer in the Exchange Toolbox to view queues

1. Click **Start** > **All Programs** > **Microsoft Exchange 2013** > **Exchange Toolbox**.
2. In the **Mail flow tools** section, double-click **Queue Viewer** to open the tool in a new window.
3. In Queue Viewer, click the **Queues** tab. A list of all queues on the server to which you're connected is displayed.
4. You can use the **Export List** link in the action pane to export the list of queues. For more information, see Export lists from Queue Viewer.

Use the Shell to view queues

To view queues, use the following syntax.

```
Get-Queue [-Filter <Filter> -Server <ServerIdentity> -
Include <Internal | External | Empty | DeliveryType> -
Exclude <Internal | External | Empty | DeliveryType>]
```

This example displays basic information about all non-empty queues on the Exchange 2013 Mailbox server named Mailbox01.

```
Get-Queue -Server Mailbox01 -Exclude Empty
```

This example displays detailed information for all queues that contain more than 100 messages on the Mailbox server on which the command is run.

```
Get-Queue -Filter {MessageCount -gt 100} | Format-List
```

Use the Shell to view queue summary information on multiple Exchange servers

The **Get-QueueDigest** cmdlet provides a high-level, aggregate view of the state of queues on all servers within a specific scope, for example, a DAG, an Active Directory site, a list of servers, or the entire Active Directory forest. Note that queues on a subscribed Edge Transport server in the perimeter network aren't included in the results. Also, **Get-QueueDigest** is available on an Edge Transport server, but the results are restricted to queues on the Edge Transport server.

Note:

By default, the **Get-QueueDigest** cmdlet displays delivery queues that contain ten or more messages, and the results are between one and two minutes old. For instructions on how to change these default values, see Configure Get-QueueDigest.

To view summary information about queues on multiple Exchange servers, run the following command:

```
Get-QueueDigest <-Server
<ServerIdentity1,ServerIdentity2,..> | -Dag
<DagIdentity1,DagIdentity2...> | -Site
<ADSiteIdentity1,ADSiteIdentity2...> | -Forest> [-Filter
<Filter>]
```

This example displays summary information about the queues on all Exchange 2013 Mailbox servers in the Active Directory site named FirstSite where the message count is greater than 100.

```
Get-QueueDigest -Site FirstSite -Filter {MessageCount -gt
100}
```

This example displays summary information about the queues on all Exchange 2013 Mailbox servers in the database availability group (DAG) named DAG01 where the queue status has the value **Retry**.

```
Get-QueueDigest -Dag DAG01 -Filter {Status -eq "Retry"}
```

Resume queues

By resuming a queue, you restart outgoing activities on a queue that has a status of Suspended. The queue must have a status of Suspended for this action to have any effect. When you resume a

queue, the status of messages in the queue doesn't change. Messages that have a status of Suspended remain suspended and don't leave the queue.

Use Queue Viewer in the Exchange Toolbox to resume queues

1. Click **Start** > **All Programs** > **Microsoft Exchange 2013** > **Exchange Toolbox**.
2. In the **Mail flow tools** section, double-click **Queue Viewer** to open the tool in a new window.
3. In Queue Viewer, click the **Queues** tab. A list of all queues on the server to which you're connected is displayed.
4. Click **Create Filter**, and enter your filter expression as follows:
   a. Select **Status** from the queue property drop-down list.
   b. Select **Equals** from the comparison operator drop-down list.
   c. Select **Suspended** from the value drop-down list.
5. Click **Apply Filter**. All queues on the server that are currently suspended are displayed.
6. Select one or more queues from the list, right-click, and then select **Resume**.

Use the Shell to resume queues

To resume queues, use the following syntax.

```
Resume-Queue <-Identity QueueIdentity | -Filter
{QueueFilter} [-Server ServerIdentity]>
```

This example resumes all queues on the local server that have a status of Suspended.

```
Resume-Queue -Filter {Status -eq "Suspended"}
```

This example resumes the suspended delivery queue named contoso.com on the server named Mailbox01.

```
Resume-Queue -Identity Mailbox01\contoso.com
```

How do you know this worked?

To verify that you have successfully resumed a queue, do the following:
1. Use the Queue Viewer or the **Get-Queue** cmdlet to find the queue you attempted to resume.
2. Verify the queue **Status** property doesn't have the value Suspended.

Retry queues

When a transport server can't connect to the next hop, the delivery queue is put in a status of Retry. When you retry a delivery queue by using Queue Viewer or the Shell, you force an immediate connection attempt and override the next scheduled retry time. If the connection isn't successful, the retry interval timer is reset. The delivery queue must be in a status of Retry for this action to have any effect.

Use Queue Viewer in the Exchange Toolbox to retry a queue

1. Click **Start** > **All Programs** > **Microsoft Exchange 2013** > **Exchange Toolbox**.
2. In the **Mail flow tools** section, double-click **Queue Viewer** to open the tool in a new window.
3. In Queue Viewer, click the **Queues** tab. A list of all queues on the server to which you're connected is displayed.
4. Click **Create Filter**, and enter your filter expression as follows:
   a. Select **Status** from the queue property drop-down list.
   b. Select **Equals** from the comparison operator drop-down list.
   c. Select **Retry** from the value drop-down list.
5. Click **Apply Filter**. All queues that currently have a **Retry** status are displayed.
6. Select one or more queues from the list. Right-click, and then select **Retry Queue**. If the connection attempt is successful, the queue status changes to **Active**. If no connection can be made, the queue remains in a status of **Retry** and the next retry time is updated.

Use the Shell to retry a queue

To retry queues, use the following syntax.

```
Retry-Queue <-Identity QueueIdentity | -Filter QueueFilter
[-Server ServerIdentity]>
```

This example retries all queues on the local server with the status of Retry.

```
Retry-Queue -Filter {status -eq "retry"}
```

This example retries the queue named contoso.com that's in the `Retry` state on the server named Mailbox01.

```
Retry-Queue -Identity Mailbox01\contoso.com
```

How do you know this worked?

To verify that you have successfully retried a queue, do the following:
1. Use the Queue Viewer or the **Get-Queue** cmdlet to find the queue you attempted to retry.
2. Verify the queue **LastRetryTime** property matches the time you attempted to retry the queue.

Resubmit messages in queues

Resubmitting a queue is similar to retrying a queue, except the messages are sent back to the Submission queue for the categorizer to reprocess. You can resubmit messages that have the following status:

- Delivery queues that have the status of Retry. The messages in the queues can't be in the Suspended state.
- Messages in the Unreachable queue that aren't in the Suspended state.
- Messages in the poison message queue.

Use the Shell to resubmit messages

To resubmit messages, use the following syntax.

```
Retry-Queue <-Identity QueueIdentity | -Filter {Status -eq "Retry"} -Server ServerIdentity> -Resubmit $true
```

This example resubmits all messages located in any delivery queues with the status of Retry on the server named Mailbox01.

```
Retry-Queue -Filter {Status -eq "Retry"} -Server Mailbox01 -Resubmit $true
```

This example resubmits all messages located in the Unreachable queue on the server Mailbox01.

```
Retry-Queue -Identity Mailbox01\Unreachable -Resubmit $true
```

Resubmit messages in the poison message queue

You resubmit messages in the poison message queue by resuming the message. You can use the Queue Viewer or the Shell to resubmit messages from the poison message queue. Note that the poison message queue is only visible in Queue Viewer when there are messages in the poison message queue.

Note:

The poison message queue contains messages that are determined to be harmful to the Exchange system after a server failure. The messages may be genuinely harmful in their content or format. Alternatively, they may be victims of a poorly written agent that crashed the Exchange server while it was processing the supposedly bad messages. If you're unsure of the safety of the messages in the poison message queue, you should export the messages to files so that you can examine them. For more information, see Export messages from queues.

Use Queue Viewer in the Exchange Toolbox to resubmit messages in the poison message queue

1. Click **Start** > **All Programs** > **Microsoft Exchange 2013** > **Exchange Toolbox**.
2. In the **Mail flow tools** section, double-click **Queue Viewer** to open the tool in a new window.
3. In Queue Viewer, click the **Queues** tab. A list of all queues on the server to which you're connected is displayed.
4. Click the poison message queue. In the action pane, select **View Messages**.
5. Select one or more messages from the list, right-click, and select **Resume**.

Use the Shell to resubmit messages in the poison message queue

To resubmit a message from the poison message queue, perform the following steps.

1. Find the identity of the message by running the following command.

```
Get-Message -Queue Poison | Format-Table Identity
```

2. Use the identity of the message from the previous step in the following command.

```
Resume-Message <PoisonMessageIdentity>
```

This example resumes a message from the poison message queue that has the message Identity value of 222.

```
Resume-Message 222
```

How do you know this worked?

To verify that you have successfully resubmitted a message from the poison message queue, do the following:

1. Use the Queue Viewer or the **Get-Queue** cmdlet to view the poison message queue where you attempted to resubmit the message.
2. Verify the message is no longer in the poison message queue. Note that an empty poison message queue doesn't appear in the Queue Viewer or the **Get-Queue** cmdlet. Therefore, if the message you resubmitted was the only message in the poison message queue, and the poison message queue is no longer visible, that is also an indication of a successful message resubmission.

Suspend queues

When you suspend a queue, you prevent messages from leaving the queue, but you don't change the status of messages in the queue. Messages that are in delivery through SMTP-send will finish operations. You can suspend a queue to stop mail flow, and then suspend one or more messages in the queue. When you resume the queue, the messages that were suspended won't leave the queue.

You can suspend a queue that has a status of Active or Retry. You can also suspend the Unreachable queue and the Submission queue.

If you suspend the Unreachable queue, items won't be resubmitted to the categorizer when configuration updates are received by the transport server until the queue is resumed. If you suspend the Submission queue, messages won't be picked up by the categorizer until the queue is resumed.

Use Queue Viewer in the Exchange Toolbox to suspend a queue

1. Click **Start** > **All Programs** > **Microsoft Exchange 2013** > **Exchange Toolbox**.
2. In the **Mail flow tools** section, double-click **Queue Viewer** to open the tool in a new window.
3. In Queue Viewer, click the **Queues** tab. A list of all queues on the server to which you're connected is displayed. You can create a filter to display only queues that meet specific criteria.
4. Select one or more queues, right-click, and then select **Suspend**.

Use the Shell to suspend a queue

To suspend a queue, use the following syntax.

```
Suspend-Queue <-Identity QueueIdentity | -Filter
```

```
{QueueFilter} [-Server ServerIdentity]>
```

This example suspends all queues on the local server that have a message count equal to or greater than 1,000 and that have a status of Retry.

```
Suspend-Queue -Filter {MessageCount -ge 1000 -and Status -
eq "Retry"}
```

This example suspends the queue named contoso.com on the server named Mailbox01.

```
Suspend-Queue -Identity Mailbox01\contoso.com
```

How do you know this worked?

To verify that you have successfully suspended a queue, do the following:
1. Use the Queue Viewer or the **Get-Queue** cmdlet to find the queue you attempted to suspend.
2. Verify the queue **Status** property has the value Suspended.

Use the Exchange Management Shell to manage queues

Exchange Server 2013 > Mail flow > Queues >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-01-31*

As in previous versions of Exchange, you can use the Exchange Management Shell in Microsoft Exchange Server 2013 to view information about queues and the messages in those queues, and to perform management actions on queues and messages. In Exchange 2013, queues exist on Mailbox servers and Edge Transport servers. This topic refers to these servers as *transport servers*.

When you use the Shell to view and manage queues and messages in queues on transport servers, it's important to understand how to identify the queues or messages you want to manage. Typically, transport servers contain a large number of queues and messages to be delivered. You use the filtering parameters that are available on the queue and message management cmdlets to identify the queues or messages that you want to view or manage.

Note that you can also use Queue Viewer in the Exchange Toolbox to manage queues and messages in queues. However, the queue and message viewing cmdlets support more filterable properties and filter options than Queue Viewer. For more information about using Queue Viewer, see Queue Viewer.

Contents

- Queue filtering parameters
  - Queue identity
  - Queue Filter parameter
  - Include and Exclude parameters
- Get-QueueDigest
- Message filtering parameters
  - Message identity
  - Message Filter parameter
  - Queue parameter
- Comparison operators to use when filtering queues or messages
- Advanced paging parameters

Queue filtering parameters

The following table describes the filtering parameters that are available on the queue management cmdlets.

Cmdlet	Filtering parameters	Comments
Get-Queue	*Identity* *Filter* *Include* *Exclude*	You can't use the *Identity* parameter in the same command with the *Filter* parameters. You can use the *Include* and *Exclude* parameters with the *Filter* parameter in the same command.
Resume-Queue **Retry-Queue** **Suspend-Queue**	*Identity* *Filter*	You need to use either the *Identity* parameter or the *Filter* parameter, but you can't use both in the same command.
Get-QueueDigest	*Server* *Dag* *Site* *Forest* *Filter*	You need to use the *Server*, *Dag*, *Site*, or *Forest* parameter, but you can't use any of them together in the same command. You can use the *Filter* parameter with any of the

		other filtering parameters.

Note that a *Server* parameter is available on all queue management cmdlets. On the **Get-QueueDigest** cmdlet, the *Server* parameter is a scope parameter that specifies the server or servers where you want to view summary information about queues. On all other queue management cmdlets, you use the *Server* parameter to connect to a specific server, and run the queue management commands on that server. You can use the *Server* parameter with or without the *Filter* parameter, but you can't use the *Server* parameter with the *Identity* parameter. You use the transport server's hostname or FQDN with the *Server* parameter.

Return to top

Queue identity

The *Identity* parameter on the queue management cmdlets identifies a specific queue. When you use the *Identity* parameter, you can't specify any other queue filtering parameters, because you've already uniquely identified the queue. The *Identity* parameter uses the basic syntax <*Server*>\<*Queue*>.

The <*Server*> placeholder is the hostname or FQDN of the Exchange server, for example `mailbox01` or `mailbox01.contoso.com`. If you omit the <*Server*> qualifier, the local server is implied.

The <*Queue*> placeholder accepts one of the following values:

- **Persistent queue name** Persistent queues have unique, consistent names on all Mailbox or Edge Transport servers. The persistent queue names are:
  - **Submission** This queue contains messages waiting to be processed by the categorizer.
  - **Unreachable** This queue contains messages that can't be routed. This queue doesn't exist until messages are placed in it.
  - **Poison** This queue contains messages that are determined to be harmful to the Exchange server. This queue doesn't exist until messages are placed in it.
- **Delivery queue name** The name of a delivery queue is the value of the **NextHopDomain** property of the queue. For example, the queue name could be the address space of a Send connector, the name of an Active Directory site, or the name of a DAG. For more information, see the "NextHopSolutionKey" section in the Queues topic.
- **Queue integer** Delivery queues and shadow queues are assigned a unique integer value in the queue database. However, you need to run the **Get-Queue** cmdlet to find the integer value for the queue in the **Identity** or **QueueIdentity** properties.
- **Shadow queue name** A shadow queue uses the syntax `Shadow\`<*QueueInteger*>

The following table summarizes the syntax you can use with *Identity* parameter on the queue management cmdlets. In all values, <*Server*> is the hostname or FQDN of the server.

Queue identity formats

Identity parameter value	Description

`<Server>\<PersistentQueueName>` or `<PersistentQueueName>`	A persistent queue on the specified server or the local server. *<PersistentQueueName>* is `Submission`, `Unreachable`, or `Poison`.
`<Server>\<NextHopDomain>` or `<NextHopDomain>`	A delivery queue on the specified server or the local server. *<NextHopDomain>* is a routing destination or delivery group for the messages in the queue. For more information, see the "NextHopSolutionKey" section in the Queues topic.
`<Server>\<QueueInteger>` or `<QueueInteger>`	A delivery queue on the specified server or the local server. *<QueueInteger>* is the unique integer value of the queue that's displayed in the **Identity** property of the **Get-Queue** cmdlet.
`<Server>\Shadow\<QueueInteger>` or `Shadow\<QueueInteger>`	A shadow queue on the specified server or the local server.
`<Server>\*` or `*`	All queues on the specified server or the local server. Note that these values can only be used with the **Get-Queue** cmdlet.

Return to top

Queue Filter parameter

You can use the *Filter* parameter on the all of the queue management cmdlets to specify the queues you want to view or manage based on the properties of the queues. The *Filter* parameter creates an expression with comparison operators that restricts the queue operation to queues that meet the filter criteria. You can use the `-and` logical operator to specify multiple conditions that the results must match.

For a complete list of queue properties you can use with the *Filter* parameter, see Queues.

For a list of comparison operators you can use with the *Filter* parameter, see the Comparison operators to use when filtering queues or messages section in this topic.

For examples of procedures that use the *Filter* parameter to view and manage queues, see Manage queues.

Return to top

Include and Exclude parameters

Exchange 2013 has the *Include* and *Exclude* parameters available on the `Get-Queue` cmdlet. You can use these parameters individually, together, and with the *Filter* parameter to fine-tune your queue results on the local or specified transport server. For example, you can:

- Exclude empty queues from the results.
- Exclude queues to external destinations from the results.
- Include queues that have a specific value of **DeliveryType** in the results.

The *Include* and *Exclude* parameters use the following queue properties to filter queues:

Value	Description	Shell code example
`DeliveryType`	This value includes or excludes queues based on the **DeliveryType** property. You can specify multiple values separated by commas. The valid values for **DeliveryType** are explained in the "NextHopSolutionKey" section in the topic Queues topic.	This example returns all delivery queues on the local server where the next hop is a Send connector on the local server that's configured for smart host routing: `Get-Queue -Include SmartHostConnectorDelivery`
`Empty`	This value includes or excludes empty queues. Empty queues have the value `0` in the **MessageCount** property.	This example returns all queues on the local server that contain messages `Get-Queue -Exclude Empty`
`External`	This value includes or excludes queues that have the value `External` in the **NextHopCategory** property. External queues always have one of the following values for	This example returns all internal queues on the local server `Get-Queue -Exclude External`

	DeliveryType: • `DeliveryAgent` • `DnsConnectorDelivery` • `NonSmtpGatewayDelivery` • `SmartHostConnectorDelivery` For more information, see the "NextHopSolutionKey" section in the Queues topic.	
`Internal`	This value includes or excludes queues that have the value `Internal` in the **NextHopCategory** property. For more information, see the "NextHopSolutionKey" section in the Queues topic.	This example returns all internal queues on the local server. `Get-Queue -Include Internal`

Note that you can duplicate the functionality of the *Include* and *Exclude* parameters by using the *Filter* parameter. For example, the command `Get-Queue -Exclude Empty` yields the same result as `Get-Queue -Filter {MessageCount -gt 0}`. However, the syntax of the *Include* and *Exclude* parameters is simpler and easier to remember.

Return to top

Get-QueueDigest

Exchange 2013 adds a new queue cmdlet named **Get-QueueDigest**. This cmdlet allows you to view information about some or all of the queues in your Exchange organization by using a single command. Specifically, the **Get-QueueDigest** cmdlet allows you to view information about queues based on their location on servers, in DAGs, in Active Directory sites, or in the whole Active Directory forest. Note that queues on a subscribed Edge Transport server in the perimeter network aren't included in the results. Also, **Get-QueueDigest** is available on an Edge Transport server, but the results are restricted to queues on the Edge Transport server.

Note:

By default, the **Get-QueueDigest** cmdlet displays delivery queues that contain ten or more messages, and the results are between one and two minutes old. For instructions on how to change these default values, see Configure Get-QueueDigest.

The filtering and sorting parameters that are available with the **Get-QueueDigest** cmdlet are described in the following table.

Parameter	Description

Dag, *Server*, or *Site*	These parameters are mutually exclusive, and set the scope for the cmdlet. You need to specify one of these parameters or the *Forest* switch. Typically, you would use the name of the server, DAG or Active Directory site, but you can use any value that uniquely identifies the server, DAG, or site. You can specify multiple servers, DAGs, or sites separated by commas.
Forest	This switch is required if you aren't using the *Dag*, *Server*, or *Site* parameters. You don't specify a value with this switch. By using this switch, you get queues from all Exchange 2013 Mailbox servers in the Active Directory forest. You can't use the *Forest* switch to view queues in remote Active Directory forests.
DetailsLevel	This parameter accepts the values `None`, `Normal`, and `Verbose`. The default value is `Normal`. When you use the value `None`, the queue name is omitted from the **Details** column in the results.
Filter	This parameter allows you to filter queues based on the queue properties. You can use any of the filterable queue properties as described in the Queue filters topic.
GroupBy	This parameter groups the queue results. You can group the results by one of the following properties: • DeliveryType • LastError • NextHopCategory • NextHopDomain • NextHopKey

	• Status • ServerName By default, the results are grouped by `NextHopDomain`. For information about these queue properties, see Queue filters.
ResultSize	This parameter limits the queue results to the value you specify. The queues are sorted in descending order based on the number of messages in the queue, and grouped by the value specified by the *GroupBy* parameter. The default value is 1000. This means that by default, the command displays the top 1000 queues grouped by **NextHopDomain**, and sorted by the queues containing the most messages to the queues containing the least messages.
Timeout	The parameter specifies the number of seconds before the operation times out. The default value is `00:00:10` or 10 seconds.

This example returns all non-empty external queues on the Exchange 2013 Mailbox servers named Mailbox01,Mailbox02, and Mailbox03.

```
Get-QueueDigest -Server Mailbox01,Mailbox02,Mailbox03 -
Include External -Exclude Empty
```

Return to top

Message filtering parameters

The following table describes the filtering parameters that are available on the message management cmdlets.

Cmdlet	Filtering parameters	Comments
Get-Message	*Identity* *Filter*	All filtering parameters are mutually exclusive, and you can use them together in the same

	Queue	command.
Remove-Message **Resume-Message** **Suspend-Message**	*Identity* *Filter*	You need to use either the *Identity* parameter or the *Filter* parameter, but you can't use both in the same command.
Export-Message	*Identity*	The *Identity* parameter is required.

Note that a *Server* parameter is available on all message management cmdlets except for the **Export-Message** cmdlet. You use the *Server* parameter to connect to a specific server, and run the message management commands on that server. You can use the *Server* parameter with or without the *Filter* parameter, but you can't use the *Server* parameter with the *Identity* parameter. You use the transport server's hostname or FQDN with the *Server* parameter.

Return to top

Message identity

The *Identity* parameter on the message management cmdlets identifies a specific message in one or more queues. When you use the *Identity* parameter, you can't specify any other message filtering parameters, because you've already uniquely identified the message. The *Identity* parameter uses the basic syntax <*Server*>\<*Queue*>\<*MessageInteger*>.

The <*Server*> placeholder is the hostname or FQDN of the Exchange server, for example `mailbox01` or `mailbox01.contoso.com`. If you omit the <*Server*> qualifier, the local server is implied.

The <*Queue*> placeholder accepts the identity of the queue as described in the "Queue identity" section in this topic. For example, you can use the persistent queue name, the **NextHopDomain** value, or the unique integer value of the queue in the queue database.

The <*MessageInteger*> placeholder represents the unique integer value that's assigned to the message when it first enters the queue database on the server. If the message is sent to multiple recipients that require multiple queues, all copies of the message in all queues in the queue database have the same integer value. However, you need to run the **Get-Message** cmdlet to find the integer value for the message in the **Identity** or **MessageIdentity** properties.

The following table summarizes the syntax you can use with *Identity* parameter on the message management cmdlets. In all values, <*Server*> is the hostname or FQDN of the server.

Message identity formats

Identity parameter value	Description
`<Server>\<Queue>\<MessageInteger>` or	A message in a specific queue on the specified

`<Queue>\<MessageInteger>`	server or the local server. *<MessageInteger>* is the unique integer value of the message that's displayed in the **Identity** property of the **Get-Message** cmdlet. *<Queue>* represents one of the following values: • **Persistent queue name** The value `Submission`, `Unreachable`, or `Poison`. • **Delivery queue name** The value of the **NextHopDomain** property of the queue, which is effectively the name of the queue. This value could be a routing destination or a delivery group. For more information, see the "NextHopSolutionKey" section in the Queues topic. • **Queue integer** The unique integer value of the delivery queue or shadow queue that's displayed in the **Identity** property of the **Get-Message** or **Get-Queue** cmdlets. • **Shadow queue identity** The shadow queue identity uses the syntax `Shadow \<QueueInteger>`.
`<Server>\*\<MessageInteger>` or `*\<MessageInteger>` or `<MessageInteger>`	All copies of the message in all queues in the queue database on the specified server or the local server.

Return to top

Message Filter parameter

You can use the *Filter* parameter on the **Get-Message**, **Remove-Message**, **Resume-Message**, and **Suspend-Message** cmdlets to specify the messages you want to view or manage based on the properties of the messages. The *Filter* parameter creates an expression with comparison operators that restricts the message operation to messages that meet the filter criteria. You can use the `-and` logical operator to specify multiple conditions that the results must match.

For a complete list of message properties you can use with the *Filter* parameter, see Queues.

For a list of comparison operators you can use with the *Filter* parameter, see the Comparison operators to use when filtering queues or messages section in this topic.

For examples of procedures that use the *Filter* parameter to view and manage messages, see Manage queues.

Return to top

Queue parameter

The *Queue* parameter is used only with the **Get-Message** cmdlet. You can use this parameter to get all messages in a specific queue, or all messages from multiple queues by using the wildcard character (*).When you use the *Queue* parameter, use the queue identity format <*Server*>\<*Queue*> as described in the "Queue identity" section in this topic.

Return to top

Comparison operators to use when filtering queues or messages

When you create a queue or message filter expression by using the *Filter* parameter, you need to include an comparison operator for the property value to match. The following table shows the comparison operators that you can use in a filter expression and how each operator functions. For all operators, the values compared aren't case sensitive.

Comparison operators

Operator	Function	Shell code example

`-eq`	This operator is used to specify that the results must exactly match the property value that's supplied in the expression.	To display a list of all queues that have a status of Retry:
		`Get-Queue -Filter {Status -eq "Retry"}`
		To display a list of all messages that have a status of Retry:
		`Get-Message -Filter {Status -eq "Retry"}`

`-ne`	This operator is used to specify that the results shouldn't match the property value that's supplied in the expression.	To display a list of all queues that don't have a status of Active: `Get-Queue -Filter {Status -ne "Active"}`

		To display a list of all messages that don't have a status of Active: `Get-Message -Filter {Status -ne "Active"}`

`-gt`	This operator is used with properties where the value is expressed as an integer or date/time. The filter results only include queues or messages where the value of the specified property is greater than the value that's supplied in the expression.	To display a list of queues that currently contain more than 1,000 messages:
		`Get-Queue -Filter {MessageCount -gt 1000}`
		To display a list of messages that currently have a retry count that's more than 3:
		`Get-Message -Filter {RetryCount -gt 3}`

`-ge`	This operator is used with properties where the value is expressed as an integer or date/time. The filter results only include queues or messages where the value of the specified property is greater than or equal to the value that's supplied in the expression.	To display a list of queues that currently contain 1,000 or more messages:
		`Get-Queue -Filter {MessageCount -ge 1000}`
		To display a list of messages that currently have a retry count that's 3 or more:
		`Get-Message -Filter {RetryCount -ge 3}`

`-lt`	This operator is used with properties where the value is expressed as an integer or date/time. The filter results only include queues or messages where the value of the specified property is less than the value that's supplied	To display a list of queues that currently contain less than 1,000 messages:
		`Get-Queue -Filter {MessageCount -lt 1000}`
		To display a list of messages that have an SCL that's less than 6:
		`Get-Message -Filter {SCL -lt 6}`

	in the expression.	

`-le`	This operator is used with properties where the value is expressed as an integer or date/time. The filter results only include queues or messages where the value of the specified property is less than or equal to the value supplied in the expression.	To display a list of queues that currently contain 1,000 or fewer messages:
		`Get-Queue -Filter {MessageCount -le 1000}`
		To display a list of messages that have an SCL that's 6 or less:
		`Get-Message -Filter {SCL -le 6}`

`-like`	This operator is used with properties where the value is expressed as a text string. The filter results only include queues or messages where the value of the specified property contains the text string that's supplied in the expression. You can include the wildcard character (*) in a **-like** expression that's applied to a text string field, but not with a field that has the enumeration type.	To display a list of delivery queues that have a destination to any SMTP domain that ends in Contoso.com:
		`Get-Queue -Filter {Identity -like "*contoso.com"}`
		To display a list of messages that have a subject that contains the text "payday loan":
		`Get-Messages -Filter {Subject -like "*payday loan*"}`

You can specify a filter that evaluates multiple expressions by using the **-and** comparison operator. The queues or messages must meet all conditions of the filter to be included in the results.

This example displays a list of queues that have a destination to any SMTP domain name that ends in Contoso.com and that currently contain more than 500 messages.

```
Get-Queue -Filter {Identity -like "*contoso.com*" -and MessageCount -gt 500}
```

This example displays a list of messages that are sent from any email address in the contoso.com domain that have an SCL that's greater than 5.

```
Get-Message -Filter {FromAddress -like "*Contoso.com*" -and
SCL -gt 5}
```

Return to top

Advanced paging parameters

Depending on current mail flow, queries against queues and messages can return a large set of objects. You can use the advanced paging parameters to control how query results are retrieved and displayed.

When you use the Shell to view queues and the messages in the queues, your query retrieves one page of information at a time. The advanced paging parameters control the size of the result set and can also be used to sort the results. All advanced paging parameters are optional and can be combined with any one of the parameter sets that can be used with the **Get-Queue** and **Get-Message** cmdlets. If you don't specify any advanced paging parameters, the query returns the results in ascending order of identity.

By default, when a sort order is specified, the message identity property is always included and is sorted in an ascending order. This is the default ordering relationship. The message identity property is included because the other properties that can be included in a sort order aren't unique. By explicitly including the message identity property in the sort order, you can specify that the results display the message identity sorted in descending order.

You can use the *BookmarkIndex* and *BookmarkObject* parameters to mark a position in the sorted result set. If the bookmark object no longer exists when the next page of results is retrieved, the default ordering relationship makes sure that the result set starts with the closest object to the bookmark. The closest object depends on the specified sort order.

The following table describes the advanced paging parameters.

Advanced paging parameters

Parameter	Description
BookmarkIndex	This parameter specifies the position in the result set where the displayed results start. The value of this parameter is a 1-based index in the total result set. If the value is less than or equal to zero, the first complete page of results is returned. If the value is set to `Int.MaxValue`, the last complete page of results is returned.
BookmarkObject	This parameter specifies the object in the result

	set where the displayed results start. If you specify a bookmark object, that object is used as the point to start the search. The rows before or after that object, depending on the value of the *SearchForward* parameter, are retrieved. You can't combine the *BookmarkObject* parameter and the *BookmarkIndex* parameter in a single query.
IncludeBookmark	This parameter specifies whether to include the bookmark object in the result set. By default, the value is set to `$true` and the bookmark object is included. You may run a query for a limited result size, and then specify the last item in that result set as the bookmark for the next query. In this case, you may want to set *IncludeBookmark* to `$false` so that the object isn't included in both result sets.
ResultSize	This parameter specifies the number of results to display per page. If you don't specify a value, the default result size of 1,000 objects is used. Exchange limits the result set to 250,000.
ReturnPageInfo	This parameter is a hidden parameter. It returns information about the total number of results and the index of the first object of the current page. The default value is `$false`.
SearchForward	This parameter specifies whether to search forward or backward in the result set. This parameter doesn't affect the order in which the result set is returned. It determines the direction of search relative to the bookmark index or object. If no bookmark index or object

	is specified, the *SearchForward* parameter determines whether the search starts from the first or last object in the result set. The default value for this parameter is `$true`. If the this parameter is set to `$true` and a bookmark is specified, the query searches forward from that bookmark. If you use this configuration and there are no results beyond the bookmark, the query returns the last full page of results. If the *SearchForward* parameter is set to `$false` and a bookmark is specified, the query searches backward from that bookmark. If you use this configuration and there is less than a full page of results beyond the bookmark, the query returns the first full page of results.
SortOrder	This parameter specifies an array of message properties used to control the sort order of the result set. The sort order properties are specified in descending order of precedence. Each property is separated by a comma and appended with a plus sign (+) to sort in ascending order, or a minus sign (-) to sort in descending order. If an explicit sort order isn't specified by using this parameter, the records that match the query are displayed and sorted by the Identity field for the respective object type. The results are always sorted by identity in ascending order when a sort order isn't explicitly specified.

The following code example shows how to use the advanced paging parameters in a query. In this

example, the command connects to the specified server and retrieves a result set that contains 500 objects. The results are displayed in a sorted order, first in ascending order by sender address, and then in descending order of message size.

```
Get-Message -Server mailbox01.contoso.com -ResultSize 500 -SortOrder +FromAddress,-Size
```

If you want to view successive pages, you can set a bookmark for the last object retrieved in a result set and run an additional query. You need to use the scripting capabilities of the Shell to perform this procedure.

The following example uses scripting to retrieve the first page of results, sets the bookmark object, excludes the bookmark object from the result set, and then retrieves the next 500 objects on the specified server.

1. Open the Shell and type the following command to retrieve the first page of results.

```
$Results=Get-message -Server mailbox01.contoso.com -
ResultSize 500 -SortOrder +FromAddress,-Size
```

2. To set the bookmark object, type the following command to save the last element of the first page to a variable.

```
$temp=$results[$results.length-1]
```

3. To retrieve the next 500 objects on the specified server and to exclude the bookmark object, type the following command.

```
Get-message -Server mailbox01.contoso.com -
BookmarkObject:$temp -IncludeBookmark $False -ResultSize
500 -SortOrder +FromAddress,-Size
```

Configure Get-QueueDigest

Topic Last Modified: *2013-10-18*

The **Get-QueueDigest** cmdlet allows you to view information about some or all of the queues in your Exchange organization by using a single command.

By default, the results returned by the **Get-QueueDigest** cmdlet are between one and two minutes old. These values are controlled by the following settings:

- **QueueLoggingInterval key in EdgeTransport.exe.config** This key specifies how frequently queue data is logged and is available to **Get-QueueDigest**. The default value is `00:01:00` (one minute). To specify a value, enter it as a time span: *hh:mm:ss* where *h* = hours, *m* = minutes, and *s*

= seconds. By default, this key isn't present in the EdgeTransport.exe.config file.

- **QueueDiagnosticsAggregationInterval parameter on Set-TransportConfig** This parameter specifies how frequently queue data is shared between Mailbox servers. The default value is `00:01:00` (one minute). To specify a value, enter it as a time span: *hh:mm:ss* where *h* = hours, *m* = minutes, and *s* = seconds.

The sum of the **QueueLoggingInterval** key and *QueueDiagnosticsAggregationInterval* parameter values determine the maximum age of the results returned by **Get-QueueDigest**.

Also, **Get-QueueDigest** returns results differently based on the type of queue and the status of the queue. For example, the following queues are displayed in the results as long as they contain at least one message:

- The Submission queue, the Unreachable queue, and the poison message queue (persistent queues).
- Delivery queues in the Suspended state (queues manually suspended by an administrator).

By default, delivery queues that have the status Active, Connecting, Ready, or Retry are returned in the results only if the queue contains 10 or more messages. This value is controlled by the **QueueLoggingThreshold** key in the EdgeTransport.exe.config file. You can specify a smaller or larger integer value. By default, this key isn't present in the EdgeTransport.exe.config file.

What do you need to know before you begin?

- Estimated time to complete: 15 minutes
- To see the Exchange permissions you need to run **Set-TransportConfig** in the Exchange Management Shell, see the "Transport configuration" entry in the Mail flow permissions topic.
- Exchange permissions don't apply to modifying the EdgeTransport.exe.config file and restarting the Microsoft Exchange Transport service. These procedures are performed in the operating system of the Exchange Server.
- Changes you save to the EdgeTransport.exe.config file are applied after you restart the Microsoft Exchange Transport service. When you restart the service, mail flow on the server is temporarily interrupted.
- Any customized per-server settings you make in Exchange XML application configuration files, for example, web.config files on Client Access servers or the EdgeTransport.exe.config file on Mailbox servers, will be overwritten when you install an Exchange Cumulative Update (CU). Make sure that you save this information so you can easily re-configure your server after the install. You must re-configure these settings after you install an Exchange CU.
- Changes you make using **Set-TransportConfig** affect all Mailbox servers in your organization. Changes you make in the EdgeTransport.exe.config file affect the local Mailbox server only.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:

Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

Configure Get-QueueDigest

1. In a Command Prompt window, open the EdgeTransport.exe.config file in Notepad by running the following command:

```
Notepad %ExchangeInstallPath%Bin\EdgeTransport.exe.config
```

2. Add one or both of the following keys in the `<appSettings>` section.

```
<add key="QueueLoggingThreshold" value="<integer>" />
<add key="QueueLoggingInterval" value="<hh:mm:ss>" />
```

For example, to set the **QueueLoggingThreshold** value to 1 and the **QueueLoggingInterval** value to 30 seconds, use the following values:

```
<add key="QueueLoggingThreshold" value="1" />
<add key="QueueLoggingInterval" value="00:00:30" />
```

3. When you are finished, save and close the EdgeTransport.exe.config file.
4. Restart the Microsoft Exchange Transport service by running the following command:

```
net stop MSExchangeTransport && net start
MSExchangeTransport
```

5. To change the value of the *QueueDiagnosticsAggregationInterval* parameter in the Exchange Management Shell, use the following syntax:

```
Set-TransportConfig -QueueDiagnosticsAggregationInterval
<hh:mm:ss>
```

For example, to change the value to 30 seconds, run the following command:

```
Set-TransportConfig -QueueDiagnosticsAggregationInterval
00:00:30
```

How do you know this worked?

To verify that you have successfully configured **Get-QueueDigest**, do the following:

1. Verify the values of the **QueueLoggingThreshold** and **QueueLoggingInterval** keys in the EdgeTransport.exe.config file. If the keys aren't present, the default values are used.
2. Verify the value of the *QueueDiagnosticsAggregationInterval* parameter by running the following command:

```
Get-TransportConfig | Format-List *queue*
```

Queue filters

Applies to: *Exchange Server 2013*

Topic Last Modified: *2013-01-31*

Filtering generates different views of queues. You use the queue properties as filter options. By specifying filter criteria, you can quickly locate queues and take action on them. The following scenarios are examples of how you might use queue filtering to manage mail flow:

- You receive a message from the Microsoft System Center Operations Manager that indicates that a queue length has exceeded the established threshold. You want to investigate whether a server-wide mail flow problem exists.

You can create a filter to view all the queues that have a message count that exceeds what you consider typical. If a mail flow problem is indicated, you can select all the queues in the filter results and suspend the queues while you continue to investigate.

- You suspend several queues to investigate the cause of mail flow problems. You determine that the problem was caused by an incorrect connector configuration and is now fixed.

You can create a filter to view all the queues that have a status of Suspended, and then select all the queues in the filter results and resume the queues.

Queue properties to use when filtering queues

You can use the queue properties to create a filter and locate queues that meet specified criteria. You can create filters in Queue Viewer, or by using the *Filter* parameter on the queue management cmdlets. Note that the queue management cmdlets support more filterable properties than the Queue Viewer. The following table lists the queue properties by which you can filter and the valid values for those properties.

Queue Viewer queue property	Shell queue property	Description
n/a	`DeferredMessageCount`	This property identifies the number of messages that were returned to the Submission queue because of transient errors that were encountered during recipient resolution. For more information about deferred messages, see

		Recipient resolution.
Delivery Type	`DeliveryType`	The valid values for **DeliveryType** are explained in the "NextHopSolutionKey" section in the Queues topic.
n/a	`Identity`	This property is the identity of the queue in the form of *<Server>**<Queue>*. For more information see the "Queue identity" section in the Queues topic.
n/a	`IncomingRate`	This property is a calculated number that indicates how quickly messages are entering the queue. For more information, see "IncomingRate, OutgoingRate, and Velocity" section in the Queues topic.
Last Error	`LastError`	This property indicates the text string of the last error that was recorded for the queue.
Last Retry Time	`LastRetryTime`	This property indicates the date/time of the last connection attempt for a queue that has a status of `Retry`.
n/a	`LockedMessageCount`	This property is reserved for internal Microsoft use, and isn't used in on-premises Exchange 2013 organizations.

Message Count	`MessageCount`	This property indicates the number of messages in the queue.
n/a	`NextHopCategory`	This property designates the next hop of the queue as `Internal` or `External` and is based on the value of the **DeliveryType** property of the queue. For more information, see the "NextHopSolutionKey" section in the Queues topic.
n/a	`NextHopConnector`	This property is the GUID of the next hop and is based on the value of the **DeliveryType** property of the queue. For more information, see the "NextHopSolutionKey" section in the Queues topic.
Next Hop Domain	`NextHopDomain`	This property is the name of next hop and is based on the value of the **DeliveryType** property of the queue . For more information, see the "NextHopSolutionKey" section in the Queues topic.
Next Retry Time	`NextRetryTime`	This property indicates the date/time of the next connection attempt for a queue that has a status of `Retry`.
n/a	`OutgoingRate`	This property is a calculated

		number that indicates how quickly messages are leaving the queue. For more information, see "IncomingRate, OutgoingRate, and Velocity" section in the Queues topic.
n/a	`RiskLevel`	This property is reserved for internal Microsoft use, and isn't used in on-premises Exchange 2013 organizations.
Status	`Status`	This property indicates the current queue status. A queue can have one of the following status values Active, Connecting, None, Suspended, Ready, or Retry. For more information, see the "Queue status" section in the Queues topic.
n/a	`TlsDomain`	This property contains the FQDN of the destination domain if the domain is configured for Domain Security.
n/a	`Velocity`	This property contains a calculated number that indicates how effectively the queue is draining. For more information, see "IncomingRate, OutgoingRate,

		and Velocity" section in the Queues topic.

Manage messages in queues

Exchange Server 2013 > Mail flow > Queues >

Applies to: *Exchange Server 2013*

Topic Last Modified: *2014-05-07*

In Microsoft Exchange Server 2013, you can use the Queue Viewer in the Exchange Toolbox or the Exchange Management Shell to manage messages in queues. For more information about using the message management cmdlets in the Exchange Management Shell, see Use the Exchange Management Shell to manage queues.

What do you need to know before you begin?

- Estimated time to complete each procedure: 15 minutes
- You need to be assigned permissions before you can perform this procedure or procedures. To see what permissions you need, see the "Queues" entry in the Mail flow permissions topic.
- For information about keyboard shortcuts that may apply to the procedures in this topic, see Keyboard shortcuts in the Exchange admin center.

Tip:
Having problems? Ask for help in the Exchange forums. Visit the forums at: Exchange Server, Exchange Online, or Exchange Online Protection.

What do you want to do?

Remove messages from queues

A message that's being sent to multiple recipients might be located in more than one queue. To remove a message from more than one queue in a single operation, you need to use a filter. You can select whether to send a non-delivery report (NDR) when you remove messages from a queue. You can't remove a message from the Submission queue.

Use Queue Viewer in the Exchange Toolbox to remove messages

1. Click **Start** > **All Programs** > **Microsoft Exchange 2013** > **Exchange Toolbox**.
2. In the **Mail flow tools** section, double-click **Queue Viewer** to open the tool in a new window.
3. In Queue Viewer, click the **Messages** tab. A list of all messages on the server to which you're

connected is displayed. To adjust the action to a single queue, click the **Queues** tab, double-click the queue name, and then click the *Server**Queue* tab that appears.

4. Select one or more messages from the list, right-click, and then select **Remove Messages (with NDR)** or **Remove Messages (without NDR)**. A dialog box appears that confirms the selected action and displays, **Do you want to continue?** Click **Yes**.
5. To remove all messages from a particular queue, click the **Queues** tab. Select a queue, right-click, and then select **Remove Messages (with NDR)** or **Remove Messages (without NDR)**. A dialog box appears that confirms the selected action and displays, **Do you want to continue?** Click **Yes**.

Note:

If you're working with a filtered list, the displayed page may not include all items in the filter. In this case, a prompt appears that displays: **This action will affect all items on this page. To expand the scope of this action to include all items in this filter, check the following box before you click OK.**

Use the Shell to remove messages

To remove messages from queues, use the following syntax.

```
Remove-Message <-Identity MessageIdentity | -Filter
{MessageFilter}> -WithNDR <$true | $false>
```

This example removes messages in the queues that have a subject of "Win Big" without sending an NDR.

```
Remove-Message -Filter {Subject -eq "Win Big"} -WithNDR
$false
```

This example removes the message with the message ID 3 from the unreachable queue on server named Mailbox01 and sends an NDR.

```
Remove-Message -Identity Mailbox01\Unreachable\3 -WithNDR
$true
```

How do you know this worked?

To verify that you have successfully removed messages from queues, do one of the following:

- In Queue Viewer, select the queue or create a filter to verify the messages no longer exist.
- Use the **Get-Message** cmdlet with the *Queue* or *Filter* parameters to verify the messages no longer exist. For more information, see Get-Message.

Resume messages in queues

You can resume a message that currently has a status of Suspended. By resuming a message, you enable delivery of the message. If you resume a message located in the poison message queue, the message will be sent to the categorizer for processing. A message being sent to multiple recipients might be located in multiple queues. To resume a message in more than one queue in a single

operation, you must use a filter.

Use Queue Viewer in the Exchange Toolbox to resume messages

1. Click **Start** > **All Programs** > **Microsoft Exchange 2013** > **Exchange Toolbox**.
2. In the **Mail flow tools** section, double-click **Queue Viewer** to open the tool in a new window.
3. In Queue Viewer, click the **Messages** tab. A list of all messages on the server to which you're connected is displayed. To adjust the action to focus on a single queue, click the **Queues** tab, double-click the queue name, and then click the *Server\Queue* tab that appears.
4. Click **Create Filter**, and enter your filter expression as follows:
   a. Select **Status** from the message property drop-down list.
   b. Select **Equals** from the comparison operator drop-down list.
   c. Select **Suspended** from the value drop-down list.
5. Click **Apply Filter**. All messages that have a status of Suspended are displayed.
6. Select one or more messages from the list, right-click, and select **Resume**.

Use the Shell to resume messages

To resume messages, use the following syntax:

```
Resume-Message <-Identity MessageIdentity | -Filter {MessageFilter}>
```
