Lync Server supports all of the phones listed in the following table. Note that not all of the supported phones can run Lync Phone Edition (some can run only earlier versions). Use the table to learn which phones can run Lync Phone Edition and where to get detailed information about all of the supported phones.

Note:

Three types of phones are supported: desk phones (handset IP or USB devices that are designed to be used by employees at their desk), conferencing devices (hands-free IP or USB phones that are designed to be used in meeting rooms), and common area phones (IP phones that are designed to be used in shared areas—such as lobbies, kitchens, factory floors, and shared workspaces—and can be customized to provide different sets of Lync Phone Edition features.

For detailed comparison tables about all devices that are optimized to work with Lync, see "Phones and Devices Qualified for Microsoft Lync" at http://go.microsoft.com/fwlink/p/?linkid=208938. The phone comparison tables at this website include pricing information and technical specifications.

Phone	Runs Lync Phone Edition	Learn More
Aastra 6721ip common area phone	X	Downloads Aastra 6721ip at the Aastra website
Aastra 6725ip desk phone	X	Downloads Aastra 6725ip at the Aastra website
HP 4110 IP Phone (common area phone)	X	HP 4110 IP Phone Series at the HP website
HP 4120 IP Phone (desk phone)	X	HP 4120 IP Phone Series at the HP website
Polycom CX300 USB desk phone		CX300 at the Polycom website
Polycom CX500 IP common area phone	X	CX500 at the Polycom website
Polycom CX600 IP desk phone	X	CX600 at the Polycom website
Polycom CX700 IP desk phone		CX700 at the Polycom website
Polycom CX3000 IP conference phone	X	CX3000 at the Polycom website
Polycom CX5000 USB conferencing device		CX5000 at the Polycom website

Note:
Support for analog devices is also provided. For details, see Planning to Deploy Analog Devices in the Lync Server 2010 TechNet Library. (Lync Phone Edition works the same way in Lync Server 2013 and Lync Server 2010).

1.3.15.3.2 Topologies for IP Phones

Topologies for IP Phones

Planning > Planning for Clients and Devices in Lync Server 2013 > Planning for Devices >

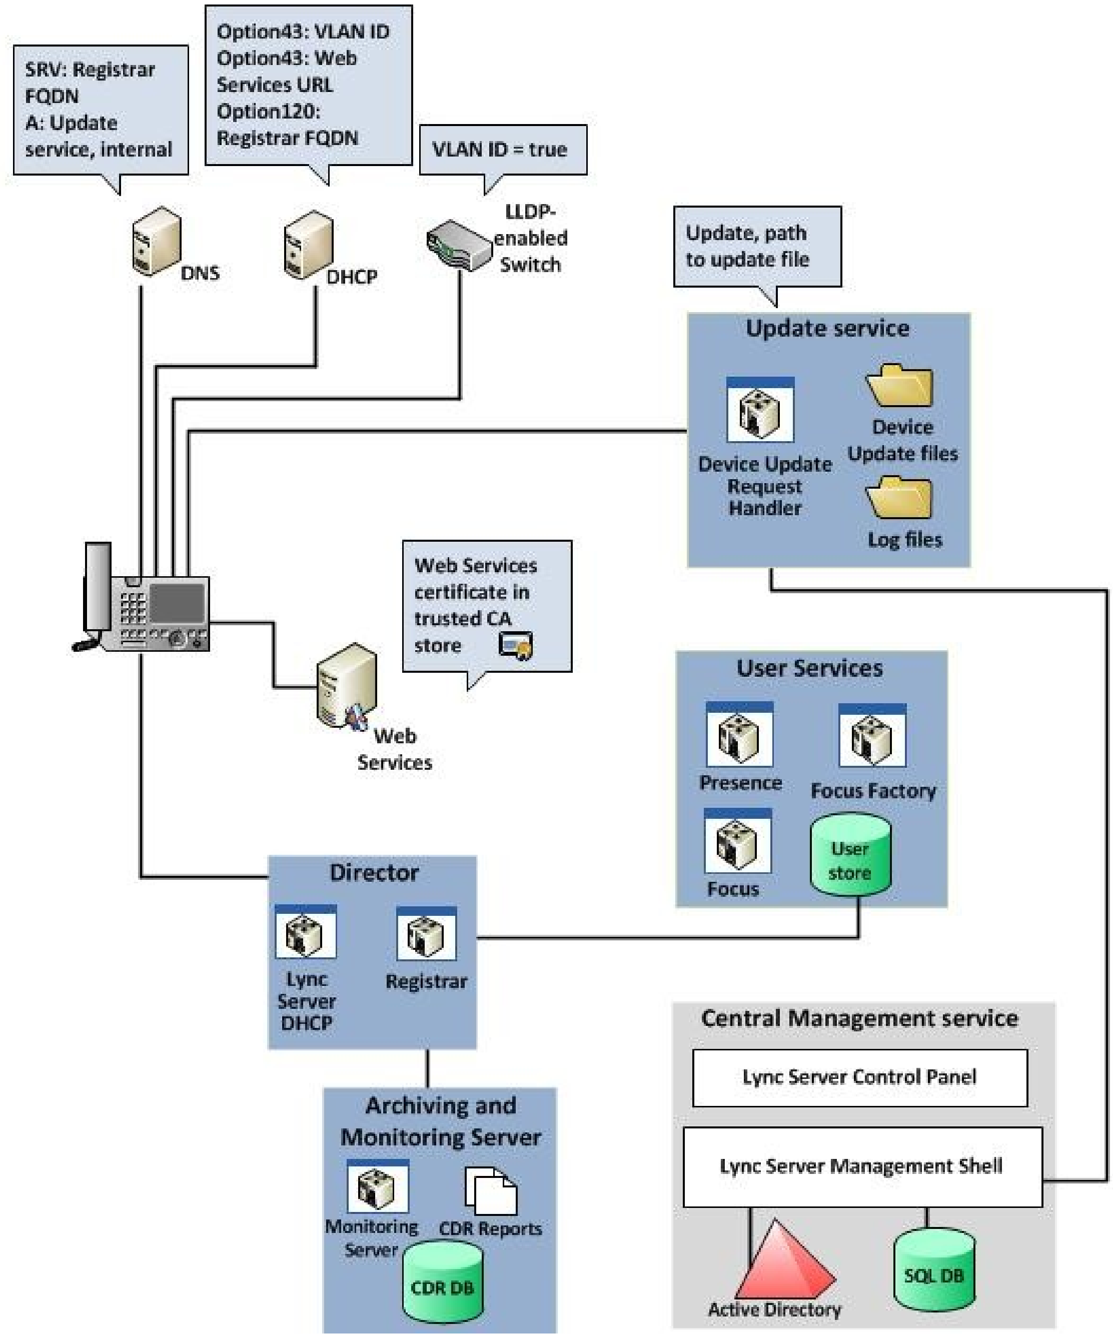
Topic Last Modified: *2012-06-21*

This section provides an overview of the connectivity process and explains the differences between how an IP phone connects in an internal and external network.

Note:

Lync Server provides support for the following IP phones: the Aastra 6721ip common area phone, Aastra 6725ip desk phone, HP 4110 IP Phone (common area phone), HP 4120 IP Phone (desk phone), Polycom CX600 IP desk phone, Polycom CX700 IP desk phone, Polycom CX500 IP common area phone, and Polycom CX3000 IP conference phone. Of those phones, all but the Polycom CX700 can run Lync Phone Edition.

The following diagram describes all the components involved in device connectivity within the corporate environment.

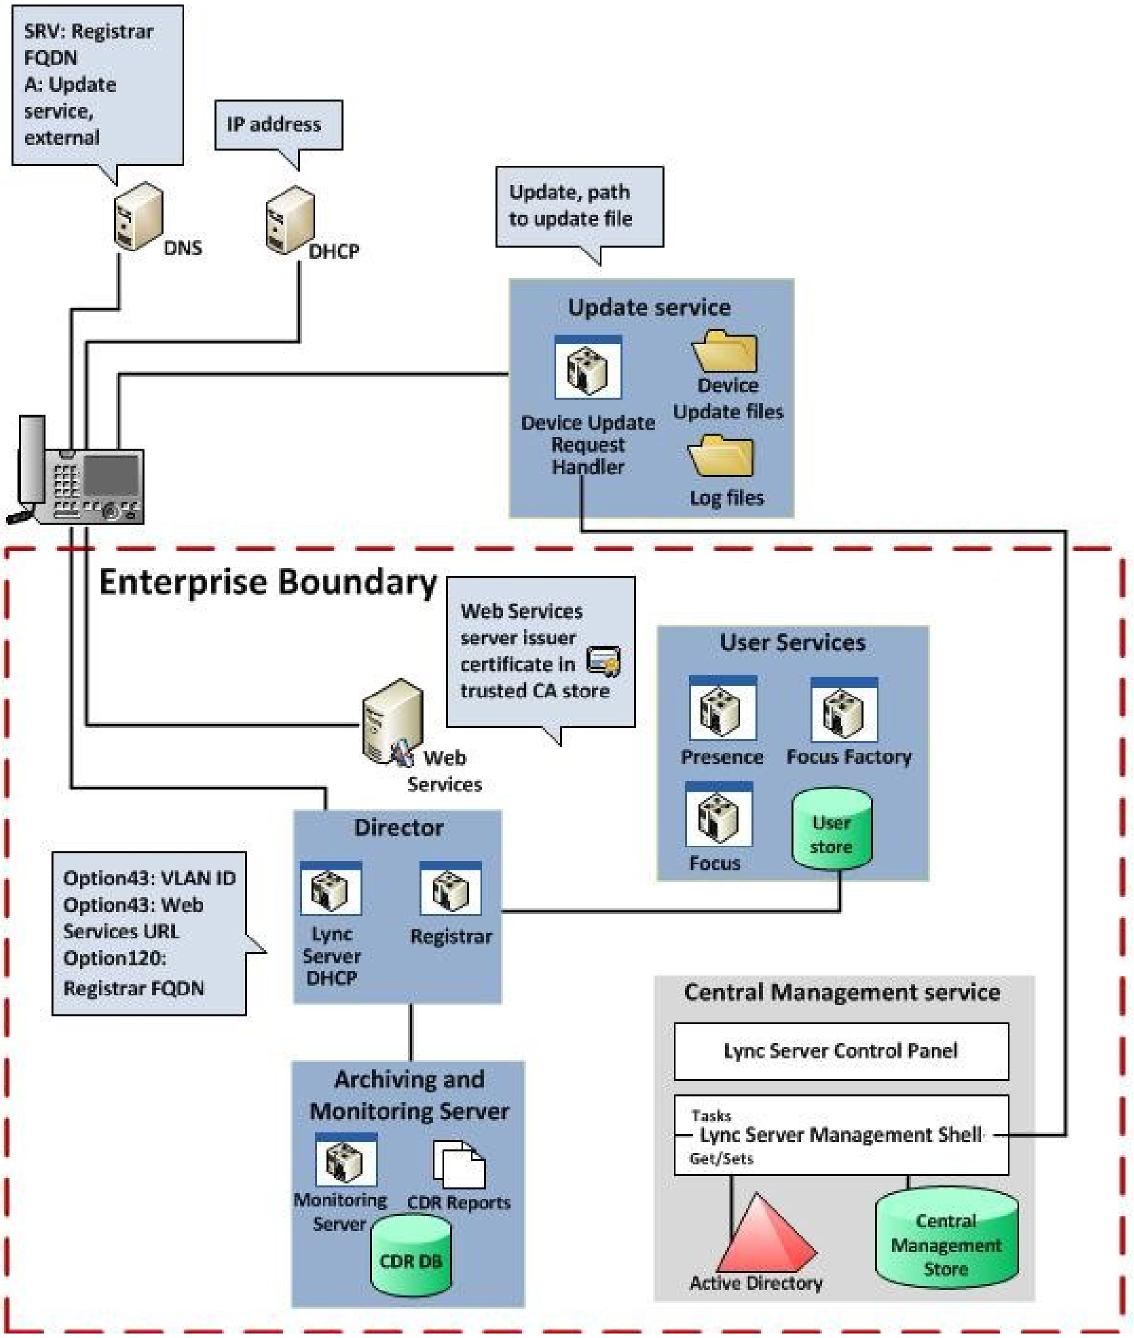


SRV: Registrar FQDN
A: Update service, internal
Option43: VLAN ID
Option43: Web Services URL
Option120: Registrar FQDN
VLAN ID = true
DNS
DHCP
LLDP-enabled Switch
Update, path to update file
Update service
Device Update Request Handler
Device Update files
Log files
Web Services certificate in trusted CA store
Web Services
User Services
Presence
Focus Factory
Focus
User store
Director
Lync Server DHCP
Registrar
Central Management service
Lync Server Control Panel
Lync Server Management Shell
Active Directory
SQL DB
Archiving and Monitoring Server
Monitoring Server
CDR Reports
CDR DB

Note:
The previous figure is a logical representation, not a physical overview. For example, Active Directory Domain Services (AD DS) is rarely located on the same machine as any

Lync Server components. The user store can be located on the Back End Server or on the Archiving and Monitoring Servers. The Lync Server Management Shell, web server, and update services are all part of the Front End Server role.

The following diagram provides an overview of the components involved when the device is located outside the corporate network.



SRV: Registrar FQDN
A: Update service, external
IP address
DNS
DHCP
Update, path to update file
Update service
Device Update Request Handler
Device Update files
Log files
Enterprise Boundary
Web Services server issuer certificate in trusted CA store
Web Services
User Services
Presence
Focus Factory
Focus
User store
Director
Lync Server DHCP
Registrar
Option43: VLAN ID
Option43: Web Services URL
Option120: Registrar FQDN
Central Management service
Lync Server Control Panel
Tasks
Lync Server Management Shell
Get/Sets
Active Directory
Central Management Store
Archiving and Monitoring Server
Monitoring Server
CDR Reports
CDR DB

Note:

The Device Update Web service provides an external and internal website, but only the external one is shown here.
The location of the Registrar and the URL of the Device Update Web service for the organization must be published in DNS if external access is to be enabled. Additionally,

the Edge Server must be deployed and correctly configured to allow external communications from the device to the corporate environment and back. This is omitted from the previous diagram because Edge deployment is not specific to device connectivity.

1.3.16 Planning for Remote Call Control

Planning for Remote Call Control

Microsoft Lync Server 2013 > Planning >

Topic Last Modified: *2012-09-05*

In Lync Server 2013, support for remote call control scenarios enables users to control their private branch exchange (PBX) phones by using Lync 2013 on their desktop computers. This section describes remote call control features and requirements for deploying remote call control.

Integration between a PBX and Lync Server 2013 makes it possible for users enabled for remote call control to use the Lync 2013 user interface (UI) to control calls on their PBX phones in the following ways:

Note:

Ultimately, the capabilities of the PBX that hosts a user's PBX phone determine the remote call control features that will be available to that user.

- Make an outgoing call
- Answer an incoming call
- Answer an incoming call with an instant message

  Note:

  That is, when the caller's phone number can be associated with an instant message address in your organization's global address list (GAL), in the callee's Lync Contacts list, or in a federated partner's organization.
- Transfer a call
- Forward an incoming call
- Place calls on hold
- Alternate between multiple concurrent calls
- Answer a second call while already in a call (that is, call waiting)
- Dial dual-tone multifrequency (DTMF) digits
- In the Conversation window, type notes in Microsoft Office OneNote note-taking program

Additionally, when a user is enabled for remote call control, Lync 2013 provides the user with the following call information:

- Identification of a caller by name when the caller's phone number exists in the Contacts list of a remote call control-enabled user's Microsoft Office Outlook messaging and collaboration client, Lync Contacts list, or your organization's GAL.
- Past incoming and outgoing calls, which are saved in the Conversation History folder in Outlook.
- Missed call notifications, which are sent to the user's Outlook Inbox folder, but are generated only if Lync is running when the incoming call is received.

Remote Call Control and Enterprise Voice

Although remote call control features are separate from Enterprise Voice features and users cannot be enabled for both, Enterprise Voice provides a subset of features that are also available to users who are enabled for remote call control. If Enterprise Voice is deployed, users who are enabled for remote call control can use Lync to access the following Enterprise Voice features:

- Make and receive audio calls to another Lync client
- Join the audio portion of a conference created by a user who is enabled for Enterprise Voice

In This Section

- Deployment Tasks for Remote Call Control

1.3.16.1 Deployment Tasks for Remote Call Control

Deployment Tasks for Remote Call Control

Microsoft Lync Server 2013 > Planning > Planning for Remote Call Control >

Topic Last Modified: *2012-10-05*

This topic describes the deployment tasks that you must perform to enable remote call control for users in your Lync Server environment.

Note:

If you are migrating users previously enabled for remote call control in Microsoft Office Communicator 2007 R2, you must perform an additional deployment task before you begin performing the remote call control deployment tasks described in this topic. During the migration process to Lync Server, trusted application entries (previously known as *authorized host entries*) must be removed by using the Office Communications Server 2007 R2 administrative tools, as appropriate.
For details about removing authorized hosts, see Remove a Legacy Authorized Host (Optional).

Step 1: Install and Configure the SIP/ CSTA Gateway to Communicate with Your PBX

You need to install at least one SIP/CSTA gateway that can connect to both Lync Server and the existing private branch exchange (PBX) in your environment in order to provide remote call control features to your users. A SIP/CSTA gateway is a gateway between SIP and a computer-supported telecommunications application (CSTA). Whether you install multiple gateways or just one, each user can be configured with only one gateway or PBX. If your existing PBX does not have a SIP/CSTA interface, ensure you deploy a SIP/ CSTA gateway that can support the PBX, including support for proprietary PBX vendor-specific signaling protocols. For details about capabilities, consult each vendor directly.

When you are ready to deploy a SIP/CSTA gateway that can integrate with Lync Server for remote call control, also consult with your gateway vendor or the vendor's gateway documentation regarding the syntax required by the gateway for the following information:

- Line server URI of the gateway
- Line URI for users that will be assigned to the gateway

The preceding settings are required during user configuration and must be specified as expected by the gateway to route and connect to the PBX properly.

You can refer to vendors on the Microsoft Unified Communications Open Interoperability Program website at http://go.microsoft.com/fwlink/p/?linkId=203309.

Step 2: Configure Lync Server to Route CSTA Requests to the SIP/CSTA Gateway

You must create static routes on Lync Server pools to the destination address (server URI) of all SIP/CSTA gateways in your deployment to which you intend to route remote call control requests. You must also create a trusted application entry that corresponds to each destination address. When you designate the gateway as a trusted application, it is given trusted status to run as part of the Lync Server environment even though it is developed by a third party (and runs what is referred to as an *external service* because it is a service that is not a built-in part of the product). Finally, if Lync Server will connect to the SIP/CSTA gateway using a Transmission Control Protocol (TCP) connection instead of a Transport Layer Security (TLS) connection, you must also define the gateway IP address by using Topology Builder.

For details about configuring static routes, see Configure a Static Route for Remote Call Control.

For details about configuring trusted application entries, see Configure a Trusted Application Entry for Remote Call Control.

For details about defining a SIP/CSTA gateway IP address in Topology Builder, see Define a SIP/CSTA Gateway IP Address.

Step 3: Configure Lync Users for Remote Call Control

After users have been enabled for Lync Server, you can use Lync Server Control Panel or Lync Server Management Shell to enable them for remote call control. It is during this deployment step that you assign each user a line server URI and a line URI. The line server URI is the SIP URI of the SIP/CSTA gateway that you plan to assign to the user. The line URI is the unique phone number assigned to the user.

For details about configuring users for remote call control, see Enable Lync Users for Remote Call Control.

Step 4: Define the Lync Server Phone Number Normalization Rules

In remote call control scenarios, Lync Server uses phone number normalization rules to convert phone numbers it receives from the SIP/CSTA gateway to E.164 format. Phone numbers must be in this standardized format for certain remote call control features to function properly. Remote call control uses the same phone number normalization rules that you configure for Address Book Service phone number normalization, which are different from the phone number normalization rules used for Enterprise Voice.

For details about how remote call control uses phone number normalization rules, see Remote Call Control and Phone Number Normalization. For details about phone number normalization rules for Address Book Service, see Administering the Address Book Service topic in the Operations documentation.

1.3.17 Planning for Mobility

Planning for Mobility

Planning > Planning for External User Access > Scenarios for External User Access >

Topic Last Modified: *2013-02-14*

With Lync Server 2013, you can deploy the mobility feature to provide Lync 2013 functionality on mobile devices. This section provides details about the mobility feature and how to plan for your deployment.

- Mobility Features and Capabilities
- Topologies and Components for Mobility
- Technical Requirements for Mobility
- Defining Your Mobility Requirements
- Deployment Process for Mobility

1.3.17.1 Mobility Features and Capabilities

Mobility Features and Capabilities

Planning for External User Access > Scenarios for External User Access > Planning for Mobility >

Topic Last Modified: *2013-02-19*

```
The information in this topic pertains to Cumulative Updates for Lync Server 2013
```

The mobility feature introduced in the Cumulative Updates for Lync Server 2013: February 2013 supports Lync 2010 Mobile and Lync 2013 Mobile clients functionality. When you deploy the Lync Server 2013 Mobility Service, users can use supported Apple iOS, Android, and Windows Phone, or Nokia Symbian mobile devices to perform activities such as sending and receiving instant messages, viewing contacts, and viewing presence. In addition, mobile devices support some Enterprise Voice features, such as click to join a conference, Call via Work, single number reach, voice mail, and missed calls. New features introduced in the Cumulative Updates for Lync Server 2013: February 2013 include Voice over IP (VoIP) capability and video (H.264) for meeting attendee.

The mobility feature introduced in the Cumulative Updates for Lync Server 2013: February 2013 supports Lync 2013 Mobile client functionality. The Cumulative Updates for Lync Server 2013: February 2013 install Unified Communications Web API, or UCWA. UCWA is the component used for Lync 2013 Mobile clients. In Lync Server 2013, Mcx is used for Lync 2010 Mobile clients. Cumulative Updates for Lync Server 2013: February 2013 introduce UCWA as the new entry point for mobility services. Lync Server 2013 concurrently implements the Mobility Service (Mcx), introduced in the Cumulative Updates for Lync Server 2010: November 2011, and provides support for Lync 2010 Mobile. When you deploy the Cumulative Updates for Lync Server 2013: February 2013, users can use supported Apple iOS, Android, and Windows Phone mobile devices to perform such activities as:

Important:
Features supported by the Mobility Service from the Cumulative Updates for Lync Server 2010: November 2011 are noted with (Mcx). All listed features are supported by the UCWA, introduced in the Cumulative Updates for Lync Server 2013: February 2013.

- Send and receive instant messages (Mcx)
- View presence (Mcx)
- View contacts (Mcx)
- Click to join a conference (Mcx)
- Call via work (Mcx)

- Single number reach (Mcx)
- Voice mail (Mcx)
- Missed call notification (Mcx)
- Voice over IP (VoIP)
- Attendee video (H.264)

Note:

Lync 2010 Mobile provided a client for Nokia Symbian devices. Lync 2013 Mobile will not have a client for Nokia Symbian-based devices.

Apple iPad users will have access to enhanced capabilities. After joining a meeting by using audio call back, an iPad user will be able to view uploaded Microsoft PowerPoint presentations within a meeting, share applications and desktops, view the meeting participant list, and receive notifications of other content types that are being shared within the meeting.

Tip:

With single number reach, a user receives calls on a mobile phone that were dialed to the work number. With Call via Work, the user places an outbound call from the Lync Mobile client by using a work phone number instead of the mobile phone number. With dial-out, the client sends a request to Mcx or UCWA (based on the Lync Mobile version) to make the call for them. The server initiates the call and then calls the user back on the mobile phone. When the user answers, the server completes the call by dialing the other party. By using Call via Work, users can maintain their work identity during a call, which means that the call recipient does not see the caller's mobile number, and the caller avoids incurring outbound calling charges.

Note:

Not all features work exactly the same on all mobile devices. For details about features supported on mobile devices, see the Mobile Client Comparison Tables at http://go.microsoft.com/fwlink/p/?LinkId=234777. For details about supported devices and operating systems, see the requirements topics under Planning for Mobile Clients.

When you use the Lync Server 2013 Autodiscover feature, mobile applications can automatically locate Lync Server 2013 Web Services without requiring users to manually enter the URLs in their device settings. Manually entering URLs in mobile device settings is also supported, primarily for troubleshooting purposes.

Important:

The Mcx and UCWA are complimentary services and both are deployed to support Lync 2010 Mobile and Lync 2013 Mobile clients. Lync 2013 Mobile will not be able to sign in to Lync Server 2010 deployments. Lync 2010 Mobile and Lync 2013 Mobile will be able to use a Lync Server 2013 deployment with the Cumulative Updates for Lync Server 2013: February 2013 applied.

The mobility feature also supports *push notifications* for mobile devices that do not support applications running in the background. A push notification is a notification that is sent to a mobile device about an event that occurs while a mobile application is inactive. For example, a missed instant messaging (IM) invitation can result in a push notification.

Mcx, UCWA, Autodiscover Service, and support for push notifications are provided in Lync Server 2013. Updated client features, capabilities, and the use of UCWA as the mobility entry point are introduced in the Cumulative Updates for Lync Server 2013: February 2013.

1.3.17.2 Topologies and Components for Mobility

Topologies and Components for Mobility

Planning for External User Access > Scenarios for External User Access > Planning for Mobility >

Topic Last Modified: *2013-02-17*

`The information in this topic pertains to Cumulative Updates for Lync Server 2013`

To support Lync mobile applications on mobile devices, Lync Server 2013 provides three services: Lync Server 2013 Mcx Mobility Service, Lync Server 2013 Autodiscover Service, and Lync Server 2013 Push Notification Service. The Cumulative Updates for Lync Server 2013: February 2013 adds a complimentary, but advanced, service for Lync 2013 Mobile clients—mobility support through the use of the Unified Communications Web API, or UCWA. This section briefly describes these components and identifies the Lync Server 2013 topologies that support mobility.

Note:

Mobility services are also available in hybrid deployments. You are not required to deploy services for supporting mobility if your users are homed online. You do need to define a setting for the Autodiscover Service to enable mobile users to find their online identity.

Important:

If you are planning any external user connectivity (for example, federation, external user access, or mobility features), you must use Edge Servers with Standard Edition server and the Front End Server or Front End pool. The Standard Edition server and the Front End Server or Front End pool do not have the necessary components to enable external users to access your internal deployment, or for the internal deployment to communicate with your external users. For all scenarios that include external users collaborating or communicating with internal users, including mobility, you must deploy at least one Edge Server and one reverse proxy.

Push notification uses a type of federation to the Lync Online services, which hosts the Push Notification Clearing House (PNCH). Push notification refers to the sound alerts, on-screen alerts (text), and badges that are pushed by applications to the Apple iPhone, iPad, and Windows Phone, when the mobile device is inactive. PNCH receives push notifications from Lync Server. When PNCH receives a notification of a message, PNCH forwards a notification to mobile clients through either the Apple Push Notification Services or Lync Server 2013 Push Notification Service, based on the mobile client that the message is intended for. PNCH is a required service for these mobile clients. To federate to Lync Online, PNCH uses Edge Servers and certificates to ensure confidentiality and authentication, policies, and correctly configured domain name system (DNS) records. Nokia Symbian and Android-based Lync Mobile clients do not use PNCH.

For details about planning and deploying Edge Servers, see Planning for External User Access and Deploying External User Access.

The Lync 2013 Mobile clients for Apple devices introduced with the Cumulative Updates for Lync Server 2013: February 2013 no longer use push notification or the push notification clearing house (PNCH). Lync 2013 Mobile clients on Windows Phone still use push notification and the (PNCH).

Mobility Components

The services that support mobility are as follows:

- **Lync Server 2013 Unified Communications Web API (UCWA)** Provides services for real-time communications with mobile and web clients in Lync Server 2013. When you deploy the Cumulative Updates for Lync Server 2013: February 2013 to the Front End Server and Director, the installation creates a virtual directory in the internal and external web services (Ucwa). A web component that is part of the Ucwa virtual directory accepts calls from UCWA-enabled clients. The client apps communicate over a REST interface for presence, contacts, instant messaging, VoIP, video conferencing, and collaboration. UCWA uses a P-GET based channel to send events, such as an incoming call, incoming instant message, or a message to the client app.

Note:

REST or representational state transfer, is a software architectural style for distributed systems that has been widely adopted in many forms and is well suited to the requirements of Web services in general.

- **Lync Server 2013 Mobility Service (Mcx)** This service supports Lync functionality, such as instant messaging (IM), presence, and contacts, on mobile devices. The Mobility Service is installed on every Front End Server in each pool that is to support Lync functionality on mobile devices. When you install Lync Server 2013, a new virtual directory (Mcx) is created under both the internal website and the external website on your Front End Servers.

Important:

Lync Server 2013 with the Cumulative Updates for Lync Server 2013: February 2013 supports both the Mobility service introduced in the Cumulative Update for Lync Server 2010: November 2011, commonly known as Mcx, and the UCWA web component. The combination of these two mobility services provides interoperability and use by users with Lync 2010 Mobile and Lync 2013 Mobile clients on Lync Server 2013.

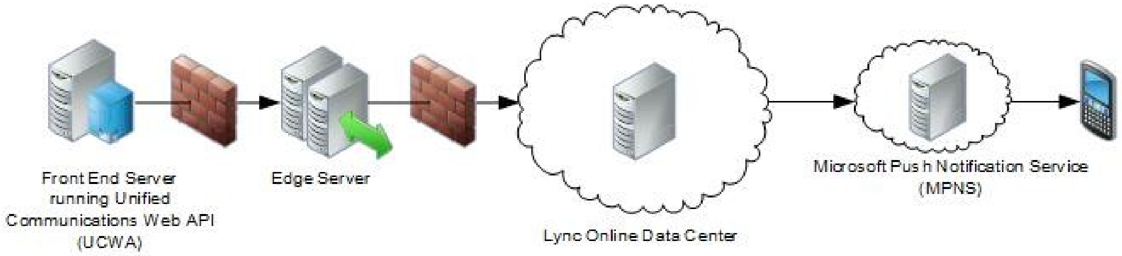
- **Lync Server 2013 Autodiscover Service** This service identifies the location of the user and enables mobile devices and other Lync clients to locate resources—such as the internal and external URLs for Lync Server 2013 Web Services, and the URL for the Mcx or UCWA—regardless of network location. Automatic discovery uses hardcoded host names (lyncdiscoverinternal for users inside the network; lyncdiscover for users outside the network) and the SIP domain of the user. It supports client connections that use either HTTP or HTTPS.
  The Autodiscover Service is installed on every Front End Server and on every Director in each pool that is to support Lync functionality on mobile devices. When you install the Autodiscover Service, a new virtual directory (Autodiscover) is created under both the internal website and the external website, on both Front End Servers and Directors.

Note:

The Autodiscover Service is listed here because it remains a critical component when providing mobile client services. The role of Autodiscover in Lync Server 2013 has been expanded to provide services for all clients. For details about planning for the Autodiscover Service, see Planning for Autodiscover.

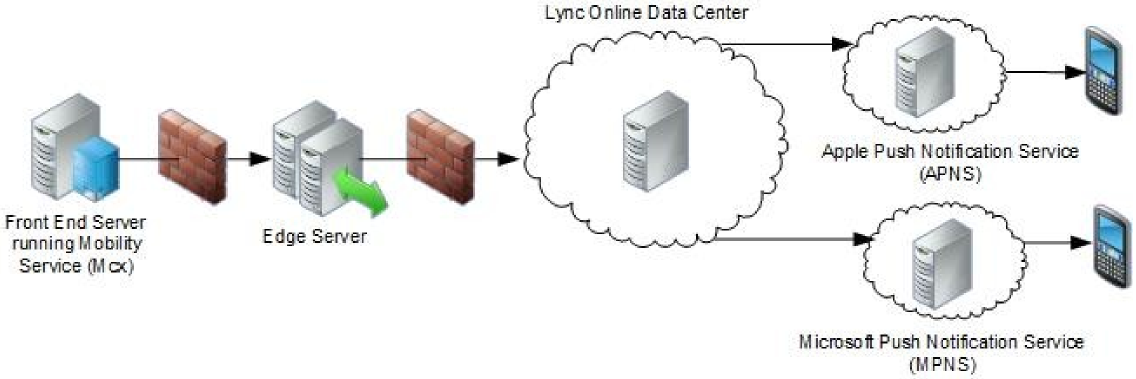
- **Push Notification Service** This service is a cloud-based service that is located in the Lync Online data center. When the Lync mobile application on a supported Apple iOS device or Windows Phone is inactive, it cannot respond to new events, such as a new instant messaging (IM) invitation, a missed instant message, a missed call, or voice mail, because these devices do not support mobile applications running in the background. In these cases, a notification of the new event—called a *push notification*—is sent to the mobile device. The Mobility Service sends the notification to the cloud-based Push Notification Service, which then sends the notification either to the Apple Push Notification Service (APNS) (for supported Apple iOS devices) or to the Microsoft Push Notification Service (MPNS) (for Windows Phone), which then sends it on to the mobile device. The user can then respond to the notification on the mobile device to activate the application.
  The Lync 2010 Mobile on Apple and Windows Phone devices use push notifications. The Lync 2013 Mobile client for Apple devices introduced with the Cumulative Updates for Lync Server 2013: February 2013 no longer uses push notification or the push notification clearing house (PNCH).

The following diagram illustrates how the Push Notification Service fits within a Lync Server 2013 topology that uses UCWA and Lync 2013 Mobile clients.



Front End Server running Unified Communications Web API (UCWA)
Edge Server
Lync Online Data Center
Microsoft Push Notification Service (MPNS)

Introduced in Cumulative Update for Lync Server 2010: November 2011, the Mcx service provides services to Lync 2010 Mobile clients. The following diagram illustrates the Push Notification Service as it applies to a topology using Mcx and Lync 2010 Mobile clients.



Lync Online Data Center
Apple Push Notification Service (APNS)
Front End Server running Mobility Service (Mcx)
Edge Server
Microsoft Push Notification Service (MPNS)

Supported Topologies

Applying the Cumulative Updates for Lync Server 2013: February 2013 adds the UCWA web components to support mobility for Lync 2013 Mobile client features in the following topologies:

- Lync Server 2013 Standard Edition
- Lync Server 2013 Enterprise Edition

The Edge Server can be a Lync Server 2010 Edge Server.

A Lync Server 2013 deployment without the Cumulative Updates for Lync Server 2013: February 2013 will use the Mcx Mobility Service and can provide services only for Lync 2010 Mobile.

Important:
The Mobility Service is supported on Front End Servers that is collocated with the Mediation Server role with two network interfaces, but you must take appropriate steps to configure the interfaces. You must assign the IP addresses to the specific interface that will communicate as the Mediation Server, and the network interface IP that will communicate as the Front End Server. You can do this in Topology Builder by selecting the correct IP address for each service, instead of using the default **Use all configured IP addresses**.

1.3.17.3 Technical Requirements for Mobility

Technical Requirements for Mobility

Planning for External User Access > Scenarios for External User Access > Planning for Mobility >

Topic Last Modified: *2013-02-19*

Some information in this topic pertains to Cumulative Updates for Lync Server 201

Mobile users encounter various mobile application scenarios that require special planning. For example, someone might start using a mobile application while away from work by connecting through the 3G network, then switch to the corporate Wi-Fi network when arriving at work, and then switch back to 3G when leaving the building. You need to plan your environment to support such network transitions and guarantee a consistent user experience. This section describes the infrastructure requirements that you must have in order to support mobile applications and automatic discovery of mobility resources.

Note:

Although mobile applications can also connect to other Lync Server 2013 services, the requirement to send all mobile application web requests to the same external web fully qualified domain name (FQDN) applies only to the Lync Server 2013 Mobility Service. Other mobility services do not require this configuration.

The requirement for cookie affinity in hardware load balancers is dramatically reduced, and you substitute Transmission Control Protocol (TCP) affinity if you are using the Lync Mobile delivered with Lync Server 2013. Cookie affinity can still be used, but the web services no longer require it.

Important:

All Mobility Service traffic goes through the reverse proxy, regardless of where the origination point is—internal or external. In the case of a single reverse proxy or a farm of reverse proxies, or a device that is providing the reverse proxy function, an issue can arise when the internal traffic is egressing through an interface and attempting to immediately ingress on the same interface. This often leads to a Security rule violation known as TCP packet spoofing or just spoofing. *Hair pinning* (the egress and immediate ingress of a packet or series of packets) must be allowed in order for mobility to function. One way to resolve this issue is to use a reverse proxy that is separate from the firewall (the spoofing prevention rule should always be enforced at the firewall, for security purposes). The hairpin can occur at the external interface of the reverse proxy instead of the firewall external interface. You detect the spoofing at the firewall, and relax the rule at the reverse proxy, thereby allowing the hairpin that mobility requires.
Use the Domain Name System (DNS) host or CNAME records to define the reverse proxy for the hairpin behavior (not the firewall), if at all possible.

Lync Server 2013 supports mobility services for Lync 2010 Mobile and Lync 2013 mobile clients. Both clients use the Lync Server 2013 Autodiscover Service to find its mobility entry point, but differ on which mobility service they use. Lync 2010 Mobile uses the Mobility Service known as *Mcx*, introduced with the Cumulative Update for Lync Server 2010: November 2011. Lync 2013 mobile clients use the Unified Communications Web API, or *UCWA*, as their mobility service provider.

Internal and External DNS Configuration

The Mobility Services Mcx (introduced with the Cumulative Update for Lync Server 2010: November 2011) and UCWA (introduced in the Cumulative Updates for Lync Server 2013: February 2013) use DNS in the same way.

When you use Automatic Discovery, mobile devices use DNS to locate resources. During the DNS lookup, a connection is first attempted to the FQDN that is associated with the internal DNS record (lyncdiscoverinternal.<*internal domain name*>). If a connection cannot be made by using the internal DNS record, a connection is attempted by using the external DNS record (lyncdiscover.<*sipdomain*>). A mobile device that is internal to the network connects to the internal Autodiscover Service URL, and a mobile device that is external to the network connects to the external Autodiscover Service URL. External Autodiscover requests go through the reverse proxy. The Lync Server 2013 Autodiscover Service returns all Web Services URLs for the user's home pool, including the Mobility Service (Mcx and UCWA) URLs. However, both the internal Mobility Service URL and the external Mobility Service URL are associated with the external Web Services FQDN. Therefore, regardless of whether a mobile device is internal or external to the network, the device always connects to the Lync Server 2013 Mobility Service externally through the reverse proxy.

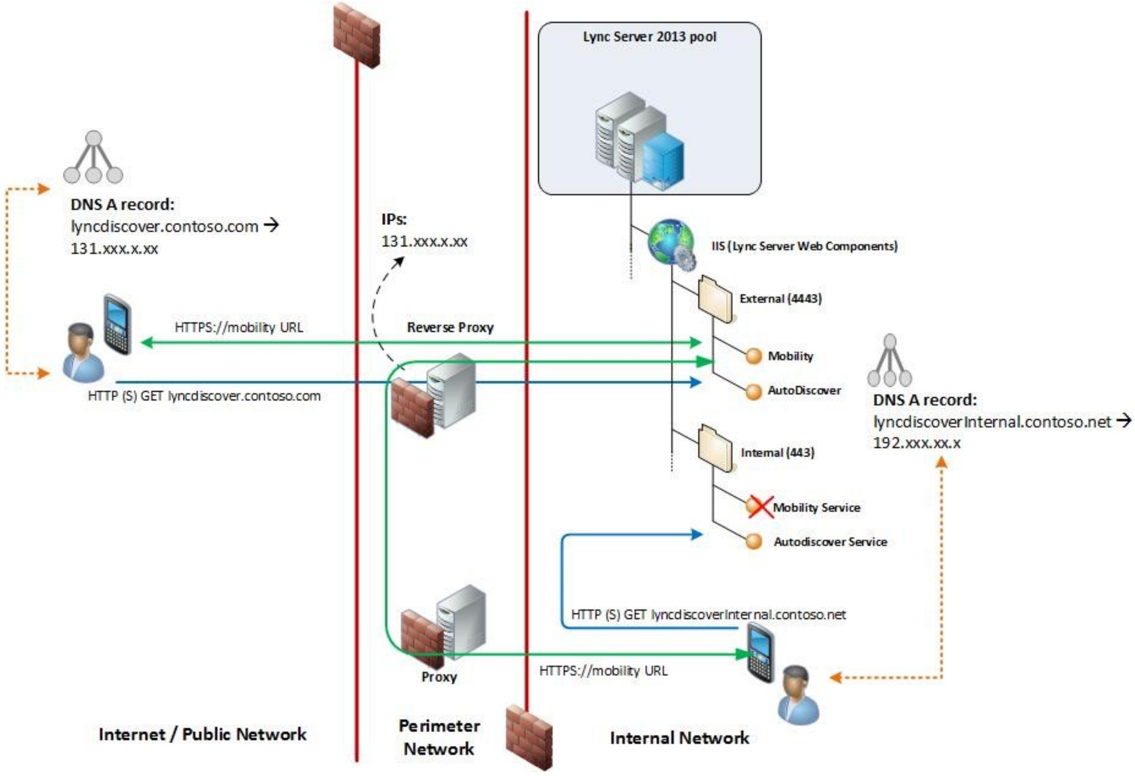
Note:

It is important to understand that your deployment can consist of multiple distinct namespaces for internal and external use. Your SIP domain name may be different than the internal deployment domain name. For example, your SIP domain may be **contoso.com**, while your internal deployment may be **contoso.net**. Users who log in to Lync Server will use the SIP domain name, such as **john@contoso.com**. When addressing the external web services (defined in Topology Builder as **External web services**), the domain name and the SIP domain name will be consistent, as defined in DNS. When addressing the internal Web services (defined in Topology Builder as **Internal web services**), the default name of the internal web services will be the FQDN of the Front End Server, Front End pool, Director, or Director pool. You have the option to override the internal web services name. You should use the internal domain name (and not the SIP domain name) for internal web services and define the DNS host A (or, for IPv6, AAAA) record to reflect the overridden name. For example, the default internal web services FQDN may be **pool01.contoso.net**. An overridden internal web services FQDN may be **webpool.contoso.net**. Defining the web services in this way helps to ensure that the internal and external locality of the services—and not the locality of the user who is using them—is observed.

However, because the web services are defined in Topology Builder and the internal web services name can be overridden, as long as the resulting web services name, the certificate that validates it, and the DNS records that define it, are consistent, you can define the internal web services with any domain name—including the SIP domain name—that you want. Ultimately, the resolution for the name to the IP address is determined by DNS host records and a consistent namespace.

For the purposes of this topic and the examples, the internal domain name is used to illustrate the topology and the DNS definitions.

The following diagram illustrates the flow of mobile application web requests for the Mobility Service and for the Autodiscover Service when using an internal and external DNS configuration.



Note:

The diagram illustrates generic web services. A virtual directory named Mobility depicts the Mobility services Mcx and/or UCWA. If you have not applied the Cumulative Updates for Lync Server 2013: February 2013, you may or may not have the virtual directory Ucwa defined on your internal and external Web services. You will have a virtual directory Autodiscover, and you may have a virtual directory Mcx.
Autodiscover and the discovery of services work the same way, regardless of the mobility services technology that you have deployed.

To support mobile users from both inside and outside the corporate network, your internal and external web FQDNs must meet some prerequisites. In addition, you may need to meet other requirements, depending on the features you choose to implement:

- New DNS, CNAME or A (host, if IPv6, AAAA) records, for automatic discovery.
- New firewall rule, if you want to support push notifications through your Wi-Fi network.
- Subject alternative names on internal server certificates and reverse proxy certificates, for automatic discovery.
- Front End Server hardware load balancer configuration changes source affinity.
- .

Your topology must meet the following requirements to support the Mobility Service and the Autodiscover Service:

- The Front End pool internal web FQDN must be distinct from the Front End pool external web FQDN.
- The internal web FQDN must only resolve to and be accessible from inside the corporate network.
- The external web FQDN must only resolve to and be accessible from the Internet.
- For a user who is inside the corporate network, the Mobility Service URL must be addressed to the external web FQDN. This requirement is for the Mobility

Service and applies only to this URL.
- For a user who is outside the corporate network, the request must go to the external web FQDN of the Front End pool or Director.

If you support automatic discovery, you need to create the following DNS records for each SIP domain:

- An internal DNS record to support mobile users who connect from within your organization's network.
- An external, or public, DNS record to support mobile users who connect from the Internet.

The internal automatic discovery URL should not be addressable from outside your network. The external automatic discovery URL should not be addressable from within your network. However, if you cannot meet this requirement for the external URL, mobile client functionally will probably not be affected, because the internal URL is always tried first.

The DNS records can be either CNAME records or A (host, if IPv6, AAAA) records.

Note:
Mobile device clients do not support multiple Secure Sockets Layer (SSL) certificates from different domains. Therefore, CNAME redirection to different domains is not supported over HTTPS. For example, a DNS CNAME record for lyncdiscover.contoso.com that redirects to an address of director.contoso.net is not supported over HTTPS. In such a topology, a mobile device client needs to use HTTP for the first request, so that the CNAME redirection is resolved over HTTP. Subsequent requests then use HTTPS. To support this scenario, you need to configure your reverse proxy with a web publishing rule for port 80 (HTTP). For details, see "To create a web publishing rule for port 80" in Configuring the Reverse Proxy for Mobility. CNAME redirection to the same domain is supported over HTTPS. In this case, the destination domain's certificate covers the originating domain.

For details about the DNS records required for your scenario, see DNS Summary - Autodiscover.

Port and Firewall Requirements

If you support push notifications and want Apple mobile devices to receive push notifications over your Wi-Fi network, you also need to open port 5223 on your enterprise Wi-Fi network. Port 5223 is an outbound TCP port used by the Apple Push Notification Service (APNS). The mobile device initiates the connection. For details, see http://support.apple.com/kb/TS1629 .

⚠**Warning:**
An Apple device using the Lync 2013 Mobile client does not require push notifications.

For additional details and guidance on port and protocol requirements for Autodiscover, see Port Summary - Autodiscover.

Certificate Requirements

If you support automatic discovery for Lync mobile clients, you need to modify the subject alternative name lists on certificates to support secure connections from the mobile clients. You need to request and assign new certificates, adding the subject alternative name entries described in this section, for each Front End Server and Director that runs the Autodiscover Service. The recommended approach is to also modify the subject alternative names lists on certificates for your reverse proxies. You need to add subject alternative name entries for every SIP domain in your organization.

Reissuing certificates by using an internal certificate authority is typically a simple process, but adding multiple subject alternative name entries to public certificates used by the reverse proxy can be expensive. If you have many SIP domains, making the addition of subject alternative names very expensive, you can configure the reverse proxy to make the initial Autodiscover Service request over port 80 using HTTP, instead of port 443 using HTTPS (the default configuration). The request is then redirected to port 8080 on the Director or Front End pool. When you publish the initial Autodiscover Service request on port 80, you do not need to change certificates for the reverse proxy, because the request uses HTTP rather than HTTPS. This approach is supported, but we do not recommend it.

Internet Information Services (IIS) Requirements

We recommend that you use IIS 7.5 or IIS 8.0 for mobility. The Mobility Service installer sets flags in ASP.NET to improve performance. IIS 7.5 is installed by default on Windows Server 2008 R2 and IIS 8.0 is installed on Windows Server 2012. The Mobility Service installer automatically changes the ASP.NET settings.

Hardware Load Balancer Requirements

On the hardware load balancer that is supporting the Front End pool, the external Web Services virtual IPs (VIPs) for Web Services traffic must be configured for source. Source affinity helps to ensure that multiple connections from a single client are sent to one server to maintain session state. For details about affinity requirements, see Load Balancing Requirements.

If you plan to support Lync mobile clients only over your internal Wi-Fi network, you should configure the internal Web Services VIPS for source as described for external Web Services VIPs. In this situation, you should use source_addr (or TCP) affinity for the internal Web Services VIPs on the hardware load balancer. For details, see Load Balancing Requirements.

Reverse Proxy Requirements

If you support automatic discovery for Lync mobile clients, you need to update the current publishing rule as follows:

- If you decide to update the subject alternative names lists on the reverse proxy certificates and use HTTPS for the initial Autodiscover Service request, you must update the web publishing rule for lyncdiscover.<*sipdomain*>. Typically, this is combined with the publishing rule for the external Web Services URL on the Front End pool.
- If you decide to use HTTP for the initial Autodiscover Service request so that you do not need to update the subject alternative names list on the reverse proxy certificates, you must create a new web publishing rule for port HTTP/ TCP 80, if one does not already exist. If a rule for HTTP/TCP 80 does already exist, you can update that rule to include the lyncdiscover.<*sipdomain*> entry.

1.3.17.4 Autodiscover Service Requirements

Autodiscover Service Requirements

Planning for External User Access > Scenarios for External User Access > Planning for Mobility >

Topic Last Modified: *2013-02-25*

The Microsoft Lync Server 2013 Autodiscover Service runs on the Director and Front End pool servers, and when published in DNS, can be used by mobile devices running Lync Mobile to locate mobility services. Before mobile devices running Lync Mobile can take advantage of automatic discovery, you need to modify certificate subject alternative name lists on any Director and Front End Server running the Autodiscover Service. In addition, it may be necessary to modify the subject alternative name lists on certificates used for external web service publishing rules on reverse proxies.

For details about the subject alternative name entries that are required for Directors, Front End Servers, and reverse proxies, see Technical Requirements for Mobility in Planning for Mobility.

The decision about using subject alternative name lists on reverse proxies is based on whether you publish the Autodiscover Service on port 80 or on port 443:

- **Published on port 80** No certificate changes are required if the initial query to the Autodiscover Service occurs over port 80. This is because mobile devices running Lync will access the reverse proxy on port 80 externally and then be redirected to a Director or Front End Server on port 8080 internally. For details, see the "Initial Autodiscover Process Using Port 80" section later in this topic.
- **Published on port 443** The subject alternative name list on certificates used by the external web services publishing rule must contain a *lyncdiscover.<sipdomain>* entry for each SIP domain within your organization.

Reissuing certificates using an internal certificate authority is typically a simple process but for public certificates used on the web service publishing rule, adding multiple subject alternative name entries can become expensive. To work around this issue, we support the initial automatic discovery connection over port 80, which is then redirected to port 8080 on the Director or Front End Server.

For example, assume that a mobile client running Lync Mobile is configured to sign in to Lync Server 2013 using the automatic discovery feature using HTTP for the initial request.

Initial Autodiscover Process for Mobile Devices Using Port 80

1. Mobile device running Lync Mobile looks up lyncdiscover.contoso.com using DNS, where an A record exists.
2. External DNS returns the IP address for the external web services to the client.
3. Mobile device running Lync Mobile sends request http://lyncdiscover.contoso.com?sipuri=lyncUser1@contoso.com to the reverse proxy
4. The web publishing rule will bridge the request from port 80 externally to port 8080 internally, which will then route it to either a Director or Front End Server.
   Since the request is HTTP and not HTTPS, no modifications are needed to the certificate on the external web service publishing rule to support the Autodiscover Service.
5. The Autodiscover Service returns the external web service URLs (in HTTPS format).
6. The mobile device running Lync Mobile can then reconnect to the reverse proxy on port 443 and is redirected over 4443 to the mobility service running on the user's home pool.
   Since the HTTPS query is to the external web services URL vs. the Autodiscover Service URL, it succeeds because the certificate will already

contain subject alternative name entries for the external web services fully qualified domain names (FQDNs).
In this scenario, there are no certificate changes required to support mobility.

> **Note:**
> If the target web server has a certificate that does not have a matching value for lyncdiscover.contoso.com as a subject alternative name list value:
> a. Web server responds with a "Server Hello" and no certificate.
> b. Mobile device running Lync Mobile immediately terminates the session.
> If the target web server has a certificate that includes lyncdiscover.contoso.com as a subject alternative name list value:
> a. Web server responds with a "Server hello" and a certificate.
> b. Mobile device running Lync Mobile validates the certificate and completes the handshake.

To support an initial connection to the Autodiscover Service using port 80 on your reverse proxy server, you can create an http publishing rule similar to this example for a Forefront Threat Management Gateway 2010 reverse proxy web publishing rule:

1. Create a new web publishing rule (for example, **Lync Server Autodiscover (HTTP)**).
2. In **Public Name**, enter lyncdiscover.contoso.com.
3. On the **Bridging** tab, select only the option to bridge requests from Port 80 to Port 8080.
4. On the **Authentication** tab, select **No authentication**, and **Client cannot authenticate directly**.
5. Commit changes, and move the rule to the top of the list of Lync rules (first in processing order).

Mobility for the Split Domain Deployment

A shared SIP address space, also known as a *split-domain*, or a *hybrid deployment* is a configuration where users are deployed across an on-premise deployment and an online environment. The desired outcome is to have a user, regardless of where their home server is located (on-premise or online), to log into the deployment and be redirected to their home server location. To accomplish this, the Autodiscover feature of Microsoft Lync Server 2013 is used to redirect the online user to the online topology. This is done by configuring the Autodiscover uniform resource locator (URL) by using the Lync Server Management Shell and the cmdlets **Get-CsHostingProvider** and **Set-CsHostingProvider**.

You will need to collect and record the following deployed attributes:

- From the Lync Server Management Shell, type

```
Get-CsHostingProvider
```

- In the results, find the online provider with the attribute **ProxyFQDN**. For example, sipfed.online.lync.com
- Record the value of the ProxyFQDN
- Enable federation in the on-premise Lync Server Control Panel, allowing federation with the online provider
- Enable federation for the online provider. By default, all online users are enabled for domain federation and can communicate with all domains
- If you will define blocked and allowed domains, determine the domains that you will explicitly allow or explicitly block
- For online federation, you must plan for firewall exceptions, certificates and DNS host (A or AAAA, if using IPv6) records. Additionally, you must configure federation policies. For details, see Planning for Lync Server and Office Communications Server Federation

1.3.17.5 Defining Your Mobility Requirements

Defining Your Mobility Requirements

See Also

Planning for External User Access > Scenarios for External User Access > Planning for Mobility >

Topic Last Modified: *2013-02-14*

```
Some information in this topic pertains to Cumulative Updates for Lync Server 201
```

During the planning phase for the Lync Server 2013 mobility feature, when you are using Lync 2010 Mobile and Lync 2013 Mobile clients, you make decisions that determine your deployment steps.

Here are the decisions that you must consider:

- **Do you want to use automatic discovery for Lync mobile clients?**
  If you want to support automatic discovery, you need to create new internal and external Domain Name System (DNS) records, add subject alternative names to certificates on the Front End Servers, Directors, and reverse proxy, and modify the existing publishing rules on the reverse proxy. For details, see Technical Requirements for Mobility. With automatic discovery, users can automatically locate Lync Server 2013 Web Services from anywhere inside or outside the corporate network, without entering URLs in their mobile device settings.
  If you use manual settings instead of automatic discovery, mobile users need to manually enter the following URLs in their mobile devices:
  - https://<ExtPoolFQDN>/Autodiscover/autodiscoverservice.svc/Root for external access
  - https://<IntPoolFQDN>/AutoDiscover/ autodiscoverservice.svc/Root for internal access

  We strongly recommend using automatic discovery. The primary use of manual settings is for troubleshooting.
- **If you decide to support automatic discovery, are you willing to update certificates on the reverse proxy with subject alternative names for each SIP domain?**
  If you have many SIP domains, updating public certificates on the reverse proxy can become very expensive. If this is the case, you can choose to implement automatic discovery so that the initial Autodiscover Service request uses HTTP on port 80, instead of using HTTPS on port 443. However, this is not the recommended approach. If you decide to choose this alternative, you do not need to update the certificates on the reverse proxy, but you need to create a web publishing rule for HTTP on port 80. For more details, see Technical Requirements for Mobility.
- **Do you want to support Lync mobile clients both internal and external to the corporate network, or support clients only inside the corporate network?**
  If you want to support mobile clients internal and external to your network, mobile devices can access mobility features from any location. The default configuration is to support clients both internal and external to the corporate network.
  Although the default configuration enables mobile client traffic to go through the external site, you can restrict mobile client traffic to the internal corporate network. When you restrict the traffic to the internal network, users can use Lync mobile applications on their mobile devices only when they are inside the network.
  For deployments that support mobility using the Mcx mobility service and Lync 2010 Mobile, you run the **Set-CsMcxConfiguration** cmdlet. To set mobility for internal use only, you would use a command similar to the following:

```
Set-CsMcxConfiguration -Identity site:Redmond -ExposedWebURL Internal
```

Note:
There are no additional configurations required for UCWA. UCWA does not have an equivalent internal-only configuration.

Important:
If you are using a Lync Server 2013 Front End Server or Front End pools and **you do not have** any Lync Server 2010 Front End Servers or Front End pools, **there is no requirement for cookie-based persistence**. If you need to retain any Lync Server 2010 Front End Servers or Front End pools, the same rules still apply as in Lync Server 2010 for cookie-based persistence.

- **Do you want to support push notifications for Apple iOS devices and Windows Phones?**
  If you support push notifications, supported Apple iOS devices and Windows Phones receive a notification of events that occur when the mobile application is inactive. You must configure your Edge Server to have a federation relationship with the cloud-based Lync Server Push Notification Service, which is located in the Lync Online datacenter, and run a cmdlet to enable push notifications.
  If you want to support push notifications over your Wi-Fi network, in addition to supporting push notifications over the mobile device providers' 3G or data networks, you must open port 5223 outbound on your enterprise Wi-Fi network. Supporting push notifications over the Wi-Fi network supports mobile devices that use only Wi-Fi and mobile devices that have poor indoor reception.

  Important:
  Opening port TCP 5223 is required only when supporting Apple devices running the Lync 2010 Mobile client.

  If you do not support push notifications, users of Apple mobile devices and Windows Phones will not find out about events—such as instant message invitations or missed messages—that occur when the mobile application is inactive.

  Note:
  Lync 2013 Mobile clients on Apple devices do not require push notification. The Lync 2013 Mobile clients on Windows Phone use push notification. Planning for push notification and the push notification clearinghouse remain the same for Lync Mobile on Windows Phone and Apple devices that are not able to run the Lync 2013 Mobile client.

- **Do you want all users to have access to mobility features, or do you want to be able to specify which users have access to these features?**
  The table describes features available to users in Lync Server 2013. The defaults allow Call via Work, allow Voice over IP (VoIP), and enable Mobility. Here is the full set of available options:

Feature/Paramater Name/Scope (Policy parameter names may not be the same)	**Description**	**Introduced**
Enable Mobility Parameter Name : `EnableMobility` Scope: Global/Site/User	Administrative setting to control users in a given scope that have the Lync Mobile installed, If the policy is set to False, the user would not be able to sign into the client. The default setting is	Cumulative Update for Lync Server 2010: November 2011

	True.	
Enable Outside Voice Parameter Name : `EnableOutsideVoice` Scope: Global/Site/User	Controls a user's ability to use Call Via Work, a feature that enables users to make and receive calls by using their work number instead of their mobile number. If set to False, the user will not be able to make or receive calls by using their work number from their mobile device. The default setting is True	Cumulative Update for Lync Server 2010: November 2011
Enable IP Audio and Video Parameter Name : `EnableIPAudioVideo` Scope: Global/Site/User	Controls whether a user can use VoIP to make or receive voice or video calls on their mobile device. If set to False, the user will not be able to make or receive VoIP or video calls on their device. The default setting is True.	Microsoft Lync Server 2013
Require WiFi for IP Audio Parameter Name : `RequireWiFiForIPAudio` Scope: Global/Site/User	This setting defines whether the client will be required to make and receive calls over VoIP on WiFi instead of the cellular data network. If set to True, the user can make and receive VoIP calls only when connected to a WiFi network. The default setting is False.	Microsoft Lync Server 2013
Require WiFi for IP Video Parameter Name : `RequireWiFiForIPVideo` Scope: Global/Site/User	This setting defines whether the client will be required to make and receive video calls on Wi-Fi instead of on the cellular data network. If set to True, the user can make and receive video calls only when connected to a Wi-Fi network. The default setting is False.	Microsoft Lync Server 2013

For a description of the policy settings that you can configure, and how to manage the policies, see New-CsMobilityPolicy, Set-CsMobilityPolicy, Get-CsMobilityPolicy, Grant-CsMobilityPolicy and Remove-CsMobilityPolicy.

- **Do you want users who are not enabled for Enterprise Voice to be able to**

use Click to Join to join conferences?
For users to have access to mobility features and Call via Work, they must be enabled for Enterprise Voice. However, users who are not enabled for Enterprise Voice can join conferences by clicking the link on their mobile device, if they have an appropriate voice policy assigned to them. You can either assign a specific voice policy to these users or make sure that a global policy or site-level policy exists that applies to them. The voice policy that you assign must have public switched telephone network (PSTN) usage records and routes that define the areas to which users can dial out to join a conference. For details about setting voice policy, PSTN usage records, and routes, see Configuring Voice Policies, PSTN Usage Records, and Voice Routes.

Note:
Mobile users who want to use Click to Join require a voice policy, along with the related PSTN usage records and voice routes, because clicking the link on the mobile device results in an outbound call from Lync Server 2013.

1.3.17.6 Deployment Process for Mobility

Deployment Process for Mobility

Planning for External User Access > Scenarios for External User Access > Planning for Mobility >

Topic Last Modified: *2013-02-19*

```
Some information in this topic pertains to Cumulative Updates for Lync Server 201
```

This section describes the sequence of steps required to deploy the Lync Server 2013 mobility feature.

Mobility Deployment Process

Phase	Steps	Permissions	Deployment documentation
Create Domain Name System (DNS) records	• Create an internal DNS CNAME or A (host, if IPv6, AAAA) record to resolve the internal Autodiscover Service URL. • Create an external DNS CNAME or A (host, if IPv6, AAAA) record to resolve the external Autodiscover Service URL.	Domain Admins DnsAdmins	Creating DNS Records for the Autodiscover Service
Modify certificates	Add subject alternative name entries to the following certificates to support secure connections for mobile users: • Director certificate • Front End pool certificate	Local administrator	Modifying Certificates for Mobility

	• Reverse proxy certificate		
Configure the reverse proxy	• Assign certificates updated with subject alternative names to the Secure Sockets Layer (SSL) Listener. • Reconfigure the web publishing rule for the external Autodiscover Service URL. • Be sure that a web publishing rule exists for the external Lync Server 2013 Web Services URL on your Front End pool. Or • If you choose to use HTTP for the initial Autodiscover request and do not update subject alternative name lists on the certificates, configure a new web publishing rule or reconfigure an existing publishing rule for port 80 HTTP.	Local administrator	Configuring the Reverse Proxy for Mobility
Test your mobility deployment for Lync 2010 Mobile using the Mcx Mobility Service	Run **Test-CsMcxP2PIM** to test sending an instant message from one person to another. See the Lync Server Management Shell cmdlet documentation for Test-CsMcxP2PIM for a complete list of options.	CsAdministrator	Verifying Your Mobility Deployment
Test your mobility deployment for Lync 2013 Mobile clients using the UCWA Web components	Use the **Test-CsUcwaConference** cmdlet to test and verify that pre-defined test users or a pair of actual users can use UCWA to create and participate in a conference. See the Lync Server Management Shell cmdlet documentation for Test-CsUcwaConference for a complete list of options.	CsAdministrator	Verifying Your Mobility Deployment

Configure for push notifications	• For Lync Server 2013 Edge Servers, add a Lync Server online hosting provider and configure hosting provider federation. • For Lync Server 2010 Edge Servers, add a Lync Server online hosting provider and configure hosting provider federation. • For Office Communications Server 2007 R2 Edge Servers, add a federated partner. • If you want to support push notifications over a Wi-Fi network, configure a firewall rule outbound for TCP port 5223. • Use the **Set-CsPushNotificationConfiguration** cmdlet to enable push notifications to the Apple Push Notification Service (APNS) and Microsoft Push Notification Service (MPNS). This feature is disabled by default. • Use the **Test-CsFederatedPartner** cmdlet to test the federation configuration and the **Test-CsMCXPushNotification** cmdlet to test push notifications. **Note:** Push notifications are used for Lync 2010 Mobile clients on Apple devices and Windows Phone Push notification is required for Lync 2013 Mobile clients on Windows Phone	RtcUniversalServerAdmins	Configuring for Push Notifications

	only		
Configure mobility policy	Use the **Set-CsMobilityPolicy** cmdlet to allow or disallow: • Call via Work • Enable IP Audio and IP Video • Require WiFi for IP Audio and/or IP Video	CsAdministrator	Configuring Mobility Policy

1.4 Deployment

Deployment

Microsoft Lync Server 2013 >

Topic Last Modified: *2012-10-18*

Deployment of Lync Server 2013 communications software includes preparing Active Directory Domain Services (AD DS), deploying the Front End Servers and other core Lync Server 2013 internal components, and then deploying any additional server roles and features that your organization may require, such as external user access and Enterprise Voice.

This documentation describes three scenarios for deploying Lync Server 2013:

- New Deployment of Lync Server 2013, Enterprise Edition
- New Deployment of Lync Server 2013, Standard Edition
- New Deployment of Lync Server 2013 Standard Edition or Enterprise Edition into an existing Lync Server 2010 Standard Edition or Enterprise Edition deployment

For information about deploying Lync Server 2013 in an existing Microsoft Office Communications Server 2007 or Microsoft Office Communications Server 2007 R2 environment, see the Migration documentation.

- Deploying Lync Server 2013
- Deploying External User Access
- Deploying Enterprise Voice
- Deploying Monitoring
- Deploying Archiving
- Configuring Dial-in Conferencing
- Configuring Video
- Deploying Branch Sites
- Deploying Persistent Chat Server
- Deploying Clients and Devices
- Planning and Deploying Unified Contact Store
- Managing Server-to-Server Authentication (Oauth) and Partner Applications
- Updating From the Evaluation Version of Lync Server 2013
- Deploying Remote Call Control
- Deploying Mobility
- Configuring Integration with Office Web Apps Server and Lync Server 2013
- Health Configuration in Lync Server 2013

1.4.1 Deploying Lync Server 2013

Deploying Lync Server 2013

Microsoft Lync Server 2013 > Deployment >

Topic Last Modified: *2012-10-18*

Your deployment process for Lync Server 2013 is determined by the Lync Server topology and components you decide to install, including whether you want to deploy a Front End pool or a Standard Edition server. The topics in this section help you determine what environment you want to deploy and guide you through the deployment process.

- Deployment Overview
- System Requirements
- Preparing the Infrastructure and Systems
- Defining and Configuring the Topology
- Finalizing and Implementing the Topology Design
- Setting Up Front End Servers and Front End Pools
- Deploying Lync Server 2013 Standard Edition into an Existing Lync Server 2013 Enterprise
- Adding Server Roles
- Setting Up Kerberos Authentication

1.4.1.1 Deployment Overview

Deployment Overview

Microsoft Lync Server 2013 > Deployment > Deploying Lync Server 2013 >

Topic Last Modified: *2013-03-12*

The main difference between Lync Server 2013 Enterprise Edition and Lync Server 2013 Standard Edition is that Standard Edition does not support the high availability features included with Enterprise Edition. For high availability, you need to deploy multiple Front End Servers to a pool and then you can mirror the server running SQL Server. With Enterprise Edition you can choose to collocate or define a stand-alone Mediation Server. The Monitoring Server and Archiving Server can use a stand-alone server running SQL Server. Or, they can have instances of SQL Server running on the database server for the Front End Servers and pools.

Servers running Lync Server 2013 Standard Edition are intended for smaller organizations and remote locations, which are geographically removed from the organization’s main deployment. Two Standard Edition server servers paired together for failover in case of disaster can support up to 5,000 users. You cannot pool Standard Edition servers like you can Front End Servers in Enterprise Edition. Also, the SQL Server database that Standard Edition uses is a collocated server running SQL Server Express that is designed to handle Standard Edition server workloads. This is not to say that all roles must reside on a Standard Edition server. You can have stand-alone Mediation Servers and Edge Servers. The SQL Server database for the Central Management store and for the purposes of Lync Server 2013 must reside on the Standard Edition server collocated with the server running SQL Server. The Monitoring Server and Archiving Server use a stand-alone server with the SQL Server database.

1.4.1.2 System Requirements

System Requirements

Microsoft Lync Server 2013 > Deployment > Deploying Lync Server 2013 >

Topic Last Modified: *2012-06-20*

This section discusses the system requirements for deploying Lync Server 2013 and all of the associated components.

- Administrator Rights and Permissions Required for Setup and Administration
- System Requirements for Servers Running Lync Server 2013
- System Requirements for SQL Server
- System Requirements for Administration Tools
- DNS Requirements

1.4.1.2.1 Administrator Rights and Permissions Required for Setup and Administration

Administrator Rights and Permissions Required for Setup and Administration

Deployment > Deploying Lync Server 2013 > System Requirements >

Topic Last Modified: *2012-06-29*

Setup and deployment of Lync Server 2013 requires that the person installing and deploying the software be a member of local or domain-level groups. Administrative tools for Lync Server 2013 can require additional permissions.

- Group Membership Requirements
- Delegate Setup Permissions

1.4.1.2.1.1 Group Membership Requirements

Group Membership Requirements

Deploying Lync Server 2013 > System Requirements > Administrator Rights and Permissions Required for Setup and Administration >

Topic Last Modified: *2012-10-05*

The following table summarizes the group or groups that a person should belong to in order to successfully install, manage, and troubleshoot Lync Server 2013.

Lync Server 2013 Executable	Group Membership Required
Setup.exe – Executable that starts the installation of the Lync Server 2013 administrative tools.	Member of the Local Administrators group on the computer from which the executable is run. Member of Domain Users group to read information in Active Directory Domain Services (AD DS). This level of permission is required because the automatic installation of required MSI packages on the local computer requires privileges that allow reading from and writing to protected local computer resources such as Program Files directories, and protected registry such as the Local Machine hive. **Tip:**

	You can also delegate setup permissions to users or groups to whom you do not want to grant membership in the Domain Admins group. For details, see Granting Setup Permissions in the Deployment documentation.
Deploy.exe – Called by setup.exe, deploy.exe is responsible for the deployment of the software components for the server roles.	Member of the Local Administrators group on the computer from which the executable is run. Member of Domain Users group to read information in AD DS. This level of permission is required because the automatic installation of required MSI packages on the local computer requires privileges that allow reading from and writing to protected local computer resources such as Program Files directories, and protected registry such as the Local Machine hive. Membership in RtcUniversalReadOnlyAdmins group is necessary to read the Central Management store. **Note:** If you are running the Windows Vista operating system or Windows 7 operating system, you will be prompted by User Account Control (UAC) to proceed with installation. If you are logged on with a standard user account, you will need someone who is a member of the Local Administrators group to provide credentials when prompted for an account with permissions to install the software.
Bootstrapper.exe – Called by setup.exe, bootstrapper.exe is responsible for deployment and configuration of server roles.	Member of the Local Administrators group on the computer from which the executable is run. Member of the RTCUniversalServerAdmins group to run Bootstrapper.exe. Member of Domain Users group to read information in AD DS. This level of permission is required because the automatic installation of required MSI packages on the local computer requires privileges that allow reading from and writing to protected local computer resources such as Program Files directories, and protected registry such as the Local Machine hive.
TopologyBuilder – Wizard-driven user interface to create, view, adjust, and validate Lync Server 2013 topologies.	Member of the Local Administrators group on the computer from which the executable is run to view the topology. Member of the RTCUniversalServerAdmins group to change configuration settings. Member of the RTCUniversalServerAdmins group and Domain Admins group, or member of the RTCUniversalServerAdmins group (only if the group has been granted delegate setup permissions), to publish the topology. For details about delegating setup permissions to allow members of the RTCUniversalServerAdmins group to publish the topology without being members of the Domain Admins group, see Granting Setup Permissions in the Deployment documentation.
AdminUIHost – Web-based graphical user interface for managing Lync	Member of CsAdministrator group or member of another role-based access control (RBAC) role to

Server 2013.	which the specific administrative task is assigned. Lync Server 2013 Control Panel implements configuration changes by running Lync Server 2013 Management Shell cmdlets. For a list of predefined roles and the cmdlets members are permitted to run, see Planning for Role-Based Access Control in the Planning documentation.
PowerShell.exe with the Lync Server 2013 module loaded – Command-line administrative tool with cmdlets specific to management of Lync Server 2013.	Member of CsAdministrator group or member of another RBAC role to which the specific cmdlet has been assigned. For a list of predefined roles and the cmdlets members are permitted to run, see Planning for Role-Based Access Control in the Planning documentation. Or, member of one or more of the following groups, depending on the cmdlet: • RTCUniversalServerAdmins • RTCUniversalUserAdmins • RTCUniversalReadOnlyAdmins

1.4.1.2.1.2 Delegate Setup Permissions

Delegate Setup Permissions

Deploying Lync Server 2013 > System Requirements > Administrator Rights and Permissions Required for Setup and Administration >

Topic Last Modified: *2012-10-01*

If you do not want to grant membership in the Domain Admins group to users or groups who are deploying Lync Server 2013, you can enable members of the RTCUniversalServerAdmins group to run the **Enable-CsTopology** Windows PowerShell cmdlet on servers running Lync Server 2013. By default, members of the RTCUniversalServerAdmins group do not have the ability to run this cmdlet. You grant administrator rights and permissions to run **Enable-CsTopology** on servers running Lync Server by using the **Grant-CsSetupPermission** cmdlet and specifying an organizational unit (OU) where computer objects for the server running Lync Server 2013 are located.

Note:

Enable-CsTopology is the key cmdlet to allow the RTCUniversalServerAdmins group members to set up and deploy Lync Server 2013.

⊟To add the ability to run Enable-CsTopology to the RTCUniversalServerAdmins group

1. Log on to a server as a member of the Domain Admins group for the domain on which the delegated user will run **Enable-CsTopology**.
2. Open the Lync Server 2013 Management Shell. The Lync Server 2013 Management Shell is automatically installed on each Front End Server or any computer where the Lync Server 2013 administrative tools have been installed. For details about the Lync Server 2013 Management Shell, see Lync Server Management Shell in the Operations documentation.
3. Run the following cmdlet from the Lync Server 2013 Management Shell:

```
Grant-CsSetupPermission -ComputerOU <DN of the OU> -Domain <Domain FQD
```

Note:

If the OU is not top level, you must provide the full domain name.

In the following example, the OU is “Lync Servers,” which is in the contoso.com domain.

```
Grant-CsSetupPermission -ComputerOU "OU=Lync Servers" -Domain contoso.
```

1.4.1.2.2 System Requirements for Servers Running Lync Server 2013

System Requirements for Servers Running Lync Server 2013

Deployment > Deploying Lync Server 2013 > System Requirements >

Topic Last Modified: *2013-03-12*

Standard Edition and Enterprise Edition servers share the same software requirements.

Servers running Lync Server 2013, Enterprise Edition are intended for large organizations as the main organizational deployment. Enterprise Edition server is designed to scale to approximately 80,000 homed users per pool. Servers running Lync Server 2013, Standard Edition are intended for smaller organizations and remote locations from the main organization deployment. One pair of Standard Edition servers can support up to 5,000 users.. For details on the differences between Standard Edition servers and Enterprise Edition servers, see Deployment Overview.

Operating System Installation

Important:

Lync Server 2013 is available only in a 64-bit edition, which requires 64-bit hardware and a 64-bit edition of the Windows Server operating system. A 32-bit edition of Lync Server 2013 is not available with this release.

Standard Edition and Enterprise Edition server can use any of the following:

- Windows Server 2008 R2 SP1 or latest service pack
- Windows Server 2012

Install the operating system software on the Standard Edition Server or Enterprise Edition Front End Server. Apply all updates in order to bring the operating system up to the latest update and required update level consistent with your organization’s standards. For more details about the operating requirements, see Server and Tools Operating System Support in the Supportability documentation.

Additional Software for Lync Server 2013

In addition to the updates required for the operating system, Lync Server 2013 requires operating system roles, features, and software to operate. For details about the additional software that must be installed prior to publishing your topology and installing Lync Server 2013, see Additional Software Requirements in the Planning documentation.

Additional Software Necessary for All Server Roles

On all server roles, you must also make sure that Windows PowerShell command-line interface 3.0 and Microsoft .NET Framework 4.5 are installed.

Additionally, Windows PowerShell command-line interface 3.0 and Microsoft .NET Framework 4.5 are required on any computer where you will run the Lync Server administrative tools.

Windows PowerShell 3.0

Lync Server 2013 requires you to install Windows PowerShell 3.0 on each computer that will take part in your Lync Server topology. For details about installing Windows PowerShell 3.0, see Installing Windows PowerShell 3.0.

Note:
On Windows Server 2008 R2 with SP1, Windows PowerShell command-line interface 3.0 cannot be installed before installing Microsoft .NET Framework 4.5.

Microsoft .NET Framework 4.5

When you install Microsoft .NET Framework 4.5 on servers that will run Lync Server 2013 and Windows Server 2012, you must perform one additional step. After .NET Framework 4.5 is installed, use Server Manager to install HTTP Activation.

To Install .NET 4.5 HTTP Activation on Windows Server 2012

1. From the **Start** menu, click **Programs**, then click **Administrative Tools**, then click **Server Manager**.
2. In Server Manager, under **Features Summary**, choose **Add Features**.
3. Expand **.NET Framework 4.5**.
4. Select **WCF Activation** if it isn't already selected. Then select **HTTP Activation**.
5. Click **Next** and follow the prompts to finish the installation.

1.4.1.2.3 System Requirements for SQL Server

System Requirements for SQL Server

Deployment > Deploying Lync Server 2013 > System Requirements >

Topic Last Modified: *2012-09-13*

Before you deploy Enterprise Edition server, install Microsoft SQL Server 2008 R2 or Microsoft SQL Server 2012 on a dedicated computer that meets the hardware requirements. For details about hardware requirements, see Server Hardware Platforms in the Supportability documentation. For details about software requirements, see Database Software Support in the Supportability documentation.

Before you create the Front End pool, you must also configure Windows Firewall to allow Lync Server 2013 access to SQL Server over specific ports by defining ports for the server using SQL Server Configuration Manager and opening ports in Windows Firewall with Advanced Security.

1.4.1.2.4 System Requirements for Administration Tools

System Requirements for Administration Tools

Deployment > Deploying Lync Server 2013 > System Requirements >

Topic Last Modified: *2012-06-29*

The following topics describe the requirements for installing the administration tool and publishing a topology.

- Administrative Tools Software Requirements

- Requirements to Publish a Topology

1.4.1.2.4.1 Administrative Tools Software Requirements

Administrative Tools Software Requirements

Deploying Lync Server 2013 > System Requirements > System Requirements for Administration Tools >

Topic Last Modified: *2013-02-21*

This topic describes the software required to install and use Lync Server 2013 administrative tools in addition to the operating system requirements.

Microsoft .NET Framework 4.5

The 64-bit edition of Microsoft .NET Framework 4.5 is required for Lync Server 2013.

Windows PowerShell 3.0

Windows PowerShell 3.0 is required for running any component of Microsoft Lync Server 2013. For more information, see Installing Windows PowerShell 3.0.

Windows Installer Version 4.5

Lync Server 2013 uses Windows Installer technology to install, uninstall, and maintain various server roles. Windows Installer version 4.5 is available as a redistributable component for the Windows Server operating system. Windows Installer 4.5 ships with Windows Server 2012 and Windows Server 2008 R2, meaning that you do not need to download the utility for any computer that is running Lync Server 2013. (Lync Server 2013 can only be installed on computers running Windows Server 2012 or Windows Server 2008 R2.)

However, if you want to install Lync Server Management Shell or Lync Server Topology Builder on an administrator workstation you might need to download Windows Installer 4.5. That utility ships with Windows 7 and Windows 2008 R2 but not with any previous versions of the Windows operating system. You can download Windows Installer 4.5 from the Microsoft Download Center at http://go.microsoft.com/fwlink/p/?linkid=197395.

Microsoft Silverlight 5 browser plug-in

Lync Server 2013 Control Panel is a web-based tool and requires that you install the latest version of Microsoft Silverlight 5 browser plug-in. When you start Lync Server 2013 Control Panel, if this software is not installed or if an earlier version is installed, Lync Server 2013 Control Panel prompts you to install the required version.

1.4.1.2.4.2 Requirements to Publish a Topology

Requirements to Publish a Topology

See Also

Deploying Lync Server 2013 > System Requirements > System Requirements for Administration Tools >

Topic Last Modified: *2013-02-21*

This topic describes the infrastructure and software requirements that are specific to publishing a topology, whether by using Topology Builder or the Lync Server 2013 Management Shell command-line interface. These requirements are in addition to the general operating system, software, and permissions requirements applicable to all Lync Server 2013 administrative tools. Make sure that you satisfy all administrative tools requirements before you publish a topology.

- You must run Topology Builder on a computer that is joined to the same domain or forest of the Lync Server 2013 deployment you are creating so that Active Directory Domain Services (AD DS) preparation steps are already completed, enabling you to use the administrative tools on that computer to successfully publish your topology.
- The computers defined in the topology must be joined to the domain, except for Edge Servers, and in AD DS. However, the computers do not need to be online when you publish the topology.
- The file share for the pool must be created and available to remote users.
- In order to publish an Enterprise Edition Front End pool, the SQL Server-based Back End Server must be joined to the domain in which you are deploying the servers, online, and configured with the appropriate firewall rules to make it available to remote users. For details about specifying firewall exceptions, see Understanding Firewall Requirements for SQL Server. For other details about configuring SQL Server, see Configure SQL Server for Lync Server 2013.

Note:

Standard Edition server has a collocated database that will accept the published configuration. You must first run the **Prepare first Standard Edition server** setup task in the Lync Server Deployment Wizard.

1.4.1.2.5 DNS Requirements

DNS Requirements

Deployment > Deploying Lync Server 2013 > System Requirements >

Topic Last Modified: *2012-06-29*

The following topics describe the DNS requirements for a Front End pool and Standard Edition Server.

- DNS Requirements for Front End Pool
- DNS Requirements for a Standard Edition Server

1.4.1.2.5.1 DNS Requirements for Front End Pool

DNS Requirements for Front End Pool

Deploying Lync Server 2013 > System Requirements > DNS Requirements >

Topic Last Modified: *2012-11-07*

To successfully complete this procedure, you should be logged on to the server or domain minimally as a member of the Domain Admins group or a member of the DnsAdmins group.

You need to configure the required Domain Name System (DNS) records prior to publishing your topology in Topology Builder. Additionally, some of the fully qualified domain names (FQDNs) used in the configuration of a Lync Server 2013 deployment are logical and not physical server FQDNs, so additional DNS configuration is required prior to publishing.

⚠**Warning:**

Lync Server 2013 does not support single-labeled domains. For example, a forest with a root domain named **contoso.local** is supported, but a root domain named **local** is not supported. For details, see Microsoft Knowledge Base article 300684, "Information about configuring Windows for domains with single-label DNS names," at http://go.microsoft.com/fwlink/p/?linkid=3052&kbid=300684.

◆**Important:**

The name you specify must be identical to the computer name configured on the server. By default the computer name of a computer that is not joined to a domain is a short name, not an FQDN. Topology Builder uses FQDNs, not short names. **Use only standard characters** (including A–Z, a–z, 0–9, and hyphens) when assigning FQDNs of your servers running Lync Server, Edge Servers, and pools. Do not use Unicode characters or underscores. Nonstandard characters in an FQDN are often not supported by external DNS and public certification authorities (CAs) (when the FQDN must be assigned to the SN in the certificate).

Prior to operating the topology after it has been deployed, ensure that the following Active Directory and DNS records are created (as your needs for specific features dictate):

- Each server role that will exist in the topology is published as an Active Directory object (joining the computer to the domain will accomplish this).
- A DNS A Record exists for each server.
- A DNS SRV Record exists for each SIP domain if you plan to use automatic logon for clients in the form of _sipinternaltls_tcp.<*SIP domain*>. If you will use manual configuration for clients, this record is not necessary.
- A DNS A Record for each configured simple URL, of which there are typically four: meet, dialin, lwa, and scheduler. Additionally, there is the admin simple URL which is a special URL for access to the Lync Server 2013 Control Panel.
- The server running SQL Server must be joined to the domain, and reachable by the computer that Topology Builder is publishing from.

The table follows the reference architectures presented in the Planning section. For details, see Scenarios for External User Access in the Planning documentation.

DNS Records Required for the Front End pool

Location	Type	FQDN	Maps to/Comments
Internal DNS	A	pool01.contoso.net	Pool01 (DNS load balancing). Requires a DNS A record for the IP address of each Front End Server within the pool,

			mapping to the pool FQDN.
Internal DNS	A	pool01.contoso.net	Pool01 (virtual IP (VIP) of hardware load balancer).
Internal DNS	A	fe01.contoso.net fe02.contoso.net fe03.contoso.net …	Pool01 Front End Server (NODE 1). Pool01 Front End Server (NODE 2). Pool01 Front End Server (NODE 3). …
Internal DNS	A	fe02.contoso.net	Pool01 Front End Server (NODE 2).
Internal DNS	A	lsweb.contoso.net	Pool01 (VIP) for client-to-server web traffic.
Internal DNS	A	sqlbe.contoso.net	Pool01 Back End Server running SQL Server 2008 R2.
Internal DNS	A	sip.contoso.com	Required for Lync Phone Edition, or automatic logon of clients without DNS SRV records, and for strict domain matching. Not required in all cases.
Internal DNS	A	sip.fabrikam.com	Assumes a second SIP domain. Required for Lync Phone Edition, automatic logon of clients without DNS SRV records, and for strict domain matching. Not required in all cases.
Internal DNS	A	dialin.contoso.com	Simple URL for dial-in conferencing published internally – Front End Server (or Director, if installed) responds to simple URL queries.
Internal DNS	A	meet.contoso.com	Simple URL for conferences published internally – Front End Server (or Director, if installed)

			responds to simple URL queries.
Internal DNS	A	admin.contoso.com admin	Optional record, simple URL for Lync Server 2013 Control Panel published internally - Front End Server (or Director, if installed) responds to simple URL queries. Host name only (no domain name) is recommended.

Note:
VIP = Virtual IP address for hardware load balancer

DNS SRV Records for the Front End pool

Location	**Type**	**FQDN**	**Target FQDN**	**Port**	**Maps to/ Comments**
Internal DNS	SRV	_sipinternaltls._tcp.contoso.com	pool01.contoso.com	5061	Required for automatic configuration of Lync 2013 clients to work internally.
Internal DNS	SRV	_sipinternaltls._tcp.fabrikam.com	pool01.fabrikam.com	5061	Required for automatic configuration of Lync 2013 clients to work internally.
Internal DNS	SRV	_ntp._udp.contoso.com	dc01.contoso.com	123	Network Time Protocol (NTP) source required for devices running Lync Phone Edition. Internally, this should point to the domain controller. If the domain controller is not defined, it will try to use the NTP server time.windows.com.

1.4.1.2.5.2 DNS Requirements for a Standard Edition Server

DNS Requirements for a Standard Edition Server

See Also

Deploying Lync Server 2013 > System Requirements > DNS Requirements >

Topic Last Modified: *2013-02-22*

This section describes the Domain Name System (DNS) records that are required for deployment of Standard Edition servers.

DNS Records for Standard Edition Servers

The following table specifies DNS requirements for Lync Server 2013 Standard Edition server deployment.

Deployment scenario	DNS requirement
Standard Edition server	An internal A record that resolves the fully qualified domain name (FQDN) of the server to its IP address.
Automatic client sign-in	For each supported SIP domain, an SRV record for _sipinternaltls._tcp.<domain> over port 5061 that maps to the FQDN of the Standard Edition server that authenticates and redirects client requests for sign-in. For details, see DNS Requirements for Automatic Client Sign-In.
Device Update Web service discovery by unified communications (UC) devices	An internal A record with the name ucupdates-r2.<SIP domain> that resolves to the IP address of the Standard Edition server hosting Device Update Web service. In the situation where a UC device is turned on, but a user has never logged into the device, the A record allows the device to discover the server hosting Device Update Web service and obtain updates. Otherwise, devices obtain the server information though in-band provisioning the first time a user logs in. For details, see Device Update Web Service in the Operations documentation.
A reverse proxy to support HTTP traffic	An external A record that resolves the external web farm FQDN to the external IP address of the reverse proxy. Clients and UC devices use this record to connect to the reverse proxy. For details, see Determine DNS Requirements in the Planning documentation.

1.4.1.3 Preparing the Infrastructure and Systems

Preparing the Infrastructure and Systems

Microsoft Lync Server 2013 > Deployment > Deploying Lync Server 2013 >

Topic Last Modified: *2013-02-21*

Deployment of Lync Server 2013 requires the use of Topology Builder to define and publish the topology design. To identify the components required for your topology, you use Topology Builder to create and save a topology design. Prior to publishing your topology in Topology Builder, you do the following:

- Acquire and install the hardware for each component in the topology design that you created and saved by using Topology Builder, including all required computers (servers running Lync Server 2013, database servers, servers running Internet Information Services (IIS), and reverse proxy servers, as appropriate), network adapters, hardware load balancers, and storage devices (such as file servers). For details about how to define a topology that specifies the components needed for your deployment, see Defining and Configuring the Topology. For details about hardware requirements for servers, see Supported Hardware in the Supportability documentation.
- Make sure that the networking infrastructure meets requirements. For details, see Network Infrastructure Requirements in the Planning documentation.
- Set up Active Directory Domain Services (AD DS). To publish and enable the topology, you need the internal servers to be represented by computer accounts in AD DS. This is accomplished by joining the computers to AD DS. For details about preparing AD DS, see Preparing Active Directory Domain Services for Lync Server 2013.
- Create a file share. Standard Edition servers can host the file share for the required file, while in an Enterprise deployment the file share cannot be hosted on the front end server. The permissions and group memberships required for deploying and setting the access control list (ACL) on the folder and the share must be set correctly for Topology Builder to complete successfully. You should make sure that the person running Topology Builder has the following permissions and group memberships:
  - Member of Local Administrators
  - Member of Domain Users
  - Full Control on share and folder of file store
- For Enterprise Edition, install and configure SQL Server. For SQL Server setup to succeed the SQL Server-based server must be online and the person publishing the topology be a local admin on the SQL Server and must be a member of the SQL Server sysadmin group on the SQL Server instance.

After you complete all of the preparation tasks as described in this topic, but prior to publishing the topology, you also need to perform the other preparation tasks, including installing the Windows operating systems and other prerequisite software, setting up IIS, and configuring DNS. For details about these tasks, see System Requirements for Servers Running Lync Server 2013, Configure IIS, and Preparing the Infrastructure and Systems. Additionally, you should familiarize yourself with the clients and client requirements. For details, see Deploying Clients and Devices.

- Hardware Setup
- Software Setup
- Preparing Active Directory Domain Services for Lync Server 2013
- Configure SQL Server for Lync Server 2013
- Configure DNS Records for a Front End Pool or Standard Edition Server

- Install Lync Server Administrative Tools

1.4.1.3.1 Hardware Setup

Hardware Setup

Deployment > Deploying Lync Server 2013 > Preparing the Infrastructure and Systems >

Topic Last Modified: *2013-02-21*

Setting up the hardware and other components required in the infrastructure that you need to implement your topology requires that, prior to publishing your topology in Topology Builder, you do the following:

- Install the hardware for each component in the topology design that you created and saved by using Topology Builder, including all required computers (servers running Lync Server 2013, database servers, servers running Internet Information Services (IIS), and reverse proxy servers, as appropriate), network adapters, hardware load balancers, and storage devices (such as file servers). Confirm that you have followed the recommendations for the number and speed for network adapters. If you will be using hardware load balancers, make sure that you have the proper information from the vendor to configure them for use with Lync Server 2013. If you will be using a file server or other server to house the file share required by Lync Server, make sure that the server is available and ready for the configuration of the file share. For details about how to define a topology that specifies the components needed for your deployment, see Defining and Configuring the Topology. For details about hardware requirements for servers, see Supported Hardware in the Supportability documentation.
- Make sure that the networking infrastructure meets requirements. For details, see Network Infrastructure Requirements in the Planning documentation.
- Set up Active Directory Domain Services (AD DS). Setting up AD DS includes preparing AD DS and defining all components that you want to deploy in AD DS. For details about preparing AD DS, see Preparing Active Directory Domain Services for Lync Server 2013 in the Deployment documentation.
- Set up the required permissions for creating the file share. Permissions for use of file shares by Lync Server 2013 are automatically configured by Topology Builder when you publish your topology. However, the user account used to publish the topology must have full control (read/write/modify) on the file share in order for Topology Builder to configure the required permissions. To make sure that the file share can be managed properly during the Topology Builder publishing process, the user or domain group that the user is a member of should be made a member of the local Administrators group on the machine where the file share is located. In a multi-domain scenario, Domain A user or group should be made a member of the local Administrators group on the machine in Domain B where the file share will be located.
  For details about updating using file shares in a Distributed File System (DFS), see Configure File Storage.

⚠**Warning:**
The file share for Lync Server 2013, Enterprise Edition cannot be located on the Front End Server.

- Install and set up the hardware load balancer for Web Services. With Domain Name System (DNS) load balancing deployed, you still need to also use hardware load balancers for these pools, but only for HTTP/HTTPS traffic. The hardware load balancer is used for HTTPS traffic from clients over ports 443 and 80. Although you still need hardware load balancers for these pools, their setup and administration will be primarily for HTTP/HTTPS traffic, which the administrators of the hardware load balancers are accustomed to.

After you complete all of the preparation tasks as described in this topic, but prior to publishing the topology, you also need to:

- Install Operating Systems and Prerequisite Software on Servers
- Configure IIS
- Configure SQL Server for Lync Server 2013
- Configure DNS Records for a Front End Pool or Standard Edition Server

1.4.1.3.2 Software Setup

Software Setup

Deployment > Deploying Lync Server 2013 > Preparing the Infrastructure and Systems >

Topic Last Modified: *2012-06-29*

This section details the software setup that is required after you have setup the hardware in your environment.

- Install Operating Systems and Prerequisite Software on Servers
- Configure File Storage
- Request Certificates in Advance (Optional)
- Configure IIS
- Installing Windows PowerShell 3.0

1.4.1.3.2.1 Install Operating Systems and Prerequisite Software on Servers

Install Operating Systems and Prerequisite Software on Servers

Deploying Lync Server 2013 > Preparing the Infrastructure and Systems > Software Setup >

Topic Last Modified: *2012-10-21*

After you have set up the hardware and system infrastructure, you need to install the appropriate Windows operating systems and updates, in addition to all other prerequisite software on each server that you are deploying. This includes each Lync Server 2013 server role and any additional infrastructure servers or servers running SQL Server that are required for your deployment.

Note:

This section describes installation of operating systems and prerequisite software for internal servers. If you are deploying Edge Servers to support external user access, you also need to install operating systems and prerequisite software for those servers, including Edge Servers and reverse proxy servers. For details about preparing servers to support external user access, see Preparing for Installation of Servers in the Perimeter Network in the Deployment documentation.

Install Windows Operating Systems on Servers

On each server that you are deploying, install the appropriate Windows operating system as follows:

- **Servers running Lync Server 2013** For details about the operating system requirements for servers running Lync Server 2013, see Server and Tools Operating System Support in the Supportability documentation.
- **Database servers** For details about operating system requirements for

database servers, including the back-end database, Archiving database, and Monitoring database, see the SQL Server documentation. For SQL Server 2012, see the SQL Server 2012 Books Online at http://go.microsoft.com/fwlink/p/?linkId=218015.

Note:

If you are installing Lync Server 2013 on Windows Server 2008 R2 with SP1, you must first install the update described in the Microsoft Knowledge Based article 2646886, "FIX: Heap corruption occurs when a module calls the InsertEntityBody method in IIS 7.5", at http://go.microsoft.com/fwlink/p/?linkid=3052&kbid=2646886.

Install Windows Update on Servers

Install the following updates from Windows Update on each server:

- **Windows Update for servers running Lync Server 2013** For details about the updates from Windows Update that are required for servers running Lync Server 2013, see Additional Software Requirements in the Planning documentation.
- **Database servers** For details about the updates from Windows Update that are required for database servers, including the back-end database, Archiving database, and Monitoring database, see the SQL Server 2012 documentation. For SQL Server 2012, see the SQL Server 2012 Books Online at http://go.microsoft.com/fwlink/p/?linkId=218015.

Install Other Prerequisite Software on Servers

Lync Server 2013 requires the installation of the following additional software on servers:

- **Prerequisite software for servers running Lync Server 2013** The additional software prerequisites for servers running Lync Server 2013 depend on the server role being deployed. For details about the specific software requirements for each server, see Additional Software Requirements in the Planning documentation.
- **Windows Identity Foundation** Lync Server 2013 requires the installation of Windows Identity Foundation in order to support server-to-server authentication scenarios. To verify that it has already been installed on your computer, go to Control Panel, click **Programs and Features**, **View installed updates**, and look under **Microsoft Windows**. For details about installing Windows Identity Foundation, see http://go.microsoft.com/fwlink/p/?linkId=204657.
- **Microsoft .NET Framework 4.5** The 64-bit edition of Microsoft .NET Framework 4.5 is required for Lync Server 2013.
- **Prerequisite software for database servers** For details about the Windows Update required for database servers, including the back-end database, Archiving database, and Monitoring database, see the SQL Server 2012 documentation at http://go.microsoft.com/fwlink/p/?linkId=218015.

  Note:

  Lync Server 2013 automatically installs Microsoft SQL Server 2012 Express on each Standard Edition server and each server running Lync Server 2013 on which the local configuration store is located.
- **Windows Desktop Experience** All Front End Servers and Standard Edition servers where conferencing will be deployed must have the Windows Media Format Runtime installed, which is installed as part of the Windows desktop experience, except for Windows Server 2012. Windows Server 2012 requires Microsoft Media Foundation. The Windows Media Format Runtime is required to run the Windows Media Audio (.wma) files that the Call Park, Announcement, and Response Group applications play for announcements and music.

We recommend that you install Windows desktop experience before you install Lync Server 2013. If Lync Server 2013 does not find this software on the server, it will prompt you to install it, and then you must restart the server to complete installation.

1.4.1.3.2.2 Installing Windows PowerShell 3.0

Installing Windows PowerShell 3.0

Deploying Lync Server 2013 > Preparing the Infrastructure and Systems > Software Setup >

Topic Last Modified: *2013-02-21*

Lync Server 2013 requires the 5/31/2012 version of Windows PowerShell 3.0 on each computer that will take part in your Lync Server topology. When the final version of Lync Server 2013 is released, it is expected that Windows PowerShell 3.0 will ship with the product, and, if necessary, be installed at the same time that you install Lync Server itself. For the Lync Server 2013 release, however, you will need to download and install Windows PowerShell 3.0 yourself.

The 5/31/2012 release of Windows PowerShell 3.0 can be found in the Microsoft Downloads Center at (http://go.microsoft.com/fwlink/p/?LinkId=268538). You should download the file Windows6.1-KB2506143-x64.msu from the Downloads Center and then save a copy of that file to each computer where you need to install Windows PowerShell 3.0. It is also recommended that you uninstall any previous version of Windows PowerShell 3.0 before installing the 5/31/2012 release. To uninstall a previous version of Windows PowerShell 3.0 complete the following procedure on each computer where the previous version has been installed:

1. In the Windows Control Panel, click **Uninstall a Program**.
2. In Programs and Features, click **View installed updates**.
3. In the **Uninstall an update** pane, in the **Microsoft Windows** section, locate the update titled **Microsoft Windows Management Framework 3.0 Beta (KB2506143)**.
4. Right-click **Microsoft Windows Management Framework 3.0 Beta (KB2506143)** and then click **Uninstall**.
5. In the **Uninstall an update** dialog box, click **Yes**.

Note that you will need to restart the computer after the update has been uninstalled.

After the computer has restarted, you can install the 5/31/2012 release of Windows PowerShell 3.0 by completing the following procedure on each computer where Lync Server 2013 will be installed:

1. Double-click the file **Windows6.1-KB2506143-x64.msu**.
2. In the **Windows Update Standalone Installer** dialog box, click **Yes** when asked if you want to install the update.
3. In the Download and Install Update wizard, on the **Read these license terms** page, click **I Accept**.
4. On the **Installation complete** page, click **Restart Now** to immediately restart your computer. (Your computer must be restarted in order for the updates to take effect.) If you prefer not to immediately restart your computer, click **Close**. As noted, you will still need to restart the computer before Windows PowerShell 3.0 is fully installed.

After the computer has restarted you can verify that Windows PowerShell 3.0 has been installed by completing the following check:

1. Click **Start**, click **All Programs**, click **Accessories**, click **Windows PowerShell**, and then click **Windows PowerShell**.
2. In the Windows PowerShell console, type the following command at the command prompt and then press ENTER:

```
Get-Host | Select-Object Version
```

3. If Windows PowerShell 3.0 has been installed you will see output that looks like this:

```
Version
-------
3.0
```

Assuming your computer meets all the other prerequisites you can now install Lync Server 2013.

1.4.1.3.2.3 Configure File Storage

Configure File Storage

Deploying Lync Server 2013 > Preparing the Infrastructure and Systems > Software Setup >

Topic Last Modified: *2012-09-13*

Lync Server 2013 supports using file shares on a Distributed File System (DFS). For details about DFS for Windows Server 2008, see the DFS Step-by-Step Guide for Windows Server 2008 at http://go.microsoft.com/fwlink/p/?linkId=202835.To use a DFS, Lync Server 2013 requires the following:

- Namespaces are domain based
- All namespace servers are running a minimum of Windows 2008

Lync Server 2013 setup requires that permissions on shared folder allow full access to Administrator. Lync Server 2013 will then use NTFS file permissions to ACL the folders. Inherited DFS share permissions will not be used to restrict access.

For more details about File Share requirements, see File Storage Support in the Supportability documentation.

The following procedure describes how to correctly configure shared folder permissions using the DFS Namespace Wizard (as described in DFS setup guide).

⊟To configure shared folder permissions

1. Click **Start**, point to **All Programs**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree of the DFS Management snap-in, right-click the namespace server (for example filesrv1.contoso.com), and then click **Edit Settings**.
3. Select **Shared Folder Permissions**.
4. Select **Use Custom Permissions**.
5. For the Administrator group, select the following under **Allow**:
   - **Full Control**
   - **Change**
   - **Read**
6. Click **Apply**, and then click **OK**.

1.4.1.3.2.4 Request Certificates in Advance (Optional)

Request Certificates in Advance (Optional)

Deploying Lync Server 2013 > Preparing the Infrastructure and Systems > Software Setup >

Topic Last Modified: *2013-02-21*

Certificates are required for all internal servers that are running Lync Server 2013, including each Enterprise Edition Front End Server, Standard Edition server, Director, Edge Server and stand-alone Mediation Server. Although an internal enterprise certification authority (CA) is recommended for internal servers, you can also use a public CA. For details about certificate requirements and about the use of a public CA, see Certificate Requirements for Internal Servers in the Planning documentation.

Lync Server 2013 setup includes the Certificate Wizard, which facilitates the tasks of requesting, assigning, and installing certificates during deployment. If you want to request certificates prior to installing servers (for instance, to save time during actual deployment of servers), you can do so by using a computer on which the Lync Server 2013 administrative tools are installed or by using a certificate request procedure defined in your organization, as long as you make sure that the certificates are exportable and contain all the required subject alternative names. Requesting certificates in advance is optional. If you do not request them in advance, you must request them as part of the setup of each server that requires a certificate.

This Deployment documentation provides procedures for using the Certificate Wizard to request certificates as part of the setup process, as described in the Configure Certificates for Servers, Configure Certificates for the Director, and Install the Files for Mediation Server sections of this Deployment documentation. If you request certificates in advance, you must modify the certificate deployment procedures in those sections as appropriate to importing and assigning the certificates instead of requesting them at the time of deployment.

Note:

Lync Server 2013 includes support for SHA-256 certificates for connections from clients running the Windows Vista, Windows Server 2008, Windows Server 2008 R2, and Windows 7 operating systems, and Lync Phone Edition. To support external access using SHA-256, the external certificate is issued by a public CA using SHA-256.

1.4.1.3.2.5 Configure IIS

Configure IIS

Deploying Lync Server 2013 > Preparing the Infrastructure and Systems > Software Setup >

Topic Last Modified: *2011-12-16*

Configuring Internet Information Services (IIS) for Lync Server 2013 involves installing the correct components to support the Web Services needed by Lync Server 2013. For details about installing IIS, see IIS Configuration. If you have a policy to run the Security Configuration Wizard on servers before putting them into service or as a typical part of your maintenance, see Re-Activate Server After Security Configuration Wizard Closes Ports in IIS for information about a side effect of running the wizard that will close ports on a Lync Server 2013 IIS configuration.

In This Section

- IIS Configuration
- Re-Activate Server After Security Configuration Wizard Closes Ports in IIS

IIS Configuration

See Also

Preparing the Infrastructure and Systems > Software Setup > Configure IIS >

Topic Last Modified: *2013-02-25*

To successfully complete this procedure, you should be logged on to the server minimally as a local administrator and a domain user.

Before you configure and install the Front End Server for Lync Server 2013, Standard Edition or the first Front End Server in a pool, you install and configure the server role and Web Services for Internet Information Services (IIS).

Important:

If your organization requires that you locate IIS and all Web Services on a drive other than the system drive, you can change the installation location path for the Lync Server 2013 files in the Setup dialog box when you initially install the Lync Server 2013 Administrative tools. You install the Administrative tools before installing IIS. If you install the Setup files to this path, including OCSCore.msi, the rest of the Lync Server 2013 files will be deployed to this drive as well. For dtails, see Install Lync Server Administrative Tools. For details about how to relocate the INETPUB deployed by Windows Server Manager when installing IIS, see http://go.microsoft.com/fwlink/p/?linkId=216888.

The following table indicates the required IIS 7.5 role services.

IIS 7.5 Role Services

Role Heading	Role Service
Common HTTP features installed	Static content
Common HTTP features installed	Default document
Common HTTP features installed	HTTP errors
Application development	ASP.NET Windows Server 2012 also requires ASP.NET4.5
Application development	.NET extensibility
Application development	Internet Server API (ISAPI) extensions
Application development	ISAPI filters
Health and diagnostics	HTTP logging
Health and diagnostics	Logging tools
Health and diagnostics	Tracing
Security	Anonymous authentication (installed and enabled by default)
Security	Windows authentication
Security	Client Certificate Mapping authentication
Security	Request filtering
Performance	Static content compression Dynamic content compression
Management Tools	IIS Management Console
Management Tools	IIS Management Scripts and Tools

On the Windows Server 2008 R2 SP1 x64 operating system, you can use Windows PowerShell 2.0. You must first import the ServerManager module, and then install the IIS 7.5 role and role services.

```
Import-Module ServerManager
```

```
Add-WindowsFeature Web-Server, Web-Static-Content, Web-Default-Doc, Web-Scripting
 Web-Asp-Net, Web-Log-Libraries, Web-Http-Tracing, Web-Stat-Compression, Web-Dyn-
 Web-ISAPI-Filter, Web-Http-Errors, Web-Http-Logging, Web-Net-Ext, Web-Client-Aut
 Web-Mgmt-Console
```

Note:

Anonymous authentication is installed by default with the IIS server role. You can manage anonymous authentication after the installation of IIS. For details, see "Enable Anonymous Authentication (IIS 7)" at http://go.microsoft.com/fwlink/p/?linkId=203935.

The following table indicates the required IIS 8.0 role services for Windows Server 2012.

IIS 8.0 Role Services

Role Heading	Role Service
Web Server (IIS)	Web Server
Common HTTP Features	Default Document
Common HTTP Features	Directory Browsing
Common HTTP Features	HTTP Errors
Common HTTP Features	Static content
Common HTTP Features	HTTP Redirection
Health and Diagnostics	HTTP Logging
Health and Diagnostics	Logging Tools
Health and Diagnostics	Request Monitor
Health and Diagnostics	Tracing
Security	Request Filtering
Security	Basic Authentication
Security	Client Certificate Mapping Authentication
Security	Windows Authentication
Application Development	.Net Extensibility 3.5
Application Development	.Net Extensibility 4.5
Application Development	ASP.Net 3.5
Application Development	ASP.Net 4.5
Application Development	ISAPI Extensions
Application Development	ISAPI Filters
Application Development	Server Side Includes
Management Tools	IIS Management Console

Management Tools	IIS 6 Metabase compatibility
Management Tools	IIS Management Scripts and Tools
.Net 3.5 Framework Features	.Net 3.5 Framework
.Net 4.5 Framework Features	.Net Framework 4.5
.Net 4.5 Framework Features	ASP.Net 4.5
.Net 4.5 Framework Features	HTTP Activation
.Net 4.5 Framework Features	TCP Port Sharing
Background Intelligent Transfer Service	IIS Server Extensions
Ink and Handwriting Services	Ink and Handwriting Services
Media Foundation	Media Foundation
User Interfaces and Infrastructure	Graphical Management Tools and Infrastructure
User Interfaces and Infrastructure	Desktop Experience
User Interfaces and Infrastructure	Server Graphical Shell
Windows Identity Foundation 3.5	Windows Identity Foundation 3.5
Windows Process Activation Service	Process Model
Windows Process Activation Service	Configuration APIs

In Windows Server 2012, you can use Windows PowerShell 3.0 to install the IIS Requirements. Using the ServerManager module in Windows PowerShell 3.0, type:

```
Import-Module ServerManager
```

```
Add-WindowsFeature Web-Server, Web-Static-Content, Web-Default-Doc, Web-Http-Erro
 Web-Net-Ext, Web-ISAPI-Ext, Web-ISAPI-Filter, Web-Http-Logging, Web-Log-Librarie
 Web-Http-Tracing, Web-Basic-Auth, Web-Windows-Auth, Web-Client-Auth, Web-Filteri
 Web-Dyn-Compression, NET-Framework-45-Core, NET-WCF-HTTP-Activation45, Web-Asp-N
 Web-Scripting-Tools, Web-Mgmt-Console Web-Mgmt-Compat, Windows-Identity-Foundati
 BITS -Source D:\sources\sxs
```

Important:

New to Windows Server 2012 is the –Source parameter that defines where the Windows Server 2012 source media can be found. The media can be defined as a DVD drive (for example, D:\Sources\Sxs), or to a network share that the media files have been copied (for example, \\fileserver\windows2012\sources\Sxs).

Concepts

IIS Requirements for Front End Pools and Standard Edition Servers

Re-Activate Server After Security Configuration Wizard Closes Ports in IIS

Preparing the Infrastructure and Systems > Software Setup > Configure IIS >

Topic Last Modified: *2012-10-01*

Some Lync Server 2013 roles run Web Services on Internet Information Services (IIS) port

4443. Running the Lync Server Deployment Wizard, Bootstrapper.exe, or using the **Enable-CsComputer** cmdlet creates an exception in the firewall and opens the port. If you then run the Windows Server 2008 R2 Security Configuration Wizard (or other hardening scripts), port 4443 will be blocked, and external clients will not be able to contact Web Services. To reopen the port you can either modify the firewall exception directly or re-activate the server.

⊟To re-activate the server by using the Deployment Wizard

1. On the Lync Server Deployment Wizard page, click **Run** next to **Step 2: Setup or Remove Lync Server Components**.
2. On **Setup Lync Server components** page, click **Next**.
3. On the **Executing Commands** page, when the task status is shown as completed, click **Finish**.

> **Note:**
> You can also use bootstrapper.exe or **Enable-CsComputer** to re-activate the server.

1.4.1.3.3 Preparing Active Directory Domain Services for Lync Server 2013

Preparing Active Directory Domain Services for Lync Server 2013

Deployment > Deploying Lync Server 2013 > Preparing the Infrastructure and Systems >

Topic Last Modified: *2013-02-21*

Before you deploy and operate Lync Server 2013, you must prepare Active Directory Domain Services (AD DS) by extending the schema and then creating and configuring objects. The schema extensions add the Active Directory classes and attributes that are required by Lync Server.

The topics in this section describe how to prepare AD DS for deploying Lync Server and how to assign setup and organizational unit (OU) permissions. For details about the schema changes required for Lync Server, see Active Directory Schema Extensions, Classes, and Attributes Used by Lync Server 2013.

- Active Directory Infrastructure Requirements
- Overview of Active Directory Domain Services Preparation
- Preparing Active Directory Domain Services
- Preparing a Locked-Down Active Directory Domain Services
- Granting Permissions

1.4.1.3.3.1 Active Directory Infrastructure Requirements

Active Directory Infrastructure Requirements

Planning > Determining Your Infrastructure Requirements > Active Directory Domain Services Requirements, Support, and Topologies >

Topic Last Modified: *2012-11-27*

Before you start the process of preparing Active Directory Domain Services (AD DS) for Lync Server 2013, make sure that your Active Directory infrastructure meets the following prerequisites:

- All domain controllers (which include all global catalog servers) in the forest where you deploy Lync Server run one of the following operating systems:

  - Windows Server 2012 operating system
  - Windows Server 2008 R2 operating system
  - Windows Server 2008 operating system
  - Windows Server 2008 Enterprise 32-Bit
  - 32-bit or 64-bit versions of the Windows Server 2003 R2 operating system
  - 32-bit or 64-bit versions of the Windows Server 2003 operating system

- All domains in which you deploy Lync Server are raised to a domain functional level of Windows Server 2012, Windows Server 2008 R2, Windows Server 2008, or at least Windows Server 2003.
- The forest in which you deploy Lync Server is raised to a forest functional level of Windows Server 2012, Windows Server 2008 R2, Windows Server 2008, or at least Windows Server 2003.

  Note:

  To change your domain or forest functional level, see "Raising domain and forest functional levels" in the TechNet Library at http://go.microsoft.com/fwlink/p/?LinkId=263775.

- A global catalog is deployed in every domain where you deploy Lync Server computers or users.

Lync Server 2013 supports the universal groups in the Windows Server 2012, Windows Server 2008 R2, Windows Server 2008, and Windows Server 2003 operating systems. Members of universal groups can include other groups and accounts from any domain in the domain tree or forest and can be assigned permissions in any domain in the domain tree or forest. Universal group support, combined with administrator delegation, simplifies the management of a Lync Server deployment. For example, it is not necessary to add one domain to another to enable an administrator to manage both.

1.4.1.3.3.2 Overview of Active Directory Domain Services Preparation

Overview of Active Directory Domain Services Preparation

See Also

Deploying Lync Server 2013 > Preparing the Infrastructure and Systems > Preparing Active Directory Domain Services for Lync Server 2013 >

Topic Last Modified: *2012-10-29*

To prepare Active Directory Domain Services (AD DS) for your Lync Server 2013 deployment, you must perform three steps in a specific sequence.

The following table describes the steps required to prepare AD DS for Lync Server.

Active Directory Preparation Steps

	Step	Description	Where run
1.	Preparing the Active Directory Schema	Extends the Active Directory schema by adding new classes and attributes that are used by Lync Server. Run once for each forest in your deployment where	Against the schema master in the root domain of each forest where Lync Server will be deployed. **Note:** You do not need to run this step in the root domain if you have permissions on

		Lync Server will be deployed.	the schema master, but you must be a member of the Schema Admins group in the root domain and a member of the Enterprise Admins group on the schema master. In a resource forest topology, run this step only in the resource forest, not in any user forests. In a central forest topology, run this step only in the central forest, not in any user forests.
2.	Preparing the Forest	Creates global settings and universal groups that are used by Lync Server. Run once for each forest in your deployment where Lync Server will be deployed.	In the root domain of each forest where Lync Server will be deployed. To run this step, you must be a member of the Enterprise Admins group. **Note:** In a resource forest topology, run this step only in the resource forest, not in any user forests. In a central forest topology, run this step only in the central forest, not in any user forests.
3.	Preparing Domains	Adds permissions on objects to be used by members of universal groups. Run once per user domain or server domain. **Note:** If you are migrating from Lync Server 2010 to Lync Server 2013, the Deployment Wizard may indicate that domain preparation is already complete. You do not need to run domain preparation again. Permissions were not	On a member server in each domain where Lync Server will be deployed. To run this step, you must be a member of the Domain Admins group.

		changed from Lync Server 2010 to Lync Server 2013.	

Lync Server 2013, like Lync Server 2010, stores much of the configuration information in the Central Management store instead of in AD DS as was the case in Office Communications Server 2007 R2. However, the following information is stored in AD DS:

- **Schema extensions**:
  - User object extensions
  - Extensions for Office Communications Server 2007 R2 classes to maintain backward compatibility
- **Data** (stored in Lync Server extended schema and in existing schema classes):
  - User SIP Uniform Resource Identifier (URI) and other user settings
  - Contact objects for applications such as Response Group and Conferencing Attendant
  - A pointer to the Central Management store
  - Kerberos Authentication Account (an optional computer object)

In Lync Server 2013, you delegate setup and administration by granting setup permissions to the RTCUniversalServerAdmins universal group so that members of that group can install and activate Lync Server 2013 on a local server (after the server has been added to the topology, published, and enabled). The delegated users must be local administrators on the computer where they are installing and activating Lync Server 2013, but they do not need to be members of the Domain Admins group. You can also grant permissions for objects in specified organizational units (OUs) so that members of the universal groups created during forest preparation can access those objects without being members of the Domain Admins group.

For new deployments of Lync Server 2013, global settings must be stored in the Configuration container. If your organization is upgrading from an earlier version and you still have global settings in the System container, the System container is still supported.

1.4.1.3.3.3 Preparing Active Directory Domain Services

Preparing Active Directory Domain Services

Deploying Lync Server 2013 > Preparing the Infrastructure and Systems > Preparing Active Directory Domain Services for Lync Server 2013 >

Topic Last Modified: *2012-10-29*

In Lync Server 2013, you can use the Lync Server Deployment Wizard to prepare Active Directory Domain Services (AD DS), or you can use Lync Server Management Shell cmdlets directly. You can also use the ldifde.exe command line tool directly on your domain controllers, as described later in this topic.

The Lync Server Deployment Wizard guides you through each Active Directory preparation task. The Deployment Wizard runs Lync Server Management Shell cmdlets. This tool is useful for environments with a single domain and single forest topology, or other similar topology.

Important:

You can deploy Lync Server in a forest or domain where domain controllers run 32-bit versions of some operating systems (for details, see Active Directory Infrastructure Requirements). However, you cannot use the Lync Server Deployment Wizard to run schema, forest, and domain preparation in these environments because the Deployment Wizard and supporting files are 64-bit only. Instead, you can use ldifde.exe and the associated .ldf files on a 32-bit domain controller to prepare the schema, forest and domain. See the section “Using Cmdlets and Ldifde.exe” later in this topic.

You can use Lync Server Management Shell cmdlets to run tasks remotely or for more complex environments.

Active Directory Preparation Prerequisites

You must run Active Directory preparation steps on a computer running Windows Server 2012 or Windows Server 2008 R2 with SP1 (64-bit). Active Directory preparation requires Lync Server Management Shell and OCSCore.

The following components are required to run Active Directory preparation tasks:

- Lync Server Core components (OCScore.msi)

  Note:

  If you plan to use Lync Server Management Shell for Active Directory preparation, you must run the Lync Server Deployment Wizard first to install Core components.

- Microsoft .NET Framework 4.5

  Note:

  For Windows Server 2012, you install and activate .NET Framework 4.5 by using Server Manager. For details, see "Microsoft .NET Framework 4.5" in Additional Software Requirements. For Windows Server 2008 R2, the file dotnetfx45.exe is provided in the \Setup\AMD64 directory of the installation media or download.

- Remote Server Administration Tools (RSAT)

  Note:

  Some RSAT tools are required if you run Active Directory preparation steps on a member server rather than on a domain controller. Install the AD DS snap-ins and command-line tools and the Active Directory Module for Windows PowerShell from the AD DS and AD LDS Tools node in Server Manager.

- Microsoft Visual C++ 11 Redistributable

  Note:

  Setup prompts you to install this prerequisite if it is not already installed on the computer. The package is supplied for you, and you will not have to acquire it separately.

- Windows PowerShell 3.0 (64-bit)

  For Windows Server 2012, Windows PowerShell 3.0 should be included with your Lync Server 2013 installation. For Windows Server 2008 R2, you need to install or upgrade to Windows PowerShell 3.0. For details, see Installing Windows PowerShell 3.0

Administrator Rights and Roles

The following table shows the administrative rights and roles required for each Active Directory preparation task.

User Rights Required for Active Directory Preparation

Procedure	Rights or roles
Schema preparation	Member of Schema Admins group for the forest root domain and administrator rights on the schema master
Forest preparation	Member of Enterprise Admins group for the forest
Domain preparation	Member of Enterprise Admins or Domain Admins group for the specified domain

Active Directory Preparation Cmdlets

The following table compares the Lync Server Management Shell cmdlets used to prepare AD DS to the LcsCmd commands used to prepare AD DS in Microsoft Office Communications Server 2007 R2.

Cmdlets Compared to LcsCmd

Cmdlets	LcsCmd
Install-CsAdServerSchema	Lcscmd /forest /action:SchemaPrep /SchemaType:Server
Get-CsAdServerSchema	Lcscmd /forest /action:CheckSchemaPrepState
Enable-CsAdForest	Lcscmd /forest /action:ForestPrep
Disable-CsAdForest	Lcscmd /forest /action:ForestUnprep
Get-CsAdForest	Lcscmd /forest /action:CheckForestPrepState
Enable-CsAdDomain	Lcscmd /domain /action:DomainPrep
Disable-CsAdDomain	Lcscmd /domain /action: DomainUnprep
Get-CsAdDomain	Lcscmd /domain /action:CheckDomainPrepState

Locked Down Active Directory Requirements

If permissions inheritance is disabled or authenticated user permissions must be disabled in your organization, you must perform additional steps during domain preparation. For details, see Preparing a Locked-Down Active Directory Domain Services.

Custom Container Permissions

If your organization uses custom containers instead of the three built-in containers (that is, Users, Computers, and Domain Controllers), you must grant read access to the custom containers for the Authenticated Users group. Read access to the containers is required for domain preparation. For details, see Preparing Domains.

Using Cmdlets and Ldifde.exe

The **Prepare Schema** step in the Lync Server Deployment Wizard and the **Install-CsAdServerSchema** cmdlet extend the Active Directory schema on domain controllers running a 64-bit operating system. If you need to extend the Active Directory schema on a domain controller running a 32-bit operating system, you can run the **Install-CsAdServerSchema** cmdlet remotely from a member server (recommended approach). If you need to run schema preparation directly on the domain controller, however, you can use the Ldifde.exe tool to import the schema files. The Ldifde.exe tool comes with most versions of the Windows operating system.

If you use Ldifde.exe to import the schema files, you must import all four files, regardless of whether you are migrating from a previous version or performing a clean installation. You must import them in the following sequence:

1. ExternalSchema.ldf
2. ServerSchema.ldf
3. BackCompatSchema.ldf
4. VersionSchema.ldf

Note:

The four .ldf files are located in \Support\Schema directory of your installation media or download.

To use Ldifde.exe to import the four schema files on a domain controller that is the schema master, use the following format:

```
ldifde -i -v -k -s <DCName> -f <Schema filename> -c DC=X <defaultNamingContext> -
```

For example:

```
ldifde -i -v -k -s DC1 -f ServerSchema.ldf -c DC=X "DC=contoso,DC=com" -j C:\Batc
```

Note:

Use the b parameter only if you are logged in as a different user. For details about the required user rights, see the "Administrator Rights and Roles" section earlier in this topic.

To use Ldifde.exe to import the four schema files on a domain controller that is not the schema master, use the following format:

```
ldifde -i -v -k -s <SchemaMasterFQDN> -f <Schema filename> -c DC=X <rootDomainNam
```

For details about using Ldifde, see Microsoft Knowledge Base article 237677, "Using LDIFDE to import and export directory objects to Active Directory," at http://go.microsoft.com/fwlink/p/?linkId=132204.

Preparing the Active Directory Schema

See Also

Preparing the Infrastructure and Systems > Preparing Active Directory Domain Services for Lync Server 2013 > Preparing Active Directory Domain Services >

Topic Last Modified: *2012-08-27*

Before you begin preparing Active Directory Domain Services (AD DS), you can open the schema files by using a text editor, such as Windows Notepad, or see Active Directory Schema Extensions, Classes, and Attributes Used by Lync Server 2013 to review all the Active Directory Domain Services (AD DS) schema extensions that will be modified for Lync Server 2013. Lync Server uses four schema files:

- ExternalSchema.ldf, which is used for interoperability with Microsoft Exchange Server
- ServerSchema.ldf, which is the primary Lync Server 2013 schema file
- BackCompatSchema.ldf, which is used for interoperability with any components from prior releases
- VersionSchema.ldf, which is used for version information of the prepared schema

All .ldf files are installed during schema preparation, regardless of whether you are migrating from a previous release or performing a clean installation. These schema files are installed in the sequence shown in the preceding list and are located in the \Support \schema folder on the installation media.

The Lync Server schema extensions are replicated across all domains, which impacts network traffic. Run schema preparation at a time when network usage is low.

Note:

If you need to add support for Microsoft® Office Communicator Mobile 2007 R2 for Java and Microsoft® Office Communicator Mobile for Nokia 1.0 mobile clients to your Lync Server 2013 deployment, you need to prepare the Active Directory schema for Microsoft Office Communications Server 2007 R2 during installation of Lync Server 2013. For the necessary software and documentation, see http://go.microsoft.com/fwlink/p/?linkId=207172.

ADSI Edit

Active Directory Service Interfaces Editor (ADSI Edit) is an AD DS administration tool that you can use to verify schema preparation and replication.

ADSI Edit is installed by default when you install the AD DS role to make a server a domain controller. For Windows Server 2008 and Windows Server 2008 R2, ADSI Edit (adsiedit.msc) is included with the Remote Server Administration Tools (RSAT). You can also install RSAT on domain member servers or stand-alone servers. The RSAT package is copied to these servers by default when you install Windows, but it is not installed by default. You install individual tools by using Server Manager. ADSI Edit is included under **Role Administration Tools**, **Active Directory Domain Services Tools**, **Active Directory Domain Controller Tools**.

For Windows Server 2003, ADSI Edit is included with the Support Tools. The Support Tools are available from the Windows Server 2003 CD in the \SUPPORT\TOOLS folder, or you can download them from "Windows Server 2003 Service Pack 2 32-bit Support Tools" at http://go.microsoft.com/fwlink/p/?linkId=125770. Instructions for installing the Support Tools from the product CD are available from "Install Windows Support Tools" at http://go.microsoft.com/fwlink/p/?linkId=125771. Adsiedit.dll is automatically registered when you install the support tools. If, however, you copied the files to your computer, you must run the **regsvr32** command to register the adsiedit.dll file before you can run the tool.

Preparing Active Directory Domain Services for Lync Server 2013 > Preparing Active Directory Domain Services > Preparing the Active Directory Schema >

Topic Last Modified: *2012-10-29*

You can use Setup or Lync Server Management Shell cmdlets to prepare the Active Directory schema. The cmdlet that extends the Active Directory schema is **Install-CsAdServerSchema**.

Note:
The schema preparation cmdlet (**Install-CsAdServerSchema**) must access the schema master, which requires that the remote registry service is running and that the remote registry key is enabled. If the remote registry service cannot be enabled on the schema master, you can run the cmdlet locally on the schema master. For details about registry remote access, see Microsoft Knowledge Base article 314837, "How to Manage Remote Access to the Registry," at http://go.microsoft.com/fwlink/p/?linkId=125769.

After you complete schema preparation, manually verify that the schema partition has been replicated before proceeding to forest preparation. For details, see Verifying Schema Replication.

To use Setup to prepare the schema of the current forest

1. Log on to a server in your forest as a member of the Schema Admins group and with administrator rights on the schema master.
2. From the Lync Server 2013 installation folder or media, run Setup.exe to start the Deployment Wizard.
3. If you are prompted to install the Microsoft Visual C++ Redistributable, click **Yes**.
4. The Lync Server 2013 Setup dialog box prompts you for a location to install the Lync Server files. Choose the default location or **Browse** to a location of your choice, and then click **Install**.
5. On the License Agreement page, check **I accept the terms in the license agreement**, and then click **OK**.
6. The installer installs the Lync Server Core Components.
7. When the Deployment Wizard is ready, click **Prepare Active Directory**, and then wait for the deployment state to be determined.
8. At **Step 1: Prepare Schema**, click **Run**.
9. On the **Prepare Schema** page, click **Next**.
10. On the **Executing Commands** page, look for **Task status: Completed**, and then click **View Log**.
11. Under the **Action** column, expand **Schema Prep**, look for the **<Success>** Execution Result at the end of each task to verify that schema preparation completed successfully, close the log, and then click **Finish**.
12. Wait for Active Directory replication to complete or force replication.
13. Manually verify that the schema changes replicated to all other domain controllers. For details, see Verifying Schema Replication.

To use cmdlets to prepare the schema of the current forest

1. Log on to a computer in the forest as a member of the Schema Admins group and with administrator rights on the schema master.
2. Install Lync Server Core components as follows:
   2.a. From the Lync Server 2013 installation folder or media, run Setup.exe to start the Lync Server Deployment Wizard.
   2.b. If you are prompted to install the Microsoft Visual C++ Redistributable, click **Yes**.
   2.c. The Lync Server 2013 Setup dialog box prompts you for a location to install the Lync Server files. Choose the default location or **Browse** to a location of your choice, and then click **Install**.
   2.d. On the License Agreement page, check **I accept the terms in the license agreement**, and then click **OK**. The installer installs the Lync Server 2013 Core Components.
3. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
4. Run:

   ```
   Install-CsAdServerSchema [-Ldf <directory where the .ldf file is locat
   ```

   If you do not specify the Ldf parameter, the default value is the Lync Server 2013 installation path that is read from the registry.
   For example:

   ```
   Install-CsAdServerSchema -Ldf "C:\Program Files\Microsoft Lync Server
   ```

5. Use the following cmdlet to verify that schema preparation ran to completion.

   ```
   Get-CsAdServerSchema
   ```

   This cmdlet returns a value of **SCHEMA_VERSION_STATE_CURRENT** if schema preparation was successful.
6. Wait for Active Directory replication to complete or force replication.
7. Manually verify that the schema changes replicated to all other domain controllers. For details, see Verifying Schema Replication.

Topic Last Modified: *2012-10-29*

Before you run forest preparation, manually verify that the schema partition has been replicated.

⊟To manually verify schema replication

1. Log on to a domain controller as a member of the Enterprise Admins group.
2. Open ADSI Edit by clicking **Start**, clicking **Administrative Tools**, and then clicking **ADSI Edit**.

   Tip:
   Alternatively, you can run **adsiedit.msc** from the command line.

3. In the Microsoft Management Console (MMC) tree, if it is not already selected, click **ADSI Edit**.
4. On the **Action** menu, click **Connect to**.
5. In the **Connection Settings** dialog box under **Select a well known Naming**

Context, select **Schema**, and then click **OK**.

6. Under the schema container, search for CN=ms-RTC-SIP-SchemaVersion. If this object exists, and the value of the **rangeUpper** attribute is 1150 and the value of the **rangeLower** attribute is 3, then the schema was successfully updated and replicated. If this object does not exist or the values of the **rangeUpper** and **rangeLower** attributes are not as specified, then the schema was not modified or has not replicated.

Preparing the Active Directory Schema

Preparing the Forest

Preparing the Infrastructure and Systems > Preparing Active Directory Domain Services for Lync Server 2013 > Preparing Active Directory Domain Services >

Topic Last Modified: *2013-02-21*

Forest preparation creates Active Directory global settings and objects and Active Directory universal groups for use by Lync Server 2013, and grants suitable access permissions on the Active Directory objects. For a description of the universal groups and the global settings and objects created by forest preparation, see Changes Made by Forest Preparation.

Forest preparation also creates objects that contain property sets and display specifiers that are used by Lync Server 2013, and stores them in the Configuration container.

◆**Important:**
Make sure that schema preparation changes have replicated to all domain controllers before performing the forest preparation procedure. If replication is not completed, an error occurs.

If you are performing a new Lync Server deployment, you must store global settings in the Configuration container. If you are upgrading from an earlier version and you still store global settings in the System container, you can continue to use the System container.

You must be a member of the Enterprise Admins or Domain Admins group for the forest root domain to perform this procedure.

You can use Setup or Lync Server Management Shell cmdlets to prepare the forest. The cmdlet that prepares the forest is **Enable-CsAdForest**.

After you prepare the forest, you must verify that global settings have been replicated before running domain preparation.

⊟To use Setup to prepare the forest

1. Log on to a computer that is joined to a domain as a member of the Enterprise Admins group for the forest root domain.
2. From the Lync Server 2013 installation folder or media, run Setup.exe to start the Deployment Wizard.
3. Click **Prepare Active Directory**, and then wait for the deployment state to be determined.
4. At **Step 3: Prepare Current Forest**, click **Run**.
5. On the **Prepare Forest** page, click **Next**.

> **Note:**
> Forest Preparation allows you to choose where to place the Universal Groups for Lync Server 2013. Choose a location that is consistent with the requirements of your organization.

6. On the **Executing Commands** page, look for **Task status: Completed**, and then click **View Log**.
7. Under the **Action** column, expand **Forest Prep**, look for a **<Success>** Execution Result at the end of each task to verify that forest preparation completed successfully, close the log, and then click **Finish**.
8. Wait for Active Directory replication to complete, or force replication to all domain controllers listed in the **Active Directory Sites and Services** snap-in for the forest root domain controller, before running domain preparation. Force replication between the domain controllers in all Active Directory sites to cause replication within the sites to occur within minutes.

To use cmdlets to prepare the forest

1. Log on to a computer that is joined to a domain as a member of the Domain Admins group in the forest root domain.
2. Install Lync Server Core components as follows:
   2.a. From the Lync Server 2013 installation folder or media, run Setup.exe to start the Lync Server Deployment Wizard.
   2.b. If you are prompted to install the Microsoft Visual C++ Redistributable, click **Yes**.
   2.c. The Lync Server 2013 Setup dialog box prompts you for a location to install the Lync Server files. Choose the default location or **Browse** to a location of your choice, and then click **Install**.
   2.d. On the License Agreement page, check **I accept the terms in the license agreement**, and then click **OK**. The installer installs the Lync Server 2013 Core Components.
3. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
4. Run:

```
Enable-CsAdForest [-GroupDomain <FQDN of the domain in which to create
```

   For example:

```
Enable-CsAdForest -GroupDomain domain1.contoso.com
```

   If you do not specify the GroupDomain parameter, the default value is the local domain. If universal groups were created previously in a domain that is not the default domain, you must specify the GroupDomain parameter explicitly.
5. Wait for Active Directory replication to complete, or force replication to all domain controllers listed in the **Active Directory Sites and Services** snap-in for the forest root domain controller, before running domain preparation.
6. Verify that forest preparation was successful. Run:

```
Get-CsAdForest
```

   This cmdlet returns a value of **LC_FORESTSETTINGS_STATE_READY** if forest preparation was successful.

Preparing Active Directory Domain Services for Lync Server 2013 > Preparing Active Directory Domain Services > Preparing the Forest >

Topic Last Modified: *2012-10-29*

Use the **Disable-CsAdForest** cmdlet to reverse the forest preparation step.

Caution:

If you run the **Disable-CsAdForest** cmdlet in an environment where you also have a previous version of Lync Server deployed, the global settings for the previous version will also be deleted.

⊟To use cmdlets to reverse forest preparation

1. Log on to a computer that is joined to a domain as a member of the Domain Admins group in the forest root domain.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run:

```
Disable-CsAdForest [-Force] [-GroupDomain <FQDN of the domain in which
```

```
Disable-CsAdForest -Force -GroupDomain contoso.net
```

The Force parameter specifies whether to force running the task. If this parameter is not present, the command will not run if even one domain in the forest is still prepared for Lync Server 2013. If the Force parameter is specified, the action will continue regardless of the state of other domains in the forest.

If you do not specify the GroupDomain parameter, the default value is the local domain.

Preparing Domains

Preparing the Infrastructure and Systems > Preparing Active Directory Domain Services for Lync Server 2013 > Preparing Active Directory Domain Services >

Topic Last Modified: *2012-10-29*

Domain preparation is the final step in preparing Active Directory Domain Services (AD DS) for Lync Server 2013. The domain preparation step adds the necessary access control entries (ACEs) to universal groups that grant permissions to host and manage users within the domain. Domain preparation creates ACEs on the domain root and three built-in containers: User, Computers, and Domain Controllers.

You can run domain preparation on any computer in the domain where you are deploying

Lync Server. You must prepare every domain that will host Lync Server or users.

If permissions inheritance is disabled or authenticated user permissions are disabled in your organization, you must perform additional steps during domain preparation. For details, see Preparing a Locked-Down Active Directory Domain Services.

If your organization uses organizational units (OU) instead of the three built-in containers (that is, Users, Computers, and Domain Controllers), you must grant read access to the OUs for the Authenticated Users group. Read access to the containers is required for domain preparation. If the Authenticated Users group does not have read access to the OU, run the **Grant-CsOuPermission** cmdlet as illustrated in the following code examples to grant read permissions for each OU.

```
Grant-CsOuPermission -ObjectType <User | Computer | InetOrgPerson | Contact | App
```

```
Grant-CsOuPermission -ObjectType "user","contact",inetOrgPerson" -OU "ou=Redmond,
```

For details about the **Grant-CsOuPermission** cmdlet, see the Lync Server Management Shell documentation.

Tip:

For details about the ACEs created on the domain root and in the Users, Computers, and Domain Controllers containers, see Changes Made by Domain Preparation.

Preparing Active Directory Domain Services for Lync Server 2013 > Preparing Active Directory Domain Services > Preparing Domains >

Topic Last Modified: *2012-10-29*

You can use Setup or Lync Server Management Shell cmdlets to prepare domains. The cmdlet that prepares a domain is **Enable-CsAdDomain**.

Domain preparation is the final step in preparing Active Directory Domain Services (AD DS) for Lync Server 2013.

⊟To use Setup to prepare domains

1. Log on to any server in the domain as a member of the Domain Admins group.
2. From the Lync Server 2013 installation folder or media, run Setup.exe to start the Lync Server Deployment Wizard.
3. Click **Prepare Active Directory**, and then wait for the deployment state to be determined.
4. At **Step 5: Prepare Current Domain**, click **Run**.
5. On the **Prepare Domain** page, click **Next**.
6. On the **Executing Commands** page, look for **Task status: Completed**, and then click **View Log**.
7. Under the **Action** column, expand **Domain Prep**, look for a **<Success>** Execution Result at the end of each task to verify that domain preparation completed successfully, close the log, and then click **Finish**.
8. Wait for Active Directory replication to complete or force replication to all the domain controllers listed in the Active Directory Sites and Services snap-in for the forest root domain controller.

⊟To use cmdlets to prepare the domain

1. Log on to any server in the domain as a member of the Domain Admins group.
2. Install Lync Server Core components as follows:
   - 2.a. From the Lync Server 2013 installation folder or media, run Setup.exe to start the Lync Server Deployment Wizard.
   - 2.b. If you are prompted to install the Microsoft Visual C++ Redistributable, click **Yes**.
   - 2.c. The Lync Server 2013 Setup dialog box prompts you for a location to install the Lync Server files. Choose the default location or **Browse** to a location of your choice, and then click **Install**.
   - 2.d. On the License Agreement page, check **I accept the terms in the license agreement**, and then click **OK**. The installer installs the Lync Server 2013 Core Components.
3. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
4. Run:

```
Enable-CsAdDomain [-Domain <DomainFQDN>]
```

For example:

```
Enable-CsAdDomain -Domain domain1.contoso.net
```

If you do not specify the Domain parameter, the default is the local domain.

5. Verify that domain preparation was successful. Run:

```
Get-CsAdDomain [-Domain <Domain FQDN>] [-DomainController <Domain cont
```

For example:

```
Get-CsAdDomain -Domain domain1.contoso.net - GlobalSettingsDomainContr
```

Note:
The parameter GlobalSettingsDomainController allows you to indicate where global settings are stored. If your settings are stored in the System container (which is typical with upgrade deployments that have not had the global settings migrated to the Configuration container), you define a domain controller in the root of your Active Directory forest. If the global settings are in the Configuration container (which is typical with new deployments or upgrade deployments where the settings have been migrated to the Configuration container), you define any domain controller in the forest. If you do not specify this parameter, the cmdlet assumes that the settings are stored in the Configuration container and refers to any domain controller in AD DS.

If you do not specify the **Domain** parameter, the default is the local domain. This cmdlet returns a value of **LC_DOMAINSETTINGS_STATE_READY** if domain preparation was successful.

Tasks

Using Cmdlets to Reverse Domain Preparation

Preparing Domains

Using Cmdlets to Reverse Domain Preparation

See Also

Preparing Active Directory Domain Services for Lync Server 2013 > Preparing Active Directory Domain Services > Preparing Domains >

Topic Last Modified: *2012-10-29*

Use the **Disable-CsAdDomain** cmdlet to reverse the domain preparation step.

To use cmdlets to reverse domain preparation

1. Log on to any server in the domain as a member of the Domain Admins group.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run:

   ```
   Disable-CsAdDomain [-Domain <Fqdn>] [-DomainController <Fqdn>] [-Force
   [-GlobalCatalog <Fqdn>] [-GlobalSettingsDomainController <Fqdn>]
   ```

   For example:

   ```
   Disable-CsAdDomain -Domain domain1.contoso.net -GlobalSettingsDomainCo
   ```

   If the Force parameter is present, domain preparation is rolled back, even if one or more Front End Servers or A/V Conferencing Servers in the domain are activated. If the Force parameter is not present, domain preparation rollback is terminated if any Front End Servers or A/V Conferencing Servers in the domain are activated.

   > **Note:**
   >
   > The parameter GlobalSettingsDomainController allows you to indicate where global settings are stored. If your settings are stored in the System container (which is typical with upgrade deployments that have not had the global setting migrated to the Configuration container), you define a domain controller in the root of your Active Directory forest. If the global settings are in the Configuration container (which is typical with new deployments or upgrade deployments where the settings have been migrated to the Configuration container), you define any domain controller in the forest. If you do not specify this parameter, the cmdlet assumes that the settings are stored in the Configuration container and refers to any domain controller in AD DS.

Preparing Domains

1.4.1.3.3.4 Preparing a Locked-Dow n Active Directory Domain Services

Preparing a Locked-Down Active Directory Domain Services

Deploying Lync Server 2013 > Preparing the Infrastructure and Systems > Preparing Active Directory Domain Services for Lync Server 2013 >

Topic Last Modified: *2012-05-14*

Organizations often lock down Active Directory Domain Services (AD DS) to help mitigate security risks. However, a locked-down Active Directory environment can limit the permissions that Lync Server 2013 requires. Properly preparing a locked-down Active Directory environment for Lync Server 2013 involves some additional considerations and steps.

Two common ways in which permissions are limited in a locked-down Active Directory environment are as follows:

- Authenticated user access control entries (ACEs) are removed from containers.
- Permissions inheritance is disabled on containers of User, Contact, InetOrgPerson, or Computer objects.

In This Section

- Authenticated User Permissions Are Removed
- Permissions Inheritance Is Disabled on Computers, Users, or InetOrgPerson Containers

Authenticated User Permissions Are Removed

Preparing the Infrastructure and Systems > Preparing Active Directory Domain Services for Lync Server 2013 > Preparing a Locked-Down Active Directory Domain Services >

Topic Last Modified: *2013-02-21*

In a locked-down Active Directory environment, authenticated user access control entries (ACEs) are removed from the default Active Directory containers, including the Users, Configuration or System, and organizational units (OUs) where User and Computer objects are stored. Removing authenticated user ACEs prevents read access to Active Directory information. However, removing the ACEs creates issues for Lync Server 2013 because it depends on read permissions to these containers to allow users to run domain preparation.

In this situation, membership in the Domain Admins group, which is required to run domain preparation, server activation, and pool creation, no longer grants read access to Active Directory information stored in the default containers. You must manually grant read-access permissions on various containers in the forest root domain to check that the prerequisite forest preparation procedure is complete.

To enable a user to run domain preparation, server activation, or pool creation on any non-forest root domain, you have the following options:

- Use an account that is a member of the Enterprise Admins group to run domain preparation.
- Use an account that is a member of the Domain Admins group and grant this account read-access permissions on each of the following containers in the forest root domain:
  - Domain
  - Configuration or System

If you do not want to use an account that is a member of the Enterprise Admins group to run domain preparation or other Setup tasks, explicitly grant the account you want to use read access on the relevant containers in the forest root.

⊟To give users read-access permissions on containers in the forest root domain

1. Log on to the computer joined to the forest root domain with an account that is a member of the Domain Admins group for the forest root domain.
2. Run adsiedit.msc for the forest root domain.

   If authenticated user ACEs were removed from the Domain, Configuration, or System container, you must grant read-only permissions to the container, as described in the following steps.
3. Right-click the container, and then click **Properties**.
4. Click the **Security** tab.

5. Click **Advanced**.
6. On the **Permissions** tab, click **Add**.
7. Type the name of the user or group receiving permissions by using the following format: `domain\account name`, and then click **OK**.
8. On the **Objects** tab, in **Applies To**, click **This Object Only**.
9. In **Permissions**, select the following Allow ACEs by clicking the **Allow** column: **List Content**, **Read All Properties**, and **Read Permissions**.
10. Click **OK** twice.
11. Repeat these steps for any of the relevant containers listed in Step 2.

Permissions Inheritance Is Disabled on Computers, Users, or InetOrgPerson Containers

Preparing the Infrastructure and Systems > Preparing Active Directory Domain Services for Lync Server 2013 > Preparing a Locked-Down Active Directory Domain Services >

Topic Last Modified: *2012-06-19*

In a locked-down Active Directory Domain Services (AD DS), Users and Computer objects are often placed in specific organizational units (OUs) with permissions inheritance disabled to help secure administrative delegation and to enable use of Group Policy objects (GPOs) to enforce security policies.

Domain preparation and server activation set the access control entries (ACEs) required by Lync Server 2013. When permissions inheritance is disabled, the Lync Server security groups cannot inherit these ACEs. When these permissions are not inherited, Lync Server security groups cannot access settings, and the following two issues arise:

- To administer Users, InetOrgPersons, and Contacts, and to operate servers, the Lync Server security groups require ACEs set by the domain preparation procedure on each user's property sets, real-time communications (RTC), RTC User Search, and Public Information. When permissions inheritance is disabled, security groups do not inherit these ACEs and cannot manage servers or users.
- To discover servers and pools, servers running Lync Server rely on ACEs set by activation on computer-related objects, including the Microsoft Container and Server object. When permissions inheritance is disabled, security groups, servers, and pools do not inherit these ACEs and cannot take advantage of these ACEs.

To address these issues, Lync Server provides the **Grant-CsOuPermission** cmdlet. This cmdlet sets required Lync Server ACEs directly on a specified container and organizational units and the objects within the container or organizational unit.

Set Permissions for User, InetOrgPerson, and Contact Objects after Running Domain Preparation

In a locked-down Active Directory environment where permissions inheritance is disabled, domain preparation does not set the necessary ACEs on the containers or organizational units holding Users or InetOrgPerson objects within the domain. In this situation, you must run the **Grant-CsOuPermission** cmdlet on each container or OU that has User or InetOrgPerson objects for which permissions inheritance is disabled. If you have a central forest topology, you must also perform this procedure on the containers or OUs that hold contact objects. For details about central forest topologies, see Supported Active Directory Topologies in the Supportability documentation. The ObjectType parameter specifies the object type. The OU parameter specifies the organizational unit.

This cmdlet adds the required ACEs directly on the specified containers or OUs and the User or InetOrgPerson objects within the container.

You need user rights equivalent to Domain Admins group membership to run this cmdlet. If the authenticated user ACEs have also been removed in the locked-down environment, you must grant this account read-access ACEs on the relevant containers or OUs in the forest root domain as described in Authenticated User Permissions Are Removed or use an account that is a member of the Enterprise Admins group.

To set required ACEs for User, InetOrgPerson, and Contact objects

1. Log on to a computer joined to the domain with an account that is a member of the Domain Admins group or that has equivalent user rights.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run:

   ```
   Grant-CsOuPermission -ObjectType <User | Computer | InetOrgPerson | Co
   -OU <DN name for the OU container relative to the domain root containe
   ```

   If you do not specify the Domain parameter, the default value is the local domain.

   For example:

   ```
   Grant-CsOuPermission -ObjectType "User" -OU "cn=Redmond,dc=contoso,dc=
   ```

4. In the log file, look for **<Success>** Execution Result at the end of each task to verify that the permissions were set, and then close the log window. Or, you can run the following command to determine whether the permissions were set:

   ```
   Test-CsOuPermission -ObjectType <type of object>
   -OU <DN name for the OU container relative to the domain root containe
   [-Domain <Domain FQDN>] [-Report <fully qualified path and name of fil
   ```

   For example:

   ```
   Test-CsOuPermission -ObjectType "User" -OU "cn=Redmond,dc=contoso,dc=n
   ```

Set Permissions for Computer Objects after Running Domain Preparation

In a locked-down Active Directory environment where permissions inheritance is disabled, domain preparation does not set the necessary ACEs on the containers or OUs that hold Computer objects within the domain. In this situation, you must run the **Grant-CsOuPermission** cmdlet on each container or OU that has computers running Lync Server where permissions inheritance is disabled. The ObjectType parameter specifies the object type.

This procedure adds the required ACEs directly on the specified containers.

You need user rights equivalent to Domain Admins group membership to run this cmdlet. If the authenticated user ACEs have also been removed, you must grant this account read-access ACEs on the relevant containers in the forest root domain as described in Authenticated User Permissions Are Removed or use an account that is a member of the Enterprise Admins group.

To set required ACEs for computer objects

1. Log on to the domain computer with an account that is a member of the Domain Admins group or that has equivalent user rights.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.

3. Run:

```
Grant-CsOuPermission -ObjectType <Computer>
-OU <DN name for the computer OU container relative to the domain root
[-Domain <Domain FQDN>][-Report <fully qualified path and name of outp
```

   If you do not specify the Domain parameter, the default value is the local domain.
   For example:

```
Grant-CsOuPermission -ObjectType "Computer" -OU "ou=Lync Servers,dc=li
```

4. In the example log file C:\Logs\OUPermissions.xml, you would look for **<Success>** Execution Result at the end of each task and verify that there are no errors, and then close the log. You can run the following cmdlet to test permissions:

```
Test-CsOuPermission -ObjectType <type of object>
-OU <DN name for the OU container relative to the domain root containe
```

   For example:

```
Test-CsOuPermission -ObjectType "user","contact" -OU "cn=Bellevue,dc=c
```

> **Note:**
> If you run domain preparation on the forest root domain in a locked-down Active Directory environment, be aware that Lync Server requires access to the Active Directory Schema and Configuration containers.
> If the default authenticated user permission is removed from the Schema or the Configuration containers in AD DS, only members of the Schema Admins group (for Schema container) or Enterprise Admins group (for Configuration container) are permitted to access the given container. Because Setup.exe, Lync Server Management Shell cmdlets, and Lync Server Control Panel require access to these containers, Setup and installation of the administrative tools will fail unless the user running the installation has user rights equivalent to Schema Admins and Enterprise Admins group membership.
> To remedy this situation, you must grant RTCUniversalGlobalWriteGroup group Read, Write access to the Schema and Configuration containers.

1.4.1.3.3.5 Granting Permissions

Granting Permissions

Deploying Lync Server 2013 > Preparing the Infrastructure and Systems > Preparing Active Directory Domain Services for Lync Server 2013 >

Topic Last Modified: *2012-10-15*

For setup, you can grant permissions to the RTCUniversalServerAdmins universal group for a specific Active Directory organizational unit (OU), enabling members of the RTCUniversalServerAdmins group in that OU to install Lync Server 2013 in the specified domain. When you grant permissions for an OU, the following permissions are granted:

- Read
- Write
- ReadSPN
- WriteSPN

For administration, you can add permissions to specified OUs so that members of the RTC universal groups created by forest preparation can access the OUs without needing to be members of the Domain Admins group. The permissions added to the specified OU are the same permissions that the **Enable-CsAdDomain** cmdlet adds to the computers and users OU containers.

Granting Setup Permissions

Preparing the Infrastructure and Systems > Preparing Active Directory Domain Services for Lync Server 2013 > Granting Permissions >

Topic Last Modified: *2012-08-27*

You can use the **Grant-CsSetupPermission** cmdlet to add Read, Write, ReadSPN, and WriteSPN permissions to the RTCUniversalServerAdmins group for a specified Active Directory organizational unit (OU). Then members of the RTCUniversalServerAdmins group in that OU can install servers running Lync Server 2013 in the specified domain without being members of the Domain Admins group.

Use the **Test-CsSetupPermission** cmdlet to verify the permissions you set up by using the **Grant-CsSetupPermission** cmdlet.

You can use the **Revoke-CsSetupPermission** cmdlet to remove permissions that you granted by using the **Grant-CsSetupPermission** cmdlet.

To grant setup permissions

1. Log on to a computer running Lync Server 2013 in the domain where you want to grant setup permissions. Use an account that is a member of the Domain Admins group or the Enterprise Admins group if the OU is in a different child domain.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run:

```
Grant-CsSetupPermission -ComputerOu <DN of the OU or container where t
```

You can specify the ComputerOu parameter as relative to the default naming context of the specified domain (for example, CN=computers). Alternatively, you can specify this parameter as the full OU distinguished name (DN) (for example, "CN=computers,DC=Contoso,DC=com"). In the latter case, you must specify an OU DN that is consistent with the domain you specify.

If you do not specify the Domain parameter, the default value is the local domain.

To verify setup permissions

1. Log on to a computer running Lync Server 2013 in the domain where you want to verify setup permissions that you granted by using the **Grant-CsSetupPermission** cmdlet. Use an account that is a member of the Domain Admins group or the Enterprise Admins group if the OU is in a different child domain.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run:

```
Test-CsSetupPermission -ComputerOu <DN of the OU or container where th
```

You can specify the ComputerOu parameter as relative to the default naming context of the specified domain (for example, CN=computers). Alternatively, you can specify this parameter as the full OU distinguished name (DN) (for example, "CN=computers,DC=Contoso,DC=com"). In the latter case, you must specify an OU DN that is consistent with the domain you specify.

If you do not specify the Domain parameter, the default value is the local domain.

⊟To revoke setup permissions

1. Log on to a computer running Lync Server 2013 in the domain where you want to revoke setup permissions that were granted by the **Grant-CsSetupPermission** cmdlet. Use an account that is a member of the Domain Admins group or the Enterprise Admins group if the OU is in a different child domain.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run:

   ```
   Revoke-CsSetupPermission -ComputerOu <DN of the OU or container where
   ```

   You can specify the ComputerOu parameter as relative to the default naming context of the specified domain (for example, CN=computers). Alternatively, you can specify this parameter as the full OU distinguished name (DN) (for example, "CN=computers,DC=Contoso,DC=com"). In the latter case, you must specify an OU DN that is consistent with the domain you specify.

   If you do not specify the Domain parameter, the default value is the local domain.

Granting Organizational Unit Permissions

Preparing the Infrastructure and Systems > Preparing Active Directory Domain Services for Lync Server 2013 > Granting Permissions >

Topic Last Modified: *2012-05-14*

You can use the **Grant-CsOuPermission** cmdlet to grant permissions to objects in specified organizational units (OUs) so that members of the RTC universal groups created by forest preparation can access them without being members of the Domain Admins group. The permissions added to the specified OU are the same permissions that the **Enable-CsAdDomain** cmdlet adds to the computers and users containers during domain preparation.

Use the **Test-CsOuPermission** cmdlet to verify the permissions you set up by using the **Grant-CsOuPermission** cmdlet.

You can use the **Revoke-CsOuPermission** cmdlet to remove permissions that you granted by using the **Grant-CsOuPermission** cmdlet.

⊟To grant OU permissions

1. Log on to a computer running Lync Server 2013 in the domain where you want to grant OU permissions. Use an account that is a member of the Domain Admins group or the Enterprise Admins group if the OU is in a different child domain.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run:

   ```
   Grant-CsOuPermission -ObjectType <User | Computer | InetOrgPerson | Co
   ```

If you do not specify the Domain parameter, the default value is the local domain.

To verify OU permissions

1. Log on to a computer running Lync Server 2013 in the domain where you want to verify OU permissions that you granted by using the **Grant-CsOuPermission** cmdlet. Use an account that is a member of the Domain Admins group or the Enterprise Admins group if the OU is in a different child domain.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run:

```
Test-CsOuPermission -ObjectType <User | Computer | InetOrgPerson | Con
```

If you do not specify the Domain parameter, the default value is the local domain.

To revoke OU permissions

1. Log on to a computer running Lync Server 2013 in the domain where you want to revoke OU permissions that were granted by the **Grant-CsOuPermission** cmdlet. Use an account that is a member of the Domain Admins group or the Enterprise Admins group if the OU is in a different child domain.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run:

```
Revoke-CsOuPermission -ObjectType <User | Computer | InetOrgPerson | C
```

If you do not specify the Domain parameter, the default value is the local domain.

1.4.1.3.4 Configure SQL Server for Lync Server 2013

Configure SQL Server for Lync Server 2013

Deployment > Deploying Lync Server 2013 > Preparing the Infrastructure and Systems >

Topic Last Modified: *2012-10-01*

The topics in this section discuss how to deploy and configure SQL Server to use in an Enterprise deployment of Lync Server. Standard Edition servers use a collocated SQL Server Express version of SQL Server that is right sized for the workloads of a Standard Edition server.

The Lync Server 2013 Central Management store holds user data for all Enterprise Edition servers within a pool, and is designed to be located on a SQL Server -based Back End Server. As a centralized repository, the Central Management store cannot be installed on the same computer as any other Lync Server 2013 role. The Central Management store cannot reside on an Enterprise Edition server in the pool. The Central Management store is created automatically when you publish the topology for the first time and select to create the databases. The computer that you designate as the Back End Server must already be running SQL Server database software in order for the installation to succeed.

- SQL Server Data and Log File Placement
- Configure SQL Server
- Deployment Permissions for SQL Server

- Database Installation Using Lync Server Management Shell
- Understanding Firewall Requirements for SQL Server

1.4.1.3.4.1 SQL Server Data and Log File Placement

SQL Server Data and Log File Placement

Deploying Lync Server 2013 > Preparing the Infrastructure and Systems > Configure SQL Server for Lync Server 2013 >

Topic Last Modified: *2013-02-21*

During the planning and deployment of Microsoft SQL Server 2012 or Microsoft SQL Server 2008 R2 SP1 for your Lync Server 2013 Front End pool, an important consideration is the placement of data and log files onto physical hard disks for performance. The recommended disk configuration is to implement a 1+0 RAID set using 6 spindles. Placing all database and log files that are used by the Front End pool and associated server roles and services (that is, Archiving and Monitoring Server, Lync Server Response Group service, Lync Server Call Park service) onto the RAID drive set using the Lync Server Deployment Wizard will result in a configuration that has been tested for good performance. The database files and what they are responsible for is detailed in the following table.

Note:

If your policies and SQL Server configurations require a more specialized installation, the database and log files can be installed to any pre-defined location using the Lync Server Management Shell. See Database Installation Using Lync Server Management Shell for more details.

Data and Log Files for Central Management Store

Central Management store database files	Data file or log purpose
Xds.ldf	Transaction log file for the Central Management store
Xds.mdf	Maintains the configuration of the current Lync Server 2013 topology, as defined and published by Topology Builder
Lis.mdf	Location Information service data file
Lis.ldf	Transaction log for the Location Information service data file

Data and Log files for User, Conferencing, and Address Book

Core Lync Server 2013 database files	Data file or log purpose
Rtc.mdf	Persistent user data (for example, access control lists (ACLs), contacts, scheduled conferences)
Rtc.ldf	Transaction log for Rtc data
Rtcdyn.mdf	Maintains transient user data (presence runtime data)
Rtcdyn.ldf	Transaction log for Rtcdyn data
Rtcab.mdf	Real-time communications (RTC) address book database is the SQL Server repository

	where Address Book service information is stored
Rtcab.ldf	Transaction log for Address Book Service
Rtclocal.mdb	Hosts the conference directory
Rtcxds.mdf	Maintains the backup for user data
Rtcxds.ldf	Transaction log for Rtcxds data

Data and Log Files for Call Park and Response Group

Application database	**Data file or log purpose**
Cpsdyn.mdf	Dynamic information database for the Call Park application
Cpsdyn.ldf	Transaction log for Call Park application data file
Rgsconfig.mdf	Lync Server Response Group service data file for the configuration of the services
Rgsconfig.ldf	Transaction log file for the Response Group application configuration
Rgsdyn.mdf	Response Group service data file for runtime operations
Rgsdyn.ldf	Transaction log for the Response Group service runtime data file

Data and Log Files for Archiving and Monitoring Server

Archiving and Monitoring database files	**Data file or log purpose**
LcsCdr.mdf	Data store for the call detail recording (CDR) process of the Monitoring Server
LcsCdr.ldf	Transaction log for call detail recording (CDR) data
QoEMetrics.mdf	Quality of Experience data file stored from the Monitoring Server
QoEMetrics.ldf	Transaction log for Monitoring data
Lcslog.mdf	Data file for the retention of instant messaging and conferencing data on an Archiving Server
Lcslog.ldf	Transaction log for Archiving data

In this topic, references are made to disk and to RAID set. Note that in the configuration of SQL Server resources, referring to a disk means a single hardware device. A hard disk drive with two partitions, one holding log files and the other partition holding data files, is not the same as two disks, each dedicated to either log or data files.

In reference to RAID sets, there are a number of different RAID technologies from various vendors. And, with the proliferation of storage area networks (SAN), RAID sets dedicated to a single system are rarer. You should consult with your RAID or SAN vendor to determine what the best configuration is for your disk layout when configuring for SQL

Server performance with Lync Server 2013.

Note also that not all disk drives are created equally; some perform better than others. Even drives from the same manufacturer can vary in performance because of rotational speed, hardware cache size, and other factors.

1.4.1.3.4.2 Configure SQL Server

Configure SQL Server

Deploying Lync Server 2013 > Preparing the Infrastructure and Systems > Configure SQL Server for Lync Server 2013 >

Topic Last Modified: *2012-10-01*

For each database that you deploy, you can use a single SQL Server instance for all databases for your Lync Server 2013 deployment that can be collocated on a database server. For details about database collocation, see Supported Server Collocation in the Supportability documentation.

Additionally, each SQL Server instance must be installed and available prior to completing the steps in Topology Builder that set up the databases, or manually creating the databases with Windows PowerShell cmdlets. For details about SQL Server supportability, see Hardware Setup.

⊟To install Microsoft SQL Server 2012

- See the Microsoft SQL Server 2012 documentation at: http://go.microsoft.com/fwlink/p/?linkId=218015.

1.4.1.3.4.3 Deployment Permissions for SQL Server

Deployment Permissions for SQL Server

Deploying Lync Server 2013 > Preparing the Infrastructure and Systems > Configure SQL Server for Lync Server 2013 >

Topic Last Modified: *2012-10-01*

Microsoft SQL Server 2012 has specific requirements when installing and deploying Lync Server 2013. Because Windows and SQL Server define their security differently, logging in as an administrator in the Active Directory domain does not implicitly grant permissions for SQL Server. You must also be a member of the sysadmin entity on the SQL Server-based server you are configuring.

Permissions Required for Database and Lync Server Installation

The following options detail three permissions and group membership associations for installation of Lync Server 2013 files and SQL Server databases. Choose the scenario that best meets the requirements of your organization.

Permissions and Group Membership Associations

SQL Server or Lync Server 2013 role	Role-Typical SQL Server permissions	Role-typical Lync Server 2013	Permissions outcome

	and group membership	**permissions and group membership**	
Lync Server 2013 administrator	Must be granted membership of sysadmins SQL Server security group and member of the SQL Server local Administrators group	Must be a member of the RTCUniversalServerAdmins group	Lync Server 2013 administrator has the proper permissions to install both Lync Server 2013 and SQL Server databases.
SQL Server administrator	SQL Server sysadmin group member (or equivalent) and member of the SQL Server local Administrators group	Must be a member of the RTCUniversalServerReadOnly group	SQL Server administrator has the proper permissions to install both Lync Server 2013 and SQL Server databases.
Both administrators sharing installation duties	SQL Server administrator is member of sysadmins group (or equivalent) and member of the SQL Server local Administrators group	Lync Server 2013 administrator is member of RTCUniversalServerAdmins	The Lync Server 2013 administrator can install Lync Server 2013, but cannot install the databases. The SQL Server administrator uses the Lync Server Management Shell and Windows PowerShell cmdlets provided by the Lync Server 2013 administrator to install the databases. The Lync Server 2013 Management Shell used by the SQL Server administrator is installed on the Front End Server. This eliminates the need to install the Lync Server 2013 administrative tools on the SQL Server-based server.

1.4.1.3.4.4 Database Installation Using Lync Server Management Shell

Database Installation Using Lync Server Management Shell

Deploying Lync Server 2013 > Preparing the Infrastructure and Systems > Configure SQL Server for Lync Server 2013 >

Topic Last Modified: *2013-02-06*

Separation of roles and responsibilities between server administrators and SQL Server administrators can result in delays in implementation. Lync Server 2013 uses role-based access control (RBAC) to mitigate these difficulties. In some instances, the SQL Server administrator must manage the installation of databases on the SQL Server-based server outside RBAC. The Lync Server 2013 Management Shell provides a way for the SQL Server administrator to run Windows PowerShell cmdlets designed to configure the databases with the correct data and log files. For details, see Deployment Permissions for SQL Server.

Important:

The following procedure assumes that at a minimum the Lync Server 2013 OCSCore.msi, SQL Server Native Client (sqlncli.msi) Microsoft SQL Server 2012 Management Objects, CLR Types for Microsoft SQL Server 2012 and Microsoft SQL Server 2012 ADOMD.NET are installed. The OCSCore.msi is located on the installation media in the \Setup\AMD64 \Setup directory. The remaining components are located in \Setup\amd64. Additionally, Active Directory preparation for Lync Server 2013 has been successfully completed.

Install-CsDatabase is the Windows PowerShell cmdlet you use to install the databases. The **Install-CsDatabase** cmdlet has a large number of parameters, only a few of which are discussed here. For details about the possible parameters, see the Lync Server 2013 Management Shell documentation.

Warning:

To avoid performance and possible time-out issues, always use fully qualified domain names (FQDNs) when referring to SQL Server-based servers. Avoid using host name-only references. For example, use sqlbe01.contoso.net, but avoid using SQLBE01.

For installing databases, **Install-CsDatabase** uses three primary methods for placing the databases onto the prepared SQL Server-based server:

- Run **Install-CsDatabase** without DatabasePaths or UseDefaultSqlPath. The cmdlet uses a built in algorithm to determine the best placement for the log and data files. The algorithm only works for stand-alone SQL Server implementations.
- Run **Install-CsDatabase** with the DatabasePaths parameter. The built-in algorithm to optimize log and data file locations is not used if the DatabasePaths parameter is defined. Using this parameter allows you to define the locations where log and data files will be deployed.
- Run **Install-CsDatabase** with UseDefaultSqlPaths. This option does not use the built-in algorithm to optimize the log and data file locations. Log and data file are deployed according to the defaults set by the SQL Server administrator. These paths are typically set for the purpose of automatic administration of log and data files on the SQL Server in advance, and are not associated with the setup of Lync Server 2013.
- The DatabasePathMap parameter can also be used to explicitly specify a location for each database and its respective log file.

To use Windows PowerShell cmdlets to configure the SQL Server Central Management store

1. On any computer, log on with administrative credentials for creating the databases on the SQL Server-based server. For details, see Deployment Permissions for SQL Server.
2. Open the Lync Server 2013 Management Shell. If you have not adjusted the execution policy for Windows PowerShell, you must adjust the policy to allow Windows PowerShell scripts to run. For details, see “Examining the Execution Policy” at http://go.microsoft.com/fwlink/p/?linkId=203093.
3. Use the **Install-CsDatabase** cmdlet to install the Central Management store.

```
Install-CsDatabase -CentralManagementDatabase -SqlServerFqdn <fully qu
-SqlInstanceName <named instance> -DatabasePaths <logfile path>,<datab
-Report <path to report file>
```

```
Install-CsDatabase -CentralManagementDatabase -SqlServerFqdn sqlbe.con
```

> **Tip:**
> The Report parameter is optional but is useful if you are documenting the installation process.

4. **Install-CsDatabase –DatabasePaths** can use up to six path parameters, each defining the paths for the drives as defined in SQL Server Data and Log File Placement. By the logical rules of the database configuration in Lync Server 2013, drives are parsed out into buckets of two, four, or six. Depending on your SQL Server configuration and the number of buckets, you will supply two paths, four paths, or six paths.

   If you have three drives, the log gets priority and the data files are distributed after. An example for a SQL Server-based server configured with six drives:

   ```
   Install-CsDatabase -ConfiguredDatases -SqlServerFqdn sqlbe.contoso.net
   ```

5. When the database installation completes, you can close Lync Server 2013 Management Shell or proceed to the installation of the Lync Server 2013 configured databases defined in Topology Builder.

To use Windows PowerShell cmdlets to configure the SQL Server topology configured databases

1. To install the Topology Builder configured databases for Lync Server 2013, the Lync Server 2013 administrator must publish the topology. For details, see Publish the Topology in the Deployment documentation.
2. On any computer, log on with administrative credentials for creating the databases on the SQL Server-based server. See the topic, Deployment Permissions for SQL Server.

   > **Important:**
   > To be able to configure the SQL Server-based databases, make sure the SQL Server administrator account used to run the steps described here is also a member of the sysadmins group (or equivalent) on the server running SQL Server and holding the Central Management Server role. This is especially important to check for any additional Lync Server 2013 pools which require SQL Server database installation or configuration. For example, if you are deploying a second pool (pool02) but the Central Management Server role is held by pool01. The SQL Server sysadmin group (or equivalent) must have permissions on both SQL Server-based databases.

3. Open Lync Server 2013 Management Shell, if it’s not already open.
4. Use the **Install-CsDatabase** cmdlet to install the Topology Builder configured databases.

   ```
   Install-CsDatabase -ConfiguredDatabases -SqlServerFqdn <fully qualifie
    -DatabasePaths <logfile path>,<database file path> -Report <path to r
   ```

   ```
   Install-CsDatabase -ConfiguredDatabases -SqlServerFqdn sqlbe.contoso.n
   -Report "C:\Logs\InstallDatabases.html"
   ```

   > **Tip:**
   > The Report parameter is optional but is useful if you are documenting the installation process.

5. When the database installation completes, close Lync Server 2013 Management Shell.

To use Windows PowerShell cmdlets to configure the SQL Server topology using the DatabasePathMap parameter

1. To install databases for Lync Server 2013, the Lync Server administrator must create the paths and deploy the databases files and log files according to a predefined set of rules.
2. On any computer, log on with administrative credentials for creating the

databases on the SQL Server-based server. See the topic, Deployment Permissions for SQL Server.

Important:
To be able to configure the SQL Server-based databases, make sure the SQL Server administrator account used to run the steps described here is also a member of the sysadmins group (or equivalent) on the server running SQL Server and holding the Central Management Server role. This is especially important to check for any additional Lync Server pools which require SQL Server database installation or configuration. For example, if you are deploying a second pool (pool02) but the Central Management Server role is held by pool01. The SQL Server sysadmin group (or equivalent) must have permissions on both SQL Server-based databases.

3. Open Lync Server Management Shell, if it's not already open.
4. Use the **Install-CsDatabase** cmdlet with the DatabasePathMap parameter and a PowerShell hash table to install the Topology Builder configured databases.
5. In the example code, the paths defined for the databases can be determined in a granular manner by using the –DatabasePathsMap parameter and a defined hash table as follows (the example uses "C:\CSData" for all database (.mdf) files, and "C:\CSLogFiles" for all log (.ldf) files. Folder will be created as needed by Install-CsDatabase):

```
$pathmap = @{
"BackendStore:BlobStore:DbPath"="C:\CsData";"BackendStore:BlobStore:Lo
"BackendStore:RtcSharedDatabase:DbPath"="C:\CsData";"BackendStore:RtcS
"ABSStore:AbsDatabase:DbPath"="C:\CsData";"ABSStore:AbsDatabase:LogPat
"ApplicationStore:RgsConfigDatabase:DbPath"="C:\CsData";"ApplicationSt
"ApplicationStore:RgsDynDatabase:DbPath"="C:\CsData";"ApplicationStore
"ApplicationStore:CpsDynDatabase:DbPath"="C:\CsData";"ApplicationStore
"ArchivingStore:ArchivingDatabase:DbPath"="C:\CsData";"ArchivingStore:
"MonitoringStore:MonitoringDatabase:DbPath"="C:\CsData";"MonitoringSto
"MonitoringStore:QoEMetricsDatabase:DbPath"="C:\CsData";"MonitoringSto
}
Install-CsDatabase -ConfigureDatabases -SqlServerFqdn sqlbe01.contoso.
```

6. Because the database and log files are explicitly named with their location on the destination database server, you can define specific locations for each service type's actual database and log location. The following example puts databases for each specific service type on separate disks, and associated log files on another. For example:
   - All RTC databases to "D:\RTCDatabase"
   - All RTC log files to "E:\RTCLogs"
   - All application store databases to "F:\CPSDatabases"
   - All application store logs to "G:\CPSLogs"
   - All response group store databases to "H:\RGSDatabases"
   - All response group store logs to "I:\RGSLogs"
   - All address book store databases to "J:\ABSDatabases"
   - All address book store log files to "K:\ABSLogs"
   - All archiving store databases to "L:\ArchivingDatabases"
   - All archiving store logs to "M:\ArchivingLogs"
   - All monitoring store databases to "N:\MonitoringDatabases"
   - All monitoring store log files to "O:\MonitoringLogfiles"

```
$pathmap = @{
"BackendStore:BlobStore:DbPath"="D:\RTCDatabase";"BackendStore:BlobSto
"BackendStore:RtcSharedDatabase:DbPath"="D:\RTCDatabase";"BackendStore
"ABSStore:AbsDatabase:DbPath"="J:\ABSDatabases";"ABSStore:AbsDatabase:
"ApplicationStore:RgsConfigDatabase:DbPath"="H:\RGSDatabases";"Applica
"ApplicationStore:RgsDynDatabase:DbPath"="H:\RGSDatabases";"Applicatio
"ApplicationStore:CpsDynDatabase:DbPath"="F:\CPSDatabases";"Applicatio
"ArchivingStore:ArchivingDatabase:DbPath"="M:\ArchivingLogs";"Archivin
"MonitoringStore:MonitoringDatabase:DbPath"="N:\MonitoringDatabases";"
"MonitoringStore:QoEMetricsDatabase:DbPath"="N:\MonitoringDatabases";"
}
Install-CsDatabase -ConfigureDatabases -SqlServerFqdn sqlbe01.contoso.
```

Using the –DatabasePathMap parameter, you can define any logical drive letter mapping combination that provides the best solution for your SQL Server performance and placement requirements.

If you configure your database data files and log files by using the **DatabasePathMap** method, you will need to make a slight change to your normal process when using Topology Builder. Typically, you would define your topology choices, publish the topology, and choose to deploy the database selections.

If you have used **DatabasePathMap** you have already accomplished the third part of the Topology Builder process. In the case of having a completely configured database server in advance of running Topology Builder, you would still define all of your server roles and options, but deselect the option to create the databases.

1.4.1.3.4.5 Understanding Firewall Requirements for SQL Server

Understanding Firewall Requirements for SQL Server

Deploying Lync Server 2013 > Preparing the Infrastructure and Systems > Configure SQL Server for Lync Server 2013 >

Topic Last Modified: *2013-02-21*

For a Standard Edition deployment, firewall exceptions are created automatically during Lync Server 2013 Setup. However, for Enterprise Edition deployments, you must configure the firewall exceptions manually on the SQL Server Back End Server. The TCP/IP protocol allows for a given port to be used once for a given IP address. This means that for the SQL Server-based server you can assign the default database instance the default TCP port 1433. For any other instances you will need to use the SQL Server Configuration Manager to assign unique and unused ports. This topic covers:

- Requirements for a firewall exception when using the default instance
- Requirements for a firewall exception for the SQL Server Browser service
- Requirements for static listening ports when using named instances

Requirements for a Firewall Exception When Using the Default Instance

If you are using the SQL Server default instance for any database when deploying Lync Server 2013, the following firewall rule requirements are used to help ensure communication from the Front End pool to the SQL Server default instance.

Protocol	Port	Direction
TCP	1433	Inbound to SQL Server

Requirements for a Firewall Exception for the SQL Server Browser Service

The SQL Server Browser service will locate database instances and communicate the port that the instance (named or default) is configured to use.

Protocol	Port	Direction

UDP	1434	Inbound

Requirements for Static Listening Ports When Using Named Instances

When using named instances in the SQL Server configuration for databases supporting Lync Server 2013, you configure static ports by using SQL Server Configuration Manager. After the static ports have been assigned to each named instance, you create exceptions for each static port in the firewall.

Protocol	Port	Direction
TCP	Statically defined	Inbound

SQL Server Documentation

Microsoft SQL Server 2012 documentation provides detailed guidance on how to configure firewall access for databases. For details about Microsoft SQL Server 2012, see “Configuring the Windows Firewall to Allow SQL Server Access” at http://go.microsoft.com/fwlink/p/?linkId=218031.

1.4.1.3.5 Configure DNS Records for a Front End Pool or Standard Edition Server

Configure DNS Records for a Front End Pool or Standard Edition Server

Deployment > Deploying Lync Server 2013 > Preparing the Infrastructure and Systems >

Topic Last Modified: *2012-10-01*

Lync Server 2013 uses the Domain Name System (DNS) to register and maintain records for proper domain name to IP address resolution. You need to configure required DNS records for your deployment prior to operating the Standard Edition server or Front End pool. The following links will provide guidance on what records need to be created to allow for the proper operation of Lync Server 2013.

- Configure DNS for Load Balancing
- Configure DNS Host Records
- Create and Verify DNS SRV Records

1.4.1.3.5.1 Configure DNS for Load Balancing

Configure DNS for Load Balancing

See Also

Deploying Lync Server 2013 > Preparing the Infrastructure and Systems > Configure DNS Records for a Front End Pool or Standard Edition Server >

Topic Last Modified: *2012-10-01*

To successfully complete this procedure, you should be logged on to the server or domain minimally as a member of the Domain Admins group or a member of the DnsAdmins group.

Domain Name System (DNS) Load Balancing balances the network traffic that is unique to

Lync Server 2013, such as SIP traffic and media traffic. DNS load balancing is supported for Front End pools, Edge pools, Director pools, and stand-alone Mediation pools. A pool that is configured to use DNS load balancing must have two fully qualified domain names (FQDNs) defined: the regular pool FQDN that is used by DNS load balancing (for example, pool1.contoso.com) and that resolves to the physical IPs of the servers in the pool, and another FQDN for the pool's Web Services (for example, web1.contoso.net), which resolves to the virtual IP address of the pool. For details about DNS Load Balancing, see DNS Load Balancing in the Planning documentation.

Note:

Hardware load balancing is still required for client to server HTTPS traffic.

Before you can use DNS load balancing, you must do the following:

1. Override the internal Web Services pool FQDN.

   ⚠Warning:

   If decide to override the Internal web services with a self-defined FQDN, each FQDN must be unique from any other Front End pool, Director or a Director pool.

2. Create DNS A host records to resolve the pool FQDN to the IP addresses of all the servers in the pool.
3. Enable IP Address randomization or, for Windows Server DNS, enable round robin.

   Note:

   Round robin should be enabled by default.

⊟To override internal Web services FQDN

1. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
2. From the console tree, expand the Enterprise Edition Front End pools node.
3. Right-click the pool, click **Edit Properties**, and then click **Web Services**.
4. Below **Internal web services**, select the **Override FQDN** check box.
5. Type the pool FQDN that resolves to the physical IP addresses of the servers in the pool.
6. Below **External web services**, type the external pool FQDN that resolves to the virtual IP addresses of the pool, and then click **OK**.
7. From the console tree, click **Lync Server 2013**, and then in the **Actions** pane, click **Publish Topology**.

⊟To create DNS Host (A) Records for all internal pool servers

1. Click **Start**, click **All Programs**, click **Administrative Tools**, and then click **DNS**.
2. In **DNS Manager**, click the DNS Server that manages your records to expand it.
3. Click **Forward Lookup Zones** to expand it.
4. Right-click the DNS domain that you need to add records to, and then click **New Host (A or AAAA)**.
5. In the **Name** box, type the name of the host record (the domain name will be automatically appended).
6. In the IP Address box, type the IP address of the individual Front End Server and then select **Create associated pointer (PTR) record** or **Allow any authenticated user to update DNS records with the same owner name**, if applicable.
7. Continue creating records for all member Front End Servers that will participate in DNS Load Balancing.

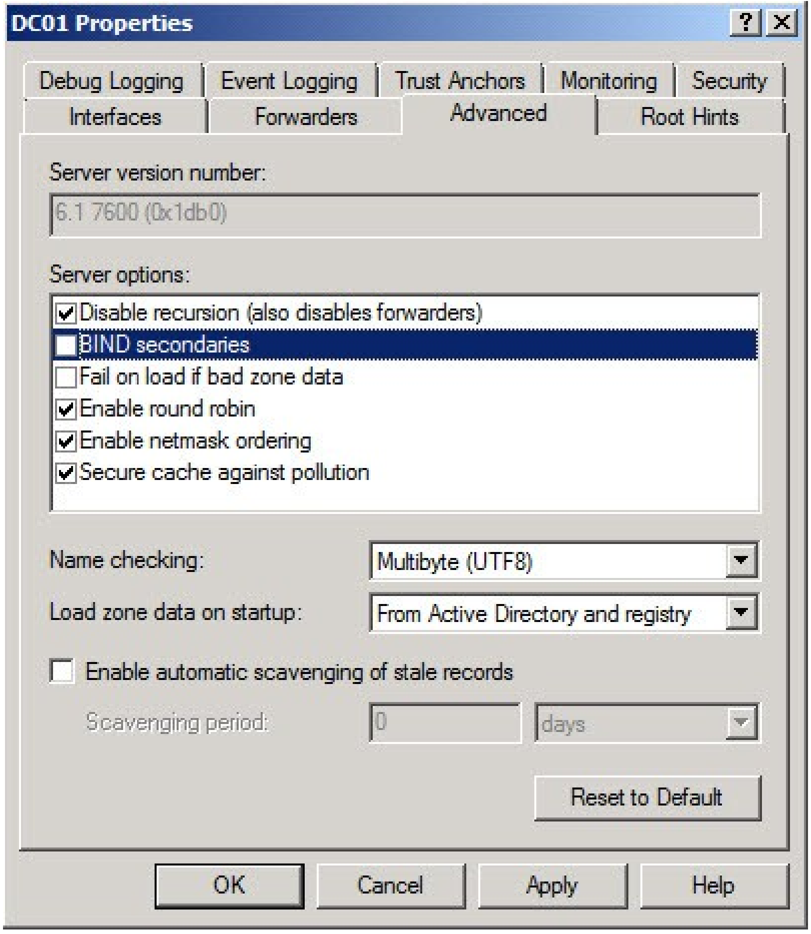
   For example, if you had a pool named pool1.contoso.com and three Front End Servers, you would create the following DNS entries:

FQDN	Type	Data
Pool1.contoso.com	Host (A)	192.168.1.1
Pool1.contoso.com	Host (A)	192.168.1.2
Pool1.contoso.com	Host (A)	192.168.1.3

For details about creating DNS Host (A) records, see Configure DNS Host Records.

⊟To enable round robin for Windows Server

1. Click **Start**, click **All Programs**, click **Administrative Tools**, and then click **DNS**.
2. Expand **DNS**, right-click the DNS server you want to configure, and then click **Properties**.
3. Click the **Advanced** tab, select **Enable round robin** and **Enable netmask ordering**, and then click **OK**.



DC01 Properties

Server version number: 6.1 7600 (0x1db0)

Server options:

☑ Disable recursion (also disables forwarders)
☐ BIND secondaries
☐ Fail on load if bad zone data
☑ Enable round robin
☑ Enable netmask ordering
☑ Secure cache against pollution

Name checking: Multibyte (UTF8)

Load zone data on startup: From Active Directory and registry

☐ Enable automatic scavenging of stale records

Scavenging period: 0 days

Note:
This feature should be enabled by default.

Concepts

DNS Load Balancing

1.4.1.3.5.2 Configure DNS Host Records

Configure DNS Host Records

Deploying Lync Server 2013 > Preparing the Infrastructure and Systems > Configure DNS Records for a Front End Pool or Standard Edition Server >

Topic Last Modified: *2012-10-01*

To successfully complete this procedure, you should be logged on to the server or domain at minimum as a member of the Domain Admins group or a member of the DnsAdmins group.

⊟To configure DNS Host A records

1. On the Domain Name System (DNS) server, click **Start**, click **Administrative Tools**, and then click **DNS**.
2. In the console tree for your domain, expand **Forward Lookup Zones**, and then right-click the domain in which Lync Server 2013 will be installed.
3. Click **New Host (A or AAAA)**.
4. Click **Name**, type the host name for the pool (the domain name is assumed from the zone that the record is defined in and does not need to be entered as part of the A record).
5. Click **IP Address**, type the virtual IP (VIP) of the load balancer for the Front End pool.

   Important:
   In deployments that use a Director pool, the host (A) records for the simple URLs should point to the VIP of the Director load balancer.

   Note:
   If you deploy only one Enterprise Edition server or Director that is connected to the topology without a load balancer, or if you deploy a Standard Edition server, type the IP address of the Enterprise Edition server, Standard Edition server, or Director. A load balancer is required if you deploy more than one Enterprise Edition server or Director in a pool. Load balancers are not used with Standard Edition servers.
6. Click **Add Host**, and then click **OK**.
7. To create an additional A record, repeat steps 4 and 5.
8. When you are finished creating all the A records that you need, click **Done**.

1.4.1.3.5.3 Create and Verify DNS SRV Records

Create and Verify DNS SRV Records

Deploying Lync Server 2013 > Preparing the Infrastructure and Systems > Configure DNS Records for a Front End Pool or Standard Edition Server >

Topic Last Modified: *2013-02-21*

To successfully complete this procedure, you should be logged on to the server or domain minimally as a member of the Domain Admins group or a member of the DnsAdmins group.

This topic describes how to configure the Domain Name System (DNS) records that you are required to create in Lync Server 2013 deployments and those required for automatic client sign in. When you create a Front End pool, Setup creates Active Directory objects and settings for the pool, including the pool fully qualified domain name (FQDN). Similar objects and settings are created for a Standard Edition server. For clients to be able to connect to the pool or Standard Edition server, the FQDN of the pool or Standard Edition server must be registered in DNS. You must create DNS SRV records in your internal DNS for every SIP domain. This procedure assumes that your internal DNS has zones for your SIP user domains.

⊟To configure a DNS SRV record

1. On the DNS server, click **Start**, click **Administrative Tools**, and then click **DNS**.
2. In the console tree for your SIP domain, expand **Forward Lookup Zones**, and then right-click the SIP domain in which Lync Server 2013 will be installed.
3. Click **Other New Records**.
4. In **Select a resource record type**, click **Service Location (SRV)**, and then click **Create Record**.
5. Click **Service**, and then type **_sipinternaltls**.
6. Click **Protocol**, and then type **_tcp**.
7. Click **Port Number**, and then type **5061**.
8. Click **Host offering this service**, and then type the FQDN of the pool or Standard Edition server.
9. Click **OK**, and then click **Done**.

⊟To verify the creation of a DNS SRV record

1. Log on to a client computer in the domain with an account that is a member of the Authenticated Users group or has equivalent permissions.
2. Click **Start**, and then click **Run**.
3. In the **Open** box, type **cmd**, and then click **OK**.
4. At the command prompt, type **nslookup**, and then press ENTER.
5. Type **set type=srv**, and then press ENTER.
6. Type **_sipinternaltls._tcp.contoso.com**, and then press ENTER. The output displayed for the Transport Layer Security (TLS) record is as follows:

   Server: *<dns server>*.contoso.com

   Address: *<IP address of DNS server>*

   Non-authoritative answer:

   _sipinternaltls._tcp.contoso.com SRV service location:

   priority = 0

   weight = 0

   port = 5061

   svr hostname = poolname.contoso.com (or Standard Edition server A record)

   poolname.contoso.com internet address = *<virtual IP Address of the load balancer>* or *<IP address of a single Enterprise Edition server for pools with only one Enterprise Edition server>* or *<IP address of the Standard Edition server>*
7. When you are finished, at the command prompt, type **exit**, and then press ENTER.

⊟To verify that the FQDN of the Front End pool or Standard Edition server can be resolved

1. Log on to a client computer in the domain.
2. Click **Start**, and then click **Run**.
3. In the **Open** box, type **cmd**, and then click **OK**.
4. At the command prompt, type **nslookup** *<FQDN of the Front End pool>* or *<FQDN of the Standard Edition server>*, and then press ENTER.
5. Verify that you receive a reply that resolves to the appropriate IP address for the FQDN.

1.4.1.3.6 Install Lync Server Administrative Tools

Install Lync Server Administrative Tools

See Also

Topic Last Modified: *2013-02-21*

This topic describes how to install the administrative tools you need to use to deploy and manage Lync Server 2013. The administrative tools are installed by default on each server running Lync Server 2013. Additionally, you can install the administrative tools on other computers, such as dedicated administrative consoles. We strongly recommend that you install the administrative tools on a computer that is in the same domain or forest as the Lync Server 2013 deployment you are creating because by doing so you make sure that Active Directory Domain Services (AD DS) preparation steps are already complete, which enables you to use the administrative tools on that computer later to publish your topology.

Make sure that you review infrastructure, operating system, software, and administrator rights requirements before you install or use the Lync Server 2013 administrative tools. For details about infrastructure requirements, see Administrative Tools Infrastructure Requirements. For details about operating system and software requirements to install the Lync Server 2013 administrative tools, see Server and Tools Operating System Support, Additional Software Requirements, and Additional Server Support and Requirements. For details about the user rights and permissions required to install and use the tools, see Administrator Rights and Permissions Required for Setup and Administration.

Important:
If your organization requires that you locate Internet Information Services (IIS) and all Web Services on a drive other than the system drive, you can change the installation location path for the Lync Server files in the Setup dialog box. If you install the Setup files to this path, including OCSCore.msi, the rest of the Lync Server 2013 files will be deployed to this drive as well.

To install the Lync Server 2013 administrative tools

1. Log on as a local administrator (minimum requirement) to the computer where you want to install the administrative tools. If you are logged on as an a standard user on the Windows Vista or Windows 7 operating systems, and User Account Control (UAC) is enabled, you will be prompted for the local administrator or a domain equivalent user name and password.
2. Locate the installation media on your computer, and then double-click \Setup \amd64\Setup.exe.
3. If you are prompted to install the Microsoft Visual C++ 2008 distributable, click **Yes**.
4. On the **Microsoft Lync Server 2013 Installation Location** page, click **OK**. Change this path to another location or drive if you need to have the files installed to another location.

Important:
If your organization requires that you locate Internet Information Services (IIS) and all Web Services on a drive other than the system drive, you can change the installation location path for the Lync Server 2013 files in the Setup dialog box. If you install the Setup files to this path, including OCSCore.msi, the rest of the Lync Server 2013 files will be deployed to this drive too.

5. On the **End User License Agreement** page, review the license terms, click **I accept**, and then click **OK**. This step is required before you can continue.
6. On the **Microsoft Lync Server 2013 – Deployment Wizard** page, click **Install Administrator Tools**.
7. When the installation successfully completes, click **Exit**.

1.4.1.4 Designing the Topology by Using the Planning Tool

Designing the Topology by Using the Planning Tool

See Also

Microsoft Lync Server 2013 > Deployment > Deploying Lync Server 2013 >

Topic Last Modified: *2013-03-04*

The Microsoft Lync Server 2013, Planning Tool is a wizard driven, interview-like tool that asks questions about the Lync Server 2013 topology that you are designing. The Planning Tool uses the information supplied, coupled with preferred practices for topology design and capacity, to present a recommended topology based on the answers supplied. You can download the Planning Tool from the Microsoft Downloads Center (http://go.microsoft.com/fwlink/?LinkID=282725).

Ultimately, the goal of the Planning Tool is to ease the potential complexity of designing a complete Lync Server 2013 topology. The tool also provides contextual references to planning and deployment documentation inside the tool, provided that an Internet connection is available to connect to the Microsoft TechNet website.

After customizing the topology with the infrastructure’s TCP/IP addresses and fully qualified domain names (FQDNs), the Planning Tool makes available a series of reports that cover Domain Name System (DNS) naming, firewall rules, certificates, and more.

The Planning Tool also provides the ability to export information in two formats:

- Microsoft Excel
- Microsoft Visio

The following topics introduce and detail the Planning Tool.

- Installing the Planning Tool
- Installing Optional Software
- Navigating the Planning Tool
- Create the Initial Design
- Reviewing the Administrator Reports

Deployment > Deploying Lync Server 2013 > Designing the Topology by Using the Planning Tool >

Topic Last Modified: *2013-02-21*

Before you begin designing and planning your Lync Server 2013 infrastructure by using the Microsoft Lync Server 2013, Planning Tool, you must first install the Planning Tool. The Planning Tool does not need to be deployed to a workstation or server that is part of the domain or infrastructure where you plan to install Lync Server 2013. The Readme file that accompanies the Planning Tool details important information about installing and using the tool. Some of the information in the Readme file is duplicated here for clarity.

◆**Important:**
The Planning Tool requires installation by a user with administrator rights and permissions on the computer on which the tool is to be installed.

The supported operating systems for installation and operation of the Planning Tool are:

- Windows 8
- Windows Server 2012
- Windows 7, 32-bit edition
- Windows 7, 64-bit edition using Windows on Win32 (WOW)
- Windows Server 2008 R2, using WOW

Additionally, the Planning Tool requires Microsoft .NET Framework 4.5.

After the preinstallation requirements are met, you can then install the Planning Tool.

⊟To install the Planning Tool

1. Log on to the local computer as a member of the Administrators group.
2. Using Windows Explorer or a command window, locate the directory where you downloaded the Planning Tool installation files.
3. Locate the LyncPlanningTool.msi. In Windows Explorer, double-click the file. In the command window, type the name of the file, and then press **Enter** to run the file.
4. On the Welcome page of the **Microsoft Lync Server 2013, Planning Tool Setup Wizard**, click **Next**.
5. Review the **End-User License Agreement**, select **I accept the terms in the License Agreement** if you choose to accept the terms of use in the license agreement, and then click **Next**.
6. Choose where to install the Planning Tool files. The default location is C:\Program Files (x86)\Microsoft Lync Server 2013\Planning Tool. If you want to change the installation location, click **Change**. On **Change destination folder**, browse or type the location to install the files, click **OK**, and then click **Next**.
7. The installer is now ready to install the Planning Tool. Click **Install** to begin the installation process.
8. The installation will start, and the progress will be displayed. After the installation is successfully completed, click **Finish**.
9. The Planning Tool is ready for use.

Deployment > Deploying Lync Server 2013 > Designing the Topology by Using the Planning Tool >

Topic Last Modified: *2013-02-21*

The Microsoft Lync Server 2013, Planning Tool is designed to export to Microsoft Excel and Microsoft Visio. While these applications are not required for the operation of the Planning Tool, they do add significant value to the deployment and documentation of your design.

Optional Software

Microsoft Excel

Exporting your design to Microsoft Excel creates a report that displays seven tabs in the spreadsheet:

- Summary – Displays information on site configuration, including user count, capacity settings, and server profile information.
- Hardware Profile – Displays a report on the recommended hardware configurations for servers that are specified in the topology, including CPU, memory, disk, and network interface. The quantity and recommended specifications for the server components are also included. In addition, each server is defined by site to provide a complete representation of server requirements by site.
- Ports Requirements – Displays a report of all ports that are enabled, and the association to Domain Name System load balancing (DNS LB) and hardware load balancers (HLB). You should use this report to plan your firewall and DNS LB and HLB configurations.
- Summary Report – Displays the general summary of the settings that are required to set up your Edge Server network.
- Certificates Report – Displays the subject name and subject alternate names that are required for the certificates needed to get the Edge Servers running.
- Firewall Report – Displays the source and destination ports and IP addresses for both External and Internal interfaces.
- DNS Report – Displays the fully qualified domain name (FQDN) and IP/VIP addresses required for each DNS entry that you create.

Microsoft Visio

Exporting your design to Microsoft Visio creates a diagram for use in your documentation purposes of your configured topology and infrastructure. The imported diagram can be edited and rearranged to meet your documentation needs. The typical Visio diagram will include:

Note:

If your design is large enough to require more than three Front End Servers, an additional page will be created for the Front End pool, Front End Servers, the computer running SQL Server, IP addresses, and FQDNs.

- Global Topology – Diagram of configured Lync Server 2013 sites.
- Site Name tab – Displays the site configuration topology with Edge Server, firewall, public switched telephone network (PSTN) with gateways, and the internal server deployment. Internal deployment consists of configured servers and pools, including the Front End pools, SQL Server-based servers, Active Directory Domain Services (AD DS), Directors, Exchange Unified Messaging (UM) servers, Exchange Mailbox Servers, Office Web Apps Servers, Mediation Servers, and Persistent Chat Servers.
- Edge Network Diagram – Diagram detailing the Edge Server configuration with associated IP addresses and FQDNs. DNS load balancing and hardware load balancers are also included. Additionally, Directors and the Front End Server or Front End pool are displayed, with associated DNS LB or HLB and the assigned IP address (the Planning Tool supports both IPv4 and IPv6 addresses) and FQDN.

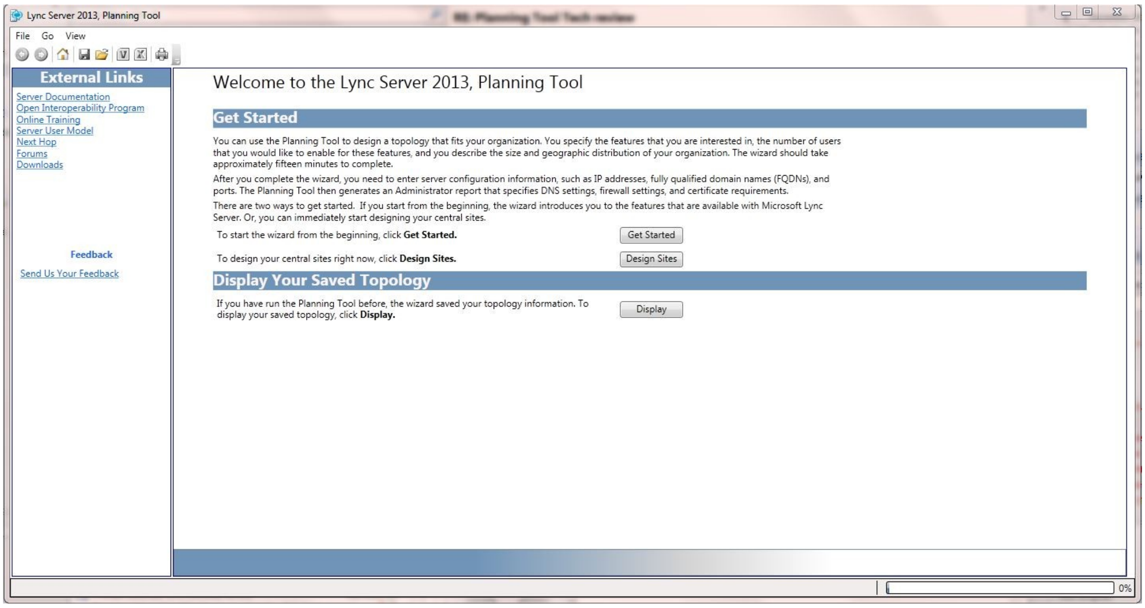
Deployment > Deploying Lync Server 2013 > Designing the Topology by Using the Planning Tool >

Topic Last Modified: *2013-02-21*

You navigate the Microsoft Lync Server 2013, Planning Tool by using a combination of a toolbar, page-specific buttons and links, and context-specific panes. The context-specific panes provide design information for planning and capacity that is relevant to the selection options on a specific page.

On starting the Planning Tool, a designer first sees the **Welcome to the Planning Tool for Microsoft Lync Server 2013** page.



Welcome to the Lync Server 2013, Planning Tool

Get Started

You can use the Planning Tool to design a topology that fits your organization. You specify the features that you are interested in, the number of users that you would like to enable for these features, and you describe the size and geographic distribution of your organization. The wizard should take approximately fifteen minutes to complete.

After you complete the wizard, you need to enter server configuration information, such as IP addresses, fully qualified domain names (FQDNs), and ports. The Planning Tool then generates an Administrator report that specifies DNS settings, firewall settings, and certificate requirements.

There are two ways to get started. If you start from the beginning, the wizard introduces you to the features that are available with Microsoft Lync Server. Or, you can immediately start designing your central sites.

To start the wizard from the beginning, click **Get Started.**

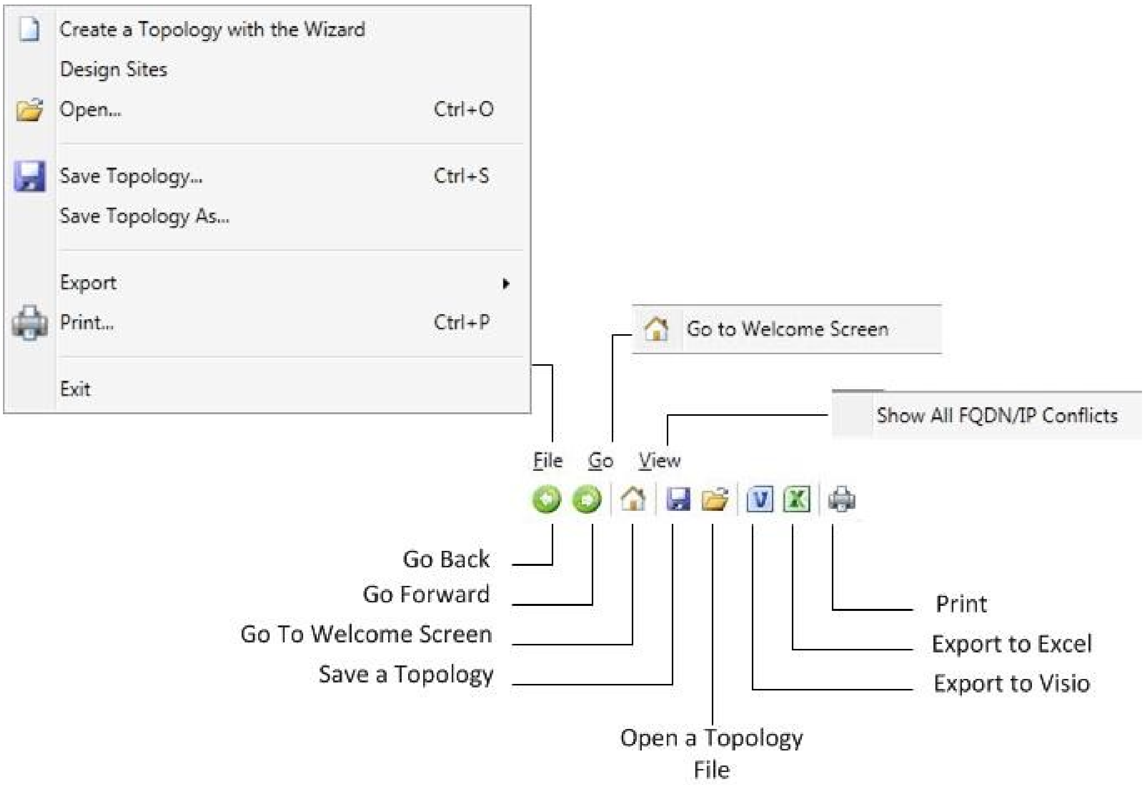
To design your central sites right now, click **Design Sites.**

Display Your Saved Topology

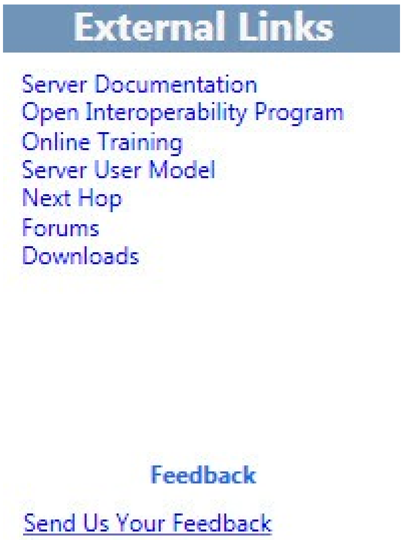
If you have run the Planning Tool before, the wizard saved your topology information. To display your saved topology, click **Display.**

On the Welcome page, the designer chooses **Get Started**, **Design Sites**, or **Display**. For details, see Create the Initial Design.

At the top of the Planning Tool is a toolbar that provides easy access to frequently used functions. The toolbar is displayed here for reference, and each function will be discussed in related topics.



The Planning Tool has an External Links section on the left side of the tool. From here, the designer has easy access to planning and deployment information, and other technical resources such as training, technical blogs, forums, and other downloadable resources. Also in the External Links section is a Feedback link to the Lync Server 2013 Planning Tool team.



A context-sensitive Actions pane is displayed on many pages in the Planning Tool. The Actions pane gives the designer easy access to main sections of the topology. The links available in the Actions pane change based on the detail level in your topology. The Actions pane is available after you have completed the interview questions and displayed your topology. Included in the Actions pane is the Overview section, which displays numbers that the designer has entered as part of the interview process. The overview is contextually related to the displayed information.

Additionally, hardware information is displayed in the overview under the Actions pane. The hardware configuration displays a list of hardware requirements that the current topology recommends.

Deployment > Deploying Lync Server 2013 > Designing the Topology by Using the Planning Tool >

Topic Last Modified: *2013-02-21*

After you have finished installing the Lync Server 2013, Planning Tool, you are ready to start the Planning Tool and begin designing the proposed Lync Server 2013 infrastructure.

Note:
The Planning Tool is a wizard-driven tool with detailed guides to inform your decision-making process in designing your sites and topology. This topic is intended not as an exhaustive guide, but simply to help get you started using the Planning Tool in your design sessions.

To get started using the Planning Tool and create the initial design

1. Start the Lync Server 2013, Planning Tool: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Planning Tool**.
2. After the Planning Tool has started, the **Welcome to the Planning Tool for Microsoft Lync Server 2013** page appears. Choose one of the following options to begin your design:
   - **Option 1: Get Started** Clicking **Get Started** provides a specific series of interview questions with relevant selections to define the criteria. After you have finished the initial **Get Started** interview section, you proceed into **Design Sites** to define your site architecture. To complete this option,

proceed to step 3.

- **Option 2: Design Sites** Clicking **Design Sites** at the Welcome page bypasses the interview questions presented in the **Get Started** section. The information that would have been gathered by responding to the interview questions in **Get Started** section is set to default values with this option. By clicking **Design Sites**, the experienced designer can bypass the initial interview and change the default values, as needed, on the **Central Sites** start page. To complete this option, skip over steps 3-5 and start at step 6.
- **Option 3: Display Your Saved Topology** If you have already completed and saved a topology through previous use of the Planning Tool, you can skip over most of these steps and start by opening and displaying the topology. You can also make changes and updates to the topology, resave it, and then export it to Microsoft Excel or Microsoft Visio. To complete this option, skip over steps 3-12 and start at step 13.

3. Click **Get Started** to begin designing your Lync Server 2013 topology.
4. Answer each section by selecting the appropriate criteria for your design, and then click **Next** to proceed to the next Wizard page. Click **Back** to make changes on previous pages.

Tip:

Each page has a description of the selection criteria, and recommendations based on preferred practices and capacity planning. If you require additional details, click **Learn more** to read detailed information from the Lync Server 2013 Planning documentation on the Microsoft TechNet website. You must have Internet connectivity to access the Microsoft TechNet website.

5. Select the appropriate options for your design. After the initial criteria are defined, a page will confirm that your Features Overview is complete.
6. Click **Design Sites** to define your central site.

Note:

Each Lync Server 2013 topology will have at least one central site. Your design may have a single central site, a central site with a number of branch sites, a number of central sites, or a number of central sites with branch sites associated with each central site.

7. In **Site Name**, type the name that will identify this central site.
8. In **Site Homed Users**, type the expected number of on-premises concurrent users who will be homed in this central site.
9. In **Cloud Homed Users**, type the expected number of online concurrent users who will be homed in this central site.
10. Modify the selections for Online Collaboration, Users, Voice, Additional Deployment Options, or Server Applications, as needed.

Important:

At this point in the design, you can only select or clear options for your deployment. However, you can configure more options in a later phase of the Planning Tool. There are also options that are unavailable and cannot be cleared. In addition, you may have to clear one option in order to clear another. For example, if you clear the **Enterprise Voice** option under Voice, then the **Response Group**, **Announcement**, and **Call Park** options under Server Applications (all of which are features of Enterprise Voice) are also cleared.

11. After defining a site name and number of users, click **Next**.
12. The following pages ask for information about SIP domains, conference settings, voice settings and infrastructure, Exchange UM, external user access, Persistent Chat settings, client settings, collocation options, and branch sites. Answer these questions as appropriate.
13. The final question asks if you want to create another central site. If you select **Yes**, then the Planning Tool returns to the Central Sites page. If you select **No**, click **Next**, and then click **Draw** to display the high-level Global

Topology view.
14.To view an existing topology, click **Display**.
15.Click the .xml file that represents the previously saved topology, and then click **Open**.
16.The Planning Tool displays the Global Topology page. You can now begin editing, updating, or changing the topology by using the tools available in the Planning Tool.

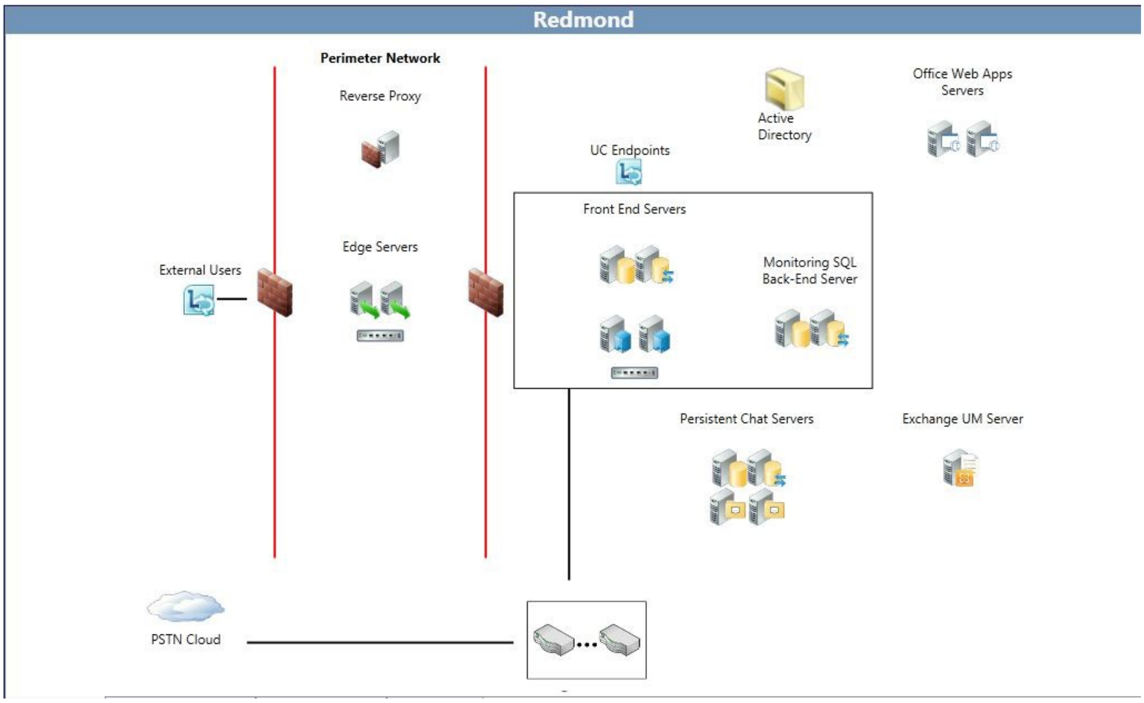
Deployment > Deploying Lync Server 2013 > Designing the Topology by Using the Planning Tool >

Topic Last Modified: *2013-02-21*

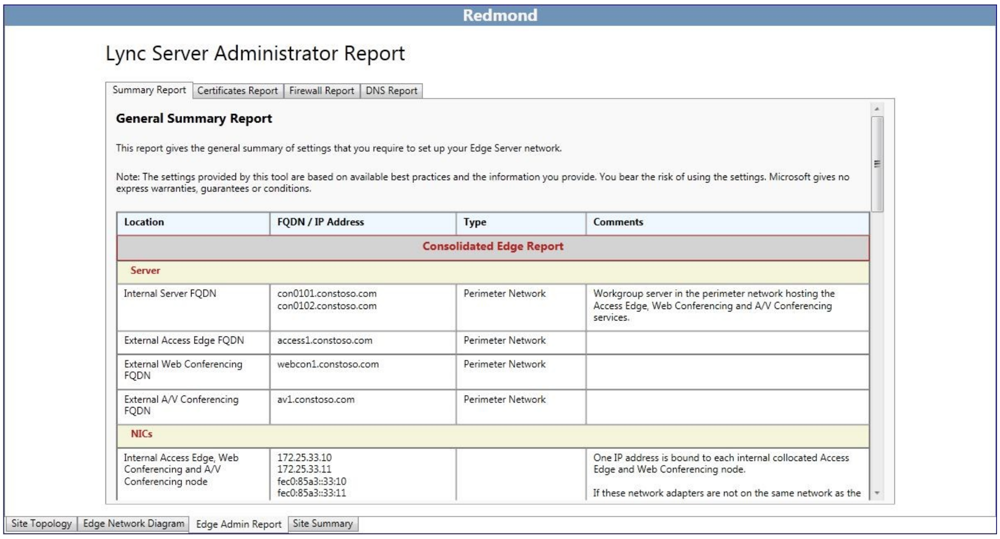
After completing the initial interview questions, you can edit the fully qualified domain name (FQDN) and IP addresses for the site. To do this, on the **Global Topology** page, double-click the site that you want to edit.

The Planning Tool displays the site topology for the selected site. At the bottom of the site page are four tabs:



- Site Topology – The currently displayed page with a visual overview of the topology as recommended.
- Edge Network Diagram – The Edge Network Diagram page is where the designer does most of the work in the Planning Tool. The diagram displays the network configuration for a recommended Lync Server 2013 topology, with editable entries for IP addresses and FQDNs for servers, pool, and both hardware and Domain Name System (DNS) load balancers.

- Edge Admin Report – The Edge Admin Report contains a total of four reports:



Lync Server Administrator Report

General Summary Report

This report gives the general summary of settings that you require to set up your Edge Server network.

Note: The settings provided by this tool are based on available best practices and the information you provide. You bear the risk of using the settings. Microsoft gives no express warranties, guarantees or conditions.

Location	FQDN / IP Address	Type	Comments
Consolidated Edge Report			
Server			
Internal Server FQDN	con0101.constoso.com con0102.constoso.com	Perimeter Network	Workgroup server in the perimeter network hosting the Access Edge, Web Conferencing and A/V Conferencing services.
External Access Edge FQDN	access1.constoso.com	Perimeter Network	
External Web Conferencing FQDN	webcon1.constoso.com	Perimeter Network	
External A/V Conferencing FQDN	av1.constoso.com	Perimeter Network	
NICs			
Internal Access Edge, Web Conferencing and A/V Conferencing node	172.25.33.10 172.25.33.11 fec0:85a3::33:10 fec0:85a3::33:11		One IP address is bound to each internal collocated Access Edge and Web Conferencing node. If these network adapters are not on the same network as the

  - Summary Report – A general report of settings for the Edge network configuration. If you edit the values on the **Edge Network Diagram** page to the topology TCP/IP and FQDN values of that will be used in the actual deployment, those addresses and names will be represented here. Otherwise, the default text will appear.
  - Certificate Report – The certificate report will list the subject name and subject alternative names for the certificates that are required for the topology.
  - Firewall Report – The firewall report lists information necessary to configure perimeter firewalls in the infrastructure. This includes the IP addresses (either the default or edited values), server role, source IP and port, destination IP and port, transport protocol, application protocol, and relevant notes.
  - DNS Report – The DNS Report lists relevant information for the DNS entries that you must create. The record type, FQDN, IP address, and comments necessary for the proper operation are included.
- Site Summary – The site summary presents an overview of the selections that you made by either answering the initial interview questions or filling in the values in **Design Sites**. Capacity information is also presented.

Note:

The information on the Site Summary page is customized for each design and may not contain all sections or information detailed here.

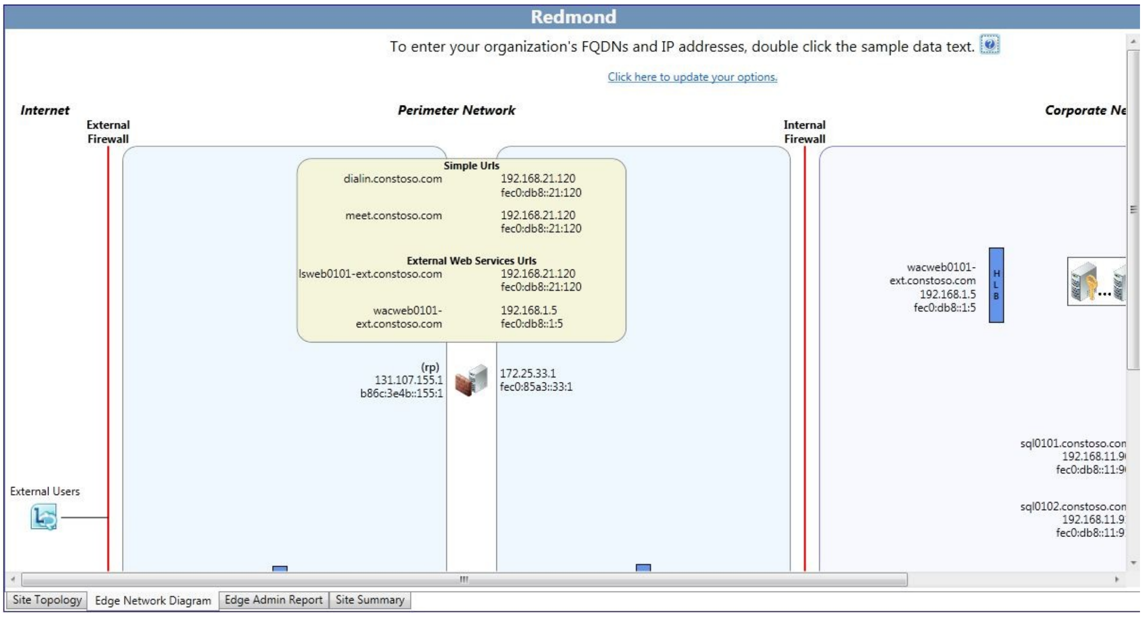
Deploying Lync Server 2013 > Designing the Topology by Using the Planning Tool > Editing the Design >

Topic Last Modified: *2013-02-21*

Most of the work that a designer does in the Lync Server 2013, Planning Tool consists of defining the entries for the IP addresses and fully qualified domain names (FQDNs) for the entries on the network diagram. The information that is entered on this page carries over into the reports and other information contained in the Planning Tool.



To enter your organization's FQDNs and IP addresses, double click the sample data text.

The Planning Tool creates a network diagram with default text for IP addresses and FQDNs.

To edit the network diagram and input values:

1. Choose a section of the network to begin working on. For example, double-click the text, **access1.contoso.com**. In the dialog box that opens, type the actual FQDN of the server access1.contoso.com and the actual IP address, replacing the 131.107.155.3.
2. Click **OK** to save the entries.
3. Continue to edit IP addresses and FQDNs, providing virtual IP addresses for hardware load balancers or server entries for Domain Name System (DNS) load balancing for servers in pools.

A helpful feature of the Planning Tool is that it can incrementally assign a range of IP addresses and server host names, rather than requiring the designer to edit each separate server in a pool. For example:

1. Double-click the pooled Front End Servers. When the dialog box opens, select **Do you want to use the IPs and FQDN as starting points for all equivalent servers in this cluster?**.
2. For example, the starting value for the first server is fe0101.contoso.com and an IP address of 192.168.21.122.
3. Type **fe0.contoso.com** in **Front End Server FQDN**, type **192.168.21.131** in **Front End Server IP address**, and then click **OK**.
4. The auto-increment feature updates all servers in the pool to fe01 through fe06, and all IP address from 192.168.21.131 to 136.

After you have completed all edits, save the topology by completing the following steps:

To save the Planning Tool design, click **File**, and then click **Save Topology** or **Save Topology As**. If a **Save Planning Tool As** dialog box appears, type a name for the file in

File name, and then click **Save**.

Concepts

Editing the Design

1.4.1.4.6 Reviewing the Administrator Reports

Reviewing the Administrator Reports

Deployment > Deploying Lync Server 2013 > Designing the Topology by Using the Planning Tool >

Topic Last Modified: *2013-02-21*

The Administrator Reports are detailed information for deployment and operations. The reports are generated based on the selections marked in **Design Sites**. The designer can further add value to the Administrator Reports by editing the network diagrams and defining the complete IP addresses and fully qualified domain names (FQDNs) for servers, pools, and load balancers.

- Reviewing the Summary Report
- Reviewing the Certificates Report
- Reviewing the Firewall Report
- Reviewing the DNS Report

1.4.1.4.6.1 Reviewing the Summary Report

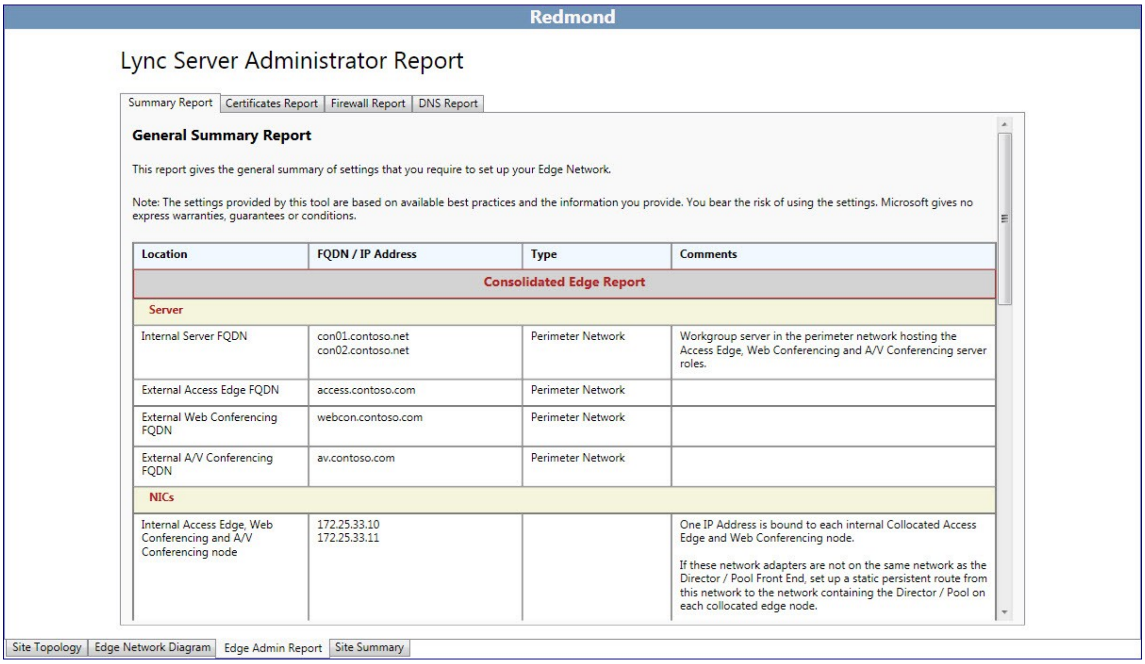
Reviewing the Summary Report

See Also

Deploying Lync Server 2013 > Designing the Topology by Using the Planning Tool > Reviewing the Administrator Reports >

Topic Last Modified: *2013-02-21*

The Lync Server Administrator Report is the first of four valuable reports that document your design in detail. The information in this report, and the other three associated reports, is excellent documentation for your Information Technology Teams:



Lync Server Administrator Report

General Summary Report

This report gives the general summary of settings that you require to set up your Edge Network.

Note: The settings provided by this tool are based on available best practices and the information you provide. You bear the risk of using the settings. Microsoft gives no express warranties, guarantees or conditions.

Location	FQDN / IP Address	Type	Comments
Consolidated Edge Report			
Server			
Internal Server FQDN	con01.contoso.net con02.contoso.net	Perimeter Network	Workgroup server in the perimeter network hosting the Access Edge, Web Conferencing and A/V Conferencing server roles.
External Access Edge FQDN	access.contoso.com	Perimeter Network	
External Web Conferencing FQDN	webcon.contoso.com	Perimeter Network	
External A/V Conferencing FQDN	av.contoso.com	Perimeter Network	
NICs			
Internal Access Edge, Web Conferencing and A/V Conferencing node	172.25.33.10 172.25.33.11		One IP Address is bound to each internal Collocated Access Edge and Web Conferencing node. If these network adapters are not on the same network as the Director / Pool Front End, set up a static persistent route from this network to the network containing the Director / Pool on each collocated edge node.

- Certificates Report
- Firewall Report
- DNS Report

The Summary Report lists general configuration information associated with your Edge network. The location, fully qualified domain name (FQDN) and IP address, type of network, and comments specific to a given role are documented.

The designer and each of the teams that will deploy, manage, and maintain the infrastructure should review the summary report for accuracy and to make sure that errors are at a minimum.

Reviewing the Administrator Reports

1.4.1.4.6.2 Reviewing the Certificates Report

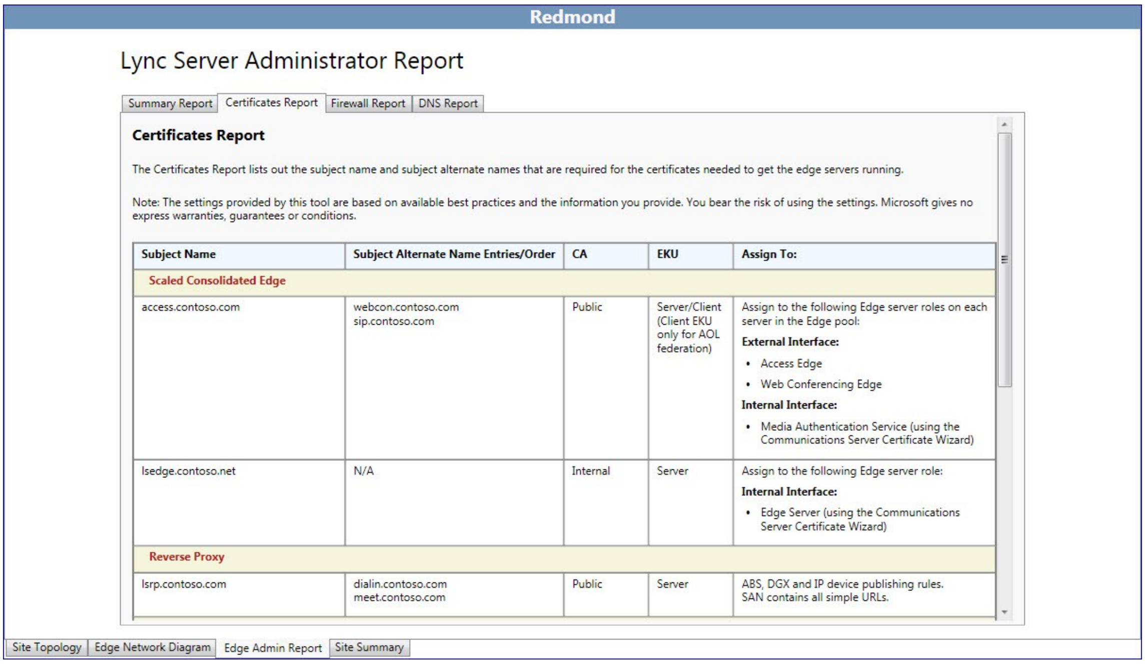
Reviewing the Certificates Report

See Also

Deploying Lync Server 2013 > Designing the Topology by Using the Planning Tool > Reviewing the Administrator Reports >

Topic Last Modified: *2013-02-21*

The Certificates Report contains all certificates that are required in the recommended Lync Server 2013 deployment. The Planning Tool accounts for the subject names and subject alternative names that are entered. Default text that is left unedited may represent a potential challenge for the team responsible for requesting and issuing the certificates. Certificate information also contains information about where the certificate can typically be issued from. If the infrastructure does not have an internal public key infrastructure (PKI) in place, all certificates can be requested through a public certificate provider. Extended key usages (EKU) and Assign To fields in the report are very helpful in understanding what the purpose and location for each certificate should be.



Redmond

Lync Server Administrator Report

Certificates Report

The Certificates Report lists out the subject name and subject alternate names that are required for the certificates needed to get the edge servers running.

Note: The settings provided by this tool are based on available best practices and the information you provide. You bear the risk of using the settings. Microsoft gives no express warranties, guarantees or conditions.

Subject Name	Subject Alternate Name Entries/Order	CA	EKU	Assign To:
Scaled Consolidated Edge				
access.contoso.com	webcon.contoso.com sip.contoso.com	Public	Server/Client (Client EKU only for AOL federation)	Assign to the following Edge server roles on each server in the Edge pool: **External Interface:** • Access Edge • Web Conferencing Edge **Internal Interface:** • Media Authentication Service (using the Communications Server Certificate Wizard)
lsedge.contoso.net	N/A	Internal	Server	Assign to the following Edge server role: **Internal Interface:** • Edge Server (using the Communications Server Certificate Wizard)
Reverse Proxy				
lsrp.contoso.com	dialin.contoso.com meet.contoso.com	Public	Server	ABS, DGX and IP device publishing rules. SAN contains all simple URLs.

Carefully review, and be sure to understand, the use and purpose of each certificate in the deployment. If there is a question about what a certificate does, determine which server or service is talking to what. Certificates in Lync Server 2013 are used for two primary purposes:

- Mutual Transport Layer Security (MTLS) – The computers involved in the communication each present a certificate that proves their identity to another computer. This is known as server authentication. Communication cannot begin until each computer trusts the other computer's identity.
- Encryption – Encryption (Secure Sockets Layer, or SSL, and Transport Layer Security, or TLS) is a critical means to help secure communications, help ensure privacy, and to create a trusted communications and collaboration system.

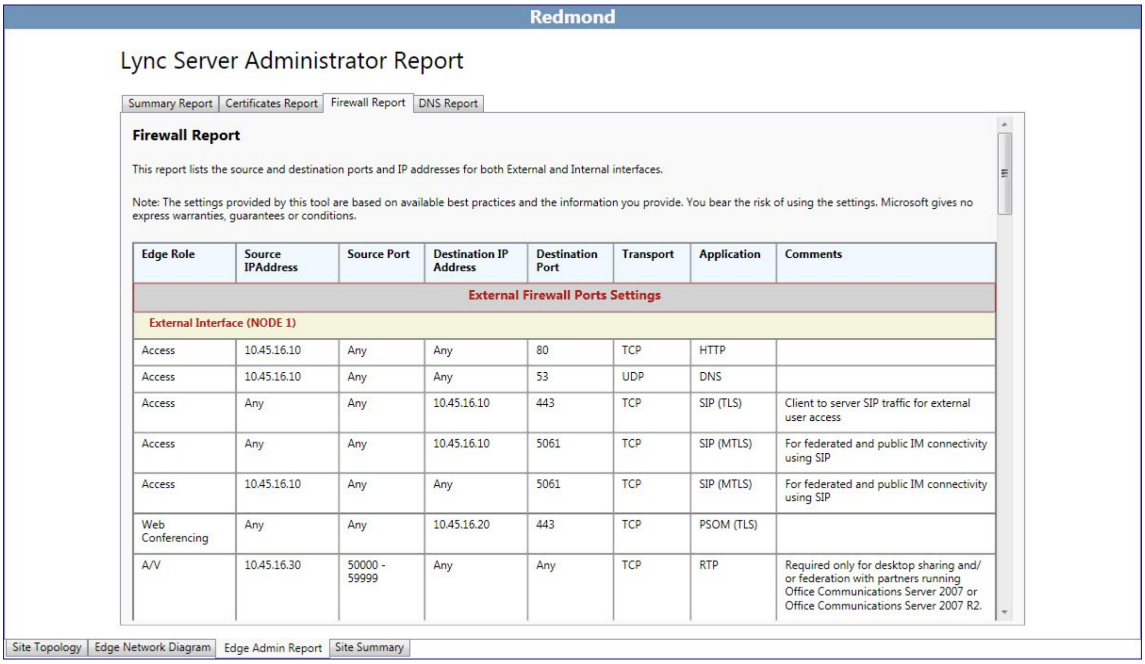
Deploying Lync Server 2013 > Designing the Topology by Using the Planning Tool > Reviewing the Administrator Reports >

Topic Last Modified: *2013-02-21*

Lync Server 2013 has a potentially complex set of firewall rules. The Planning Tool reduces this complexity by generating a report that defines in detail all firewall requirements, based on the designer's input criteria. The IT firewall administrator will be able to use this report to configure and define the necessary rules.

From the standpoint of firewall management, the report should be carefully reviewed to make sure that there are no conflicts with exiting firewall rules and that there are no policies or procedures that might be violated.



Firewall Report

This report lists the source and destination ports and IP addresses for both External and Internal interfaces.

Note: The settings provided by this tool are based on available best practices and the information you provide. You bear the risk of using the settings. Microsoft gives no express warranties, guarantees or conditions.

Edge Role	Source IPAddress	Source Port	Destination IP Address	Destination Port	Transport	Application	Comments
External Firewall Ports Settings							
External Interface (NODE 1)							
Access	10.45.16.10	Any	Any	80	TCP	HTTP	
Access	10.45.16.10	Any	Any	53	UDP	DNS	
Access	Any	Any	10.45.16.10	443	TCP	SIP (TLS)	Client to server SIP traffic for external user access
Access	Any	Any	10.45.16.10	5061	TCP	SIP (MTLS)	For federated and public IM connectivity using SIP
Access	10.45.16.10	Any	Any	5061	TCP	SIP (MTLS)	For federated and public IM connectivity using SIP
Web Conferencing	Any	Any	10.45.16.20	443	TCP	PSOM (TLS)	
A/V	10.45.16.30	50000 - 59999	Any	Any	TCP	RTP	Required only for desktop sharing and/ or federation with partners running Office Communications Server 2007 or Office Communications Server 2007 R2.

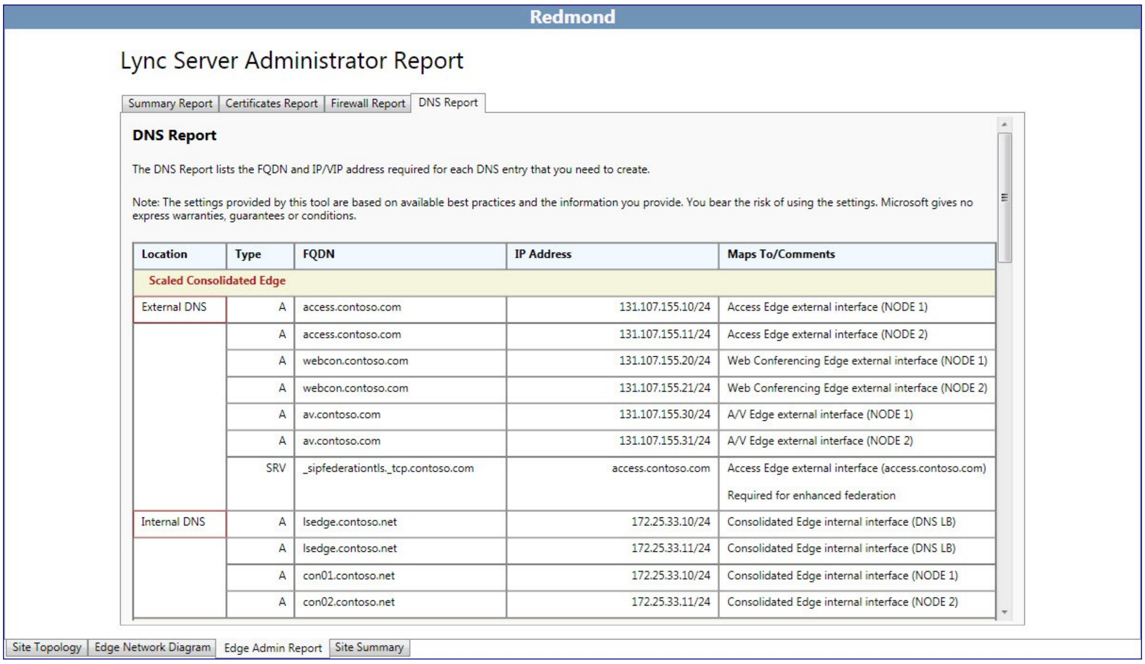
Topic Last Modified: *2013-02-21*

The DNS Report, which is part of the Administrator Report, details all of the recommended and known entries for the Domain Name System (DNS) in the internal, perimeter, and external networks. If the designer has completed the edits to the network diagram, and all IP addresses and fully qualified domain names (FQDNs) are defined to their production values, the DNS Report provides an excellent configuration resource. This report can also serve as an operational troubleshooting document.



Lync Server Administrator Report

DNS Report

The DNS Report lists the FQDN and IP/VIP address required for each DNS entry that you need to create.

Note: The settings provided by this tool are based on available best practices and the information you provide. You bear the risk of using the settings. Microsoft gives no express warranties, guarantees or conditions.

Location	Type	FQDN	IP Address	Maps To/Comments
Scaled Consolidated Edge				
External DNS	A	access.contoso.com	131.107.155.10/24	Access Edge external interface (NODE 1)
	A	access.contoso.com	131.107.155.11/24	Access Edge external interface (NODE 2)
	A	webcon.contoso.com	131.107.155.20/24	Web Conferencing Edge external interface (NODE 1)
	A	webcon.contoso.com	131.107.155.21/24	Web Conferencing Edge external interface (NODE 2)
	A	av.contoso.com	131.107.155.30/24	A/V Edge external interface (NODE 1)
	A	av.contoso.com	131.107.155.31/24	A/V Edge external interface (NODE 2)
	SRV	_sipfederationtls._tcp.contoso.com	access.contoso.com	Access Edge external interface (access.contoso.com) Required for enhanced federation
Internal DNS	A	lsedge.contoso.net	172.25.33.10/24	Consolidated Edge internal interface (DNS LB)
	A	lsedge.contoso.net	172.25.33.11/24	Consolidated Edge internal interface (DNS LB)
	A	con01.contoso.net	172.25.33.10/24	Consolidated Edge internal interface (NODE 1)
	A	con02.contoso.net	172.25.33.11/24	Consolidated Edge internal interface (NODE 2)

You should have your DNS management team review the DNS Report thoroughly to make sure that there are no errors that may cause difficulty during deployment or that may complicate a troubleshooting session.

Reviewing the Administrator Reports

1.4.1.5 Defining and Configuring the Topology

Defining and Configuring the Topology

Microsoft Lync Server 2013 > Deployment > Deploying Lync Server 2013 >

Topic Last Modified: *2012-09-14*

You define and configure your topology by using Topology Builder. Topology Builder does not require you to be a member of the local Administrators group or a privileged domain group (such as Domain Admins). You can define your topology as a standard user. When you start Topology Builder on first use and subsequent edit sessions, you are prompted for the location where you want Topology Builder to load the current configuration document. The choices are the following:

- Download topology from existing deployment
- Open topology from a local file
- New topology

If you have already defined a topology and have established the Central Management store, you should choose to download a topology from an existing deployment. Topology Builder will read the database and retrieve the current definition. If you have an existing Central Management store, you should always choose this option.

If you have not established a Central Management store and want to edit a previously saved configuration, you should choose to open the topology from a local file. The file that you will open would be the configuration file that was saved in a previous session. You can use this option to edit the previously saved topology.

⚠**Warning:**
If you already have a published topology, you should not load a local configuration file. You should choose to download the topology from an existing deployment.

Choose to create a new topology, if you want to create a new Topology Builder configuration. A previously saved design is not overwritten unless you choose to save it as the same file that you created in an earlier design session.

In each of these options, you will be prompted for a location to store the Topology Builder configuration file. The location for the file could be a local location, a shared location on an established file share, or removable media.

- Define and Configure a Topology in Topology Builder
- Define and Configure a Front End Pool or Standard Edition Server
- Deploying Paired Front End Pools for Disaster Recovery
- Deploying SQL Mirroring for Back End Server High Availability
- Edit or Configure Simple URLs
- Select the Central Management Server

1.4.1.5.1 Define and Configure a Topology in Topology Builder

Define and Configure a Topology in Topology Builder

Deployment > Deploying Lync Server 2013 > Defining and Configuring the Topology >

Topic Last Modified: *2013-02-21*

Running Topology Builder to define a new topology or to modify an existing topology does not require membership in a local administrator or privileged domain group. Topology Builder guides you through the steps necessary to define your topology for an Enterprise Edition Front End pool or a Standard Edition, based on your configuration requirements.

You must use Topology Builder to complete and publish the topology before you can install Lync Server 2013 on servers. The following procedure includes the steps required to define a new topology.

⊟To define a topology

1. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
2. In Topology Builder, select **New Topology**. You are prompted for a location and file name for saving the topology. Give the topology file a meaningful name and accept the default extension of .tbxml. Click **OK**.
3. Navigate to the location where you want to save the new topology XML file, enter a name for the file, and then click **Save**.
4. On the **Define the primary domain** page, enter the name of the primary SIP domain for your organization, and then click **Next**.
5. On the **Specify additional supported domains** page, enter the names of additional domains, if any, and then click **Next**.
6. On the **Define the first site** page, enter a name and a description for the first site, and then click **Next**.
7. On the **Specify site details** page, enter the location information for the site, and then click **Next**.
8. On the **New topology was successfully defined** page, make sure the **Open the New Front End Wizard when this wizard closes** check box is selected, and then click **Finish**.

After you’ve defined and saved the topology, use the New Front End Wizard to define a

Front End pool or Standard Edition server for your site. For details, see Define and Configure a Front End Pool or Standard Edition Server.

1.4.1.5.2 Define and Configure a Front End Pool or Standard Edition Server

Define and Configure a Front End Pool or Standard Edition Server

Deployment > Deploying Lync Server 2013 > Defining and Configuring the Topology >

Topic Last Modified: *2013-03-08*

This procedure does not require membership in a local administrator or privileged domain group. You should log on to a computer as a standard user.

If you are deploying an Enterprise server, a minimum number of Front End Servers in a pool must be running at all times. The following table summarizes these requirements.

Total number of Front End Servers in the pool	Number of servers that must be running for pool to be functional
1-2	1
3-4	2
5-6	3
7-8	4
9-10	5
11-12	6

Note:

For Lync Server 2013, any time you add or remove a Front End Server from the pool, you must restart services. Removing and adding servers should be done as separate operations. For example, if you are going to add two Front End Servers and remove two Front End Servers, use the following process:

1. Remove the two Front End Servers.
2. Publish and re-activate the topology.
3. Restart the services
4. Add the two Front End Servers.
5. Publish and re-activate the topology.
6. Restart the services.

After you have defined your topology, use the following procedure to define a Front End pool for your site. For details about defining the topology, see Define and Configure a Topology in Topology Builder.

⊟To define a Front End pool

1. In the Define New Front End Pool Wizard, on the **Define the New Front End pool** page, click **Next**.
2. On the **Define the Front End pool FQDN** page, enter a fully qualified domain name (FQDN) for the pool you are creating, click **Enterprise Edition Front End pool**, and then click **Next**.
3. On the **Define the computers in this pool** page, enter a computer FQDN for the first Front End Server in the pool, and then click **Add**. Repeat this step for any additional computers (up to twelve) that you want to add to the pool,

and then click **Next**.

4. On the **Select features** page, select the check boxes for the features that you want on this Front End pool. For example, if you are deploying only instant messaging (IM) and presence features, you would select the **Conferencing** check box to allow multiparty IM but would not select the **Dial-in (PSTN) conferencing**, **Enterprise Voice**, or **Call Admission Control** check boxes, because they represent voice, video, and collaborative conferencing features.
   - **Conferencing** This selection enables a rich set of features including:
     - IM with more than two parties in an IM session.
     - Conferencing, which includes document collaboration, application sharing, and desktop sharing.
     - A/V conferencing, which enables users to have real-time audio/video (A/V) conferences without the need for external services such as the Live Meeting service or a third-party audio bridge.
   - **Dial-in (PSTN) conferencing** Allows users to join the audio portion of a Lync Server 2013 conference by using a public switched telephone network (PSTN) phone without requiring an audio conferencing provider.
   - **Enterprise Voice** Enterprise Voice is the Voice over IP (VoIP) solution in Lync Server 2013 that allows users to make and receive phone calls. You would deploy this feature if you plan to use Lync Server 2013 for voice calls, voice mail, and other functions that use a hardware device or a software client.
   - **Call admission control (CAC)** CAC determines, based on available network bandwidth, whether to allow real-time communications sessions such as voice or video calls to be established. If you have deployed only IM and presence, CAC is not needed because neither of these two features uses CAC.
   - **Archiving** Archiving provides a way for you to archive IM content, conferencing (meeting) content, or both that is sent through Lync Server 2013.
   - **Monitoring** Monitoring Server enables you to collect numerical data that describes the media quality on your network and endpoints, usage information related to VoIP calls, IM messages, A/V conversations, meetings, application sharing, and file transfers, and call error and troubleshooting information for failed calls.

   Note:
   If you would like to enable CAC in your deployment, it is required that you enable CAC in exactly one pool per central site. CAC is recommended if you are deploying voice features or A/V conferencing.

   The following table shows the available features (top) and the functions offered to users (left). The selections in the table are what you should select to enable those features for your organization.

	Conferencing	Dial-In Conferencing	Enterprise Voice	Call Admission Control
Instant messaging and presence	X			
Conferencing	X	X		
A/V conferencing	X	X		X
Enterprise Voice			X	X

5. On the **Select collocated server roles** page, you can to collocate the Mediation Server on the Front End Server or to deploy it as a stand-alone server.

You can collocate the Mediation Server on the Front End pool.

- If you intend to collocate the Mediation Server on the Enterprise Edition Front End pool, ensure the check box is selected. The server role will be deployed on the pool servers.
- If you intend to deploy the Mediation Server as a stand-alone server, clear the appropriate check box. You will deploy Mediation Server in a separate deployment step after you completely deploy the Front End Server.

> **Note:**
>
> We recommend that you collocate the Mediation Server if possible. For details about support for collocated or stand-alone Mediation Servers, see Components and Topologies for Mediation Server in the Planning documentation.

6. The **Associate server roles with this Front End pool** page lets you define and associate server roles with the Front End pool. The following role is available:

   Enable an Edge pool Defines and associates a single Edge Server or a pool of Edge Servers. An Edge Server facilitates communication and collaboration between users inside the organization and people outside the organization, including federated users.

   There are two possible scenarios that you can use to deploy and associate the server roles:

   For scenario one, you are defining a new topology for a new installation. You can approach the installation in one of two ways:

   - Leave the check box clear and proceed with defining the topology. After you have published, configured, and tested the Front End and Back End Server roles, you can run Topology Builder again to add the role servers to the topology. This strategy will enable you to test the Front End pool and the server running SQL Server without additional complications from additional roles. After you have completed your initial testing, you can run Topology Builder again to select the roles you need to deploy.
   - Select roles that you need to install, and then set up the hardware to accommodate the selected roles.

   For scenario two, you have an existing deployment and your infrastructure is ready for new roles or you need to associate existing roles with a new Front End Server:

   - In this case, you will select the roles that you intend to deploy or associate with the new Front End Server. In either case, you will proceed with the definition of the roles, set up any needed hardware, and proceed with the installation.
7. On the **Define the SQL store** page, do one of the following:
   - To use an existing SQL Server store that has already been defined in your topology, select an instance from **SQL store**.
   - To define a new SQL Server instance to store pool information, click **New** and then specify the **SQL Server FQDN**in the **Define New SQL Store** dialog box.
   - To specify the name of a SQL Server instance, select **Named Instance**, and then specify the name of the instance.
   - To use the default instance, click **Default instance**.
   - To use SQL Mirroring, select **Enable SQL mirroring** and select an existing instance or create a new instance.
8. On the **Define the file share** page, do one of the following:
   - To use a file share that has already been defined in your topology, select **Use a previously defined file share**.
   - To define a new file share, select **Define a new file share**, in the **File Server FQDN** box, enter the FQDN of the existing file server where the file share is to reside, and then enter a name for the file share in the **File Share** box.

Important:

The file share for Lync Server 2013 cannot be located on the Front End Server. Note that in this example, the file share has been located on the SQL Server-based Back End Server. This might not be an optimal location for your organization's requirements, and a file server might be a better choice. You can define the file share without the file share having been created. You will need to create the file share in the location you define before you publish the topology.

9. On the **Specify the Web Services URL** page, do one or both of the following:

Important:

The base URL is the Web Services identity for the URL, minus the https://. For example, if the full URL for the Web Services of the pool is https://pool01.contoso.net, the base URL is pool01.contoso.net.

Warning:

If you have more than one Front End pool or Front End Server, the external Web services FQDN must be unique. For example, if you define the external Web services FQDN of a Front End Server as **pool01.contoso.com**, you cannot use **pool01.contoso.com** for another Front End pool or Front End Server.

- If you are configuring DNS load balancing, select the **Override internal Web Services pool FQDN** check box, enter the internal base URL (which must be different from the pool FQDN and could be, for example, internal-<your base URL>) in **Internal Base URL**.

  Warning:

  If you decide to override the Internal web services with a self-defined FQDN, each FQDN must be unique from any other Front End pool, Director or a Director pool. **Use only standard characters** (including A–Z, a–z, 0–9, and hyphens) when defining URLs or fully qualified domain names. Do not use Unicode characters or underscores. Nonstandard characters in a URL or FQDN are often not supported by external DNS and public CAs (that is, when the URL or FQDN must be assigned to the subject name or subject alternative name in the certificate).

- Optionally enter the external base URL in **External Base URL**. You would enter the external base URL to differentiate it from your internal domain naming. For example, your internal domain is contoso.net, but your external domain name is contoso.com. You would define the URL using the contoso.com domain name. This is also important in the case of a reverse proxy. The external base URL domain name would be the same as the domain name of the FQDN of the reverse proxy. Instant messaging and presence does require HTTP access to the Front End pool.

Note:

To use DNS load balancing, you must create the appropriate DNS records. For details, see Configure DNS for Load Balancing.

10. If you selected **Conferencing** on the **Select Features** page, on the **Select an Office Web Apps Server** page select **Associate pool with an Office Web Apps Server** and then click **New** (or select an existing Office Web Apps Server from the drop-down list).
11. In the **Define New Office Web Apps Server** dialog box, type the fully qualified domain name (FQDN) of your Office Web Apps Server computer in the **Office Web Apps Server FQDN** box; when you do this, your Office Web Apps Server discovery URL should automatically be entered into the **Office Web Apps Server discovery URL** box.

    If the Office Web Apps Server is installed on-premises and in the same network zone as Lync Server 2013 then the option **Office Web Apps Server**

is deployed in an external network (that is, perimeter/Internet) should not be selected.

If the Office Web Apps Server is deployed outside your internal firewall, then select the option **Office Web Apps Server is deployed in an external network (that is, perimeter/Internet)**.

> **Note:**
>
> For details, see Configuring Integration with Office Web Apps Server and Lync Server 2013.

12. On the **Define the Archiving SQL store** page, select an existing instance or SQL Server, or define a new instance to store the data associated with archiving data.
13. On the **Define the Monitoring SQL store** page, select an existing instance or SQL Server, or define a new instance to store the data associated with monitoring data.
14. Click **Next**. If you defined other role servers on the **Associate server roles with this Front End pool** page, separate role configuration wizard pages will open to let you configure the server roles. For details, see the following:

    Deploying External User Access
15. If you did not select additional server roles to configure and deploy, or when you have finished the configuration of the additional role servers, click **Finish**.

1.4.1.5.3 Deploying Paired Front End Pools for Disaster Recovery

Deploying Paired Front End Pools for Disaster Recovery

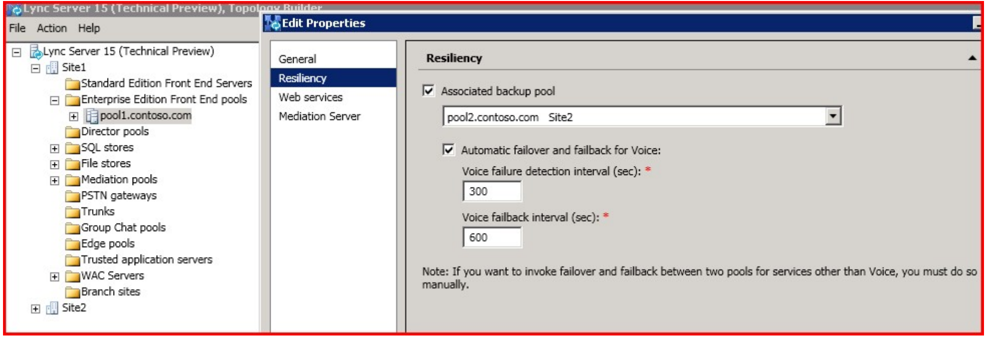
Deployment > Deploying Lync Server 2013 > Defining and Configuring the Topology >

Topic Last Modified: *2013-02-21*

You can easily deploy the disaster recovery topology of paired Front End pools using Topology Builder.

To deploy a pair of Front End pools

1. If the pools are new and not yet defined, use Topology Builder to create the pools.
2. In Topology Builder, right-click one of the two pools, and then click **Edit Properties**.
3. Click **Resiliency** in the left pane, and then select **Associated Backup Pool** in the right pane.
4. In the box below **Associated Backup Pool**, select the pool that you want to pair with this pool. Only existing pools that are not already paired with another pool will be available to select from.



☑ Associated backup pool

pool2.contoso.com Site2

☑ Automatic failover and failback for Voice:

Voice failure detection interval (sec): *

300

Voice failback interval (sec): *

600

Note: If you want to invoke failover and failback between two pools for services other than Voice, you must do so manually.

5. Select **Automatic failover and failback for Voice**, and then click **OK**.

   When you view the details about this pool, the associated pool now appears in the right pane under **Resiliency**.

6. Use Topology Builder to publish the topology.
7. If the two pools were not yet deployed, deploy them now and the configuration will be complete. You can skip the final two steps in this procedure.
   However, if the pools were already deployed before you defined the paired relationship, you must complete the following two final steps.
8. On every Front End Server in both pools, run the following:

   ```
   <system drive>\Program Files\Microsoft Lync Server 2013\Deployment\Boo
   ```

   This configures other services required for backup pairing to work correctly.
9. From a Lync Server Management Shell command prompt, run the following:

   ```
   Start-CsWindowsService -Name LYNCBACKUP
   ```

10. Force the user and conference data of both pools to be synchronized with each other, with the following cmdlets:

   ```
   Invoke-CsBackupServiceSync -PoolFqdn <Pool1 FQDN>
   ```

   ```
   Invoke-CsBackupServiceSync -PoolFqdn <Pool2 FQDN>
   ```

   Synchronizing the data may take some time. You can use the following cmdlets to check the status. Make sure that the status in both directions is in steady state.

   ```
   Get-CsBackupServiceStatus -PoolFqdn <Pool1 FQDN>
   ```

   ```
   Get-CsBackupServiceStatus -PoolFqdn <Pool2 FQDN>
   ```

Note:
The **Automatic failover and failback for Voice** option and the associated time intervals in Topology Builder apply only to the voice resiliency features that were introduced in Lync Server 2010. Selecting this option does not imply that the pool failover discussed in this document is automatic. Pool failover and failback always require an administrator to manually invoke the failover and failback cmdlets, respectively.

1.4.1.5.4 Deploying SQL Mirroring for Back End Server High Availability

Deploying SQL Mirroring for Back End Server High Availability

Deployment > Deploying Lync Server 2013 > Defining and Configuring the Topology >

Topic Last Modified: *2012-10-11*

To be able to deploy SQL mirroring, your servers must run a minimum of SQL Server 2008 R2. This version must run on all the involved servers: the primary, mirror, and the witness. For details, see http://go.microsoft.com/fwlink/p/?linkid=3052&kbid=2083921.

In general, setting up SQL mirroring between the two Back End Servers with a witness requires the following:

- The primary server’s version of SQL Server must support SQL mirroring.
- The primary, mirror, and the witness (if deployed) must have the same version of SQL Server.
- The primary and the mirror must have the same edition of SQL Server. The witness may have a different edition.

For SQL best practices in terms of what SQL versions are supported for a Witness role, see "Database Mirroring Witness" in the MSDN Library at http://go.microsoft.com/fwlink/p/?LinkId=247345.

You use Topology Builder to deploy SQL mirroring. You select an option in Topology Builder to mirror the databases, and Topology Builder sets up the mirroring (including setting up a witness, if you want) when you publish the topology. Note that you set up or remove the witness at the same time you set up or remove the mirror. There is no separate command to deploy or remove only a witness.

To configure server mirroring, you must first set up SQL database permissions correctly. For details, see "Set Up Login Accounts for Database Mirroring or AlwaysOn Availability Groups (SQL Server)" at http://go.microsoft.com/fwlink/p/?LinkId=268454.

With SQL mirroring, database recovery mode is always set to **Full**, which means you must closely monitor transaction log size and back up transaction logs on a regular basis to avoid running out of disk space on the Back End Servers. The frequency of transaction log backups depends on the log growth rate, which in turn depends on database transactions incurred by user activities on the Front End pool. We recommend that you determine how much transaction log growth is expected for your Lync deployment workload so that you can do the planning accordingly. The following articles provide additional information on SQL backup and log management:

- Database recovery models: "Recovery Models (SQL Server)" at http://go.microsoft.com/fwlink/p/?LinkId=268446
- Backup overview: "Backup Overview (SQL Server)" at http://go.microsoft.com/fwlink/p/?LinkId=268449
- Backup transaction log: "Backup a Transaction Log (SQL Server)" at http://go.microsoft.com/fwlink/p/?LinkId=268452

With SQL mirroring, you can either configure the topology for mirroring when you create the pools, or after the pools are already created.

Important:

Using Topology Builder or cmdlets to set up and remove SQL mirroring is supported only when the primary, mirror, and witness (if desired) servers all belong to the same domain. If you want to set up SQL mirroring among servers in different domains, see your SQL Server documentation.

To configure SQL mirroring while creating a pool in Topology Builder

1. On the **Define the SQL Store** page, click **New** next to the **SQL store** box.
2. On the **Define new SQL Store** page, specify the primary store, select **This SQL instance is in mirroring relation**, specify the SQL mirroring port number (the default is 5022), and then click **OK**.
3. Back on the **Define the SQL store** page, select **Enable SQL Store mirroring**.
4. In the **Define new SQL Store** page, specify the SQL store to be used as the mirror. Select **This SQL instance is in mirroring relation**, specify the port number (the default is 5022), and then click **OK**.
5. If you want a witness for this mirror, do the following:
   5.a. Select **Use SQL mirroring witness to enable automatic failover**.
   5.b. In the **Define the SQL Store** page, select **Use SQL mirroring witness to enable automatic failover**, and specify the SQL store to be used as the witness.
   5.c. Specify the port number (the default is 7022) and click **OK**.
6. After you are done defining your Front End pool and all other roles in your topology, use Topology Builder to publish the topology. When the topology is published, if the Front End pool that hosts Central Management store has SQL mirroring enabled, you will see an option to create both primary and mirror SQL store databases.
   Click **Settings**, and type the path to use as the file share for the mirroring backup.

Click **OK** and then **Next** to create the databases and publish the topology. The mirroring and the witness (if specified) will be deployed.

You can use Topology Builder to edit the properties of an already existing pool to enable SQL mirroring.

To add SQL mirroring to an existing Front End pool in Topology Builder

1. In Topology Builder, right-click the pool and then click **Edit Properties**.
2. Select **Enable SQL Store Mirroring**, and then click **New** next to **Mirroring SQL Store**.
3. Specify the SQL store that you want to use as the mirror.
4. Select **This SQL instance is in mirroring relation**, specify the SQL mirroring port number the default port is 5022), and then click **OK**.
5. If you want to configure a witness, select **Use SQL mirroring witness to enable automatic failover**, and click **New**.
6. Specify the SQL store that you want to use as the witness.
7. Select **This SQL instance is in mirroring relation**, specify the SQL mirroring port number (the default port is 7022), and then click **OK**.
8. Click **OK**.
9. Publish the topology. When you do so, you will be prompted to install the database.

You must then install the database before going on to the next procedure.

You should keep the following in mind when setting up SQL mirroring:

- If a mirroring endpoint already exists, it will be reused using the ports defined there, and will ignore the ones you specify in the topology.
- Any port already allocated for other applications on the same server, including those for other SQL instances, should not be used for the installed SQL instances at hand. This implies that if you have more than one SQL instance installed on the same server, they must not use the same port for mirroring. For details, see the following articles:
  - "Specify a Server Network Address (Database Mirroring)" in the MSDN Library at http://go.microsoft.com/fwlink/p/?LinkId=247346
  - "The Database Mirroring Endpoint (SQL Server)" at http://go.microsoft.com/fwlink/p/?LinkId=247347

Using Lync Server Management Shell Cmdlets to Set Up SQL Mirroring

The easiest way to set up mirroring is by using Topology Builder, but you can also do so using cmdlets.

1. Open a Lync Server Management Shell window and run the following cmdlet:

   ```
   Install-CsMirrorDatabase [-ConfiguredDatabases] [-ForInstance] [-ForDe
   ```

   For example:

   ```
   Install-CsMirrorDatabase -ConfiguredDatabases -FileShare \\PRIMARYBE\c
   ```

   You will see the following:

   ```
   Database Name:rtcxds
           Data File:D:\CsData\BackendStore\rtc\DbPath\rtcxds.mdf
            Log File:D:\CsData\BackendStore\rtc\LogPath\rtcxds.ldf
         Primary SQL: e04-ocs.los_a.lsipt.local\rtc
             Account: LOS_A\e04-ocs$
          Mirror SQL: K16-ocs.los_a.lsipt.local\rtc
   ```

```
          Account: LOS_A\K16-ocs$
     Witness SQL : AB14-lct.los_a.lsipt.local\rtc
          Account: LOS_A\AB14-lct$
    Database Name:rtcshared
        Data File:D:\CsData\BackendStore\rtc\DbPath\rtcshared.mdf
         Log File:D:\CsData\BackendStore\rtc\LogPath\rtcshared.ldf
      Primary SQL: e04-ocs.los_a.lsipt.local\rtc
          Account: LOS_A\e04-ocs$
       Mirror SQL: K16-ocs.los_a.lsipt.local\rtc
          Account: LOS_A\K16-ocs$
     Witness SQL : AB14-lct.los_a.lsipt.local\rtc
          Account: LOS_A\AB14-lct$
    Database Name:rtcab
        Data File:D:\CsData\ABSStore\rtc\DbPath\rtcab.mdf
         Log File:D:\CsData\ABSStore\rtc\LogPath\rtcab.ldf
      Primary SQL: e04-ocs.los_a.lsipt.local\rtc
          Account: LOS_A\e04-ocs$
       Mirror SQL: K16-ocs.los_a.lsipt.local\rtc
          Account: LOS_A\K16-ocs$
     Witness SQL : AB14-lct.los_a.lsipt.local\rtc
          Account: LOS_A\AB14-lct$
    Database Name:rgsconfig
        Data File:D:\CsData\ApplicationStore\rtc\DbPath\rgsconfig.mdf
         Log File:D:\CsData\ApplicationStore\rtc\LogPath\rgsconfig.ldf
      Primary SQL: e04-ocs.los_a.lsipt.local\rtc
          Account: LOS_A\e04-ocs$
       Mirror SQL: K16-ocs.los_a.lsipt.local\rtc
          Account: LOS_A\K16-ocs$
     Witness SQL : AB14-lct.los_a.lsipt.local\rtc
          Account: LOS_A\AB14-lct$
    Database Name:rgsdyn
        Data File:D:\CsData\ApplicationStore\rtc\DbPath\rgsdyn.mdf
         Log File:D:\CsData\ApplicationStore\rtc\LogPath\rgsdyn.ldf
      Primary SQL: e04-ocs.los_a.lsipt.local\rtc
          Account: LOS_A\e04-ocs$
       Mirror SQL: K16-ocs.los_a.lsipt.local\rtc
          Account: LOS_A\K16-ocs$
     Witness SQL : AB14-lct.los_a.lsipt.local\rtc
          Account: LOS_A\AB14-lct$
    Database Name:cpsdyn
        Data File:D:\CsData\ApplicationStore\rtc\DbPath\cpsdyn.mdf
         Log File:D:\CsData\ApplicationStore\rtc\LogPath\cpsdyn.ldf
      Primary SQL: e04-ocs.los_a.lsipt.local\rtc
          Account: LOS_A\e04-ocs$
       Mirror SQL: K16-ocs.los_a.lsipt.local\rtc
          Account: LOS_A\K16-ocs$
     Witness SQL : AB14-lct.los_a.lsipt.local\rtc
          Account: LOS_A\AB14-lct$
    Database Name:xds
        Data File:D:\CsData\CentralMgmtStore\rtc\DbPath\xds.mdf
         Log File:D:\CsData\CentralMgmtStore\rtc\LogPath\xds.ldf
      Primary SQL: e04-ocs.los_a.lsipt.local\rtc
          Account: LOS_A\e04-ocs$
       Mirror SQL: K16-ocs.los_a.lsipt.local\rtc
          Account: LOS_A\K16-ocs$
     Witness SQL : AB14-lct.los_a.lsipt.local\rtc
          Account: LOS_A\AB14-lct$
    Database Name:lis
        Data File:D:\CsData\CentralMgmtStore\rtc\DbPath\lis.mdf
         Log File:D:\CsData\CentralMgmtStore\rtc\LogPath\lis.ldf
      Primary SQL: e04-ocs.los_a.lsipt.local\rtc
          Account: LOS_A\e04-ocs$
       Mirror SQL: K16-ocs.los_a.lsipt.local\rtc
          Account: LOS_A\K16-ocs$
     Witness SQL : AB14-lct.los_a.lsipt.local\rtc
          Account: LOS_A\AB14-lct$
[Y] Yes  [A] Yes to All  [N] No  [L] No to All  [S] Suspend  [?] Help
```

2. Verify the following:
   - Port 5022 is accessible through the firewall if Windows Firewall is enabled

in the primary SQL Server e04-ocs.los_a.lsipt.local\rtc.
- Port 5022 is accessible through the firewall if Windows Firewall is enabled in the mirror SQL Server K16-ocs.los_a.lsipt.local\rtc.
- Port 7022 is accessible through the firewall if Windows Firewall is enabled in the witness SQL Server AB14-lct.los_a.lsipt.local\rtc.
- Accounts running the SQL Servers on all primary and mirror SQL servers have read/write permission to the file share \\E04-OCS\csdatabackup
- Verify that the Windows Management Instrumentation (WMI) provider is running on all these servers. The cmdlet uses this provider to find the account information for SQL Server services running on all primary, mirror and witness servers.
- Verify that the account running this cmdlet has permission to create the folders for the data and log files for all the mirror servers.
- Note that the user account that the SQL instance uses to run must have read/write permission to the file share. If the file share is on a different server, and the SQL instance runs a local system account, you must grant file share permissions to the server that hosts the SQL instance.

3. Type A and press ENTER.
   The mirroring will be configured.

Install-CsMirrorDatabase installs the mirror and configures mirroring for all the databases that are present on the primary SQL store. If you want to configure mirroring for only specific databases, you can use the –DatabaseType option, or if you want to configure mirroring for all databases except for a few, you can use the -ExcludeDatabaseList option, along with a comma-separated list of database names to exclude.

For example, if you add the following option to **Install-CsMirrorDatabase**, all databases except rtcab and rtcxds will be mirrored.

```
-ExcludeDatabaseList rtcab,rtcxds
```

For example, if you add the following option to **Install-CsMirrorDatabase**, only the rtcab, rtcshared, and rtcxds databases will be mirrored.

```
-DatabaseType User
```

Removing or Changing SQL Mirroring

To remove the SQL mirroring of a pool in Topology Builder, you must first use a cmdlet to remove the mirror in SQL Server. You can then use Topology Builder to remove the mirror from the topology. To remove the mirror in SQL Server, use the following cmdlet:

```
Uninstall-CsMirrorDatabase -SqlServerFqdn <SQLServer FQDN> [-SqlInstanceName <SQL
```

For example, to remove mirroring and drop the databases for the User databases, type the following:

```
Uninstall-CsMirrorDatabase -SqlServerFqdn primaryBE.contoso.com -SqlInstanceName
```

The `-DropExistingDatabasesOnMirror` option causes the affected databases to be deleted from the mirror.

Then, to remove the mirror from the topology, do the following:

1. In Topology Builder, right-click the pool and click **Edit Properties**.
2. Uncheck **Enable SQL Store Mirroring** and click **OK**.
3. Publish the topology.

◆Important:

Whenever you make a change to a Back End Database mirroring relationship, you must

restart all the Front End Servers in the pool.
For a change in mirroring, (such as changing the location of a mirror), you must use Topology Builder to perform these three steps:

1. Remove mirroring from the old mirror server.
2. Add mirroring to the new mirror server.
3. Publish the topology.

Removing a Mirroring Witness

Use this procedure if you need to remove the witness from a Back End Server mirroring configuration.

1. In Topology Builder, right-click the pool and click **Edit Properties**.
2. Uncheck **Use SQL Server mirroring witness to enable automatic failover** and click **OK**.
3. Publish the topology.
   After publishing the topology, Topology Builder you will see a message that includes the following
   ```
   Run the Uninstall-CsMirrorDatabase cmdlet to remove databases that are
   ```
   However, do not follow that step, and do not type `Uninstall-CsMirrorDatabase` as that would uninstall the entire mirroring configuration.
4. To remove just the witness from the SQL Server configuration, follow the instructions in "Remove the Witness from a Database Mirroring Session (SQL Server)" at http://go.microsoft.com/fwlink/p/?LinkId=268456.

1.4.1.5.5 Edit or Configure Simple URLs

Edit or Configure Simple URLs

See Also

Deployment > Deploying Lync Server 2013 > Defining and Configuring the Topology >

Topic Last Modified: *2013-02-21*

This procedure does not require membership in a local administrator or privileged domain group. You should log on to a computer as a standard user.

Lync Server 2013 uses simple URLs to direct internal and external calls to services on the Front End Server or on the Director, if one has been deployed. For more information about simple URLs, see Planning for Simple URLs in the Planning documentation. You can select the format for your simple URLs from several options. For details about these options, see DNS Requirements for Simple URLs in the Planning documentation.

By default, simple URLs will be configured in the form of (for example, the dial-in simple URL): https://dialin.<SIP Domain>

⊟To configure simple URLs

1. In Topology Builder, right-click the **Lync Server 2013** node, and then click **Edit Properties**.
2. In the **Simple URLs** pane, select either **Phone access URLs:** (Dial-in) or **Meeting URLs:** (Meet) to edit, and then click **Edit URL**.
3. Update the URL to the value you want, and then click **OK** to save the edited URL. The example shown here has modified the Dial-in URL to https://pool01.contoso.net/dialin.
4. Edit the Meet URL by using the same steps, if necessary.

⊟To define the optional Admin simple URL

1. In Topology Builder, right-click the **Lync Server 2013** node, and then click **Edit Properties**.
2. In the **Administrative access URL** box, enter the simple URL you want for administrative access to Lync Server 2013 Control Panel, and then click **OK**.

> **Tip:**
> We recommend using the simplest possible URL for the Admin URL. The simplest option is **https://admin.**<*domain*>.

> **Important:**
> If you change a simple URL after initial deployment, you must be aware of what changes impact your Domain Name System (DNS) records and certificates for simple URLs. If the change impacts the base of a simple URL, then you must change the DNS records and certificates as well. For example, changing from https://lync.contoso.com/Meet to https://meet.contoso.com changes the base URL from lync.contoso.com to meet.contoso.com, so you would need to change the DNS records and certificates to refer to meet.contoso.com. If you changed the simple URL from https://lync.contoso.com/Meet to https://lync.contoso.com/Meetings, the base URL of lync.contoso.com stays the same, so no DNS or certificate changes are needed. Whenever you change a simple URL name, however, you must run the **Enable-CsComputer** cmdlet on each Director and Front End Server to register the change.

Concepts

Planning for Simple URLs

1.4.1.5.6 Select the Central Management Server

Select the Central Management Server

Deployment > Deploying Lync Server 2013 > Defining and Configuring the Topology >

Topic Last Modified: *2012-01-02*

Before you can define and configure your topology, you must first define the location to install the Central Management Server.

> **Note:**
> This will not take effect until you have published a topology in Topology Builder. To set the Central Management Server before the topology is created and published, run **Set-CSConfigurationStoreLocation**.

⊟To select the Central Management Server

1. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
2. Right-click the Lync Server 2013 node, and then click **Edit Properties**.
3. In the Central Management Server pane, select the Front End Server to install the Central Management Server on and then click **OK**.

1.4.1.6 Finalizing and Implementing the Topology Design

Finalizing and Implementing the Topology Design

Microsoft Lync Server 2013 > Deployment > Deploying Lync Server 2013 >

Topic Last Modified: *2012-06-19*

After you complete the preparation of your environment, you should be ready to finalize and implement your topology design. This includes using Topology Builder to publish your topology, which is required in order to install Lync Server 2013 server roles.

- Install Standard Edition Server Database
- Verify the Topology Design
- Publish the Topology

1.4.1.6.1 Install Standard Edition Server Database

Install Standard Edition Server Database

Deployment > Deploying Lync Server 2013 > Finalizing and Implementing the Topology Design >

Topic Last Modified: *2012-10-01*

Setting up a Standard Edition server as the only server in your infrastructure that homes users differs from other server installations in that there is a selection in the **Deployment Wizard** specifically for setting up the initial server.

⊟To install a Standard Edition server

1. Log on to the server where you are going to install Standard Edition server as a local administrator or a domain equivalent.
2. If you have not prepared Active Directory Domain Services (AD DS), then first perform those procedures. For details, see Preparing Active Directory Domain Services for Lync Server 2013.
3. In the Lync Server Deployment Wizard, click **Prepare first Standard Edition server**.
4. On the **Prepare single Standard Edition Server** page, click **Next**.
5. On the **Executing Commands** page, the SQL Server 2012 Express is installed as the Central Management store. Necessary firewall rules are created. When the installation of the database and prerequisite software is completed, click **Finish**.

   Note:
   The initial installation may take some time with no visible updates to the command output summary screen. This is due to the installation of the SQL Server Express. If you need to monitor the installation of the database, use Task Manager to monitor the setup.

6. On the Lync Server Deployment Wizard page, click **Install Topology Builder** if you have not previously installed the administrative tools. For details, see Install Lync Server Administrative Tools.
7. Confirm that there are green check marks next to "Prepare Active Directory," "Prepare first Standard Edition server," and "Install Topology Builder."

1.4.1.6.2 Verify the Topology Design

Verify the Topology Design

Deployment > Deploying Lync Server 2013 > Finalizing and Implementing the Topology Design >

Topic Last Modified: *2012-01-02*

Topology Builder automatically verifies the topology. Any topology error is identified as a validation error, indicated by the validation error icon next to the server role. It is important to also verify that the topology correctly represents the topology for your deployment.

⊟To verify the topology prior to publication

1. Check that all simple URLs are configured correctly.
2. Confirm that the SQL Server-based server is online and available to the computer where Topology Builder is installed, including any necessary firewall rules.
3. Confirm that the file share is available and has the proper permissions defined.
4. Confirm that the correct server roles that meet the deployment requirements are defined in the topology.
5. Verify that the servers exist in Active Directory Domain Services (AD DS). This will happen automatically if you have joined the servers to the domain.

When you have verified the topology and there are no validation errors, you should be ready to publish the topology. If there are validation errors, you must correct these before you can publish the topology. For details about publishing your topology, see Publish the Topology.

1.4.1.6.3 Publish the Topology

Publish the Topology

See Also

Deployment > Deploying Lync Server 2013 > Finalizing and Implementing the Topology Design >

Topic Last Modified: *2013-02-21*

To successfully publish, enable, or disable a topology when adding or removing a server role, you should be logged in as a user who is a member of the RTCUniversalServerAdmins and Domain Admins groups. It is also possible to delegate the proper administrator rights and permissions. For details, see Delegate Setup Permissions. For other configuration changes, only membership in the RTCUniversalServerAdmins group is required.

After you define your topology in Topology Builder, you must publish the topology to the Central Management store. The Central Management store provides a robust, schematized storage of the data needed to define, set up, maintain, administer, describe, and operate a Lync Server 2013 deployment. It also validates the data to help ensure configuration consistency. All changes to this configuration data happen at the Central Management store, eliminating "out-of-sync" issues. Read-only copies of the data are replicated to all servers in the topology, including Edge Servers.

Note:
For Enterprise Edition only: In order to publish the topology, the SQL Server-based Back End Server must be online and accessible with firewall exceptions in place. For details about specifying firewall exceptions, see Understanding Firewall Requirements for SQL Server. For details about configuring SQL Server, see Configure SQL Server for Lync Server 2013.

⊟To publish a topology

1. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
2. Select to open the topology from a local file. If you are on the computer where you defined the topology, this will be in the location where you saved it in earlier steps. Typically, this will be the Documents folder of the user who configured the topology.
3. Right-click the **Lync Server 2013** node, and then click **Publish Topology**.
4. On the **Publish the topology** page, click **Next**.

5. On the **Create databases** page, select the databases you want to publish.

> **Note:**
> If you don’t have the appropriate rights to create the databases, you can clear the check boxes next to those databases, and someone with appropriate rights can later create the databases. For details, see Deployment Permissions for SQL Server.

6. Optionally click **Advanced**. The Advanced SQL Server data file placement options let you select between the following options:
   - **Automatically determine database file location** – This option will determine the best operational performance based on the disk configuration on your SQL Server-based server by distributing the log and data files to the best location.
   - **Use SQL Server instance defaults** – This option puts log and data files onto the SQL Server-based server by using the instance settings. This option does not use the operational functionality of the SQL Server-based server to determine optimal locations for logs and data. The SQL Server administrator would typically move the log and data files to locations that are appropriate for the SQL Server-based server and organization management procedures.

   Click **OK**, and then click **Next**.
7. On the **Select Central Management Server** page, select a Front End pool.
8. Optionally click **Advanced**. The Advanced SQL Server data file placement options enables you to select between the following options:
   - **Automatically determine database file location** – This option will determine the best operational performance based on the disk configuration on your SQL Server-based server by distributing the log and data files to the best location.
   - **Use SQL Server instance defaults** – This option puts log and data files onto the SQL Server-based server by using the instance settings. This option does not use the operational functionality of the SQL Server-based server to determine optimal locations for logs and data. The SQL Server administrator would typically move the log and data files to locations that are appropriate for the SQL Server-based server and organization management procedures.

   Click **OK**.
9. Click **Next** to complete the publishing process.
10. When the publish process has completed, click **Finish**.

    When the topology has been published successfully, you can begin installing a local replica of the Central Management store on each server running Lync Server 2013 in your topology. We recommend that you begin with the first Front End pool.

Setting Up Front End Servers and Front End Pools

1.4.1.7 Setting Up Front End Servers and Front End Pools

Setting Up Front End Servers and Front End Pools

Microsoft Lync Server 2013 > Deployment > Deploying Lync Server 2013 >

Topic Last Modified: *2012-10-01*

This section guides you through installing Lync Server 2013 and setting up the server roles for the Standard Edition server and the Front End pool, including the Front End Servers and any server roles that are collocated with the Front End Servers. To install and set up server roles, you run the Lync Server Deployment Wizard on each computer on which you are installing a server role. You use the Deployment Wizard to complete all four deployment steps, including installing the Local Configuration store, installing the Front End Servers, configuring certificates, and starting services.

Note:

Before you can set up server roles, you must have successfully published a topology. For details about publishing a topology, see Finalizing and Implementing the Topology Design.

- Install the Local Configuration Store
- Install Lync Servers Server Components
- Configure Certificates for Servers
- Start Services on Servers
- Test the Pool Deployment
- Test the Standard Edition Server

1.4.1.7.1 Install the Local Configuration Store

Install the Local Configuration Store

Deployment > Deploying Lync Server 2013 > Setting Up Front End Servers and Front End Pools >

Topic Last Modified: *2013-02-25*

To successfully complete this procedure, you should be logged on to the server minimally as a local administrator and a domain user who has membership in at least the RTCUniversalReadOnlyAdmin group.

The first step of the Lync Server Deployment Wizard is to install the Local Configuration store. The Local Configuration store is SQL Server Express, which installs a local database that will retain a read-only copy of the Central Management store. The Central Management store is added to the existing SQL Server database installed on the Standard Edition server or SQL Server Express-based database.

Important:

If this is the first time that you have run Lync Server 2013 setup on this server, you will be prompted for a drive and path to install Lync Server 2013. If your organization requires that you locate Internet Information Services (IIS) and all Web Services on a drive other than the system drive, you can change the installation location path for the Lync Server files in the Setup dialog box. If you install the Setup files to this path, including OCSCore.msi, the rest of the Lync Server 2013 files will be deployed to this drive as well.

To install the Local Configuration store

1. From the installation media, browse to \setup\amd64\Setup.exe, and then click **OK**.
2. If you are prompted to install the Microsoft Visual C++ 2012 Redistributable, click **Yes**.
3. On the **Lync Server 2013 Installation Location** page, click **OK**.
4. On the **End User License Agreement** page, review the license terms, select **I accept the terms in the license agreement**, and then click **OK**. This step is required before you can continue.
5. On the Deployment Wizard page, click **Install or Update Lync Server System**.
6. On the **Lync Server 2013** page, next to **Step1: Install Local Configuration Store**, click **Run**.
7. On the **Local Server Configuration** page, make sure that the **Retrieve configuration automatically from the Central Management Store** option is

selected, and then click **Next**.

8. When the local server configuration installation is complete, click **Finish**.

1.4.1.7.2 Install Lync Servers Server Components

Install Lync Servers Server Components

Deployment > Deploying Lync Server 2013 > Setting Up Front End Servers and Front End Pools >

Topic Last Modified: *2012-04-16*

To successfully complete this procedure, you should be logged on to the server as minimally a local administrator and a domain user who has membership in at least the RTCUniversalReadOnlyAdmins group.

The Lync Server Deployment Wizard is used to install the components that are necessary for each server role and to activate the server. This procedure walks you through the steps of deploying the Standard Edition server or the Front End Server in your infrastructure.

⊟To install Lync Server components

1. If the Lync Server Deployment Wizard is not running, start it on the server that you are setting up.
2. Click **Install or Update Lync Server System**.
3. In the Deployment Wizard, verify that **Step 1: Install Local Configuration Store** has a green check mark, which means that the step has been completed. If it is not complete, install the Local Configuration store on the server. For details, see Install the Local Configuration Store.
4. To install the Lync Server 2013 components for the server, click **Run** next to **Step 2: Setup or Remove Lync Server Components**.
5. On the **Setup Lync Server Components** page, click **Next** to set up components as defined in the published topology.
6. The **Executing Commands** page displays a summary of commands and installation information as it proceeds. When finished, you can use the list to select a log to view, and then click **View Log**.
7. When Lync Server 2013 components setup completes, click **Finish**.

> **Note:**
> If you are prompted to restart the computer (which may be required if Windows Desktop Experience was not already installed on the computer), do so. When the computer is back up and running, repeat this procedure, starting from step three (run Step 2 in the Deployment Wizard again).

1.4.1.7.3 Configure Certificates for Servers

Configure Certificates for Servers

See Also

Deployment > Deploying Lync Server 2013 > Setting Up Front End Servers and Front End Pools >

Topic Last Modified: *2013-02-21*

To successfully complete this procedure you should be logged on as a user who is a member of the RTCUniversalServerAdmins group or have the correct permissions delegated. For details about delegating permissions, see Delegate Setup Permissions. Depending on your organization and requirements for requesting certificates, you may require other group memberships. Consult with the group that manages your public key infrastructure (PKI) certification authority (CA).

Note:

Lync Server 2013 includes support for SHA-256 certificates for connections from clients running the Windows 7, Windows Server 2008 R2, Windows Server 2008, Windows Vista, or Windows XP operating systems, in addition to Lync Phone Edition. To support external access using SHA-256, the external certificate is issued by a public CA using SHA-256.

Each Standard Edition server or Front End Server requires up to four certificates: the oAuthTokenIssuer certificate, a default certificate, a web internal certificate, and a web external certificate. However, it is possible to request and assign a single default certificate with appropriate subject alternative name entries as well as the oAuthTokenIssuer certificate. For details about the certificate requirements, see Certificate Requirements for Internal Servers. For details about requesting, assigning and installing the oAuthTokenIssuer certificate, see Managing Server-to-Server Authentication (Oauth) and Partner Applications

Use the following procedure to request, assign, and install the Standard Edition server or Front End Server certificates. Repeat the procedure for each Front End Server.

Important:

The following procedure describes how to configure certificates from an internal enterprise PKI deployed by your organization and with offline request processing. For information about obtaining certificates from a public CA, see Certificate Requirements for Internal Servers in the Planning documentation. Also, this procedure describes how to request, assign, and install certificates during set up of the Front End Server. If you requested certificates in advance, as described in the Request Certificates in Advance (Optional) section of this Deployment documentation, or you do not use an internal enterprise PKI deployed in your organization to obtain certificates, you must modify this procedure as appropriate.

⊟To configure certificates for a Front End Server

1. In the Lync Server Deployment Wizard, click **Run** next to **Step 3: Request, Install or Assign Certificates**.
2. On the **Certificate Wizard** page, click **Request**.
3. On the **Certificate Request** page, click **Next**.
4. On the **Delayed or Immediate Requests** page, you can accept the default **Send the request immediately to an online certification authority** option by clicking **Next**. The internal CA with automatic online enrollment must be available if you select this option. If you choose the option to delay the request, you will be prompted for a name and location to save the certificate request file. The certificate request must be presented and processed by a CA either inside your organization, or by a public CA. You will then need to import the certificate response and assign it to the proper certificate role.
5. On the **Choose a Certificate Authority (CA)** page, select the **Select a CA from the list detected in your environment** option, and then select a known (through registration in Active Directory Domain Services (AD DS)) CA from the list. Or, select the **Specify another certification authority** option, enter the name of another CA in the box, and then click **Next**.
6. On the **Certificate Authority Account** page, you are prompted for credentials to request and process the certificate request at the CA. You should have determined if a user name and password is necessary to request a certificate in advance. Your CA administrator will have the required information and may have to assist you in this step. If you need to supply alternate credentials, select the check box, provide a user name and password in the text boxes, and then click **Next**.
7. On the **Specify Alternate Certificate Template** page, to use the default Web Server template, click **Next**.

Note:
If your organization has created a template for use as an alternative for the default Web server CA template, select the check box, and then enter the name of the alternate template. You will need the template name as defined by the CA administrator.

8. On the **Name and Security Settings** page, specify a **Friendly Name** that should allow you to identify the certificate and purpose. If you leave it blank, a name will be generated automatically. Set the **Bit length** of the key, or accept the default of 2048 bits. Select the **Mark the certificate's private key as exportable** if you determine that the certificate and private key needs to be moved or copied to other systems, and then click **Next**.

Note:
Lync Server 2013 has minimal requirements for an exportable private key. One such place is on the Edge Servers in a pool, where the Media Relay Authentication Service uses copies of the certificate, rather than individual certificates for each instance in the pool.

9. On the **Organization Information** page, optionally provide organization information, and then click **Next**.
10. On the **Geographical Information** page, optionally provide geographical information, and then click **Next**.
11. On the **Subject Name / Subject Alternate Names** page, review the subject alternative names that will be added, and then click **Next**.
12. On the **SIP Domain setting** page, select the **SIP Domain**, and then click **Next**.
13. On the **Configure Additional Subject Alternate Names** page, add any additional required subject alternative names, including any that might be required for additional SIP domains in the future, and then click **Next**.
14. On the **Certificate Request Summary** page, review the information in the summary. If the information is correct, click **Next**. If you need to correct or modify a setting, click **Back** to the proper page to make the correction or modification.
15. On the **Executing Commands** page, click **Next**.
16. On the **Online Certificate Request Status** page, review the information returned. You should note that the certificate was issued and installed into the local certificate store. If it is reported as having been issued and installed, but is not valid, make sure that the CA root certificate has been installed in the server's Trusted Root CA store. Refer to your CA documentation on how to retrieve a Trusted Root CA certificate. If you need to view the retrieved certificate, click **View Certificate Details**. By default, the check box for **Assign the certificate to Lync Server certificate usages** is checked. If you want to manually assign the certificate, clear the check box, and then click **Finish**.
17. If you cleared the check box for **Assign the certificate to Lync Server certificate usages** on the previous page, you will be presented with the **Certificate Assignment** page. Click **Next**.
18. On the **Certificate Store** page, select the certificate that you requested. If you want to view the certificate, click **View Certificate Details**, and then click **Next** to continue.

Note:
If the **Online Certificate Request Status** page reported an issue with the certificate, such as the certificate not being valid, viewing the actual certificate can assist in resolving the issue. Two specific issues that can cause a certificate to not be valid is the previously mentioned missing Trusted Root CA certificate, and a missing private key that is associated with the certificate. Refer to your CA documentation to resolve these two issues.

19. On the **Certificate Assignment Summary** page, review the information presented to make sure that this is the certificate that should be assigned, and then click **Next**.

20. On the **Executing Commands** page, review the output of the command. Click **View Log** if you want to review the assignment process or if there was an error or warning issued. When you are finished with your review, click **Finish**.
21. On the **Certificate Wizard** page, verify that the **Status** of the certificate is “Assigned,” and then click **Close**.

Certificate Infrastructure Requirements

1.4.1.7.4 Start Services on Servers

Start Services on Servers

Deployment > Deploying Lync Server 2013 > Setting Up Front End Servers and Front End Pools >

Topic Last Modified: *2012-10-01*

To successfully complete this procedure you should be logged in as a user who is a member of the RTCUniversalServerAdmins group or have the correct permissions delegated. For details about delegating permissions, see **Delegate Setup Permissions**.

⚠**Warning:**
For Lync Server 2013, KB2713435-x64-RP.msu must be installed on Windows Server 2012 computers before some Lync Server services can be restarted.

After you install the Local Configuration store on your servers, install the Lync Server 2013 components, and configure certificates on a Front End Server or Front End Server, you must start the Lync Server 2013 services on the server. Use the following procedure to start services on each Front End Server in your deployment.

⊟To start services on a Standard Edition or Front End Server

1. In the Lync Server Deployment Wizard, on the **Lync Server 2013** page, click **Run** next to **Step 4: Start Services**.
2. On the **Start Services** page, click **Next** to start the Lync Server services on the server.
3. On the **Executing Commands** page, after all services have started successfully, click **Finish**.

◆**Important:**
The command to start the services on the server is a best effort method to report that the services have in fact started. It might not reflect the actual state of the service. We recommend that you use the step **Service Status (Optional)** immediately following **Start Services** to open the Microsoft Management Console (MMC) and confirm that the services have started successfully. If any Lync Server service has not started, you can right-click that service in the MMC, and then click **Start**.

1.4.1.7.5 Configure an Existing Central Management Server

Configure an Existing Central Management Server

Deployment > Deploying Lync Server 2013 > Setting Up Front End Servers and Front End Pools >

Topic Last Modified: *2013-02-21*

If you reuse a Central Management Server from an existing Lync Server 2013 deployment, you must run the procedure described below to make sure that Lync Server Control Panel and Windows PowerShell function correctly.

⊟To configure an existing Central Management Server

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Use the **Update-CsAdminRole** cmdlet to update the role-based access control (RBAC) roles stored in the Central Management Server.

   Note:
   No output is expected unless there is an error.

1.4.1.7.6 Test the Pool Deployment

Test the Pool Deployment

See Also

Deployment > Deploying Lync Server 2013 > Setting Up Front End Servers and Front End Pools >

Topic Last Modified: *2012-10-01*

The following procedure describes how to test the deployment of the Front End pool.

⊟To test the pool deployment

1. Use Active Directory Computers and Users to add the Active Directory user object of the administrator role for the Lync Server 2013 deployment (on which Lync Server 2013 Control Panel is installed) to the **CSAdministrator** group.

   Important:
   If you do not add the appropriate users and groups to the CsAdministors group, you will receive an error when opening Lync Server Control Panel, which states that "Unauthorized: Access is denied due to a role-based access control (RBAC) authorization failure."
2. If the user object is currently logged on, log off and then log on again to register the new group assignment.

   Note:
   The user account cannot be the local administrator of any server running Lync Server 2013.
3. Use the administrative account to log on to the computer where Lync Server Control Panel is installed.
4. Start Lync Server Control Panel, and then provide credentials, if prompted. Lync Server Control Panel displays deployment information.
5. In the left navigation bar, click **Topology**, and then confirm that the service status shows a computer with a green arrow and that a green check mark for replication status is next to each Lync Server server role that has been deployed and brought online.
6. In the left navigation bar, click **Users**, and then click **Enable users**.
7. On the **New Lync Server User** page, click **Add**.
8. To define search parameters for the objects you want to find, on the **Select from Active Directory** page, you can select **Search**, and then optionally click **Add Filter**. You can also select **LDAP search** and enter an LDAP expression to filter or limit the objects that will be returned. After you have decided on your Search options, clink **Find**.
9. In the Search results pane, select all the objects for this search session, and then click **OK**.
10. On the **New Lync Server User** page, the object or objects you selected are

in the **Users** display. In the **Assign users to a pool** list, select the server where the objects should be homed.

Following are a number of options for configuring the objects.

- **Generate user's SIP URI**
- **Telephony**
- **Line URI**
- **Conferencing policy**
- **Client version policy**
- **PIN policy**
- **External access policy**
- **Archiving policy**
- **Location policy**
- **Client policy**

For the purposes of testing the basic functionality, select the option you prefer for the **Generate user's SIP URI** setting (the other options in the configuration will use default settings), and then click **Enable**.

11. A summary page is displayed that shows a check mark in the **Enabled** column to indicate that the objects are now ready for use. The **SIP address** column displays the address you need for the user sign-in configuration.
12. Log one user on to a computer that is joined to the domain, and another user on to another computer in the domain.
13. Install Lync Server 2013 on each of the two client computers, and then verify that both users can sign in to Lync Server 2013 and can send instant messages to each other.

Concepts

Deploying Clients and Devices

1.4.1.7.7 Test the Standard Edition Server

Test the Standard Edition Server

See Also

Deployment > Deploying Lync Server 2013 > Setting Up Front End Servers and Front End Pools >

Topic Last Modified: *2012-10-01*

The following procedure describes how to test the deployment of a Standard Edition server.

⊟To test the deployment of a Standard Edition Server

1. Use Active Directory Computers and Users to add the Active Directory user object of the administrator role for the Lync Server 2013 deployment (on which Lync Server Control Panel is installed) to the **CSAdministrator** group.
2. If the user object is currently logged on, log off and then log on again to register the new group assignment.

> **Note:**
> The user account cannot be the local administrator of the server running Lync Server 2013, Standard Edition. If you do not add the appropriate users and groups to the CsAdministors group, you will receive an error when opening Lync Server 2013 Control Panel, which states that "Unauthorized: Access is denied due to a role-based access control (RBAC) authorization failure."

3. Use the administrative account to log on to the computer where Lync Server Control Panel is installed.
4. Start Lync Server Control Panel and provide credentials, if prompted. Lync Server 2013 Control Panel displays deployment information.

5. In the left navigation bar, click **Topology**, and then confirm that the service status is a computer icon with a green arrow and there is a green check mark next to each Lync Server server role that has been deployed and brought online.
6. In the left navigation bar, click **Users**, and then enable the two users for Lync Server 2013.
7. Log one user on to a computer that is joined to the domain, and the other user on to another computer in the domain.
8. Install Lync Server 2013 on each of the two client computers, and then verify that both users can sign in to Lync Server 2013 and can send instant messages to each other.

Concepts

Deploying Clients and Devices

1.4.1.8 Deploying Lync Server 2013 Standard Edition into an Existing Lync Server 2013 Enterprise

Deploying Lync Server 2013 Standard Edition into an Existing Lync Server 2013 Enterprise

Microsoft Lync Server 2013 > Deployment > Deploying Lync Server 2013 >

Topic Last Modified: *2012-10-01*

Deploying a Standard Edition server into an existing Enterprise Edition deployment is similar to deploying additional server roles. A Standard Edition server might be deployed to another site, allowing for users in that site to be homed on the Standard Edition server rather than the Front End pool across a wide area network (WAN). The procedures for installing the new site and servers in that site are already defined in other sections of the Deploying Lync Server 2013 documentation.

To define a new site

1. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
2. In the console tree, right-click **Lync Server 2013**, and then click **New Central Site**.
3. On the **Identify the site** page, give a name to the site and optionally enter a description.
4. Follow the procedures for defining the rest of the site topology. For details, see Defining and Configuring the Topology.
5. Publish the updated topology. For details, see Publish the Topology.
6. Set up and install a Standard Edition server.

Caution:

If you have deployed an environment with only a Standard Edition server, you would have begun the setup process from the Lync Server Deployment Wizard by using the **Prepare first Standard Edition server** link to install the initial database files to the new Standard Edition server. **Do not** follow that process when installing a Standard Edition server into an existing Lync Server 2013 deployment.

1.4.1.9 Adding Server Roles

Adding Server Roles

Microsoft Lync Server 2013 > Deployment > Deploying Lync Server 2013 >

Topic Last Modified: *2012-06-19*

After you have your initial deployment up and running, you can add additional server roles for Lync Server 2013, such as a Director or a stand-alone Mediation Server.

Note:
Before undertaking the task of installing additional server roles, see the Planning topics related to each role.

- Configuring Dial-in Conferencing

Additionally, for details about the deployment of your client software and devices that can be used with Lync Server 2013, see Deploying Clients and Devices.

1.4.1.10 Setting Up Kerberos Authentication

Setting Up Kerberos Authentication

Microsoft Lync Server 2013 > Deployment > Deploying Lync Server 2013 >

Topic Last Modified: *2013-02-21*

Lync Server 2013 supports NTLM and Kerberos authentication for Web Services. Office Communications Server 2007 and Office Communications Server 2007 R2 used the default RTCComponentService and RTCService as the user accounts to run the Web Services application pools, allowing for a service principal name (SPN) to be assigned to the user accounts and to act as the authentication principal. Lync Server uses NetworkService to run Web Services and NetworkService cannot have SPNs assigned to it.

To solve the issue of not having Active Directory objects to hold the SPNs, Lync Server Control Panel can use computer account objects for this purpose. The computer account objects can hold the SPNs and are not subject to password expiration, which was an issue with using user accounts in previous versions.

You use Windows PowerShell cmdlets to configure the computer objects to provide Kerberos authentication.

- Prerequisites for Enabling Kerberos Authentication
- Create a Kerberos Authentication Account
- Assign a Kerberos Authentication Account to a Site
- Setting Up Kerberos Authentication Account Passwords
- Add Kerberos Authentication to Other Sites
- Remove Kerberos Authentication from a Site
- Testing and Reporting the Status and Assignment of Kerberos Authentication

1.4.1.10.1 Prerequisites for Enabling Kerberos Authentication

Prerequisites for Enabling Kerberos Authentication

Deployment > Deploying Lync Server 2013 > Setting Up Kerberos Authentication >

Topic Last Modified: *2013-02-21*

Before enabling Kerberos authentication, make sure that you complete all prerequisite configuration and infrastructure preparations:

- Active Directory schema is extended for Lync Server 2013.
- Active Directory forest preparation is completed for Lync Server 2013.
- Active Directory domain preparation is completed for Lync Server 2013.
- Central Management store is successfully installed and available.
- The topology has been created and published by using Topology Builder.
- Servers and roles that require Web Services have been defined and deployed, including Front End Servers, Standard Edition servers, and Directors.
- Internet Information Services (IIS) is configured and deployed with the recommended role services to support Web Services in Lync Server 2013.

After the prerequisites have been met, you should be ready to create one or more accounts for Web Services to use for Kerberos authentication for your deployment. At a minimum, you need to create one Kerberos authentication account for each deployment. However, you can create an account for each site to provide local Kerberos authentication at the site. You can only specify one Kerberos authentication account per site.

1.4.1.10.2 Create a Kerberos Authentication Account

Create a Kerberos Authentication Account

Deployment > Deploying Lync Server 2013 > Setting Up Kerberos Authentication >

Topic Last Modified: *2012-01-02*

To successfully complete this procedure, you should be logged on to the server or domain minimally as a member of the Domain Admins group.

You can create Kerberos authentication accounts for each site or you can create a single Kerberos authentication account and use it for all sites. You use Windows PowerShell cmdlets to create and manage the accounts, including identifying the accounts assigned to each site. Topology Builder and the Lync Server 2013 Control Panel do not display Kerberos authentication accounts. Use the following procedure to create one or more user accounts to be used for Kerberos authentication.

⊟To create a Kerberos account

1. As a member of the Domain Admins group, log on to a computer in the domain running Lync Server 2013 or on to a computer where the administrative tools are installed.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. From the command line, run the following command:

   ```
   New-CsKerberosAccount -UserAccount "Domain\UserAccount" -ContainerDN "
   ```

   For example:

   ```
   New-CsKerberosAccount -UserAccount "Contoso\KerbAuth" -ContainerDN "CN
   ```

4. Confirm that the Computer object was created by opening Active Directory User and Computers, expand the **Users** container, and then confirm that the Computer object for the user account is in the container.

1.4.1.10.3 Assign a Kerberos Authentication Account to a Site

Assign a Kerberos Authentication Account to a Site

Deployment > Deploying Lync Server 2013 > Setting Up Kerberos Authentication >

Topic Last Modified: *2012-01-16*

To successfully complete this procedure you should be logged on as a user who is a member of the RTCUniversalServerAdmins group.

After creating the Kerberos account, you must assign it to a site. This is a Lync Server 2013 site, not an Active Directory site. You can create multiple Kerberos authentication accounts per deployment, but you can assign only one account to a site. Use the following procedure to assign a previously created Kerberos authentication account to a site. For details about creating the Kerberos account, see Create a Kerberos Authentication Account.

⊟To assign a Kerberos authentication account to a site

1. As a member of the RTCUniversalServerAdmins group, log on to a computer in the domain running Lync Server 2013 or on to a computer where the administrative tools are installed.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. From the command line, run the following two commands:

```
New-CsKerberosAccountAssignment -UserAccount "Domain\UserAccount" -Ide
```

```
Enable-CsTopology
```

For example:

```
New-CsKerberosAccountAssignment -UserAccount "contoso\kerbauth" -Ident
```

```
Enable-CsTopology
```

Note:
You must specify the UserAccount parameter by using the Domain\User format. The User@Domain.extension format is not supported for referring to the computer objects created for Kerberos authentication purposes.

Important:
After making any changes to Kerberos authentication, such as adding an account or removing an account, you must run **Enable-CsTopology** from the Lync Server Management Shell command prompt.

1.4.1.10.4 Setting Up Kerberos Authentication Account Passwords

Setting Up Kerberos Authentication Account Passwords

Deployment > Deploying Lync Server 2013 > Setting Up Kerberos Authentication >

Topic Last Modified: *2010-11-03*

After you create the computer object for the Kerberos authentication account, you can set up the password for the account. You run the Windows PowerShell cmdlet for setting the Kerberos account password on one server. You can set the password on the object that you created for the Kerberos authentication. The password can be set to a known value, but by default is a random password. The password is available to all Kerberos authentication sources that use the account. You use Windows PowerShell cmdlets to set up and manage Kerberos account passwords.

Note:
The Kerberos account object is a computer object, but uses the UserAccount parameter for operations in the Windows PowerShell cmdlets that are referenced. Note that this is not a mistake, but the intended behavior of the cmdlet when used with the Kerberos account creation and maintenance.

- Set a Kerberos Authentication Account Password on a Server
- Synchronize a Kerberos Authentication Account Password to IIS

1.4.1.10.4.1 Set a Kerberos Authentication Account Password on a Server

Set a Kerberos Authentication Account Password on a Server

Deploying Lync Server 2013 > Setting Up Kerberos Authentication > Setting Up Kerberos Authentication Account Passwords >

Topic Last Modified: *2012-01-16*

To successfully complete this procedure you should be logged on as a user who is a member of the RTCUniversalServerAdmins group.

You must set up a password on the Kerberos account for each site that has Front End Servers, Standard Edition servers, and Directors. You can set up the password by running the **Set-CsKerberosAccountPassword** Windows PowerShell cmdlet on one server in the site (for example, one Front End Server). For each site, you must run the **Set-CsKerberosAccountPassword** cmdlet. The cmdlet configures Internet Information Services (IIS) for the Web Services service, and then sets the password on the computer account in Active Directory Domain Services (AD DS). An alternate method, based on which parameter is used with the cmdlet, configures IIS on one server while using another server that has been configured as the source of the Kerberos account password.

When you use the **Set-CsKerberosAccountPassword** cmdlet to set a password, Kerberos sets the password to a randomly generated string. This cmdlet contacts all IIS instances in all Lync Server 2013 central sites to which this account is assigned.

⊟To set a password for a Kerberos authentication account

1. Log on to any domain computer with Lync Server Management Shell installed as a member of the RTCUniversalServerAdmins group.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. From the command line, run the following two commands:

```
Set-CsKerberosAccountPassword -UserAccount "Domain\UserAccount"
```

For example:

```
Set-CsKerberosAccountPassword -UserAccount "contoso\KerbAuth"
```

Note:
You must specify the UserAccount parameter by using the Domain\User format. The User@Domain.extension format is not supported for referencing the computer objects created for Kerberos authentication purposes.

Important:

After making any changes to Kerberos authentication, such as adding an account or removing an account, you must run **Enable-CsTopology** from the Lync Server Management Shell command prompt.

1.4.1.10.4.2 Synchronize a Kerberos Authentication Account Password to IIS

Synchronize a Kerberos Authentication Account Password to IIS

Deploying Lync Server 2013 > Setting Up Kerberos Authentication > Setting Up Kerberos Authentication Account Passwords >

Topic Last Modified: *2010-11-08*

To successfully complete this procedure you should be logged on as a user who is a member of the RTCUniversalServerAdmins group.

In a site, Front End Servers, Standard Edition servers, and Directors can use a Kerberos authentication account for purposes of authenticating requests to the Web Services service. This procedure locates each server running Web Services in a site that has been assigned a Kerberos account and updates the Internet Information Services (IIS) configuration settings to use the Kerberos account. For details, see Set a Kerberos Authentication Account Password on a Server.

⊟To set and configure a Kerberos authentication account password

1. Log on to a source computer (such as fe01.contoso.com) as a member of RTCUniversalServerAdmins group.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. From the Lync Server Management Shell command line, run the following two commands:

   ```
   Set-CsKerberosAccountPassword -FromComputer SourceComputer -ToComputer
   ```

   For example:

   ```
   Set-CsKerberosAccountPassword -FromComputer fe01.contoso.com -ToComput
   ```

◆Important:

The name of the source computer and destination computer must be a fully qualified domain (FQDN) name of the server. You cannot use the pool FQDN unless the pool name is the same as the name of the computer that you are using as a source computer or destination computer.

◆Important:

After making any changes to Kerberos authentication, such as adding an account or removing an account, you must run **Enable-CsTopology** from the Lync Server Management Shell command prompt.

1.4.1.10.5 Add Kerberos Authentication to Other Sites

Add Kerberos Authentication to Other Sites

Deployment > Deploying Lync Server 2013 > Setting Up Kerberos Authentication >

Topic Last Modified: *2010-11-03*

If you need to add sites to an existing deployment that you have configured for Kerberos authentication, you can use an existing Kerberos authentication account for the new site or create a new account. For details about creating a new account for a site, see Create a Kerberos Authentication Account. For details about using the same account for a new site by assigning an existing account to the site, see Assign a Kerberos Authentication Account to a Site.

1.4.1.10.6 Remove Kerberos Authentication from a Site

Remove Kerberos Authentication from a Site

Deployment > Deploying Lync Server 2013 > Setting Up Kerberos Authentication >

Topic Last Modified: *2012-01-16*

To successfully complete this procedure you should be logged on as a user who is a member of the RTCUniversalServerAdmins group.

If you need to remove Kerberos authentication from a site or retire a site, you must remove the Kerberos authentication account assignment from the site by using the **Remove-CsKerberosAccountAssignment** cmdlet. Use the following procedure to remove the Kerberos authentication account assignment, which removes the assignment from all computers in the site.

⚠**Warning:**

If you are permanently retiring the Kerberos-enabled account, you should use Active Directory Users and Computers to delete it from Active Directory Domain Services (AD DS) after you have removed the assignment. If you plan to use the object in the future, you might want to keep the Active Directory object.

⊟To remove Kerberos authentication from a site

1. As a member of the RTCUniversalServerAdmins group, log on to a computer in the domain running Lync Server 2013 or on to a computer where the administrative tools are installed.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. From the command line, run the following two commands:

```
Remove-CsKerberosAccountAssignment -Identity "site:SiteName"
```

```
Enable-CsTopology
```

For example:

```
Remove-CsKerberosAccountAssignment -Identity "site:Redmond"
```

```
Enable-CsTopology
```

Important:

After making any changes to Kerberos authentication, such as adding an account or removing an account, you must run **Enable-CsTopology** from the Lync Server Management Shell command prompt.

1.4.1.10.7 Testing and Reporting the Status and Assignment of Kerberos Authentication

Testing and Reporting the Status and Assignment of Kerberos Authentication

Deployment > Deploying Lync Server 2013 > Setting Up Kerberos Authentication >

Topic Last Modified: *2010-11-03*

If you need to test the Kerberos assignments or determine the status of Kerberos authentication, you can use Windows PowerShell cmdlets.

- Test and Report Functional Readiness for Kerberos Authenticaion
- Report Kerberos Account Assignments

1.4.1.10.7.1 Test and Report Functional Readiness for Kerberos Authenticaion

Test and Report Functional Readiness for Kerberos Authenticaion

Deploying Lync Server 2013 > Setting Up Kerberos Authentication > Testing and Reporting the Status and Assignment of Kerberos Authentication >

Topic Last Modified: *2012-01-16*

To successfully complete this procedure you should be logged on as a user who is a member of the RTCUniversalServerAdmins group.

You can use the **Test-CsKerberosAccountAssignment** Windows PowerShell cmdlet to test and report the functional readiness of a site assignment for Kerberos authentication. This command queries the site specified in the required Identity parameter. The optional Report parameter causes the cmdlet to write an HTML report to C:\Logs on the computer on which the command is run. The optional Verbose parameter reports activity information to the screen.

To test and report functional readiness for Kerberos authentication for a site

1. As a member of the RTCUniversalServerAdmins group, log on to a computer in the domain running Lync Server 2013 or on to the computer where the administrative tools are installed.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. From the command line, run the following command:

   ```
   Test-CsKerberosAccountAssignment -Identity "site:SiteName" -Report "c:
   ```

   For example:

   ```
   Test-CsKerberosAccountAssignment -Identity "site:Redmond" -Report "c:\
   ```

1.4.1.10.7.2 Report Kerberos Account Assignments

Report Kerberos Account Assignments

Deploying Lync Server 2013 > Setting Up Kerberos Authentication > Testing and Reporting the Status and Assignment of Kerberos Authentication >

Topic Last Modified: *2012-01-16*

To successfully complete this procedure you should be logged on as a user who is a member of the RTCUniversalServerAdmins group.

You can use the **Get-CsKerberosAccountAssignment** cmdlet to query information about the Kerberos authentication account assignments and report information about the current assignments in your deployment.

⊟To query Kerberos authentication account assignments for a site

1. As a member of the RTCUniversalServerAdmins group, log on to a computer in the domain running Lync Server 2013 or on to a computer where the administrative tools are installed.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. From the command line, run one of the following commands:
   - To query all Kerberos authentication account assignments in your organization and return assignment information about each of them, run the cmdlet without any parameters:

     ```
     Get-CsKerberosAccountAssignment
     ```

   - To query all Kerberos authentication account assignments in your deployment and return site assignment information about each of them, run the cmdlet with the Identity parameter:

     ```
     Get-CsKerberosAccountAssignment -Identity "site:SiteName"
     ```

     For example:

     ```
     Get-CsKerberosAccountAssignment -Identity "site:Redmond"
     ```

   - To query all Kerberos authentication account assignments in a single site and return assignment information about each of them, run the cmdlet with the Filter parameter:

     ```
     Get-CsKerberosAccountAssignment -Filter "SiteName"
     ```

     For example:

     ```
     Get-CsKerberosAccountAssignment -Filter "*Redmond"
     ```

     Note:
     Specifying *SiteName for the Filter parameter returns information about all sites that contain the specified site name anywhere in the site identifier (for example, all sites that contain the string Redmond in the site identifier).

1.4.2 Deploying External User Access

Deploying External User Access

Microsoft Lync Server 2013 > Deployment >

Topic Last Modified: *2012-09-20*

Deploying edge components for Microsoft Lync Server 2013 makes it possible for external users who are not logged into your organization’s internal network, including authenticated and anonymous remote users, federated partners (including XMPP partners), mobile clients and users of public instant messaging (IM) services, to communicate with other users in your organization using Lync Server. The deployment and configuration processes for Lync Server 2013 are not significantly different from Lync Server 2010. The tools for installation and administration are much the same as in Lync Server 2010.

> **Important:**
> Microsoft Lync Server 2013 Edge Server installation and configuration can be a complex process requiring a potentially significant amount of planning and coordination with your internal teams, including – but not limited to – security, networking, firewall, domain name system (DNS), load balancer, and public key infrastructure (PKI) considerations. It is strongly recommended that you review and use the planning process and documentation provided before deploying your external access components. This will assist in limiting the number and frequency of undesired changes and problems as you proceed through the deployment process. For information on planning you external user access, see Planning for External User Access.

- Deployment Checklist for External User Access
- System Requirements for External User Access Components
- Preparing for Installation of Servers in the Perimeter Network
- Building an Edge and Director Topology
- Setting Up the Director (optional)
- Setting Up Edge Servers
- Setting Up Reverse Proxy Servers
- Configuring Support for External User Access
- Configuring SIP Federation, XMPP Federation and Public Instant Messaging
- Deploying Mobility
- Verifying Your Edge Deployment

1.4.2.1 Deployment Checklist for External User Access

Deployment Checklist for External User Access

Microsoft Lync Server 2013 > Deployment > Deploying External User Access >

Topic Last Modified: *2013-01-11*

Before you deploy your perimeter network and implement support for external users, you must already have deployed your Microsoft Lync Server 2013 internal servers, including a Front End pool or a Standard Edition server. If you plan to deploy the optional Directors in your internal network, you should also deploy them prior to deploying Edge Servers. For details about the Director deployment process, see Scenarios for the Director in the Planning documentation.

Microsoft Lync Server 2013 includes tools to facilitate planning and deployment of both internal servers and Edge Servers. After the topology is completed, publish the resulting topology definition to your production environment. To do this, you must be a member of the **Domain Admins** group and the **RTCUniversalServerAdmins** group.

- **Planning Tool** Office Communications Server 2007 R2 included a Planning Tool and an Edge Planning Tool that you could use to help guide topology design. In Lync Server 2010, these two tools were combined into a single Planning Tool that has additional features and functionality, such as collecting planned user count, voice requirements, external user access types, and federation options. Additionally, you can plan your infrastructure’s network parameters, such as IP addresses, load balancer types and other perimeter network considerations.
- **Topology Builder** Lync Server 2013 Topology Builder helps you define your topology and components. Topology Builder is essential to deploying servers running Lync Server 2013. Topology Builder publishes the results to a Central Management store that is used to configure all of the servers running Lync Server 2013 in your organization. You cannot install Lync Server 2013 on servers without using Topology Builder.

If you designed your edge topology during your planning process, including running

Topology Builder to define your edge topology, you can use those results to start your Edge Server deployment. If you did not finish building your edge topology earlier or you want to change the information you previously specified, you must finish running Topology Builder before proceeding with other deployment steps. For details about how to build your topology, see Scenarios for External User Access.

For details about the Planning Tool and Topology Builder, see Beginning the Planning Process in the Planning documentation.

The following table provides an overview of the Edge Server deployment process. To review the planning decisions that must be made before deploying external user access, see Scenarios for External User Access.

⚠**Warning:**

The information in the following table focuses on a new deployment. If you have deployed Edge Servers in an Lync Server 2013, Office Communications Server 2007 R2 or Office Communications Server 2007 environment, see the Migration for details about migrating to Lync Server 2013. Migration is not supported from any version prior to Office Communications Server 2007 R2, including Office Communications Server 2007, Live Communications Server 2005, and Live Communications Server 2003.

To enhance Edge Server performance and security, and to facilitate deployment, apply the following best practices when you deploy your perimeter network and Edge Servers:

- Deploy Edge Servers only after you have tested and verified operation of Lync Server 2013 inside your organization.
- We recommend that you deploy Edge Servers in a workgroup rather than a domain. Doing so simplifies installation and keeps Active Directory Domain Services (AD DS) out of the perimeter network. Locating AD DS in the perimeter network can present a significant security risk.
- Joining an Edge Server to a domain located entirely in the perimeter network is supported but not recommended. An Edge Server as part of the internal domain violates trusted network boundaries, where the Internet is least trusted, perimeter network is more trusted than the Internet, and the internal network is most trusted. An Edge server as a member of the domain is automatically a part of the most trusted network, but resides in a less trusted network (the perimeter).

Deployment Process for Edge Servers

Phase	**Steps**	**Permissions**	**Documentation**
Create the appropriate edge topology and determine the appropriate components.	• Run Topology Builder to configure Edge Server settings and create and publish the topology, and then use Lync Server Management Shell to export the topology configuration file.	**Domain Admins** group and **RTCUniversalServerAdmins** or **CsAdmins** group 📝**Note:** You can define a topology using an account that is a member of the local users group, but publishing a	Building an Edge and Director Topology in the Deployment documentation

		topology requires an account that is a member of the **Domain Admins** group and the **RTCUniversalServerAdmins** group.	
Prepare for setup.	1. Ensure that system prerequisites are met. 2. Configure IP addresses (IPv4 and IPv6, if used) for both internal and public facing network interfaces on each Edge Server. 3. Configure internal and external DNS records (host A and AAAA for IPv4 and IPv6), including configuring the DNS suffix on the computer to be deployed as an Edge Server. 4. (Optional) Create and install public certificates. The time required to obtain certificates depends on which certification authority (CA) issues the certificate. If you do not perform this step at this point, you must do it during Edge Server installation. The Edge Server services cannot be started until certificates are obtained and installed. 5. Provision support for public IM connectivity, if your deployment is to support communications with Windows Live, AOL, or Yahoo! users. **Important:** - As of September 1st, 2012, the Microsoft Lync Public IM Connectivity User Subscription License (“PIC USL”) is no longer available for purchase for new or renewing agreements. Customers with active licenses will be able to	As appropriate to your organization	Preparing for Installation of Servers in the Perimeter Network in the Deployment documentation

	continue to federate with Yahoo! Messenger until the service shut down date (exact date TBD, but no sooner than June 2013). • The PIC USL is a per-user per-month subscription license that is required for Lync Server or Office Communications Server to federate with Yahoo! Messenger. Microsoft's ability to provide this service has been contingent upon support from Yahoo!, the underlying agreement for which is winding down. • More than ever, Lync is a powerful tool for connecting across organizations and with individuals around the world. Federation with Windows Live Messenger requires no additional user/ device licenses beyond the Lync Standard CAL. Skype federation will be added to this list, enabling Lync users to reach hundreds of millions of people with IM		

	and voice. 1. Provision support for XMPP and federation support for Office Communications Server 2007, Office Communications Server 2007 R2, Lync Server 2010 partners, if your deployment will use these 2. Configure firewalls.		
Set up reverse proxy.	• Set up the reverse proxy (for example, for Microsoft Forefront Threat Management Gateway 2010 or Microsoft Internet Security and Acceleration (ISA) Server with Service Pack 1) in the perimeter network, obtain the necessary public certificates, and configure the web publishing rules on the reverse proxy server. Prepare the reverse proxy for Mobility services if you have planned for Mobility and are deploying the Mobility services on the Front End pool or Standard Edition server.	**Administrators** group or Reverse Proxy administrator	Setting Up Reverse Proxy Servers in the Deployment documentation
Setup a Director (optional).	• (Optional) Install and configure one or more Directors in the internal network.	**Administrators** group	Setting Up the Director in the Deployment documentation
Set up Edge Servers.	1. Install prerequisite software. 2. Transport the exported topology configuration file to each Edge Server. 3. Install the Lync Server 2013 software on each Edge Server. 4. Configure the Edge Servers. 5. Request and install certificates for each Edge Server. 6. Start the Edge Server services.	**Administrators** group	Setting Up Edge Servers in the Deployment documentation
Configure deployment for external user access.	1. Use the Lync Server Control Panel to configure support for each of the following (as applicable): • Media relay • Federation route • Remote user access • Federation with Lync Server, Office Communications Server and Live Communications Server • Public IM connectivity • XMPP federation • Anonymous users	**RTCUniversalServerAdmins** group or user account that is assigned to the **CSAdministrator** role	Configuring Support for External User Access in the Deployment documentation

	2. Configure user accounts for remote user access, federation, public IM connectivity, XMPP and anonymous user support (as applicable)		
Verify your Edge Server configuration.	1. Verify server connectivity and replication of configuration data from internal servers. 2. Verify that external users can connect, including remote users, users in federated domains, public IM users, and anonymous users, as appropriate to your deployment. 3. Verify configuration and communication using the Lync Server Remote Connectivity Analyzer https://www.testocsconnectivity.com 4. Troubleshoot configuration and communication difficulties	For verification of replication, **RTCUniversalServerAdmins** group or user account that is assigned to the **CSAdministrator** role For verification of user connectivity, a user for each type of external user access that you support Remote users	Verifying Your Edge Deployment in the Deployment documentation

1.4.2.2 System Requirements for External User Access Components

System Requirements for External User Access Components

Microsoft Lync Server 2013 > Planning > Planning for External User Access >

Topic Last Modified: *2013-01-17*

System requirements for edge components include hardware, software, and collocation requirements for Edge Servers, reverse proxy servers and optional Directors that you plan to deploy.

- Components Required for External User Access
- Configuration Requirements for Reverse Proxy
- Hardware Load Balancer Requirements
- Hardware and Software Requirements for Edge Components
- Supported Server Collocation for Edge Components

1.4.2.2.1 Components Required for External User Access

Components Required for External User Access

See Also

Planning > Planning for External User Access > System Requirements for External User Access Components >

Topic Last Modified: *2013-01-17*

Most Edge components are deployed in a perimeter network. The following components make up the edge topology of the perimeter network. Except where noted, the components are part of the Scenarios for External User Access and are in the perimeter network. Edge components include the following:

- Edge Servers
- Reverse proxies
- Firewalls
- Directors (optional, and logically located on the internal network)
- Load balancing for Scaled Edge Topologies (either DNS load balancing or a hardware load balancer)

Important:

Using DNS load balancing on one interface and hardware load balancing on the other is not supported. You must use hardware load balancing for both interfaces or DNS load balancing for both.

Edge Servers

The Edge Servers send and receive network traffic for the services offered by internal deployment by external users. The Edge Server runs the following services:

- **Access Edge service** The Access Edge service provides a single, trusted connection point for both outbound and inbound Session Initiation Protocol (SIP) traffic.
- **Web Conferencing Edge service** The Web Conferencing Edge service enables external users to join meetings that are hosted on your internal Lync Server 2013 deployment.
- **A/V Edge service** The A/V Edge service makes audio, video, application sharing, and file transfer available to external users. Your users can add audio and video to meetings that include external participants, and they can communicate using audio and/or video directly with an external user in point-to-point sessions. The A/V Edge service also provides support for desktop sharing and file transfer.
- **XMPP Proxy service** The XMPP Proxy service accepts and sends extensible messaging and presence protocol (XMPP) messages to and from configured XMPP Federated partners.

Authorized external users can access the Edge Servers in order to connect to your internal Lync Server 2013 deployment, but the Edge Servers do not provide a means for any other access to the internal network.

Reverse Proxy

The reverse proxy is required for the following:

- To allow users to connect to meetings or dial-in conferences using simple URLs
- To enable external users to download meeting content
- To enable external users to expand distribution groups
- To allow the user to obtain a user-based certificate for client certificate based authentication
- To enable remote users to download files from the Address Book Server or to submit queries to the Address Book Web Query service
- To enable remote users to obtain updates to client and device software
- To enable mobile devices to automatically discover Front End Servers offering mobility services
- To enable push notifications to mobile devices from the Office 365 or Apple push notification services

For additional information related to reverse proxies and the requirements that reverse proxies must meet, see the details in Configuration Requirements for Reverse Proxy.

Note:

External users do not need a virtual private network (VPN) connection to your organization in order to participate in communications using Lync Server 2013. If you have implemented VPN technology in your organization and your users use the VPN for Lync, media traffic (such as video conferencing) can be adversely affected. You should consider providing a means for media traffic to connect to the AV Edge service directly and bypass the VPN. For details, see the NextHop Blog article, "Enabling Lync Media to Bypass a VPN Tunnel," at http://go.microsoft.com/fwlink/p/?LinkId=256532.

Firewall

You can deploy your edge topology with only an external firewall or both external and internal firewalls. The scenario architectures include two firewalls. Using two firewalls is the recommended approach because it ensures strict routing from one network edge to the other, and it protects your internal deployment behind two levels of firewall.

Director

A Director is a separate, optional server role in Lync Server 2013 that does not home user accounts, or provide presence or conferencing services. It serves as an internal next hop server to which an Edge Server routes inbound SIP traffic destined for internal servers. The Director preauthenticates inbound requests and redirects them to the user's home pool or server. By preauthenticating at the Director, you can drop requests from user accounts that are unknown to the deployment.

A Director helps insulate Standard Edition servers and Front End Servers in Enterprise Edition Front End pools from malicious traffic such as denial-of-service (DoS) attacks. If the network is flooded with invalid external traffic in such an attack, the traffic ends at the Director. For details about the use of Directors, see Scenarios for the Director.

Concepts

Hardware Load Balancer Requirements

1.4.2.2.2 Hardware Load Balancer Requirements

Hardware Load Balancer Requirements

Planning > Network Planning for Lync Server > Load Balancing Requirements >

Topic Last Modified: *2012-10-22*

The Lync Server 2013 scaled consolidated Edge topology is optimized for DNS load balancing for new deployments federating primarily with other organizations using Lync Server. If high availability is required for any of the following scenarios, a hardware load balancer must be used on Edge Server pools for the following:

- Federation with organizations using Office Communications Server 2007 R2 or Office Communications Server 2007
- Exchange UM for remote users using Exchange UM prior to Exchange 2010 with SP1
- Connectivity to public IM users

Important:

Using DNS load balancing on one interface and hardware load balancing on the other is not supported. You must use hardware load balancing for both interfaces or DNS load balancing for both.

Note:

If you are using a hardware load balancer, the load balancer deployed for connections with the internal network must be configured to load balance only the traffic to servers running the Access Edge service and the A/V Edge service. It cannot load balance the traffic to the internal Web Conferencing Edge service or the internal XMPP Proxy service.

Note:

The direct server return (DSR) NAT is not supported with Lync Server 2013.

To determine whether your hardware load balancer supports the necessary features required by Lync Server 2013, see "Lync Server 2010 Load Balancer Partners" at http://go.microsoft.com/fwlink/p/?linkId=202452.

Hardware Load Balancer Requirements for Edge Servers Running the A/V Edge Service

Following are the hardware load balancer requirements for Edge Servers running the A/V Edge service:

- Turn off TCP nagling for both internal and external ports 443. Nagling is the process of combining several small packets into a single, larger packet for more efficient transmission.
- Turn off TCP nagling for external port range 50,000 – 59,999.
- Do not use NAT on the internal or external firewall.
- The edge internal interface must be on a different network than the Edge Server external interface and routing between them must be disabled.
- The external interface of the Edge Server running the A/V Edge Service must use publically routable IP addresses and no NAT or port translation on any of the edge external IP addresses.

Hardware Load Balancer Requirements

Cookie-based affinity requirements are greatly reduced in Lync Server 2013 for Web services. If you are deploying Lync Server 2013 and will not retain any Lync Server 2010 Front End Servers or Front End pools, you do not need cookie-based persistence. However, if you will temporarily or permanently retain any Lync Server 2010 Front End Servers or Front End pools, you still use cookie-based persistence as it is deployed and configured for Lync Server 2010.

Note:

If you decide to use cookie-based affinity even though your deployment does not require it, there is no negative impact to doing so.

For deployments that **will not use** cookie-based affinity:

- On the reverse proxy publishing rule for port 4443, set **Forward host header** to True. This will ensure that the original URL is forwarded.

For deployments that **will use** cookie-based affinity:

- On the reverse proxy publishing rule for port 4443, set **Forward host header** to True. This will ensure that the original URL is forwarded.
- Hardware load balancer cookie MUST NOT be marked httpOnly
- Hardware load balancer cookie MUST NOT have an expiration time

- Hardware load balancer cookie MUST be named **MS-WSMAN** (This is the value that the Web services expect, and cannot be changed)
- Hardware load balancer cookie MUST be set in every HTTP response for which the incoming HTTP request did not have a cookie, regardless of whether a previous HTTP response on that same TCP connection had already obtained a cookie. If the load balancer optimizes cookie insert to only occur once per TCP connection, that optimization MUST NOT be used

Note:

Typical hardware load balancer configurations use source-address affinity and a 20 min. TCP session lifetime, which is fine for Lync Server and Lync 2013 clients because session state is maintained through client usage and/or and application interaction.

If you are deploying mobile devices, your hardware load balancer must be able to load balance individual request within a TCP session (in effect, you must be able to load balance an individual request based on the target IP address).

Warning:

F5 hardware load balancers have a feature called OneConnect that ensures each request within a TCP connection is individually load balanced. If you are deploying mobile devices, ensure your hardware load balancer vendor supports the same functionality. The latest Apple iOS mobile apps require Transport Layer Security (TLS) version 1.2. F5 provides specific settings for this.
For details on third party hardware load balancers, see http://go.microsoft.com/fwlink/p/?linkId=230700

Following are the hardware load balancer requirements for Director and Front End pool Web Services:

- For internal Web Services VIPs, set Source_addr persistence (internal port 80, 443) on the hardware load balancer. For Lync Server 2013, Source_addr persistence means that multiple connections coming from a single IP address are always sent to one server to maintain session state.
- Use TCP idle timeout of 1800 seconds.
- On the firewall between the reverse proxy and the next hop pool’s hardware load balancer, create a rule to allow https: traffic on port 4443, from the reverse proxy to the hardware load balancer. The hardware load balancer must be configured to listen on ports 80, 443, and 4443.

Summary of Hardware Load Balancer Affinity Requirements

Client/user location	External web services FQDN affinity requirements	Internal web services FQDN affinity requirements
Lync Web App (internal and external users) Mobile device (internal and external users)	No affinity	Source address affinity
Lync Web App (external users only) Mobile device (internal and external users)	No affinity	Source address affinity
Lync Web App (internal users only)	No affinity	Source address affinity

Mobile device (not deployed)		

Port Monitoring for Hardware Load Balancers

You define port monitoring on the hardware load balancers to determine when specific services are no longer available due to hardware or communications failure. For example, if the Front End Server service (RTCSRV) stops because the Front End Server or Front End pool fails, the HLB monitoring should also stop receiving traffic on the Web Services. You implement port monitoring on the HLB to monitor the following:

Front End Server User Pool – HLB Internal Interface

Virtual IP/Port	Node Port	Node Machine/ Monitor	Persistence Profile	Notes
<pool>web-int_mco_443_vs 443	443	Front End 5061	Source	HTTPS
<pool>web-int_mco_80_vs 80	80	Front End 5061	Source	HTTP

Front End Server User Pool – HLB External Interface

Virtual IP/Port	Node Port	Node Machine/ Monitor	Persistence Profile	Notes
<pool>web_mco_443_vs 443	4443	Front End 5061	None	HTTPS
<pool>web_mco_80_vs 80	8080	Front End 5061	None	HTTP

1.4.2.2.3 Hardware and Software Requirements for Edge Components

Hardware and Software Requirements for Edge Components

Planning > Planning for External User Access > System Requirements for External User Access Components >

Topic Last Modified: *2013-02-21*

The hardware and software requirements for edge components include those for the Microsoft Lync Server 2013 communications software components, including Edge Servers and the optional Directors, as well as those for other components, including reverse proxy servers, firewalls, and load balancers to be deployed the perimeter network to support external user access. For details about the components required to support external user access and supported topologies, see Components Required for External User Access.

Hardware and Software Requirements for Edge Servers

The operating system requirements for Edge Servers are the same as for the other Lync Server 2013 roles: the 64-bit edition of the Windows Server 2008 R2 SP1 or Windows Server 2012.

The following table shows the hardware requirements for Edge Servers.

Hardware System Requirements for Edge Servers

Hardware component	Minimum requirement
CPU	One of the following: • 64-bit dual processor, quad-core, 2.0 GHz or higher • 64-bit 4-way processor, dual-core, 2.0 GHz or higher
Memory	12 GB recommended
Disk	• One of the following: • 10K RPM hard disk drive (HDD) • High-performance solid state drive (SSD) with performance equal to or better than 10K RPM HDD • 2x RAID 10 (striped and mirrored) 15K RPM disk set
Network	Two interfaces required, either one 2-port 1 Gbps NIC or two 1-port 1 Gbps NICs.

Lync Server 2013 is available only in 64-bit, therefore each Edge Server requires one of the following operating systems.

- Windows Server 2008 R2 Enterprise Edition with SP1 operating system, or Windows Server 2008 R2 Standard Edition with SP1 operating system.
- Windows Server 2012 Enterprise or Datacenter operating system.

Directors are internal components and installed as part of the internal network prior to deployment of Edge Servers. For hardware and software requirements for Directors, see Hardware and Software Requirements for the Director.

Lync Server 2013 Edge Servers require the installation of additional programs and updates. The requirements for additional software on Edge Servers are listed here.

- Each server running Lync Server 2013 must have the correct release of Windows PowerShell 3.0 installed. For details, see Installing Windows PowerShell 3.0.
- Lync Server requires Microsoft .NET Framework 4.5. For Lync Server 2013 installed on Windows Server 2008 R2, you must manually install the 64-bit edition of Microsoft .NET Framework 4.5 on the server prior to installing Lync Server 2013. To manually install it, download the Microsoft .NET 4.5 Framework from the Microsoft Download Center at http://go.microsoft.com/fwlink/p/?LinkId=268529
- **Windows Identity Foundation** in Lync Server 2013 requires the installation of Windows Identity Foundation in order to support server to server authentication scenarios. Windows Server 2008 R2 and Windows Server 2012

require different procedures to install the Windows Identify Foundation. Select your server operating system from the following list:

- Windows Server 2008 R2   For Windows Server 2008 R2, you check to see if it has already been installed on your computer. To do this, go to **Add/ Remove Programs**, **View Installed Updates**, and look under **Windows** for the entry **Windows Identity Foundation (KB974405)**. For details about installing Windows Identity Foundation, see http://go.microsoft.com/fwlink/?LinkId=285258.
- Windows Server 2012   For Windows Server 2012, you use **Server Manager** to install the Windows Identity Foundation. In the Server Manager **Add Roles and Features Wizard**, select **Features**. Select **Windows Identity Foundation 3.5** from the list. Click **Next**, then click **Install**.

1.4.2.2.4 Supported Server Collocation for Edge Components

Supported Server Collocation for Edge Components

Planning > Planning for External User Access > System Requirements for External User Access Components >

Topic Last Modified: *2012-09-08*

The Access Edge service, Web Conferencing Edge service, A/V Edge service and XMPP Proxy service are collocated on the Edge Servers. The following servers provide functions needed for external user access and must be deployed as dedicated servers:

- Edge Server
- Director (Optional)
- Reverse proxy

Important:

The reverse proxy does not need to be dedicated to serving only Lync Server 2013. For example, you can provide services to publish the Lync Server Web services, and concurrently provide a published Web site for another Web site that has no bearing on Lync Server at all. If you already have a reverse proxy server in the perimeter network to support other services, you can use it for Lync Server 2013.

1.4.2.3 Preparing for Installation of Servers in the Perimeter Network

Preparing for Installation of Servers in the Perimeter Network

Microsoft Lync Server 2013 > Deployment > Deploying External User Access >

Topic Last Modified: *2012-09-08*

Before you set up Edge Server components, you need to ensure that computers that you are setting up meet system requirements and complete other prerequisite steps required for deployment of Edge Server components.

Before you begin, review the details in the following topics in the Planning documentation for the reference architecture that you want to deploy:

- Single Consolidated Edge with Private IP Addresses and NAT
- Single Consolidated Edge with Public IP Addresses
- Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT
- Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses

- Scaled Consolidated Edge with Hardware Load Balancers
- Configure DNS for Edge Support
- Set Up Hardware Load Balancers for Scaled Edge Topologies
- Configure Firewalls and Ports for External User Access
- Determine External A/V Firewall and Port Requirements
- Request Certificates for Edge Components

1.4.2.3.1 Configure DNS for Edge Support

Configure DNS for Edge Support

See Also

Deployment > Deploying External User Access > Preparing for Installation of Servers in the Perimeter Network >

Topic Last Modified: *2013-02-15*

You must configure Domain Name System (DNS) records for internal and external edge interfaces, including both Edge Server and reverse proxy interfaces. By default, Edge Servers are not joined to a domain and will not have a fully qualified domain name (fully qualified domain name). The Edge Server is only referred to by the short (machine) name, not a fully qualified domain name. However, Topology Builder uses FQDNs, not short names. The name of the Edge Server must match the FQDN used by Topology Builder. To do this, you define a DNS suffix that, when combined with the machine name, results in the expected FQDN. Use the following procedure in "To add the DNS suffix to the computer name on and Edge Server that is not joined to a domain" to add the DNS suffix to the computer name.

Note:

By default, DNS uses a round robin algorithm to rotate the order of resource record data returned in query answers where multiple resource records of the same type exist for a queried DNS domain name. Lync Server 2013 DNS load balancing, depends on DNS round-robin as a part of the DNS Load Balancing mechanism. Verify that round-robin setting has not been disabled. If you are using a DNS server that is not running a Windows operating system, verify that round-robin resource record ordering is enabled.

Use the following procedures in "**To create a DNS SRV record**" to create and verify each DNS SRV record. Use the procedure in "**To create a DNS A record**" to define the DNS A records required for external user access. To confirm that the records are configured and working correctly, see "**To verify a DNS record**" in this topic. For details about each record required to support external user access, see Determine DNS Requirements.

⊟To add the DNS suffix to the computer name on an Edge Server that is not joined to a domain

1. On the computer, click **Start**, right-click **Computer**, and then click **Properties**.
2. Under **Computer name, domain, and workgroup settings**, click **Change settings**.
3. On the **Computer Name** tab, click **Change**.
4. In **Computer Name/Domain Changes**, click **More**.
5. In **DNS Suffix and NetBIOS Computer Name**, in **Primary DNS suffix of this computer**, type the name of your internal domain (for example, corp.contoso.com), and then click **OK** three times.
6. Restart the computer.

⊟To create a DNS SRV record

1. On the appropriate DNS server, click **Start**, click **Control Panel**, click **Administrative Tools**, and then click **DNS**.

Important:
You need to configure DNS so that there are: 1) external DNS entries for external DNS lookups by remote users and federated partners; 2) entries for DNS lookups for use by the Edge Servers within the perimeter network (also known as DMZ, demilitarized zone, and screened subnet), including A records for the internal servers running Lync Server 2013; and 3) internal DNS entries for lookups by the internal clients and servers running Lync Server 2013.

2. In the console tree for your SIP domain, expand **Forward Lookup Zones**, and then right-click the domain where Lync Server 2013 is installed.
3. Click **Other New Records**.
4. In **Select a resource record type**, type **Service Location (SRV)**, and then click **Create Record**.
5. Provide all required information for the DNS SRV record.

⊟To create a DNS A record

1. On the DNS server, click **Start**, click **Control Panel**, click **Administrative Tools**, and then click **DNS**.
2. In the console tree for your SIP domain, expand **Forward Lookup Zones**, and then right-click the domain in which Lync Server 2013 is installed.
3. Click **New Host (A)**.
4. Provide all required information for the DNS SRV record.

⊟To verify a DNS record

1. Log on to a client computer in the domain.
2. Click **Start**, and then click **Run**.
3. At the command prompt, run the following command:

```
nslookup <FQDN edge interface>
```

4. Verify that you receive a reply that resolves to the appropriate IP address for the FQDN.

Tasks

Create a DNS SRV Record for Integration with Hosted Exchange UM

If you are configuring a scaled edge topology using a hardware load balancer, see Scaled Consolidated Edge with Hardware Load Balancers in the Planning documentation.

1.4.2.3.3 Configure Firewalls and Ports for External User Access

Configure Firewalls and Ports for External User Access

See Also

Deployment > Deploying External User Access > Preparing for Installation of Servers in the Perimeter Network >

Topic Last Modified: *2012-05-21*

To configure firewalls and ports, you need to configure them for Edge Servers, reverse proxy servers, and possibly hardware load balancers (for a scaled deployment that does not use DNS load balancing). This section provides information about firewall and port requirements for all Edge Server components and the configuration of firewall ports for Edge Servers. For details about configuring ports for reverse proxy servers, see Setting Up Reverse Proxy Servers. If you are deploying a scaled edge topology and are using hardware load balancing instead of DNS load balancing, see Scaled Consolidated Edge with Hardware Load Balancers in the Planning documentation for details about configuring ports for hardware load balancers.

Concepts

Determine External A/V Firewall and Port Requirements

1.4.2.3.4 Determine External A/V Firewall and Port Requirements

Determine External A/V Firewall and Port Requirements

Microsoft Lync Server 2013 > Planning > Planning for External User Access >

Topic Last Modified: *2012-10-29*

Audio/Video (A/V) communication can be a complex. Because of the nature of protocols used in A/V and how clients and servers use the protocols, a special section is warranted to explain the differences between client and server versions.

Use the following A/V Firewall and Port table to determine firewall requirements and which ports to open. Then, review the network address translation (NAT) terminology because NAT can be implemented in many different ways. For a detailed example of firewall port settings, see the reference architectures in Scenarios for External User Access.

General Protocol Usage for UDP and TCP in Audio/Video and Media Traffic

Audio/Video Transport	Usage
UDP	Preferred transport layer protocol for audio and video
TCP	Fallback transport layer protocol for audio and video Required transport layer protocol for application sharing to Office Communications Server 2007 R2, Lync Server 2010 and Lync Server 2013 Required transport layer protocol for file transfer to Lync Server 2010 and Lync Server 2013

External A/V Firewall Port Requirements for External User Access

The firewall port requirements for external (and internal) SIP and conferencing interfaces are consistent, regardless of the version of your client or the version of the federation partner.

The same is not true for the Audio/Video Edge external interface. For federation with Office Communications Server 2007, the A/V Edge service requires that external firewall rules allow RTP/TCP and RTP/UDP traffic in the 50,000 through 59,999 port range to flow in both directions. The previous table assumes that Lync Server 2013 is the primary federation partner and it is being configured to communicate with one of the other federation partner types listed.

Configuring the Audio/Video port range of 50,000-59,999 must take into account that the port range will contain the source ports for communications to federation partners. In detail, consider that a communication is initiated from a federation partner. The communication from the A/V Edge service ports in the 50,000-59,999 range will connect to the expected port TCP 443 of the partner’s A/V Edge service. Conversely, inbound traffic to your A/V Edge service port TCP 443 will have a source port in the range of 50,000-59,999.

Different firewalls and policies for firewall administration may require only destination rules to be configured, or they may require both source and destination to be configured. If your requirements are for destination ports only, the Audio/Video requirements are:

Source IP	Destination IP	Destination Port
A/V Edge service interface	Any	TCP 443
A/V Edge service interface	Any	UDP 3478
Any	A/V Edge service interface	TCP 443
Any	A/V Edge service interface	UDP 3478

If your policies require both inbound and outbound firewall rule definitions, the Audio/Video requirements are:

Source IP	Destination IP	Source Port	Destination Port
A/V Edge service interface	Any	TCP 50,000-59,999	TCP 443
A/V Edge service interface	Any	UDP 3478	UDP 3478
Any	A/V Edge service interface	Any	TCP 443
Any	A/V Edge service interface	Any	UDP 3478

◆**Important:**

Microsoft Office Communications Server 2007 requires a slightly different configuration. The TCP and UDP port range of 50,000-59,999 must be open inbound and outbound. This requirement is only for Office Communicator 2007. Office Communications Server 2007 R2, Lync Server 2010 and Lync Server 2013 only require TCP range 50,000-59,999 open outbound.

NAT Requirements for External User Access

NAT has typically been a routing function, but newer devices such as firewalls and even hardware load balancers can be configured for NAT. Rather than focusing on which device is performing NAT, this topic describes the required NAT behavior instead.

Lync Server 2013 communications software does not support NAT for traffic to or from the Edge internal interface, but for the Edge external interface, the following NAT behavior is required.

> **◆Important:**
>
> You must configure symmetric NAT for incoming and outgoing traffic. Symmetric NAT is the NAT technology described in this topic.

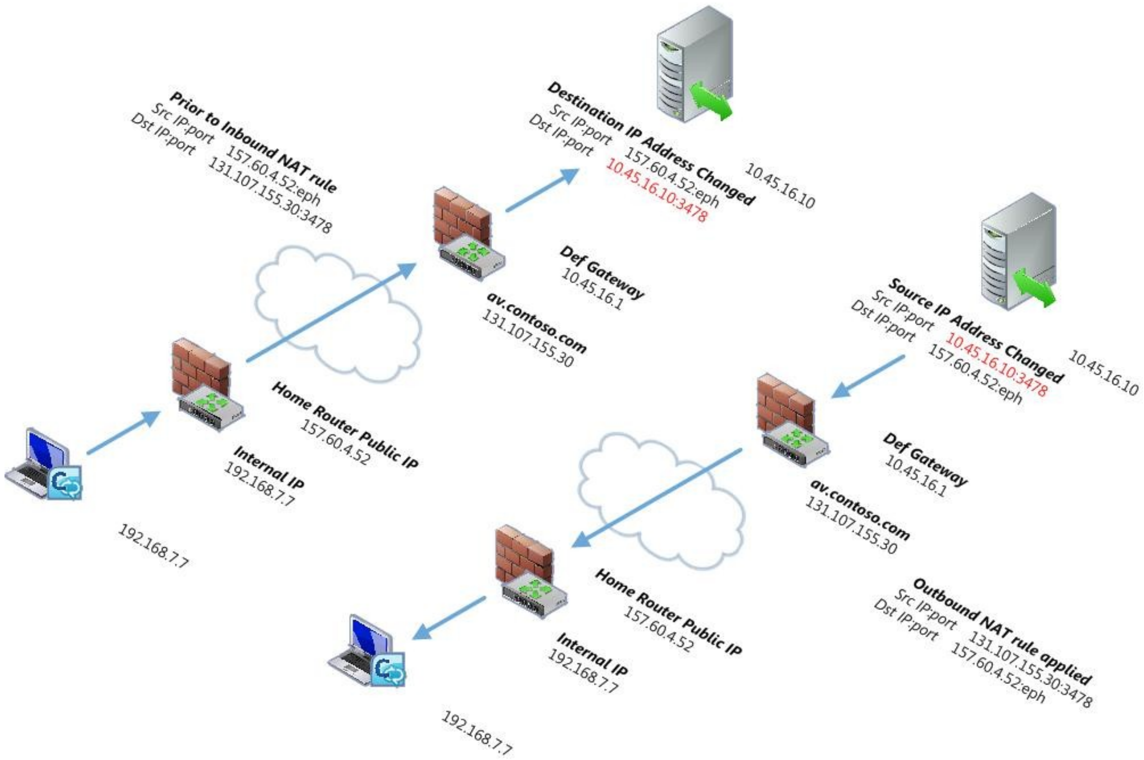
This documentation uses the acronyms ChangeDST and ChangeSRC in tables and drawings to define the following required behavior:

- **ChangeDST** The process of changing the destination IP address on packets destined for the network that is using NAT. This is also known as transparency, port forwarding, destination NAT mode, or half-NAT mode.
- **ChangeSRC** the process of changing the source IP address on packets leaving the network that is using NAT. This is also known as proxy, secure NAT, stateful NAT, source NAT or full-NAT mode.

Regardless of the naming convention used, the NAT behavior required for the external interface of the Edge Server is as follows:

- For traffic from the Internet to the Edge external interface:
  - Change the destination IP address of the incoming packet from the Edge external interface public IP address to the translated IP address of the Edge external interface.
  - Leave the source IP address intact so that there is a return route for the traffic.
- For traffic from the Edge external interface to the Internet:
  - Change the source IP address of the packet leaving the Edge external interface, from the translated IP address to the public IP address of the Edge external interface so that the internal Edge IP address is not exposed and because it is a non-routable IP address.
  - Leave the destination IP address intact on the outgoing packets.

The following figure shows the distinction between changing the destination IP address (ChangeDST) for inbound traffic and changing the source IP Address (ChangeSRC) for outbound traffic using the A/V edge as an example.



Prior to Inbound NAT rule
Src IP:port 157.60.4.52:eph
Dst IP:port 131.107.155.30:3478
Destination IP Address Changed
Src IP:port 157.60.4.52:eph
Dst IP:port 10.45.16.10:3478
10.45.16.10
Def Gateway
10.45.16.1
av.contoso.com
131.107.155.30
Home Router Public IP
157.60.4.52
Internal IP
192.168.7.7
192.168.7.7
Source IP Address Changed
Src IP:port 10.45.16.10:3478
Dst IP:port 157.60.4.52:eph
10.45.16.10
Def Gateway
10.45.16.1
av.contoso.com
131.107.155.30
Outbound NAT rule applied
Src IP:port 131.107.155.30:3478
Dst IP:port 157.60.4.52:eph
Home Router Public IP
157.60.4.52
Internal IP
192.168.7.7
192.168.7.7

The key points are:

- Traffic that is inbound to the server running the A/V Edge service, the source IP address does not change but the destination IP address changes from 131.107.155.30 to the translated IP address of 10.45.16.10.
- Traffic that is outbound from the server running the A/V Edge service back to the workstation, the source IP address changes from the server's public IP address to the public IP address of the server running the A/V Edge service. The destination IP remains the workstation's public IP address. After the packet leaves the first NAT device outbound, the rule on the NAT device changes the source IP address of the server running the A/V Edge service external interface IP address (10.45.16.10) to its public IP address (131.107.155.30).

1.4.2.3.5 Request Certificates for Edge Components

Request Certificates for Edge Components

Deployment > Deploying External User Access > Preparing for Installation of Servers in the Perimeter Network >

Topic Last Modified: *2012-09-08*

The certificates required to support external user access include certificates issued by a public certification authority (CA), and certificates issued by an internal Enterprise CA:

- Certificates required for the external interface of Edge Server and the reverse proxy must be issued by a public CA.
- Certificates required for the internal interface can be issued by either a public CA or an internal enterprise CA. We recommend using an internal Windows Server 2008 CA, Windows Server 2008 R2 CA, or Windows Server 2012 CA for

creating these certificates to save on the expense of using public certificates.

Important:
It can take time to process certificate requests, especially requests to public CAs, so you should request certificates for your Edge Servers early enough to ensure that they are available when you start deployment of your Edge Server components. For a summary of certificate requirements for Edge Servers, see Certificate Requirements for External User Access.

Although you can choose to use a public CA for the internal edge certificate, we recommend that you use an internal enterprise CA for those other certificates instead to minimize the cost of certificates. For a summary of certificate requirements for Edge Servers, see Certificate Requirements for External User Access.

Note:
When you install an Edge Server, setup includes a certificate wizard that facilitates the tasks of requesting, assigning, and installing certificates, as described in the Set Up Edge Certificates section. If you want to request certificates prior to installing an Edge Server (such as to save time during actual deployment of Edge Server components), you can do so using internal servers as long as you ensure that the certificates are exportable and contain all of the required subject alternative names. This documentation does not provide procedures for using internal servers to request certificates.

Request certificates from a public CA

Your Edge Server deployment requires a single public certificate for the external interfaces of Edge Servers, which is used for the Access Edge service, the Web Conferencing Edge service, and for A/V authentication service. This certificate must have an exportable private key to ensure that the A/V authentication service uses the same keys on all Edge Servers in a pool. The reverse proxy, which is used with Microsoft Internet Security and Acceleration (ISA) Server 2006 or Microsoft Forefront Threat Management Gateway 2010, also requires a public certificate.

Request certificates from an internal Enterprise CA

The certificates required for the internal edge interface can be issued by either a public certification authority (CA) or an internal CA. You can use an internal enterprise CA to help minimize the cost of certificates. If your organization has an internal CA deployed, the certificates for the internal edge should be issued by the internal CA. Using an internal enterprise CA for internal certificates can reduce the cost of certificates.

For a summary of certificate requirements for edge components, see Certificate Requirements for External User Access. For details about using a public CA to obtain certificates, see Request Certificates for Edge Components. For details about requesting, installing, and assigning certificates, see Set Up Edge Certificates.

1.4.2.4 Building an Edge and Director Topology

Building an Edge and Director Topology

Microsoft Lync Server 2013 > Deployment > Deploying External User Access >

Topic Last Modified: *2012-09-08*

Building the topology involves the following planning and deployment tasks:

- **Planning** You need to define an appropriate topology for your organization and identify the components required to deploy it. These are standard steps in the planning process. The Microsoft Lync Server 2013, Planning Tool provided with Lync Server 2013 makes it easy to start the planning process, as well as including the ability to easily make changes as your requirements and plans are finalized.
- **Deployment** The topology that you define using Topology Builder is essential to the deployment of any Lync Server 2013 server. If you do not finish defining and publishing your topology by using Topology Builder as part of your planning efforts, you must complete it and publish the topology before you deploy your Edge Servers.

You cannot deploy Edge Server components until you have deployed at least one internal pool, and you must install Topology Builder to deploy an internal pool. This section does not cover installation of Topology Builder because that is part of the installation process for the internal pool.

For details about these tools, see Deployment Checklist for External User Access.

Note:

If you previously used Topology Builder to define a complete topology, including the edge topology, you do can skip the Define Your Edge Topology and Publish Your Topology tasks in this section, but you do need to complete the Export Your Topology and Copy It to External Media for Edge Installation task.

- Define Your Edge Topology
- Define Optional Director Topologies in Your Topology
- Publish Your Topology
- Export Your Topology and Copy It to External Media for Edge Installation

1.4.2.4.1 Define Your Edge Topology

Define Your Edge Topology

Deployment > Deploying External User Access > Building an Edge and Director Topology >

Topic Last Modified: *2012-09-28*

You must use Topology Builder to build your topology and you must set up at least one internal Front End pool or Standard Edition server before you can deploy your Edge Server. Use the following procedure to define the edge topology for a single Edge Server, and then use the procedures in Publish Your Topology and Export Your Topology and Copy It to External Media for Edge Installation to publish the topology and make it available to your Edge Server.

Note:

The internal Edge interface and external Edge interface must use the same type of load balancing. You cannot use DNS load balancing on one Edge interface and hardware load balancing on the other Edge interface.

To successfully publish, enable, or disable a topology when adding or removing a server role, you must be logged in as a user who is a member of the RTCUniversalServerAdmins and Domain Admins groups. You can also grant the administrator rights and permissions required for adding server roles to a user account. For details, see Delegate Setup Permissions in the Standard Edition server or Enterprise Edition server Deployment documentation. For other configuration changes, only membership in the RTCUniversalServerAdmins group is required.

If you defined your edge topology when you defined and published your internal topology, and no changes are required to the edge topology that you previously defined, you do not need to do define it and publish it again. Use the following procedure only if you need to make changes to your edge topology. You must make the previously defined and published topology available to your Edge Servers, which you do by using the procedure in Export Your Topology and Copy It to External Media for Edge Installation.

Important:

You cannot run Topology Builder from an Edge Server. You must run it from your Front End Server or Standard Edition servers.

The process to define your Edge Server topology is done in Topology Builder. The three primary types of Edge Server topologies that you plan and configure are listed below:

- To define the Topology for a Single Edge Server
- To define the Topology for a Load Balanced Edge Server Pool
- To define the Topology for a Hardware Load Balanced Edge Pool

⊟To define the topology for a single Edge Server

1. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
2. In the console tree, expand the site in which you want to deploy an Edge Server.
3. Right-click **Edge pools**, and then click **New Edge Pool**.
4. In **Define the New Edge Pool**, click **Next**.
5. In **Define the Edge pool FQDN**, do the following:
   - In **Pool FQDN**, type the fully qualified domain name (FQDN) of the internal interface for the Edge Server.

     Important:

     The name you specify must be identical to the computer name configured on the server. By default the computer name of a computer that is not joined to a domain is a short name, not an FQDN. Topology Builder uses FQDNs, not short names. So, you must configure a DNS suffix on the name of the computer to be deployed as an Edge Server that is not joined to a domain. Use only standard characters (including A–Z, a–z, 0–9, and hyphens) when assigning FQDNs of your Lync Servers, Edge Servers, and pools. Do not use Unicode characters or underscores. Nonstandard characters in an FQDN are often not supported by external DNS and public CAs (when the FQDN must be assigned to the SN in the certificate). For details about adding a DNS suffix to a computer name, see Configure DNS for Edge Support.

   - Click **Single computer pool**, and then click **Next**.
6. In **Select features**, do the following:
   - If you plan to use a single FQDN and IP address for the SIP Access service, Lync Server 2013 Web Conferencing service, and A/V Edge services, select the **Use a single FQDN and IP Address** check box.
   - If you plan to enable federation select the **Enable federation for this Edge pool (Port 5061)** check box.

     Note:

     You can select this option, but only one Edge pool or Edge Server in your organization can be published externally for federation. All access by federated users, including public instant messaging (IM) users, go through the same Edge pool or single Edge Server. For example, if your deployment includes an Edge pool or single Edge Server deployed in New York and one deployed in London and you enable federation support on the New York Edge pool or single Edge Server, signal traffic for federated users will go through the New York Edge pool or single Edge Server. This is true even for communications with London users, although a London internal user calling a London federated user uses the

> London pool or Edge Server for A/V traffic.

- If you plan to support the extensible messaging and presence protocol (XMPP) for your deployment, select the **Enable XMPP federation (port 5269)** check box

7. In **Select IP Options**, do the following:
   - **Enable IPv4 on internal interface**: Select the check box if you want to apply an IPv4 address to the Edge Server or Edge pool internal interface
   - **Enable IPv6 on internal interface**: Select the check box if you want to apply an IPv6 address to the Edge Server or Edge pool internal interface
   - **Enable IPv4 on external interface**: Select the check box if you want to apply an IPv4 address to the Edge Server or Edge pool external interface
   - **Enable IPv6 on external interface**: Select the check box if you want to apply an IPv6 address to the Edge Server or Edge pool external interface

   You can also configure the Edge Server or Edge pool to use a network address translation address for the external IP addresses. You do this by selecting the check box **The external IP address of this Edge pool is translated by NAT**.
8. In **External FQDNs**, do the following:
   - If in **Select features** you chose to use a single FQDN and IP address for the SIP access, Web Conferencing service, and A/V Edge service, type the external FQDN in **SIP Access**.

     > **Note:**
     >
     > If you choose this option, you must specify a different port number for each of the edge services (recommended port settings: 5061 for Access Edge service, 444 for Web Conferencing Edge service, and 443 for A/V Edge service). Selecting this option can help prevent potential connectivity issues, and simplify the configuration because you can then use the same port number (for example, 443) for all three services.

   - If in **Select features** you did not chose to use a single FQDN and IP Address, type the External FQDNs for **SIP Access**, **Web Conferencing** and **Audio Video**, keeping the default ports.
9. Click **Next**.
10. In **Define the Internal IP address**, type the IP address of your Edge Server in **Internal IPv4 address** and **Internal IPv6 address** as is appropriate for your requirements. Click **Next**.
11. In **Define the External IP address**, do the following:
    - If you chose to use a single FQDN and IP Address for the SIP access, Web Conferencing service, and A/V Edge service, type the external IPv4 address of the Edge Server in **SIP Access**, and then, click **Next**.
    - If you chose to use IPv6 addresses, type the external IPv6 address of the Edge Server in **SIP Access**, and then, click **Next**.
    - If you did not chose to use a single FQDN and IP Address for the SIP access, Web Conferencing service, and A/V Edge service, type the external IPv4 addresses of the Edge Server in **SIP Access**, **Web Conferencing**, and **A/V Conferencing**, and then click **Next**.
    - If you chose to use IPv6 addresses and did not chose to use a single FQDN and IP Address for the SIP access, Web Conferencing service, and A/V Edge service, type the external IPv6 addresses of the Edge Server in **SIP Access**, **Web Conferencing**, and **A/V Conferencing**, and then click **Next**.

      > **Note:**
      >
      > If you did not choose to enable and assign IPv6 addressing, you will not see this dialog box.
12. If you chose to use NAT, a dialog box appears. In **Public IPv4 address for the A/V Edge service**, type the public IPv4 address to be translated by NAT, and then click **Next**.

> **Note:**
> This should be the external IP address of the A/V Edge service.

13. If you chose to use NAT and IPv6 addresses, a dialog box appears. In **Public IPv6 address for the A/V Edge service**, type the public IPv6 address to be translated by NAT, and then click **Next**.

> **Note:**
> This should be the external IP address of the A/V Edge service.

14. In **Define the next hop**, in **Next hop pool**, select the name of the internal pool, which can be either a Front End pool or a Standard Edition pool. Or, if your deployment includes a Director, select the Director. Then, click **Next**.
15. In **Associate Front End pools**, specify one or more internal pools, which can include Front End pools and Standard Edition servers, to be associated with this Edge Server, by selecting the names of the internal pools that are to use this Edge Server for communication with supported external users.

> **Note:**
> Only one load-balanced Edge pool or single Edge Server can be associated with each internal pool for A/V traffic. If you already have an internal pool associated with an Edge pool or Edge Server, a warning appears indicating that the internal pool is already associated an Edge pool or Edge Server. If you select a pool that is already associated with another Edge Server, it will change the association.

16. Click **Finish**.
17. Publish your topology.

To define the topology for a DNS load balanced Edge Server pool

1. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
2. In the console tree, expand the site in which you want to deploy Edge Servers.
3. Right-click **Edge Pools**, and then click **New Edge Pool**.
4. In **Define the New Edge Pool**, click **Next**.
5. In **Define the Edge pool FQDN**, do the following:
   - In **Pool FQDN**, type the fully qualified domain name (FQDN) for the internal connection of the Edge pool.

     > **Important:**
     > The name you specify for the pool must be the internal edge pool name. This must be defined as a FQDN. Topology Builder uses FQDNs, not short names. Use only standard characters (including A–Z, a–z, 0–9, and hyphens) when assigning FQDNs of your Lync Servers, Edge Servers, and pools. Do not use Unicode characters or underscores. Nonstandard characters in an FQDN are often not supported by external DNS and public CAs (when the FQDN must be assigned to the SN in the certificate).

   - Click **Multiple computer pool**, and then click **Next**.
6. In **Select features**, do the following:
   - If you plan to use a single FQDN and IP address for the SIP access, Lync Server 2013 Web Conferencing service and A/V Edge services, select the **Use a single FQDN and IP Address** check box.
   - If you plan to enable federation, select the **Enable federation for this Edge pool (Port 5061)** check box. Click **Next**

     > **Note:**
     > You can select this option, but only one Edge pool or Edge Server in your organization can be published externally for federation. All access by federated users, including public instant messaging (IM) users, go through the same Edge pool or single Edge Server.

> For instance, if your deployment includes an Edge pool or single Edge Server deployed in New York and one deployed in London and you enable federation support on the New York Edge pool or single Edge Server, signal traffic for federated users will go through the New York Edge pool or single Edge Server. This is true even for communications with London users, although a London internal user calling a London federated user uses the London pool or Edge Server for A/V traffic.

- If you plan to support the extensible messaging and presence protocol (XMPP) for your deployment, select the **Enable XMPP federation (port 5269)** check box

7. Click **Next**.
8. In **Select IP Options**, do the following:
   - **Enable IPv4 on internal interface**: Select the check box if you want to apply an IPv4 address to the Edge Server or Edge pool internal interface
   - **Enable IPv6 on internal interface**: Select the check box if you want to apply an IPv6 address to the Edge Server or Edge pool internal interface
   - **Enable IPv4 on external interface**: Select the check box if you want to apply an IPv4 address to the Edge Server or Edge pool external interface
   - **Enable IPv6 on external interface**: Select the check box if you want to apply an IPv6 address to the Edge Server or Edge pool external interface

   You can also configure the Edge Server or Edge pool to use a network address translation address for the external IP addresses. You do this by selecting the check box **The external IP address of this Edge pool is translated by NAT**.
9. In **External FQDNs**, do the following:
   - If in **Select features** you chose to use a single FQDN and IP Address for the SIP access, Web Conferencing service, and A/V Edge service, type the external FQDN in **SIP Access**.

     > **Note:**
     >
     > If you choose this option, you must specify a different port number for each of the Edge services (recommended port settings: 5061 for Access Edge service, 444 for Web Conferencing Edge service, and 443 for A/V Edge service). By selecting this option, you can help prevent potential connectivity issues and simplify the configuration because you can then use the same port number (for example, 443) for all three services.

   - If in **Select features** you did not chose to use a single FQDN and IP Address, type the FQDN that you have chosen for your public facing side of the edge pool for in **SIP Access**. In **Web Conferencing**, type the FQDN you have chosen for your public facing side of the Edge pool. In **Audio/Video**, type the FQDN you have chosen for your public facing side of the Edge pool. Use the default ports.
10. Click **Next**.
11. In **Define the computers in this pool**, click **Add**.
12. In **Internal FQDN and IP address**, do the following:
    - In **Internal IPv4 address**, type the IPv4 address and **Internal IPv6 address** as is appropriate for your requirements for the first Edge Server that you want to create in this pool.
    - In **Internal FQDN**, type the FQDN of the first Edge Server that you want to create in this pool.

      > **Note:**
      >
      > The name you specify must be identical to the computer name configured on the server. By default, the computer name of a computer that is not joined to a domain is a short name, not an FQDN. Topology Builder uses FQDNs, not short names. So, you must configure a DNS suffix on the name of the computer to be

deployed as an Edge Server that is not joined to a domain. Use only standard characters (including A–Z, a–z, 0–9, and hyphens) when assigning FQDNs of your Lync Servers, Edge Servers, pools, and arrays. Do not use Unicode characters or underscores. Nonstandard characters in an FQDN are often not supported by external DNS and public CAs (when the FQDN must be assigned to the SN in the certificate). For details about adding a DNS suffix to a computer name, see Configure DNS for Edge Support.

13. Click **Next**.
14. In **Define the external IP addresses**, do the following:
    - If you chose to use a single FQDN and IP Address for the SIP access, Web Conferencing service, and A/V Edge service, type the external IP address of the Edge Server in **SIP Access**.
    - If you did not chose to use a single FQDN and IP Address for the SIP access, Web Conferencing service, and A/V Conferencing service, type the IP address that you have chosen for your public facing side of this Edge pool server for **SIP Access**. In **Web Conferencing**, type the IP address that you have chosen for your public facing side of this Edge pool server. In **A/V Conferencing**, type the IP address you have chosen for your public facing side of this Edge pool server.
15. Click **Next**.
16. If you chose to enable IPv6 addresses, In **Define the external IP addresses**, do the following:
    - If you chose to use a single FQDN and IP Address for the SIP access, Web Conferencing service, and A/V Edge service, type the external IPv6 address of the Edge Server in **SIP Access**.
    - If you did not chose to use a single FQDN and IP Address for the SIP access, Web Conferencing service, and A/V Conferencing service, type the IPv6 address that you have chosen for your public facing side of this Edge pool server for **SIP Access**. In **Web Conferencing**, type the IPv6 address that you have chosen for your public facing side of this Edge pool server. In **A/V Conferencing**, type the IPv6 address you have chosen for your public facing side of this Edge pool server.

Note:

If you did not choose to enable and assign IPv6 addressing, you will not see this dialog box.

17. Click **Finish**.

Note:

You will now see the first Edge Server you created in your pool in the **Define the computers in this pool** dialog box.

18. In **Define the computers in this pool**, click **Add**, and then repeat steps 11 through 14 for the second Edge Server that you want to add to you Edge pool.
19. After you repeat steps 11 through 14, click **Next** in **Define the computers in this pool**.

Note:

At this point, you can see both of the Edge Servers in your pool.

20. If you chose to use NAT, a dialog box appears. In **Public IP address**, type the public IPv4 and IPv6 (as appropriate) addresses to be translated by NAT, and then click **Next**.

Note:

This should be the external IP Address of the A/V Edge.

21. In **Define the next hop**, in the **Next hop pool** list, select the name of the internal pool, which can be either a Front End pool or a Standard Edition pool. Or, if your deployment includes a Director, select the name of the Director.

Then, click **Next**.

22. In **Associate Front End pools**, specify one or more internal pools, which can include Front End pools and Standard Edition servers, to be associated with this Edge Server, by selecting the names of the internal pool(s) that is to use this Edge Server for communication with supported external users.

> **Note:**
> Only one load-balanced Edge pool or single Edge Server can be associated with each internal pool for A/V traffic. If you already have an internal pool associated with an Edge pool or Edge Server, a warning appears indicating that the internal pool is already associated an Edge pool or Edge Server. If you select a pool that is already associated with another Edge Server, it will change the association.

23. Click **Finish**.
24. Publish your topology.

⊟To define the topology for a hardware load balanced Edge Server pool

1. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
2. In the console tree, expand the site in which you want to deploy Edge Servers.
3. Right-click **Edge Pools**, and then select **New Edge Pool**.
4. In **Define the New Edge Pool**, click **Next**.
5. In **Define the Edge pool FQDN**, do the following:
   - In **FQDN**, type the fully qualified domain name (FQDN) you have chosen for the internal side of the Edge pool.

     > **Important:**
     > The name you specify for the pool must be the internal edge pool name. This must be defined as a FQDN. Topology Builder uses FQDNs, not short names. Use only standard characters (including A–Z, a–z, 0–9, and hyphens) when assigning FQDNs of your Lync Servers, Edge Servers, and pools. Do not use Unicode characters or underscores. Nonstandard characters in an FQDN are often not supported by external DNS and public CAs (when the FQDN must be assigned to the SN in the certificate).

   - Click **Multiple computer pool**, and then **Next**.
6. In **Select features** do the following:
   - If you plan to use a single FQDN and IP address for the SIP access service, Lync Server Web Conferencing service, and A/V Edge service, select the **Use a single FQDN & IP Address** check box.
   - If you plan to enable federation, select the **Enable federation for this Edge pool (Port 5061)** check box.

     > **Note:**
     > You can select this option, but only one Edge pool or Edge Server in your organization may be published externally for federation. All access by federated users, including public instant messaging (IM) users, go through the same Edge pool or single Edge Server. For instance, if your deployment includes an Edge pool or single Edge Server deployed in New York and one deployed in London and you enable federation support on the New York Edge pool or single Edge Server, signal traffic for federated users will go through the New York Edge pool or single Edge Server. This is true even for communications with London users, although a London internal user calling a London federated user uses the London pool or Edge Server for A/V traffic.

   - If you plan to support the extensible messaging and presence protocol (XMPP) for your deployment, select the **Enable XMPP federation (port 5269)** check box

7. Click **Next**.
8. In **Select IP Options**, do the following:
   - **Enable IPv4 on internal interface**: Select the check box if you want to apply an IPv4 address to the Edge Server or Edge pool internal interface
   - **Enable IPv6 on internal interface**: Select the check box if you want to apply an IPv6 address to the Edge Server or Edge pool internal interface
   - **Enable IPv4 on external interface**: Select the check box if you want to apply an IPv4 address to the Edge Server or Edge pool external interface
   - **Enable IPv6 on external interface**: Select the check box if you want to apply an IPv6 address to the Edge Server or Edge pool external interface

Important:

Do Not select the **The external IP address of the Edge pool is translated by NAT** check box. Network address translation (NAT) is not supported when you are using hardware load balancing.

9. In **External FQDNs**, do the following:
   - If in **Select features** you chose to use a single FQDN and IP address for the SIP access, Web Conferencing service, and A/V Edge service, type the external FQDN in **SIP Access**.

Note:

If you choose to select this option, you must specify a different port number for each of the Edge services (recommended port settings: 5061 for Access Edge service, 444 for Web Conferencing Edge service, and 443 for A/V Edge service). By selecting this option, you can help prevent potential connectivity issues and simplify the configuration because you can then use the same port number (for example, 443) for all three services.

   - If in **Select features** you did not chose to use a single FQDN and IP address, type the FQDN that you have chosen for your public facing side of the edge pool for in **SIP Access**. In **Web Conferencing**, type the FQDN you have chosen for your public facing side of the Edge pool. In **Audio/Video**, type the FQDN you have chosen for your public facing side of the Edge pool. Use the default ports.

Note:

These will be the publicly facing virtual IP (VIP) FQDNs for the pool.

10. Click **Next**.
11. In **Define the computers in this pool**, click **Add**.
12. In **Define the external IP addresses**, do the following:
    - If you chose to use a single FQDN and IP Address for the SIP access, Web Conferencing service, and A/V Edge service, type the external IPv4 address of the Edge Server in **SIP Access**.external IP address of the Edge Server in **SIP Access**.
    - If you did not chose to use a single FQDN and IP Address for the SIP access, Web Conferencing service, and A/V Conferencing service, type the IP address that you have chosen for your public facing side of this Edge pool server for **SIP Access**. In **Web Conferencing**, type the IP address that you have chosen for your public facing side of this Edge pool server. In **A/V Conferencing**, type the IP address you have chosen for your public facing side of this Edge pool server.
13. Click **Next**.
14. If you chose to enable IPv6 addresses, In **Define the external IP addresses**, do the following:
    - If you chose to use a single FQDN and IP Address for the SIP access, Web Conferencing service, and A/V Edge service, type the external IPv6 address of the Edge Server in **SIP Access**.
    - If you did not chose to use a single FQDN and IP Address for the SIP access, Web Conferencing service, and A/V Conferencing service, type the

IPv6 address that you have chosen for your public facing side of this Edge pool server for **SIP Access**. In **Web Conferencing**, type the IPv6 address that you have chosen for your public facing side of this Edge pool server. In **A/V Conferencing**, type the IPv6 address you have chosen for your public facing side of this Edge pool server.

> **Note:**
> If you did not choose to enable and assign IPv6 addressing, you will not see this dialog box.

15. Click **Finish**.

> **Note:**
> You will now see the first Edge Server you created in your pool in the **Define the computers in this pool** dialog box.

16. In **Define the computers in this pool**, click **Add**, and then repeat steps 11 through 14 for the second Edge Server that you want to add to your Edge pool.
17. After you repeat steps 11 through 14, click **Next** in **Define the computers in this pool**.

> **Note:**
> At this point, you can see both of the Edge Servers in your pool.

18. In **Define the next hop**, in the **Next hop pool** list, select the name of the internal pool, which can be either a Front End pool or a Standard Edition pool. Or, if your deployment includes a Director, select the name of the Director. Then, click **Next**.
19. In **Associate Front End pools**, specify one or more internal pools, which can include Front End pools and Standard Edition servers, to be associated with this Edge Server, by selecting the names of the internal pool(s) that is to use this Edge Server for communication with supported external users.

> **Note:**
> Only one load-balanced Edge pool or single Edge Server can be associated with each internal pool for A/V traffic. If you already have an internal pool associated with an Edge pool or Edge Server, a warning appears indicating that the internal pool is already associated an Edge pool or Edge Server. If you select a pool that is already associated with another Edge Server, it will change the association.

20. Click **Finish**.

21. Publish your topology.

1.4.2.4.2 Define Optional Director Topologies in Your Topology

Define Optional Director Topologies in Your Topology

Deployment > Deploying External User Access > Building an Edge and Director Topology >

Topic Last Modified: *2012-09-08*

Lync Server 2013 Directors can be single-instance servers or they can be installed as a load-balanced pool of multiple Directors for higher availability and capacity. Both hardware load balancing and Domain Name System (DNS) load balancing are supported. This topic explains how to configure DNS load balancing for Director pools.

To successfully publish, enable, or disable a topology when you add or remove a server role, you should be logged on as a user who is a member of the **RTCUniversalServerAdmins** and **Domain Admins** groups. You can also delegate the proper administrator rights and permissions for adding server roles. For details, see Delegate Setup Permissions in the Standard Edition server or Enterprise Edition server Deployment documentation. For other configuration changes, only membership in the **RTCUniversalServerAdmins** group is required.

This topic describes the steps to define and publish the topology for the two Director topologies:

- To define the Director (single instance)
- To define the Director (multiple Director pool)

⊟To define the Director (single instance)

1. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
2. On the welcome page, click **Download Topology from Existing Deployment**.
3. In the **Save Topology As** dialog box, type the name and location of the local copy of the existing topology, and then click **Save**.
4. Expand the site in which you plan to add the Director, right-click **Director pools**, and then click **New Director Pool**.
5. In the **Define the Director pool FQDN** dialog box, do the following:
   - In **Pool FQDN**, type the FQDN for the Director pool.
   - Click **Single computer pool**, and then click **Next**.
6. In the **Define the file share** dialog box, do one of the following:
   - To use an existing file share, click **Use a previously defined file share**, select a file share from the list, and then click **Next**.
   - To create a new file share, click **Define a new file share**, type the FQDN for the location of the file share in **File Server FQDN**, type the name of the share in **File Share**, and then click **Next**.

   Important:

   The file share that you specify or create in this step must exist or be created prior to publishing the topology.

   The file share assigned to a Director is not actually used, so you can assign the file share of any pool in the organization.
7. In the **Specify the Web Services URL** dialog box, in **External Base URL**, specify the FQDN for the Directors, and then click **Finish**.

   Important:

   The name must be resolvable from Internet DNS servers and point to the public IP address of the reverse proxy, which listens for HTTP/HTTPS requests to that URL and proxies them to the external Web Services virtual directory on that Director.

   ⚠Warning:

   If you have more than one Front End pool or Front End Server the external Web services FQDN must be unique. For example, if you define the external Web services FQDN of a Front End Server as **pool01.contoso.com**, you cannot use **pool01.contoso.com** for another Front End pool or Front End Server. If you are also deploying Directors, the external Web services FQDN defined for any Director or Director pool must be unique from any other Director or Director pool as well as any Front End pool or Front End Server. If decide to override the Internal web services with a self-defined FQDN, each FQDN must be unique from any other Front End pool, Director or a Director pool.
8. Publish the topology.

⊟To define the Director (multiple Director pool)

1. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.

2. On the welcome page, click **Download Topology from Existing Deployment**.
3. In the **Save Topology As** dialog box, type the name and location of the local copy of the existing topology, and then click **Save**.
4. Expand the site in which you plan to add the Director, right-click **Director pools**, and then click **New Director Pool**.
5. In the **Define the Director pool FQDN** dialog box, do the following:
   - In **Pool FQDN**, type the FQDN for the Director pool.
   - Click **Multiple computer pool**, and then click **Next**.
6. In the **Define the computers in this pool** dialog box, do the following:
   - Specify the computer FQDN of the first pool member, and then click **Add**.
   - Repeat the previous step for each computer that you want to add. When you are finished, click **Next**.
7. In the **Define the file share** dialog box, do one of the following:
   - To use an existing file share, click **Use a previously defined file share**, select a file share from the list, and then click **Next**.
   - To create a new file share, click **Define a new file share**, type the FQDN for the location of the file share in **File Server FQDN**, type the name of the share in **File Share**, and then click **Next**.

> **Important:**
>
> The file share that you specify or create in this step must exist or be created prior to publishing the topology.
>
> The file share assigned to a Director is not actually used, so you can assign the file share of any pool in the organization.

8. In the **Specify the Web Services URL** dialog box, in **External Base URL**, specify the FQDN for the Directors, and then click **Finish**.

> **Important:**
>
> The name must be resolvable from Internet DNS servers and point to the public IP address of the reverse proxy, which listens for HTTP/HTTPS requests sent to that URL and proxies them to the external Web Services virtual directory on that Director pool.

> **Warning:**
>
> If you have more than one Front End pool or Front End Server the external Web services FQDN must be unique. For example, if you define the external Web services FQDN of a Front End Server as **pool01.contoso.com**, you cannot use **pool01.contoso.com** for another Front End pool or Front End Server. If you are also deploying Directors, the external Web services FQDN defined for any Director or Director pool must be unique from any other Director or Director pool as well as any Front End pool or Front End Server. If decide to override the Internal web services with a self-defined FQDN, each FQDN must be unique from any other Front End pool, Director or a Director pool.

9. Publish the topology.

1.4.2.4.3 Publish Your Topology

Publish Your Topology

Deployment > Deploying External User Access > Building an Edge and Director Topology >

Topic Last Modified: *2012-09-08*

Each time you use Topology Builder to build your topology, you must publish the topology to a database in the Central Management store so that the data can be used to deploy Lync Server 2013. Use the following procedure to publish your topology.

⊟To publish the topology

1. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
2. In Topology Builder, in the console tree, right-click **Lync 2013**, and then click **Publish Topology**.
3. On the **Welcome** page of the wizard, click **Next**.
4. On the **Topology Builder found a CMS store** page, click **Next**.
5. On the **Create other databases** page, click **Next**.
6. When the status indicates that database creation succeeded, do the following:
   - To view the log, click **View log**.
   - To close the wizard, click **Finish**.

Important:

If this is a new installation of an Edge Server or Edge pool, you must export the Edge Server configuration from an existing Front End Server, Front End pool, or Standard Edition server. To export the configuration, see Export Your Topology and Copy It to External Media for Edge Installation. You will import the configuration file from the external media or network share during the setup and deployment phase of the Edge Servers through the Lync Server Deployment Wizard.

Once the Edge Servers are operational and the local configuration management store database is replicating with the internal deployment, subsequent updates to the Lync Server 2013 configuration will be published and replicated to the Edge Servers.

1.4.2.4.4 Export Your Topology and Copy It to External Media for Edge Installation

Export Your Topology and Copy It to External Media for Edge Installation

Deployment > Deploying External User Access > Building an Edge and Director Topology >

Topic Last Modified: *2012-09-08*

After you publish your topology, the Lync Server Deployment Wizard needs access to the Central Management store data in order to start the deployment process on the server. In the internal network, the data is available directly from the servers, but Edge Servers that are not in the internal domain cannot access the data. To make the topology configuration data available for an Edge Server deployment, you must export the topology data to a file and copy it to external media (for example, a USB drive or a network share that is available from the Edge Server) before you run the Lync Server Deployment Wizard on the Edge Server. Use the following procedure to make your topology configuration data available on the Edge Server that you are deploying.

Note:

After you install Lync Server 2013 on an Edge Server, you manage the Edge Server using the administrative tools in the internal network, which automatically replicate configuration to any Edge Servers in your deployment. The only exception is assigning and installing certificates and stopping and starting services, both of which must be done on the Edge Server.

⊟To make your topology data available on an Edge Server by using Lync Server Management Shell

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. In the Lync Server Management Shell, run the following cmdlet:

```
Export-CsConfiguration -FileName <ConfigurationFilePath.zip>
```

3. Copy the exported file to external media (for example, a USB drive or a network share that is available from the Edge Server during deployment).

1.4.2.5 Setting Up the Director

Setting Up the Director

Microsoft Lync Server 2013 > Deployment > Deploying External User Access >

Topic Last Modified: *2012-09-08*

If you enable access for external users by deploying Edge Servers, you optionally can deploy a Director. A Director is a server running Microsoft Lync Server 2013 that authenticates user requests, but does not home any user accounts. The primary steps required to setting up a Director or Director pool are similar to that of setting up an Enterprise Edition Front End pool or Standard Edition server. After you have defined your Director(s) in Topology Builder, you need to perform the steps in this section.

- Install the Local Configuration Store
- Install Lync Server 2013 on the Director
- Configure Certificates for the Director
- Start Services on the Director
- Test the Director
- Configure Automatic Client Sign-In To Use the Director

1.4.2.5.1 Install the Local Configuration Store

Install the Local Configuration Store

Deployment > Deploying Lync Server 2013 > Setting Up Front End Servers and Front End Pools >

Topic Last Modified: *2013-02-25*

To successfully complete this procedure, you should be logged on to the server minimally as a local administrator and a domain user who has membership in at least the RTCUniversalReadOnlyAdmin group.

The first step of the Lync Server Deployment Wizard is to install the Local Configuration store. The Local Configuration store is SQL Server Express, which installs a local database that will retain a read-only copy of the Central Management store. The Central Management store is added to the existing SQL Server database installed on the Standard Edition server or SQL Server Express-based database.

◆**Important:**
If this is the first time that you have run Lync Server 2013 setup on this server, you will be prompted for a drive and path to install Lync Server 2013. If your organization requires that you locate Internet Information Services (IIS) and all Web Services on a drive other than the system drive, you can change the installation location path for the Lync Server files in the Setup dialog box. If you install the Setup files to this path, including OCSCore.msi, the rest of the Lync Server 2013 files will be deployed to this drive as well.

⊟To install the Local Configuration store

1. From the installation media, browse to \setup\amd64\Setup.exe, and then click **OK**.
2. If you are prompted to install the Microsoft Visual C++ 2012 Redistributable, click **Yes**.
3. On the **Lync Server 2013 Installation Location** page, click **OK**.
4. On the **End User License Agreement** page, review the license terms, select **I accept the terms in the license agreement**, and then click **OK**. This step is required before you can continue.
5. On the Deployment Wizard page, click **Install or Update Lync Server System**.
6. On the **Lync Server 2013** page, next to **Step1: Install Local Configuration Store**, click **Run**.
7. On the **Local Server Configuration** page, make sure that the **Retrieve configuration automatically from the Central Management Store** option is selected, and then click **Next**.
8. When the local server configuration installation is complete, click **Finish**.

1.4.2.5.2 Install Lync Server 2013 on the Director

Install Lync Server 2013 on the Director

Deployment > Deploying External User Access > Setting Up the Director >

Topic Last Modified: *2012-09-08*

Use the following steps to install the Lync Server 2013 components on a Director.

⊟To install Lync Server components on a Director

1. In the Lync Server Deployment Wizard, on the Lync Server 2013 page, next to **Step 2: Setup or Remove Lync Server Components**, click **Run**.
2. On the **Setup Lync Server components** page, click **Next** to set up components as defined in the published topology.
3. When Lync Server components setup has completed, click **Finish**.

1.4.2.5.3 Configure Certificates for the Director

Configure Certificates for the Director

Deployment > Deploying External User Access > Setting Up the Director >

Topic Last Modified: *2012-09-08*

Important:
When you run the Certificate Wizard, ensure that you are logged in using an account that is a member of a group that has been assigned the appropriate permissions for the type of certificate template you will use. By default, a Lync Server 2013 certificate request will use the Web Server certificate template. If you use an account that is a member of the RTCUniversalServerAdmins group to request a certificate using this template, verify that the group has been assigned the Enroll permissions required to use that template.

Each Director requires a default certificate, a web internal certificate, and a web external certificate. For details about the certificate requirements for Directors, see Certificate Requirements for Internal Servers in the Planning documentation.

Use the following procedure to configure Director certificates. Repeat the procedure for each Director. The steps of this procedure describe how to configure a certificate from an Internal Enterprise Root certification authority (CA) deployed by your organization and with offline request processing. For details about obtaining certificates from an external CA, contact your support team.

⊟To configure certificates for the Director or Director pool

1. In the Lync Server Deployment Wizard, next to **Step 3: Request, Install or Assign Certificates**, click **Run**.
2. On the **Certificate Wizard** page, click **Request**.
3. On the **Certificate Request** page, click **Next**.
4. On the **Delayed or Immediate Requests** page, accept the default **Send the request immediately to an online certification authority** option, and then click **Next**.
5. On the **Choose a Certification Authority (CA)** page, click the internal Windows certification authority that you want to use, and then click **Next**.
6. On the **Certification Authority Account** page, specify alternate credentials to be used if the account you are logged on with does not have sufficient authority to request the certificate, and then click **Next**.
7. On the **Specify Alternate Certificate Template** page, click **Next**.
8. On the **Name and Security Settings** page, you can specify a **Friendly Name**, accept the 2048-bit key length, and then click **Next**.
9. On the **Organization Information** page, optionally specify organization information, and then click **Next**.
10. On the **Geographical Information** page, optionally specify geographical information, and then click **Next**.
11. On the **Subject Name / Subject Alternative Names** page, click **Next**.

> **Note:**
> The subject alternative name list should contain the name of the computer on which you are installing the Director (if a single Director) or the Director pool name, and the simple URL names configured for the organization.

12. On the **SIP Domain Setting on Subject Alternate Names (SANs)** page, select the **Configured SIP Domains** for all domains that you want the Director to handle, and then click **Next**.
13. On the **Configure Additional Subject Alternative Names** page, add any additional required subject alternative names, and then click **Next**.
14. On the **Certificate Request Summary** page, click **Next**.
15. On the **Executing Commands** page, click **Next** after the commands have finished running.
16. On the **Online Certificate Request Status** page, click **Finish**.
17. On the **Certificate Assignment** page, click **Next**.

> **Note:**
> if you want to view the certificate, double-click the certificate in the list.

18. On the **Certificate Assignment Summary** page, click **Next**.
19. On the **Executing Commands** page, click **Finish** after the commands have finished running.
20. On the **Certificate Wizard** page, click **Close**.

1.4.2.5.4 Start Services on the Director

Start Services on the Director

Deployment > Deploying External User Access > Setting Up the Director >

Topic Last Modified: *2012-09-08*

After you install the Local Configuration Store, install the Lync Server Components, and configure certificates on a Director, you must start the Lync Server services on the server. You can use the following procedure to start services on each Director in your deployment.

To start services on a Director

1. In the Lync Server Deployment Wizard, on the **Lync Server 2013** page, click the **Run** button next to **Step 4: Start Services**.
2. On the **Start Services** page, click **Next** to start the Lync Server services on the server.
3. On the **Executing Commands** page, after all services have started successfully, click **Finish**.
4. Below **Step 4: Start Services**, click **Services Status (Optional)**.
5. In the **Services** Microsoft Management Console (MMC) on the server, verify that all of the Lync Server 2013 services are running.

1.4.2.5.5 Test the Director

Test the Director

Deployment > Deploying External User Access > Setting Up the Director >

Topic Last Modified: *2012-09-08*

At this stage, you have a Director or Director pool configured, but your Domain Name System (DNS) SRV entries still point clients to log on by using a pool or Standard Edition server. Before changing the DNS record to make Lync 2013 clients log on automatically by using the Director, test a client by manually pointing it to the Director.

To test the deployment

1. Log on to the computer on which you have the Lync Server Control Panel installed with a domain account that is part of the **CSAdministrator** group.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the navigation pane, click **Topology**, and in the **Status** column confirm that there is a green server with an arrow (that is,) for your Director or Director pool.
4. Connect two client computers that have the Lync Server 2013 client installed and log on with a different user account enabled for Lync Server 2013 to each computer.
5. On one of the client computers, click the **Options** menu, select the **Personal** settings group, click **Advanced**, click **Manual Configuration**, and then set the **Internal Server name or IP address** to the fully qualified domain name (FQDN) of the new Director or Director pool.
6. Log on to both clients and verify that the client logging on by using the Director is able to log on successfully, see the presence status of the other user, and that they can exchange instant messages.

1.4.2.5.6 Configure Automatic Client Sign-In To Use the Director

Configure Automatic Client Sign-In To Use the Director

Deployment > Deploying External User Access > Setting Up the Director >

Topic Last Modified: *2012-09-08*

When you deploy a Lync Server 2013, Director or a pool of Directors, we recommend that you use Automatic Client Sign-In as a best practice. For details about how to configure DNS servers for automatic client sign-in, see DNS Requirements for Automatic Client Sign-

In in the Planning documentation.

If you have already deployed Automatic Client Sign-In, see the following sections to configure it on your Director(s).

Single Director Instance

If you already have Automatic Client Sign-In deployed and it is pointing to a Front End Server or a Front End pool, you need to change the DNS SRV record to point to the Director.

Director Pool

If you already have Automatic Client Sign-In deployed and it is pointing to a Front End Server or a Front End pool, you need to change the DNS SRV record to point to the Director pool.

1.4.2.6 Setting Up Edge Servers

Setting Up Edge Servers

Microsoft Lync Server 2013 > Deployment > Deploying External User Access >

***Topic Last Modified:** 2012-09-08*

The primary tasks required to set up Edge Servers are the same for installing a single Edge Server or a load-balanced pool of Edge Servers, except that a pool of hardware load balanced Edge Servers requires deployment of the load balancers and additional steps for replicating the set up on multiple Edge Servers.

- Set Up Network Interfaces for Edge Servers
- Install Prerequisite Software on Edge Servers
- Export Your Topology and Copy It to External Media for Edge Installation
- Install Edge Servers
- Set Up Edge Certificates
- Start Edge Servers
- Setting Up Reverse Proxy Servers

1.4.2.6.1 Set Up Network Interfaces for Edge Servers

Set Up Network Interfaces for Edge Servers

Deployment > Deploying External User Access > Setting Up Edge Servers >

***Topic Last Modified:** 2012-09-08*

Each Edge Server is a multihomed computer with external and internal facing interfaces. The adapter Domain Name System (DNS) settings depend on whether there are DNS servers in the perimeter network. If DNS servers exist in the perimeter, they must have a zone containing one or more DNS A records for the next hop server or pool (that is, either a Director or a designated Front End pool), and for external queries they refer name lookups to other public DNS servers. If no DNS servers exist in the perimeter, the Edge Server(s) use external DNS servers to resolve Internet name lookups, and each Edge Server uses a HOST to resolve the next hop server names to IP addresses.

Security Note:

For security reasons, we recommend that you do not have your Edge Servers access a DNS server located in the internal network.

⊟To configure interfaces with DNS servers in the perimeter network

1. Install two network adapters for each Edge Server, one for the internal-facing interface and one for the external-facing interface.

   Important:

   The internal and external subnets must not be routable to each other.

2. On the external interface, configure three static IP addresses on the external perimeter network (also known as DMZ, demilitarized zone, and screened subnet) subnet, and point the default gateway to the internal interface of the external firewall. Configure adapter DNS settings to point to a pair of perimeter DNS servers.

   Note:

   It is possible to use as few as one IP address for this interface, but to do this you need to change the port assignments to non-standard values. You determine this when you create the topology in Topology Builder.

3. On the internal interface, configure one static IP address on the internal perimeter network subnet and do not set a default gateway. Configure adapter DNS settings to point to at least one DNS server, preferably a pair of perimeter DNS servers.
4. Create persistent static routes on the internal interface to all internal networks where clients, Lync Server 2013, and Exchange Unified Messaging (UM) servers reside.

⊟To configure interfaces without DNS servers in the perimeter network

1. Install two network adapters for each Edge Server, one for the internal-facing interface and one for the external-facing interface.

   Important:

   The internal and external subnets must not be routable to each other.

2. On the external interface, configure three static IP addresses on the external perimeter network subnet. You also configure the default gateway on the external interface. For example, define the Internet-facing router or the external firewall as the default gateway. Configure DNS settings to point to a DNS server, preferably to a pair of external DNS servers.

   Note:

   It is possible, but not recommended, to use as few as one IP address for the external interface. To allow this to work, you need to change the port assignments to non-standard values, and away from the default port 443 that is typically "firewall friendly" for client communication. You determine the IP address setting and the port settings when you create the topology in Topology Builder.

3. On the internal interface, configure one static IP address on the internal perimeter network subnet and do not set a default gateway. Leave adapter DNS settings empty.
4. Create persistent static routes on the internal interface to all internal networks where Lync clients or servers running Lync Server 2013 reside.
5. Edit the HOST file on each Edge Server to contain a record for the next hop server or virtual IP (VIP) (the record will be the Director, Standard Edition server, or a Front End pool that was configured as the Edge Server next hop address in Topology Builder). If you are using DNS load balancing, include a line for each member of the next hop pool.

1.4.2.6.2 Install Prerequisite Software on Edge Servers

Install Prerequisite Software on Edge Servers

Deployment > Deploying External User Access > Setting Up Edge Servers >

Topic Last Modified: *2012-09-08*

You need to deploy prerequisite software on each Edge Server that you deploy prior to installing Lync Server 2013. This includes installing the operating system on a server that meets system requirements. For details about system requirements, including the supported operating systems, see System Requirements for External User Access Components.

1.4.2.6.3 Install Edge Servers

Install Edge Servers

Deployment > Deploying External User Access > Setting Up Edge Servers >

Topic Last Modified: *2012-09-08*

You install Lync Server 2013 on Edge Servers by using Lync Server Deployment Wizard. By running the Deployment Wizard on each Edge Server, you can complete most of the tasks required to set up the Edge Server. In order to deploy Lync Server 2013 on an Edge Server, you must have already run Topology Builder to define and publish your Edge Server topology, and exported it to media that is available from the Edge Server. For details, see Scenarios for External User Access and Export Your Topology and Copy It to External Media for Edge Installation.

After using the Deployment Wizard to install each Edge Server, install and assign the required certificates, and start the required services, you can complete the setup by using the information in Configuring Support for External User Access to enable and configure external user access and the information in Verifying Your Edge Deployment to validate the setup, including server and client connectivity.

⊟To install an Edge Server

1. Log on to the computer on which you want to install your Edge Server as a member of the local Administrators group or an account with equivalent user rights and permissions.
2. Ensure that the topology configuration file you created using Topology Builder, and then exported and copied to external media, is available on the Edge Server (for example, access to the USB drive onto which you copied the topology configuration file, or verify access to the network share where you copied the file).
3. Start the Deployment Wizard.

Note:
If you get a message saying that you need to install Microsoft Visual C++ Redistributable, click **Yes**. In the next dialog box, you can accept the default **Installation Location** or click the **Browse** to select an alternate location, and then click **Install**. In the next dialog box, select the **I accept the terms in the license agreement** check box, and then click **OK**.

4. In the Deployment Wizard, click **Install or Update Lync Server System**.
5. After the wizard determines the deployment state, for **Step 1. Install Local Configuration Store**, click **Run** and then do the following:
   - In the **Configure Local Replica of Central Management Store** dialog box, click **Import from a file (Recommended for Edge Servers)**, go to the

location of the exported topology configuration file, select the .zip file, click **Open**, and then click **Next**.
- The Deployment Wizard reads the configuration information from the configuration file and writes the XML configuration file to the local computer.
- After the **Executing Commands** process is finished, click **Finish**.

6. In the Deployment Wizard, click **Step 2: SetUp or Remove Lync Server Components** to install the Lync Server 2013 edge components specified in the XML configuration file that is stored on the local computer.
7. After completing the installation, use the information in Set Up Edge Certificates to install and assign the required certificates before you start services.

1.4.2.6.4 Set Up Edge Certificates

Set Up Edge Certificates

Deployment > Deploying External User Access > Setting Up Edge Servers >

Topic Last Modified: *2012-09-08*

When you install an Edge Server, you need to request, install, and assign the required certificates for the internal and external interfaces.

- Certificate Requirements for External User Access
- Set Up Certificates for the Internal Edge Interface
- Set Up Certificates for the External Edge Interface
- Set Up Certificates for the Reverse Proxy

1.4.2.6.4.1 Certificate Requirements for External User Access

Certificate Requirements for External User Access

See Also

Planning > Determining Your Infrastructure Requirements > Certificate Infrastructure Requirements >

Topic Last Modified: *2012-09-08*

Microsoft Lync Server 2013 communications software supports the use of a single public certificate for access and web conferencing Edge external interfaces, plus the A/V Authentication service. The Edge internal interface typically uses a private certificate issued by an internal certification authority (CA), but can also use a public certificate, provided that it is from a trusted public CA. The reverse proxy in your deployment uses a public certificate and encrypts the communication from the reverse proxy to clients and the reverse proxy to internal servers by using HTTP (that is, Transport Layer Security over HTTP).

Following are the requirements for the public certificate used for access and web conferencing Edge external interfaces, and the A/V authentication service:

- The certificate must be issued by an approved public CA that supports subject alternative name. For details, see Microsoft Knowledge Base article 929395, "Unified Communications Certificate Partners for Exchange Server and for Communications Server," at http://go.microsoft.com/fwlink/p/?linkId=202834.
- If the certificate will be used on an Edge pool, it must be created as exportable, with the same certificate used on each Edge Server in the Edge pool. The exportable private key requirement is for the purposes of the A/V Authentication service, which must use the same private key across all Edge Servers in the pool.
- If you want to maximize the uptime for your Audio/Video services, review the

certificate requirements for implementing a decoupled A/V Edge service certificate (that is, a separate A/V Edge service certificate from the other External Edge certificate purposes). For details, see Changes in Lync Server 2013 That Affect Edge Server Planning, Plan for Edge Server Certificates and Staging AV and OAuth Certificates Using -Roll in Set-CsCertificate.

- The subject name of the certificate is the Access Edge service external interface fully qualified domain name (FQDN) or hardware load balancer VIP (for example, access.contoso.com).

  > **Note:**
  > For Lync Server 2013, this is no longer a requirement, but it is still recommended for compatibility with Office Communications Server.

- The subject alternative name list contains the FQDNs of the following:
  - The Access Edge service external interface or hardware load balancer VIP (for example, sip.contoso.com).

    > **Note:**
    > Even though the certificate subject name is equal to the access Edge FQDN, the subject alternative name must also contain the access Edge FQDN because Transport Layer Security (TLS) ignores the subject name and uses the subject alternative name entries for validation.

  - The web conferencing Edge external interface or hardware load balancer VIP (for example, webcon.contoso.com).
  - If you are using client auto-configuration or federation, also include any SIP domain FQDNs used within your company (for example, sip.contoso.com, sip.fabrikam.com).
  - The A/V Edge service does not use the subject name or the subject alternative names entries.

  > **Note:**
  > The order of the FQDNs in the subject alternative names list does not matter.

If you are deploying multiple, load-balanced Edge Servers at a site, the A/V authentication service certificate that is installed on each Edge Server must be from the same CA and must use the same private key. Note that the certificate's private key must be exportable, regardless of whether it is used on one Edge Server or many Edge Servers. It must also be exportable if you request the certificate from any computer other than the Edge Server. Because the A/V authentication service does not use the subject name or subject alternative name, you can reuse the access Edge certificate as long as the subject name and subject alternative name requirements are met for the access Edge and the web conferencing Edge and the certificate’s private key is exportable.

Requirements for the private (or public) certificate used for the Edge internal interface are as follows:

- The certificate can be issued by an internal CA or an approved public certificate CA.
- The subject name of the certificate is typically the Edge internal interface FQDN or hardware load balancer VIP (for example, lsedge.contoso.com). However, you can use a wildcard certificate on the Edge internal.
- No subject alternative name list is required.

The reverse proxy in your deployment services requests for:

- External user access to meeting content for meetings
- External user access to expand and display members of distribution groups
- External user access to downloadable files from the Address Book Service
- External user access to the Lync Web App client
- External user access to the Dial-in Conferencing Settings web page
- External user access to the Location Information Service

- External device access to the Device Update Service and obtain updates

The reverse proxy publishes the internal server Web Components URLs. The Web Components URLs are defined on the Director, Front End Server or Front End pool as the **External web services** in Topology Builder.

Wildcard entries are supported in the subject alternative name field of the certificate assigned to the reverse proxy. For details about how to configure the certificate request for the reverse proxy, see Request and Configure a Certificate for Your Reverse HTTP Proxy.

Concepts

Wildcard Certificate Support

1.4.2.6.4.2 Set Up Certificates for the Internal Edge Interface

Set Up Certificates for the Internal Edge Interface

Deploying External User Access > Setting Up Edge Servers > Set Up Edge Certificates >

Topic Last Modified: *2012-09-08*

Important:

When you run the Certificate Wizard, ensure that you are logged in using an account that is a member of a group that has been assigned the appropriate permissions for the type of certificate template you will use. By default, a Lync Server 2013 certificate request will use the Web Server certificate template. If you use an account that is a member of the RTCUniversalServerAdmins group to request a certificate using this template, verify that the group has been assigned the Enroll permissions required to use that template.

A single certificate is required on the internal interface of each Edge Server. Certificates for the internal interface can be issued by an internal enterprise certification authority (CA) or a public CA. If your organization has an internal CA deployed you can save on the expense of using public certificates by using the internal CA to issue the certificate for the internal interface. You can use an internal Windows Server 2008 CA or Windows Server 2008 R2 CA to create these certificates.

For details about this and other certificate requirements, see Certificate Requirements for External User Access.

To set up certificates on the internal edge interface at a site, use the procedures in this section to do the following:

1. Download the CA certification chain for the internal interface to each Edge Server.
2. Import the CA certification chain for the internal interface, on each Edge Server.
3. Create the certificate request for the internal interface, on one Edge Server, called the first Edge Server.
4. Import the certificate for the internal interface on the first Edge Server.
5. Import the certificate on the other Edge Servers at this site (or deployed behind this load balancer).
6. Assign the certificate for the internal interface of every Edge Server.

If you have more than one site with Edge Servers (that is, a multiple-site edge topology), or separate sets of Edge Servers deployed behind different load balancers, you need to follow these steps for each site that has Edge Servers, and for each set of Edge Servers deployed behind a different load balancer.

Note:

The steps for procedures in this section are based on using a Windows Server 2008 CA Windows Server 2008 R2 CA or Windows Server 2012 CA to create a certificate for each Edge Server. For step-by-step guidance for any other CA, consult the documentation for that CA. By default, all authenticated users have the appropriate user rights to request certificates.

The procedures in this section are based on creating certificate requests on the Edge Server as part of the Edge Server deployment process. It is possible to create certificate requests using the Front End Server. You can do this to complete the certificate request early in the planning and deployment process, before you start deployment of the Edge Servers. To do this, you must ensure that the certificate you request is defined with an exportable private key.

The procedures in this section describe using a .cer and a .p7b file for the certificate. If you use a different type of file, modify these procedures as appropriate.

⊟To download the CA certification chain for the internal interface using certsrv Web site

1. Log on to an Lync Server 2013 server in the internal network (that is, not the Edge Server) as a member of the **Administrators** group.
2. Run the following command at a command prompt by clicking **Start**, clicking **Run**, and then typing the following:

   ```
   https://<name of your Issuing CA Server>/certsrv
   ```

   For example:

   ```
   https://ca01.contoso.net/certsrv
   ```

   Note:

   If you are using a Windows Server 2008 or Windows Server 2008 R2 enterprise CA, you must use https, not http.
3. On the issuing CA's certsrv web page, under **Select a task**, click **Download a CA certificate, certificate chain, or CRL**.
4. Under **Download a CA Certificate, Certificate Chain, or CRL**, click **Download CA certificate chain**.
5. In the **File Download** dialog box, click **Save**.
6. Save the .p7b file to the hard disk drive on the server, and then copy it to a folder on each Edge Server.

   Note:

   The .p7b file contains all of the certificates that are in the certification path. To view the certification path, open the server certificate and click the certification path.

⊟To export the CA certification chain for the internal interface using MMC

1. You can export the CA root certificate from any domain joined machine using the Microsoft Management Console (MMC). Click **Start**, click **Run**, and then type **MMC**.
2. In the MMC console, click **File**, click **Add/Remove**.
3. From the **Add or Remove Snap-ins** dialog list, select **Certificates**, then click **Add**. When prompted, select **Computer Account**. On the **Select Computer** dialog, select **Local Computer**. Click **Finish**. Click **OK**.
4. Expand **Certificates (Local Computer)**. Expand **Trusted Root Certification Authorities**, select **Certificates**.
5. Click the root certificate issued by your CA. Right click the certificate, select **All Tasks**, select **Export**. The **Certificate Export Wizard** will open.
6. In the **Certificate Export Wizard**, click **Next**.
7. On the **Export File Format** dialog, select a format to export to. We recommend the **Cryptographic Message Syntax Standard – PKCS #7 Certificates (.P7B)**. If you select the **Cryptographic Message Syntax Standard – PKCS #7 Certificates (.P7B)**, select the **Include all certificates**

in the certification path if possible checkbox to export the certificate chain, including the root CA certificate and any Intermediate CA certificates. Click **Next**.

8. On the **File to Export** dialog in the file name entry, type a path and file name (default extension is .p7b) for the exported certificate. Optionally, click **Browse**, locate a directory to place the exported certificate in and provide a name for the exported certificate. Click **Save**. Click **Next**.
9. Review the summary of actions, and click **Finish** to complete the export of the certificate. Click **OK** to confirm the successful export.

⊟To import the CA certification chain for the internal interface

1. On each Edge Server, open the Microsoft Management Console (MMC) by clicking **Start**, clicking **Run**, typing **mmc** in the **Open** box, and then clicking **OK**.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. In the **Add Standalone Snap-ins** box, click **Certificates**, and then click **Add**.
4. In the **Certificate snap-in** dialog box, click **Computer account**, and then click **Next**.
5. In the **Select Computer** dialog box, ensure that the **Local computer: (the computer this console is running on)** check box is selected, and then click **Finish**.
6. Click **Close**, and then click **OK**.
7. In the console tree, expand **Certificates (Local Computer)**, right-click **Trusted Root Certification Authorities**, point to **All Tasks**, and then click **Import**.
8. In the wizard, in **File to Import**, specify the file name of the certificate (that is, the name of that you specified when you downloaded the CA certification chain for the internal interface in the previous procedure).
9. Repeat this procedure on each Edge Server.

⊟To create the certificate request for the internal interface

1. On one of the Edge Servers, start the Deployment Wizard, and next to **Step 3: Request, Install, or Assign Certificates**, click **Run**.

Note:
If you have multiple Edge Servers in one location in a pool, you can run the Certificate Wizard on any one of the Edge Servers. After you run Step 3 the first time, the button changes to **Run again**, and a green check mark that indicates successful completion of the task is not displayed until all require certificates have been requested, installed, and assigned.

2. On the **Available Certificate Tasks** page, click **Create a new certificate request**.
3. On the **Certificate Request** page, click **Next**.
4. On the **Delayed or Immediate Requests** page, click **Prepare the request now, but send it later**.
5. On the **Certificate Request File** page, type the full path and file name to which the request is to be saved (for example, **c:\cert_internal_edge.cer**).
6. On the **Specify Alternate Certificate Template** page, to use a template other than the default WebServer template, select the **Use alternative certificate template for the selected Certificate Authority** check box.
7. On the **Name and Security Settings** page, do the following:
   - In **Friendly name**, type a display name for the certificate (for example, Internal Edge).
   - In **Bit length**, specify the bit length (typically, the default of **2048**).

Note:
Higher bit lengths offer more security, but they have a negative impact on speed.

   - If the certificate needs to be exportable, select the **Mark certificate**

private key as exportable check box.

8. On the **Organization Information** page, type the name for the organization and the organizational unit (OU) (for example, a division or department).
9. On the **Geographical Information** page, specify the location information.
10. On the **Subject Name/Subject Alternate Names** page, the information to be automatically populated by the wizard is displayed.
11. On the **Configure Additional Subject Alternate Names** page, specify any additional subject alternative names that are required.
12. On the **Request Summary** page, review the certificate information that is going to be used to generate the request.
13. After the commands complete, do the following:
    - To view the log for the certificate request, click **View Log**.
    - To complete the certificate request, click **Next**.
14. On the **Certificate Request File** page, do the following:
    - To view the generated certificate signing request (CSR) file, click **View**.
    - To close the wizard, click **Finish**.
15. Submit this file to your CA (by email or other method supported by your organization for your enterprise CA) and, when you receive the response file, copy the new certificate to this computer so that it is available for import.

⊟To import the certificate for the internal interface

1. Log on to the Edge Server on which you created the certificate request as a member of the local Administrators group.
2. In the Deployment Wizard, next to **Step 3: Request, Install, or Assign Certificates**, click **Run again**.

   After you run Step 3 the first time, the button changes to **Run again**, but a green check mark (indicating successful completion of the task) is not displayed until all require certificates have been requested, installed, and assigned.
3. On the **Available Certificate Tasks** page, click **Import a certificate from a .P7b, .pfx or .cer file**.
4. On the **Import Certificate** page, type the full path and file name of the certificate that you requested and received for the internal interface of this Edge Server (or, click **Browse** to locate and select the file).
5. If you are importing certificates for other members of the pool a certificate containing a private key, select the **Certificate file contains certifcate's private key** check box and specify the password.

⊟To export the certificate with the private key for Edge Servers in a pool

1. Log on as a member of the Administrators group to the same Edge Server on which you imported the certificate.
2. Click **Start**, click **Run**, and type **MMC**.
3. From the MMC console, click **File**, click **Add/Remove Snap-in**.
4. From Add or Remove Snap-ins page, click **Certificates**, click **Add**.
5. In the Certificates snap-in dialog, select **Computer account**. Click **Next**. In Select Computer, select **Local computer: (the computer this console is running on)**. Click **Finish**. Click **OK** to complete configuration of the MMC console.
6. Double-click **Certificates (Local Computer)** to expand the certificate stores. Double-click **Personal**, then double-click **Certificates**.

   Important:

   If there are no certificates in the Certificates Personal store for the local computer, there is no private key associated with the certificate that was imported. Review the request and import steps. If the problem persists, contact your certification authority administrator or provider.
7. In the Certificates Personal store for the local computer, right-click the certificate that you are exporting. Click **All Tasks**, click **Export**.
8. In the Certificate Export Wizard, click **Next**. Select **Yes, export the private**

key. Click **Next**.

> **Note:**
>
> If the selection **Yes, export the private key** is not available, the private key associated with this certificate was not marked for export. You will need to request the certificate again, ensuring that the certificate is marked to allow for the export of the private key before you can continue with the export. Contact your certification authority administrator or provider.

9. On the Export File Formats dialog, select **Personal Information Exchange – PKCS#12 (.PFX)** and then select the following:
   - Include all certificates in the certification path if possible
   - Export all extended properties

   > **Warning:**
   >
   > When exporting the certificate from an Edge server, do not select **Delete the private key if the export is successful**. Selecting this option will require that you import the certificate and the private key to this Edge server.

   Click **Next** to continue.
10. If you want to assign password to protect the private key, type a password for the private key. Re-enter the password to confirm. Click **Next**.
11. Type a path and file name for the exported certificate, using a file extension of .pfx. The path must either be accessible to all other Edge servers in the pool or available to transport by means of removable media - for example, a USB flash drive. Click **Next**.
12. Review the summary on the Completing the Certificate Export Wizard dialog. Click **Finish**.
13. Click **OK** in the successful export dialog.
14. Import the exported certificate file to the other Edge servers following the steps outlined in the Set Up Certificates for the External Edge Interface procedures.

⊟To assign the internal certificate on the Edge Servers

1. On each Edge Server, in the Deployment Wizard, next to **Step 3: Request, Install, or Assign Certificates**, click **Run again**.
2. On the **Available Certificate Tasks** page, click **Assign an existing certificate**.
3. On the **Certificate Assignment** page, select **Edge Internal** in the list.
4. On the **Certificate Store** page, select the certificate that you imported for the internal edge (from the previous procedure).
5. On the **Certificate Assignment Summary** page, review your settings, and then click **Next** to assign the certificates.
6. On the wizard completion page, click **Finish**.
7. After using this procedure to assign the internal edge certificate, open the Certificate snap-in on each server, expand **Certificates (Local computer)**, expand **Personal**, click **Certificates**, and then verify in the details pane that the internal edge certificate is listed.
8. If your deployment includes multiple Edge Servers, repeat this procedure for each Edge Server.

1.4.2.6.4.3 Set Up Certificates for the External Edge Interface

Set Up Certificates for the External Edge Interface

Deploying External User Access > Setting Up Edge Servers > Set Up Edge Certificates >

Topic Last Modified: *2012-09-08*

> **Important:**

When you run the Certificate Wizard, ensure that you are logged in using an account that is a member of a group that has been assigned the appropriate permissions for the type of certificate template you will use. By default, a Lync Server certificate request will use the Web Server certificate template. If you use an account that is a member of the RTCUniversalServerAdmins group to request a certificate using this template, verify that the group has been assigned the Enroll permissions required to use that template.

Each Edge Server requires a public certificate on the interface between the perimeter network and the Internet, and the certificate's subject alternative name must contain the external names of the Access Edge service and Web Conferencing Edge service fully qualified domain names (FQDNs).

For details about this and other certificate requirements, see Certificate Requirements for External User Access.

For a list of public certification authorities (CAs) that provide certificates that comply with specific requirements for unified communications certificates and have partnered with Microsoft to ensure they work with the Lync Server 2013 Certificate Wizard, see Microsoft Knowledge Base article 929395, "Unified Communications Certificate Partners for Exchange Server and for Communications Server," at http://go.microsoft.com/fwlink/p/?linkId=202834.

Configuring Certificates on the External Interfaces

To set up a certificate on the external edge interface at a site, use the procedures in this section to do the following:

- Create the certificate request for the external interface of the Edge Server.
- Submit the request to your public CA.
- Import the certificate for the external interface of each Edge Server.
- Assign the certificate for the external interface of each Edge Server.
- If your deployment includes multiple Edge Servers, export the certificate along with its private key, and then copy it to the other Edge Servers. Then, for each Edge Server, import it and assign it as previously described. Repeat this procedure for each Edge Server.

You can request public certificates directly from a public certification authority (CA) (such as from the website of a public CA). The procedures in this section use the Certificate Wizard for most certificate tasks. If you chose to request a certificate directly from a public CA, then you will need to modify each procedure as appropriate to request, transport, and import the certificate and also to import the certificate chain.

When you request a certificate from an External CA, the credentials provided must have rights to request a certificate from that CA. Each CA has a security policy that defines which credentials (that is, specific user and group names) are allowed to request, issue, manage, or read certificates.

If you decide to use the Certificates Microsoft Management Console (MMC) to import the certificate chain and certificate, you must import them to the certificate store for the computer. If you import them to the user or service certificate store, the certificate will not be available for assignment in the Lync Server 2013 Certificate Wizard.

⊟To create the certificate request for the external interface of the Edge Server

1. On the Edge Server, in the Deployment Wizard, next to **Step 3: Request, Install, or Assign Certificates**, click **Run again**.

   Note:

> If your organization wants to support public instant messaging (IM) connectivity with AOL, you cannot use the Lync Server Deployment Wizard to request the certificate. Instead, perform the steps in the “To create a certificate request for the external interface of the Edge Server to support public IM connectivity with AOL” procedure later in this topic.
> If you have multiple Edge Servers in one location in a pool, you can run the Lync Server 2013 Certificate Wizard on any one of the Edge Servers.

2. On the **Available Certificate Tasks** page, click **Create a new certificate request**.
3. On the **Certificate Request** page, click **External Edge Certificate**.
4. On the **Delayed or Immediate Request** page, select the **Prepare the request now, but send it later** check box.
5. On the **Certificate Request File** page, type the full path and file name of the file to which the request is to be saved (for example, c:\cert_exernal_edge.cer).
6. On the **Specify Alternate Certificate Template** page, to use a template other than the default WebServer template, select the **Use alternative certificate template for the selected certification authority** check box.
7. On the **Name and Security Settings** page, do the following:
   - In **Friendly name**, type a display name for the certificate.
   - In **Bit length**, specify the bit length (typically, the default of **2048**).
   - Verify that the **Mark certificate private key as exportable** check box is selected.
8. On the **Organization Information** page, type the name for the organization and the organizational unit (for example, a division or department).
9. On the **Geographical Information** page, specify the location information.
10. On the **Subject Name/Subject Alternate Names** page, the information to be automatically populated by the wizard is displayed. If additional subject alternative names are needed, you specify them in the next two steps.
11. On the **SIP Domain Setting on Subject Alternate Names (SANs)** page, select the domain check box to add a sip.<*sipdomain*> entry to the subject alternative names list.
12. On the **Configure Additional Subject Alternate Names** page, specify any additional subject alternative names that are required.
13. On the **Request Summary** page, review the certificate information to be used to generate the request.
14. After the commands finish running, do the following:
    - To view the log for the certificate request, click **View Log**.
    - To complete the certificate request, click **Next**.
15. On the **Certificate Request File** page, do the following:
    - To view the generated certificate signing request (CSR) file, click **View**.
    - To close the wizard, click **Finish**.
16. Copy the output file to a location where you can submit it to the public CA.

⊟To create a certificate request for the external interface of the Edge Server to support public IM connectivity with AOL

1. When the required template is available to the CA, use the following Windows PowerShell cmdlet from at the Edge Server to request the certificate:

```
Request-CsCertificate -New -Type AccessEdgeExternal  -Output C:\ <cert
```

   The default certificate name of the template provided in Lync Server 2013 is Web Server. Only specify the <*template name*> if you need to use a template that is different from the default template.

Note:

> If your organization wants to support public IM connectivity with AOL, you must use Windows PowerShell instead of the Certificate Wizard to request the certificate to be assigned to the external edge for the Access Edge

> service. This is because the Lync Server 2013 Web Server template that the Certificate Wizard uses to request a certificate does not support client EKU configuration. Before using Windows PowerShell to create the certificate, the CA administrator must create and deploy a new template that supports client EKU.

To submit a request to a public certification authority

1. Open the output file.
2. Copy and paste the contents of the Certificate Signing Request (CSR).
3. If prompted, specify the following:
   - **Microsoft** as the server platform.
   - **IIS** as the version.
   - **Web Server** as the usage type.
   - **PKCS7** as the response format.
4. When the public CA has verified your information, you will receive an email message containing text required for your certificate.
5. Copy the text from the email message and save the contents in a text file (.txt) on your local computer.

To import the certificate for the external interface of the Edge Server

1. Log on as a member of the Administrators group to the same Edge Server on which you created the certificate request.
2. In the Deployment Wizard, on the **Deploy Edge Server** page, next to **Step 3: Request, Install, or Assign Certificates**, click **Run again**.
3. On the **Available Certificate Tasks** page, click **Import a certificate from a .p7b, pfx or .cer file**.
4. On the **Import Certificate** page, click **Browse** to locate and select the certificate that you requested for the external interface of the Edge Server (or, you can type the full path and file name). If the certificate contains a private key, select **Certificate file contains certificate's private key** and type the password for the private key. Click **Next**.
5. On **Import Certificate Summary** page, review the summary and then click **Next**.
6. On **Executing Commands**, review the results of the import, click **View Log** for more information as needed, and then click **Finish** to complete the certificate import.
7. If you are configuring an Edge Server pool, export the certificate with its private key as outlined in the "To export the certificate with the private key for Edge Servers in a pool" procedure later in this topic. Copy the exported certificate file to the other Edge Servers, and import it into the computer store on each Edge Server.

To export the certificate with the private key for Edge Servers in a pool

1. Log on as a member of the Administrators group to the same Edge Server on which you imported the certificate.
2. Click **Start**, click **Run**, and type **MMC**.
3. In the Microsoft Management Console (MMC) console, click **File**, and then click **Add/Remove Snap-in**.
4. In **Add or Remove Snap-ins**, click **Certificates**, and then click **Add**.
5. In the **Certificates** dialog box, select **Computer account**, click **Next**, select **Local computer: (the computer this console is running on)** in **Select Computer**, click **Finish** and then click **OK** to complete configuration of the MMC console.
6. Double-click **Certificates (Local Computer)** to expand the certificate stores, double-click **Personal**, and then double-click **Certificates**.

> **Important:**
>
> If there are no certificates in the Certificates Personal store for the local

> computer, there is no private key associated with the certificate that was imported. Review the request and import steps. If the problem persists, contact your certification authority administrator or provider.

7. In the **Certificates Personal store for the local computer**, right-click the certificate that you are exporting, click **All Tasks**, and then click **Export**.
8. In the Certificate Export Wizard, click **Next**, select **Yes, export the private key**, and then click **Next**.

> **Note:**
>
> If the selection **Yes, export the private key** is not available, the private key associated with this certificate was not marked for export. You will need to request the certificate again, ensuring that the certificate is marked to allow for the export of the private key before you can continue with the export. Contact your certification authority administrator or provider.

9. On the Export File Formats dialog, select **Personal Information Exchange – PKCS#12 (.PFX)** and then select the following:
   - Include all certificates in the certification path if possible
   - Export all extended properties

> ⚠**Warning:**
>
> When exporting the certificate from an Edge server, do not select **Delete the private key if the export is successful**. Selecting this option will require that you import the certificate and the private key to this Edge server.

10. Click **Next**.
11. Type a password for the private key, type the password again to confirm, and then click **Next**.
12. Type a path and file name for the exported certificate, using a file extension of .pfx. The path must either be accessible to all other Edge servers in the pool or available to transport by means of removable media - for example, a USB flash drive. Click **Next**.
13. Review the summary in **Completing the Certificate Export Wizard**, and then click **Finish**.
14. In the successful export dialog box, click **OK**.
15. Import the exported certificate file to the other Edge servers following the steps outlined in the "To import the certificate for the external interface of the Edge Server" procedure earlier in this topic.

⊟To assign the certificate for the external interface of the Edge Server

1. On each Edge Server, in the Deployment Wizard, next to **Step 3: Request, Install, or Assign Certificates**, click **Run again**.
2. On the **Available Certificate Tasks** page, click **Assign an existing certificate**.
3. On the **Certificate Assignment** page, click **External Edge Certificate** and select the **Advanced Certificate Usages** check box.
4. On the **Advanced Certificate Usages** page, select all check boxes to assign the certificate for all usages.
5. On the **Certificate Store** page, select the public certificate that you requested and imported for the external interface of the Edge Server.

> **Note:**
>
> If the certificate you requested and imported is not in the list, one of the trouble shooting methods is to verify that subject name and subject alternative names of the certificate meet all requirements for the certificate and, if you manually imported the certificate and certificate chain instead of using the preceding procedures, that the certificate is in the correct certificate store (the computer certificate store, not the user or service certificate store).

6. On the **Certificate Assignment Summary** page, review your settings, and then click **Next** to assign the certificates.

7. On the wizard completion page, click **Finish**.
8. After using this procedure to assign the edge certificate, open the Certificate snap-in on each server, expand **Certificates (Local computer)**, expand **Personal**, click **Certificates**, and then verify in the details pane that the certificate is listed.
9. If your deployment includes multiple Edge Servers, repeat this procedure for each Edge Server.

1.4.2.6.4.4 Set Up Certificates for the Reverse Proxy

Set Up Certificates for the Reverse Proxy

Deploying External User Access > Setting Up Edge Servers > Set Up Edge Certificates >

Topic Last Modified: *2012-09-08*

Each reverse proxy server requires a web server certificate for use by the listening service. The web server certificate must be issued by a public certification authority (CA).

For details about this and other certificate requirements, see Certificate Requirements for External User Access.

⊟To set up a Web Services certificate for the reverse proxy

- You should have already set up your reverse proxy, including setting up the Web Services certificate. If you did not do so before starting your deployment of your Edge Servers, use the procedures in Setting Up Reverse Proxy Servers to create request and install the Web Services certificate, and then create each web publishing rule and configure it to use the certificate.

1.4.2.6.5 Start Edge Servers

Start Edge Servers

Deployment > Deploying External User Access > Setting Up Edge Servers >

Topic Last Modified: *2012-01-16*

After completing the set up of the Edge Servers and load balancers, you need to start the services on each Edge Server.

⊟To start the services

1. On each Edge Server, in the Deployment Wizard, next to **Step 4: Start Services**, click **Run**.
2. On the **Start Lync Server 15 Services** page, review the list of services, and then click **Next** to start the services.
3. After the services are started, click **Finish** to close the wizard.
4. Under **Step 4: Start Services**, click **Services Status (Optional)**.
5. In the **Services** Microsoft Management Console (MMC) on the server, verify that all of the Lync Server 2013 services are running.

1.4.2.7 Setting Up Reverse Proxy Servers

Setting Up Reverse Proxy Servers

Microsoft Lync Server 2013 > Deployment > Deploying External User Access >

Topic Last Modified: *2012-05-26*

For Microsoft Lync Server 2013 Edge Server deployments, an HTTPS reverse proxy in the perimeter network is required for external clients to access the Lync Server 2013 Web Services (called *Web Components* in Office Communications Server) on the Director and the user's home pool. Some of the features that require external access through a reverse proxy include the following:

- Enabling external users to download meeting content for your meetings.
- Enabling external users to expand distribution groups.
- Enabling remote users to download files from the Address Book service.
- Accessing the Lync Web App client.
- Accessing the Dial-in Conferencing Settings webpage.
- Accessing the Location Information service.
- Enabling external devices to connect to Device Update web service and obtain updates.
- Enabling mobile applications to automatically discover mobility URLs from the Internet.

We recommend that you configure your HTTP reverse proxy to publish all Web Services in all pools. Publishing https:// *ExternalFQDN*/* publishes all IIS virtual directories for a pool. You need one publishing rule for each Standard Edition server, Front End pool, or Director or Director pool in your organization.

In addition, you need to publish the simple URLs. If the organization has a Director or Director pool, the HTTP reverse proxy listens for HTTP/HTTPS requests to the simple URLs and proxies them to the external Web Services virtual directory on the Director or Director pool. If you have not deployed a Director, you need to designate one pool to handle requests to the simple URLs. (If this is not the user's home pool, it will redirect them onward to the Web Services on the user's home pool). The simple URLs can be handled by a dedicated web publishing rule, or you can add it to the public names of the web publishing rule for the Director.

If you are deploying mobile applications and plan to use automatic discovery, you also need to publish the external Autodiscover Service URL.

You can use Microsoft Forefront Threat Management Gateway 2010 or Microsoft Internet Security and Acceleration (ISA) Server 2006 SP1 as a reverse proxy. The detailed steps in this section describe how to configure Forefront Threat Management Gateway 2010, and the steps for configuring ISA Server 2006 are almost identical. If you are using a different reverse proxy, consult the documentation for that product and map the requirements defined here to the associated features in other reverse proxies.

The following topics and procedures use Forefront Threat Management Gateway 2010 as the basis for the deployment and configuration procedures.

- Configure Web Farm FQDNs
- Configure Network Adapters
- Request and Configure a Certificate for Your Reverse HTTP Proxy
- Configure Web Publishing Rules for a Single Internal Pool
- Verify or Configure Authentication and Certification on IIS Virtual Directories
- Create DNS Records for Reverse Proxy Servers
- Verify Access through Your Reverse Proxy

Before You Begin

To successfully deploy Forefront Threat Management Gateway 2010 as your reverse proxy, you need to setup and configure a server, using the prerequisites and hardware requirements defined in the Forefront Threat Management Gateway 2010 documentation.

See the following topics to properly configure the hardware and to install Forefront Threat Management Gateway 2010 on the server before proceeding.

1.4.2.7.1 Configure Web Farm FQDNs

Configure Web Farm FQDNs

Deployment > Deploying External User Access > Setting Up Reverse Proxy Servers >

Topic Last Modified: *2012-06-20*

When you defined the configuration of the Standard Edition server, Front End pool, and Director or Director pool in Topology Builder, you configure an external web services fully qualified domain name (FQDN). During the log on process of a client homed in the Standard Edition server or Front End pool, the configured web services FQDNs are sent by way of in-band provisioning. If you need to add or change the external web services URL, you use Topology Builder to configure or reconfigure the web services configuration using the procedure in this topic.

To configure an external pool FQDN for web services

1. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
2. In Topology Builder, in the console tree under **Standard Edition Front Ends**, **Enterprise Edition Front Ends**, and **Directors**, right-click the pool name that you need to edit, and then click **Edit Properties**.
3. In the **Web services** section, add or edit the **External web services FQDN**.
4. Review and adjust the **Listening ports** for both HTTP and HTTPS. The defaults will be:
   - **Listening ports:** HTTP 8080, HTTPS 4443
   - **Published ports:** HTTP 80, HTTPS 443

   Where the **Listening ports** is the port that the external web services will be configured to receive requests from the reverse proxy, and the **Published ports** is the ports that are published externally by the reverse proxy and is communicated to clients during in-band provisioning.
5. When you have completed your additions and updates, click **OK** to continue.
6. Right-click **Lync Server 2013**, and then click **Publish**.

   > **Important:**
   >
   > After publishing successfully completes, a link may be presented that informs you that there are additional steps that need to be taken. The link, if clicked, opens a list of servers affected by the changes made in Topology Builder that will require you to re-run the Lync Server Deployment Wizard on each listed server to update the configuration for added, removed, or changed components.
7. Repeat these steps for all Standard Edition servers, Front End pools, Directors, and Director pools in the organization.

1.4.2.7.2 Configure Network Adapters

Configure Network Adapters

Deployment > Deploying External User Access > Setting Up Reverse Proxy Servers >

Topic Last Modified: *2012-10-21*

You must assign one or more IP addresses to the external network adapter and at least one IP address to the internal network adapter.

If this is a new installation, install Microsoft Forefront Threat Management Gateway 2010 according to the setup instructions included with the product.

In the following procedures, the server running Forefront Threat Management Gateway (TMG) 2010 has two network adapters:

- A public, or external, network adapter, for clients that attempt to connect to your website (that is, usually over the Internet).
- A private, or internal, network interface, for internal servers running Lync Server that are hosting Web Services.

Important:

Similar to the Edge Servers, you set the default gateway on the, external network adapter only. The default gateway will be the IP address of the router or external facing firewall that directs traffic to the Internet. For traffic that is destined from the reverse proxy to the internal facing network adaptor, you must use persistent static routes (such as the route command in Windows Server) for all subnets containing servers referenced by the web publishing rules.

However, creating persistent routes for all subnets may not be necessary if your network’s routers are configured to summarize routes. Create a persistent route to the network where the router is defined and use the router as the default gateway. If you are not sure how your network is configured and need guidance on what persistent routes need to be created, consult with your company’s Network Engineers.

The reverse proxy must be able to resolve the DNS host (A) records for the internal Director and next hop pool FQDNs used in the web publishing rules. As with the Edge Servers, for security reasons, we recommend that you do not have reverse proxy servers access a DNS server located in the internal network. This means you either need DNS servers in the perimeter, or you need HOSTS file entries on the reverse proxy that resolves each of these FQDNs to the internal IP address of the servers.

To configure the network adapter cards on the reverse proxy computer

1. On the Windows Server 2008 or Windows Server 2008 R2 server running TMG 2010, open Change Adapter Settings by clicking **Start**, pointing to **Control Panel**, clicking **Network and Sharing Center**, and then clicking **Change Adapter Settings**.
2. Right-click the external network connection that you want to use for the external interface, and then click **Properties**.
3. On the **Properties** page, click the **Networking** tab, click **Internet Protocol Version 4 (TCP/IPv4)** in the **This connection uses the following items** list, and then click **Properties**.
4. On the **Internet Protocol (TCP/IP) Properties** page, configure the IP addresses as appropriate for the network subnet to which the network adapter is attached.

   Note:

   If the reverse proxy is already being used by other applications that use HTTPS/443, such as for publishing Outlook Web Access, you either need to add another IP address so that you can publish the Lync Server 2013 Web Services on HTTPS/443 without interfering with the existing rules and web listeners, or you need to replace the existing certificate with one that adds the new external FQDN names to the subject alternative name.

5. Click **OK**, and then click **OK**.
6. In **Network Connections**, right-click the internal network connection that you want to use for the internal interface, and then click **Properties**.
7. Repeat steps 3 through 5 to configure the internal network connection.

1.4.2.7.3 Request and Configure a Certificate for Your Reverse HTTP Proxy

Request and Configure a Certificate for Your Reverse HTTP Proxy

Deployment > Deploying External User Access > Setting Up Reverse Proxy Servers >

Topic Last Modified: *2013-02-15*

You need to install the root certification authority (CA) certificate on the server running Microsoft Forefront Threat Management Gateway 2010 for the CA infrastructure that issued the server certificates to the internal servers running Microsoft Lync Server 2013.

You also must install a public web server certificate on your reverse proxy server. This certificate's subject alternative names should contain the published external fully qualified domain names (FQDNs) of each pool that is home to users enabled for remote access, and the external FQDNs of all Directors or Director pools that will be used within that Edge infrastructure. The subject alternative name must also contain the meeting simple URL, the dial-in simple URL, and, if you are deploying mobile applications and plan to use automatic discovery, the external Autodiscover Service URL as shown in the following table.

	Value	**Example**
Subject name	Pool FQDN	webext.contoso.com
Subject alternative name	Pool FQDN	webext.contoso.com **Important:** The subject name must also be present in the subject alternative name.
Subject alternative name	Meeting simple URL **Note:** All meeting simple URLs must be in the subject alternative name. Each SIP domain must have at least one active meeting simple URL.	meet.contoso.com
Subject alternative name	Dial-in simple URL	dialin.contoso.com
Subject alternative name	External Autodiscover Service URL	lyncdiscover.contoso.com

Note:
If your internal deployment consists of more than one Standard Edition server or Front End pool, you must configure web publishing rules for each external web farm FQDN and you will either need a certificate and web listener for each, or you must obtain a certificate whose subject alternative name contains the names used by all of the pools, assign it to a web listener, and share it among multiple web publishing rules.

Create a Certificate Request

You create a certificate request on the reverse proxy. You create a request on another computer, but you must export the signed certificate with the private key and import it onto the reverse proxy once you have received it from the public certification authority.

Note:

> A certificate request or a certificate signing request (CSR) is a request to a trusted public certification authority (CA) to validate and sign the requesting computer's public key. When a certificate is generated, a public key and a private key are created. Only the public key is shared and signed. As the name implies, the public key is made available to any public request. The public key is for use by clients, servers and other requesters that need to exchange information securely and validate a computer's identity. The private key is kept secured and is used only by the computer that created the key pair to decrypt messages encrypted with its public key. The private key can be used for other purposes. For reverse proxy purposes, data encipherment is the primary use. Secondarily, the certificate authentication at the certificate key level is another use, and is limited only to validation that a requester has the computer's public key, or that the computer that you have a public key for is actually the computer that it claims to be.

To generate a certificate signing request on the computer where the certificate and private key will be assigned, you do the following:

Creating a certificate signing request

1. Open the Microsoft Management Console (MMC) and add the Certificates snap-in and select **Computers**, then expand **Personal**. For details on how to create a certificates console in the Microsoft Management Console (MMC), see http://go.microsoft.com/fwlink/?LinkId=282616.
2. Right-click **Certificates**, click **All Tasks**, click **Advanced Operations**, click **Create Custom Request**.
3. On the **Certificate Enrollment** page, click **Next**.
4. On the **Select Certificate Enrollment Policy** page under **Custom Request**, select **Proceed without enrollment policy**. Click **Next**.
5. On the **Custom Request** page, for **Template** select **(No template) Legacy key**. Unless otherwise directed by your certificate provider, leave **Suppress default extensions** unchecked and the **Request format** selection on **PKCS #10**. Click **Next**.
6. On the **Certificate Information** page, click **Details**, then click **Properties**.
7. On the **Certificate Properties** page on the **General** tab in the **Friendly Name** field, type a name for this certificate. Optionally, type a description in the **Description** field. The Friendly Name and description are typically used by the Administrator to identify what the certificate purpose is, such as **Reverse Proxy Listener for Lync Server**.
8. Select the **Subject** tab. Under **Subject name** for the **Type**, select **Common name** for the Subject name type. For the **Value**, type the subject name that you will use for the reverse proxy. In the example provided in the table in this topic, the subject name is webext.contoso.com and would be typed into the Value field for the Subject name.
9. On the **Subject** tab under **Alternative name**, select **DNS** from the drop down for **Type**. For each defined subject alternative name that you require on the certificate, type the fully qualified domain name, then click **Add**. For example, in the table there are three subject alternative names, meet.contoso.com, dialin.contoso.com, and lyncdiscover.contoso.com. In the **Value** field, type meet.contoso.com, then click **Add**. Repeat for each subject alternative names that you need to define.
10. On the **Certificate Properties** page, click the **Extensions** tab. On this page, you will define the cryptographic key purposes in **Key usage** and the extended key usage in **Extended Key Usage (application policies)**.
11. Click the **Key usage** arrow to show the **Available options**. Under Available options, click **Digital signature**, then click **Add**. Click **Key encipherment**, then click **Add**. If the checkbox for **Make these key usages critical** is unchecked, select the checkbox.
12. Click the **Extended Key Usage (application policies)** arrow to show the **Available options**. Under Available options, click **Server Authentication**, then click **Add**. Click **Client Authentication**, then click **Add**. If the check box for **Make the Extended Key Usages critical** is checked, unselect the checkbox. Contrary to the Key usage checkbox (which must be checked) you must be

sure that the Extended Key Usage checkbox is not checked.

13. On the **Certificate Properties** page, click the **Private Key** tab. Click the **Key options** arrow. For **Key size**, select **2048** from the drop down. If you are generating this key pair and CSR on a computer other than the reverse proxy that this certificate is intended for, select **Make private key exportable**.

Security Note:

Selecting **Make a private key exportable** is generally advised when you have more than one reverse proxy in a farm because you will copy the certificate and the private key to each machine in the farm. If you do allow for an exportable private key, you must take extra care with the certificate and the computer that it is generated on. The private key, if compromised, will render the certificate useless as well as potentially expose the computer or computers to external access and other security vulnerabilities.

14. On the **Private Key** tab, click the **Key options** arrow. Select the **Exchange** option.
15. Click **OK** to save the **Certificate Properties** that you have set.
16. On the **Certificate Enrollment** page, click **Next**.
17. On the **Where do you want to save the offline request?** page, you are prompted for a **File Name** and a **File Format** for saving the certificate signing request.
18. In the **File Name** entry field, type a path and filename for the request, or click **Browse** to select a location for the file and type the filename for the request.
19. For **File format**, click either **Base 64** or **Binary**. Select **Base 64** unless you are instructed otherwise by the vendor for your certificates.
20. Locate the request file that you saved in the previous step. Submit to your public certification authority.

Important:

Microsoft has identified Public CAs that meet the requirements for Unified Communications purposes. A list is maintained in the following knowledge base article. http://go.microsoft.com/fwlink/?LinkId=282625

1.4.2.7.4 Configure Web Publishing Rules for a Single Internal Pool

Configure Web Publishing Rules for a Single Internal Pool

Deployment > Deploying External User Access > Setting Up Reverse Proxy Servers >

Topic Last Modified: *2012-05-26*

Microsoft Forefront Threat Management Gateway 2010 uses web publishing rules to publish internal resources, such as a meeting URL, to users on the Internet.

In addition to the Web Services URLs for the virtual directories, you must also create publishing rules for simple URLs. For each simple URL, you must create an individual rule on the reverse proxy that points to that simple URL.

If you are deploying mobility and using automatic discovery, you need to create a publishing rule for the external Autodiscover Service URL. Automatic discovery also requires publishing rules for the external Lync Server Web Services URL for your Director pool and Front End pool. For details about creating the web publishing rules for automatic discovery, see Configuring the Reverse Proxy for Mobility.

Use the following procedures to create web publishing rules.

Note:

These procedures assume that you have installed the Standard Edition of Forefront

Threat Management Gateway (TMG) 2010.

⊟To create a web server publishing rule on the computer running TMG 2010

1. Click **Start**, select **Programs**, select **Microsoft Forefront TMG**, and then click **Forefront TMG Management**.
2. In the left pane, expand **ServerName**, right-click **Firewall Policy**, select **New**, and then click **Web Site Publishing Rule**.
3. On the **Welcome to the New Web Publishing Rule** page, type a display name for the publishing rule (for example, LyncServerWebDownloadsRule).
4. On the **Select Rule Action** page, select **Allow**.
5. On the **Publishing Type** page, select **Publish a single Web site or load balancer**.
6. On the **Server Connection Security** page, select **Use SSL to connect to the published Web server or server farm**.
7. On the **Internal Publishing Details** page, type the fully qualified domain name (FQDN) of the internal web farm that hosts your meeting content and Address Book content in the **Internal Site name** box.

   Note:

   If your internal server is a Standard Edition server, this FQDN is the Standard Edition server FQDN. If your internal server is a Front End pool, this FQDN is a hardware load balancer virtual IP (VIP) that load balances the internal web farm servers. The TMG server must be able to resolve the FQDN to the IP address of the internal web server. If the TMG server is not able to resolve the FQDN to the proper IP address, you can select **Use a computer name or IP address to connect to the published server**, and then in the **Computer name or IP address** box, type the IP address of the internal web server. If you do this, you must ensure that port 53 is open on the TMG server and that it can reach a DNS server that resides in the perimeter network. You can also use entries in the local hosts file to provide name resolution.

8. On the **Internal Publishing Details** page, in the **Path (optional)** box, type **/*** as the path of the folder to be published.

   Note:

   In the website publishing wizard you can only specify one path. Additional paths can be added by modifying the properties of the rule.

9. On the **Public Name Details** page, confirm that **This domain name** is selected under **Accept Requests for**, type the external Web Services FQDN, in the **Public Name** box.
10. On **Select Web Listener** page, click **New** to open the New Web Listener Definition Wizard.
11. On the **Welcome to the New Web Listener Wizard** page, type a name for the web listener in the **Web listener name** box (for example, LyncServerWebServers).
12. On the **Client Connection Security** page, select **Require SSL secured connections with clients**.
13. On the **Web Listener IP Address** page, select **External**, and then click **Select IP Addresses**.
14. On the **External Listener IP selection** page, select **Specified IP address on the Forefront TMG computer in the selected network**, select the appropriate IP address, click **Add**.
15. On the **Listener SSL Certificates** page, select **Assign a certificate for each IP address**, select the IP address that is associated with the external web FQDN, and then click **Select Certificate**.
16. On the **Select Certificate** page, select the certificate that matches the public names specified in step 9, click **Select**.
17. On the **Authentication Setting** page, select **No Authentication**.
18. On the **Single Sign On Setting** page, click **Next**.
19. On the **Completing the Web Listener Wizard** page, verify that the **Web**

listener settings are correct, and then click **Finish**.

20. On the **Authentication Delegation** page, select **No delegation, but client may authenticate directly**.
21. On the **User Set** page, click **Next**.
22. On the **Completing the New Web Publishing Rule Wizard** page, verify that the web publishing rule settings are correct, and then click **Finish**.
23. Click **Apply** in the details pane to save the changes and update the configuration.

⊟To modify the properties of the web publishing rule

1. Click **Start**, point to **Programs**, select **Microsoft Forefront TMG**, and then click **Forefront TMG Management**.
2. In the left pane, expand **ServerName**, and then click **Firewall Policy**.
3. In the details pane, right-click the web server publishing rule that you created in the previous procedure (for example, LyncServerExternalRule), and then click **Properties**.
4. On the **Properties** page, on the **From** tab, do the following:
    - In the **This rule applies to traffic from these sources** list, click **Anywhere**, and then click **Remove**.
    - Click **Add**.
    - In **Add Network Entities**, expand **Networks**, click **External**, click **Add**, and then click **Close**.
5. On the **To** tab, ensure that the **Forward the original host header instead of the actual one** check box is selected.
6. On the **Bridging** tab, select the **Redirect request to SSL port** check box, and then specify port **4443**.
7. On the **Public Name** tab, add the simple URLs (for example, meet.contoso.com and dialin.contoso.com).
8. Click **Apply** to save changes, and then click **OK**.
9. Click **Apply** in the details pane to save the changes and update the configuration.

1.4.2.7.5 Verify or Configure Authentication and Certification on IIS Virtual Directories

Verify or Configure Authentication and Certification on IIS Virtual Directories

See Also

Deployment > Deploying External User Access > Setting Up Reverse Proxy Servers >

Topic Last Modified: *2012-05-25*

Use the following procedure to configure the certificate on your Internet Information Services (IIS) virtual directories or verify that the certificate is configured correctly. Perform the following procedure on each server running IIS in your internal Lync Server pool and the optional Director.or Director pool servers.

Note:

The following procedure defines a procedure to request a combined certificate that is used for all purposes Lync Server, Internal Web Site and External Web Site in IIS. Lync Server 2010 introduced a set of Lync Server Management Shell Windows PowerShell cmdlets for the express purpose of managing certificate request, import, and assignment. The procedure assumes that there is an internally deployed certification authority (CA) that can process the request. If you use public certificates for your Lync Server purposes, or your CA requires an offline request, see the detailed syntax in this topic for information on the –Output parameter. Request-CsCertificate

⊟To configure authentication and certificates on IIS virtual directories

1. To successfully complete the following, you must be logged on to the computer (Front End Server or Director) where the web services are installed and be a local administrator. You must have the **read** and **enroll** permissions on the certification authority that you will be requesting certificates from, if the certification authority is your organization's certification authority. You do not need permissions to the certification authority if you will configure and send an offline certificate request.
2. Click **Start**, select **All Programs**, select **Administrative Tools**, and then click **Internet Information Services (IIS) Manager**.
3. In **Internet Information Services (IIS) Manager**, select **ServerName**. In **Features View**, select **Server Certificates**, right-click and select **Open Feature**.

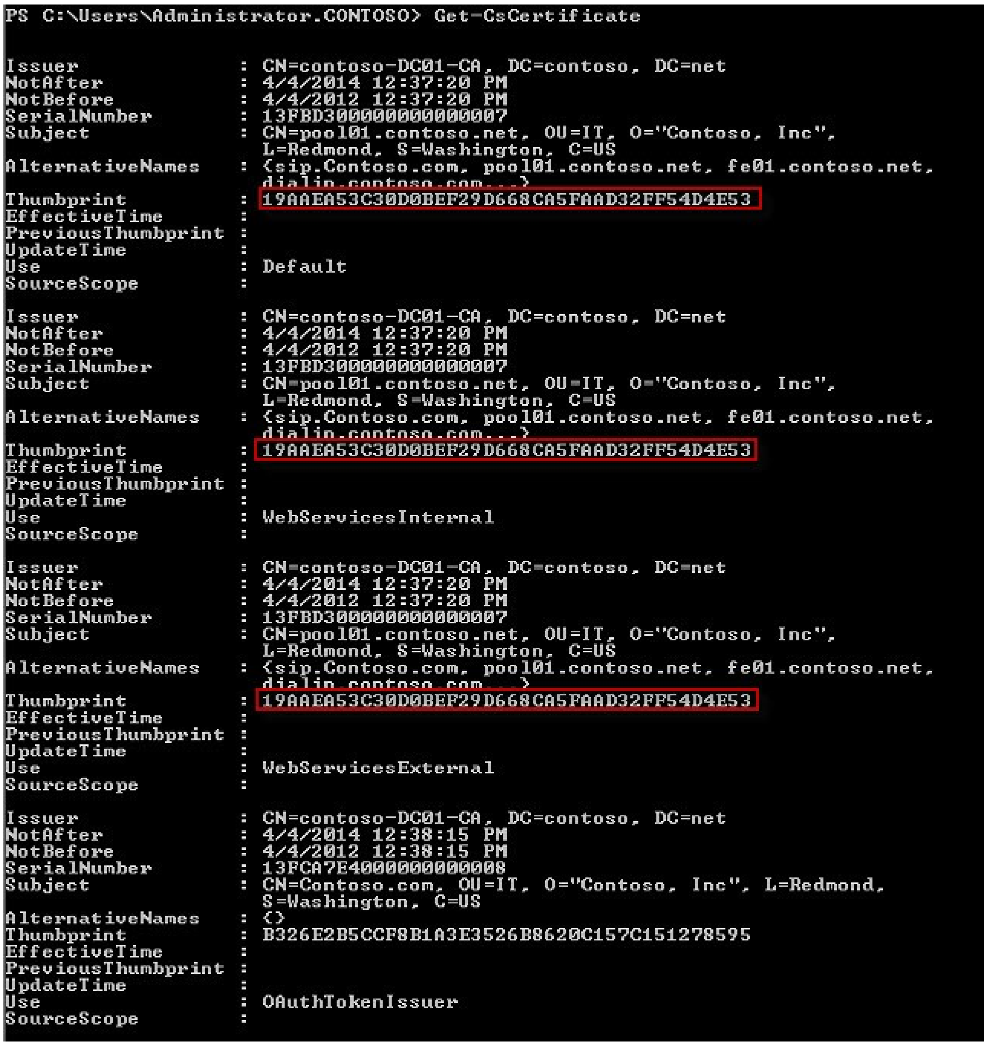
   Tip:

   In the Server Certificates Feature View, if there are certificates assigned to the server, they will appear here. If there is a certificate that matches the requirements for the External Web Site in IIS, you can re-use that certificate. To view a certificate, right-click the certificate and select **View...**

4. On the Front End Server or Director that you are requesting the certificate for, click **Start**, select **All Programs**, select **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
5. In the Lync Server Management Shell, type the following:

   ```
   Get-CsCertificate
   ```

   The output is a list of the certificates that are currently on the server in the Computer Personal certificate store. Note that in the combined certificate (that is, where the default, web services internal and web services external are using the same certificate) you will see that the Use property will be populated with Default, WebServicesInternal and WebServicesExternal. Also, the Thumbprint property will be the same for each of the Use types. An example output of Get-CsCertificate is shown in this example:



```

6. In the Lync Server Management Shell, type the following:

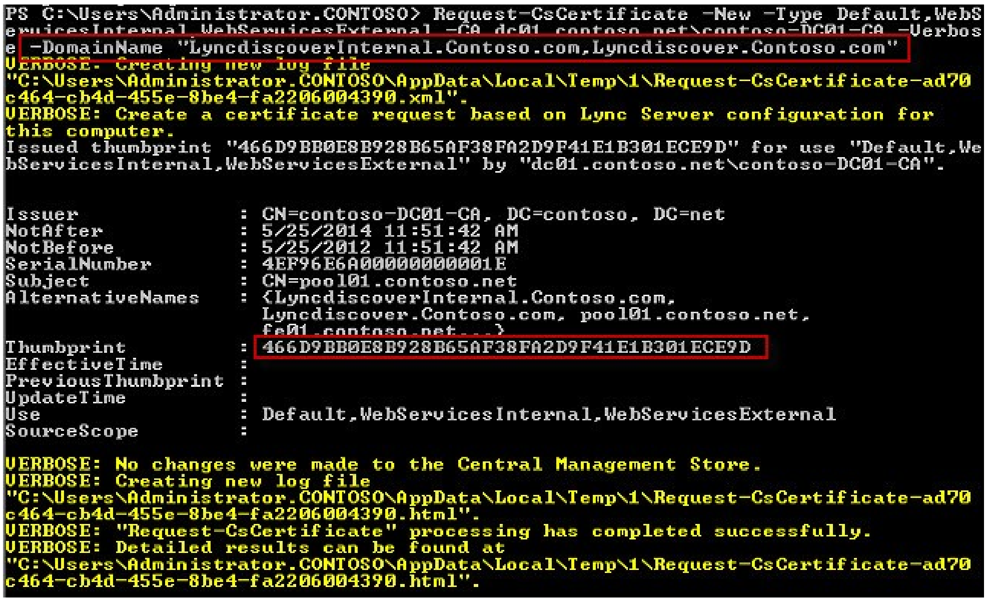
```
Request-CsCertificate -New -Type Default,WebServicesInternal,WebServic
```

Where the full command would appear like following example:

```
Request-CsCertificate -New -Type Default,WebServicesInternal,WebServic
```

Tip:

By default, Request-CsCertificate will populate the subject name with the server or pool name and populate entries in the subject alternative name with the server FQDN, pool FQDN, Simple URL FQDNs, and internal and external web services FQDNs. It does this by referencing to the topology document in your deployment. If there is a missing value and you have specified the –Verbose parameter, you will be notified that the computed and actual values for alternative names are different, but it does not inform you which values are missing. It does supply you with the entire computed value that the cmdlet references. Use the computed alternative names string in the output to re-request a new certificate that will include all values.



```

1.4.2.7.6 Create DNS Records for Reverse Proxy Servers

Create DNS Records for Reverse Proxy Servers

Deployment > Deploying External User Access > Setting Up Reverse Proxy Servers >

Topic Last Modified: *2012-09-27*

Create external DNS A records that point to the public external interface of your Microsoft Internet Security and Acceleration (ISA) Server 2006 SP1 or Forefront Threat Management Gateway 2010 Server, as described in Configure DNS for Edge Support. You need DNS records for the external Web Service FQDNs for each pool, the Director (or Director pool), and each simple URL.

The minimum DNS records for client resolution to the reverse proxy, the following records must be created:

- Host (A) record that defines the reverse proxy (for example, **lsrp.contoso.com**)
- Host (A) record(s) that define the published external web services for Directors and Director pools (for example, **webdirexternal.contoso.com**)
- Host (A) record(s) that define the published external web services for external web services hosted on the any Front End pools and Standard Edition server roles (for example, **webexternal.contoso.com**)
- Host (A) records for the Simple URLs (for example, **dialin.contoso.com** and **meet.contoso.com**)
- Host (A) record for the Lync Discover External record, and also provides pointer to AutoDiscover for all Web apps, including the Lync Web App, scheduler and Mobility (for example, **lyncdiscover.contoso.com**)

For details, see DNS Summary - Reverse Proxy.

1.4.2.7.7 Verify Access through Your Reverse Proxy

Verify Access through Your Reverse Proxy

Deployment > Deploying External User Access > Setting Up Reverse Proxy Servers >

Topic Last Modified: *2012-05-26*

Use the following procedure to verify that your users can access information on the reverse proxy. You might need to complete the firewall configuration and Domain Name System (DNS) configuration before access will work correctly.

⊟To verify that you can access the website through the Internet

- Open a web browser, type the URLs in the **Address** bar that clients use to access the Address Book files and the website for conferencing as follows:
  - For Address Book Server, type a URL similar to the following: **https://*externalwebfarmFQDN*/abs** where *externalwebfarmFQDN* is the external FQDN of the external web services that hosts Address Book services. The user should receive an HTTP challenge, because directory security on the Address Book Server folder is configured to Windows authentication by default.
  - For conferencing, type a URL similar to the following: **https://*externalwebfarmFQDN*/meet** where *externalwebfarmFQDN* is the external FQDN of the web farm that hosts meeting content. This URL should display the troubleshooting page for conferencing. Alternatively, confirm that your Simple URL for conferencing functions correctly. An example Simple URL for

the conference join might be https://meet.contoso.com

- For distribution group expansion, type a URL similar to the following: **https://*externalwebfarmFQDN*/GroupExpansion/service.svc**. The user should receive an HTTP challenge, because directory security on the distribution group expansion service is configured to Windows authentication by default.
- For dial-in, type the simple URL similar to the following **https://*externalwebfarmFQDN*/dialin** where *externalwebfarmFQDN* is the external FQDN of the web farm that hosts the dial-in page for dial-in conferencing. The user should be directed to the dial-in page. Alternatively, confirm that your Simple URL dial-in functions correctly. An example Simple URL for dial-in might be https://dialin.contoso.com

1.4.2.8 Configuring Support for External User Access

Configuring Support for External User Access

Microsoft Lync Server 2013 > Deployment > Deploying External User Access >

Topic Last Modified: *2013-02-21*

Deploying an Edge Server or Edge pool is the first step to supporting external users. For details about deploying Edge Servers, see Deploying External User Access in the Deployment documentation. An important consideration for the configuration of policies is to understand the precedence of policies and how the policies are applied. Lync Server policy settings that are applied at one policy level can override settings that are applied at another policy level. Lync Server policy precedence is: User policy (most influence) overrides a Site policy, and then a Site policy overrides a Global policy (least influence). This means that the closer the policy setting is to the object that the policy is affecting, the more influence it has on the object.

After completing the setup of an Edge Server or Edge pool, you must enable the types of external user access that you want to provide, and configure the settings for the external access. In Lync Server 2013, you enable and configure external user access and policies using the Lync Server Control Panel, the Lync Server Management Shell or both, based on the task requirements.

To support external user access, you must do both of the following:

- **Enable support for your organization** To enable support for external user access in your deployment, you enable each type of external access that you want to support. You enable and disable support for external user access by editing the global settings or creating and configuring a site or user policy on the **External Access Policy** page in the **Federation and External Access** group of the Lync Server Control Panel or by using the Lync Server Management Shell and associated cmdlets. Cmdlets for managing the **External Access Policy** are found in the topic Federation and External Access Cmdlets. Enabling support for external access specifies that your servers running the Lync Server Access Edge service support communications with external users and servers. Internal and external users cannot communicate while external user access is disabled or if policies have not yet been configured to support it.
- **Configure and assign one or more policies** To support external user access, you configure policies to address requirements that include:
  - **External access policies** Created with either a site or user scope (a global policy exists by default and has no enabled settings). You create and configure policies to control the use of one or more types of external user access, including, federated user access (including, if selected, federated XMPP domains)remote users user access, and supported public IM service providers. You configure external policies in Lync Server Control Panel using

the global policy or one or more administratively created site and user policies, on the **External Access Policy** page in the **Federation and External Access** group. The global policy cannot be deleted. You create and configure any site and user policies that you want to use to limit external user access for specific sites or users. Global and site policies are automatically assigned. If you create and configure a user policy, you must then assign it to the specific users by using the user configuration page in the Lync Server Control Panel on the **Users** page. Find the user or users that you want this policy to apply to and assign the policy. to whom you want it to apply. To assign a configured user policy to a user, see Assign an External User Access Policy to a Lync Enabled User. Each external user access policy can support one or more of the following: remote user access, SIP federated user access, XMPP federated user access and public IM connectivity.

- **Conferencing policies** You create and configure policies to control conferencing in your organization, including which users in your organization can invite anonymous users to conferences that they host. On the Lync Server Control Panel **Conferencing** page are policy settings at the global, site and user scope that control settings for the actual conferences. For details, see Managing Meetings and Conferences. You enable anonymous users for conferencing, remote users and federated users on the **Access Edge Configuration** page. The policy on the **Access Edge Configuration** is global in scope. There are no options to define a site or user policy. The scope is controlled on the **External Access Policy** page through the use of global, site, or user policy settings.

  For example, if you want to allow users to create, invite and manage conferencing with remote users, you must set **Enable communications with remote users** on the **External Access Policy** global, site or user policy, and **Enable Communications with remote users** on the **Access Edge Configuration** page. Similarly, to allow conferencing with anonymous users or federated partners that you have a defined relationship with (such as configured federated SIP domains and providers – XMPP federation does not support conferencing), you set **Enable communications with public users** and **Enable communications with federated users** in the **External Access Policy** global, site or user policy. You then select complimentary global policy settings **Enable anonymous user access to conferences** and **Enable federated and public IM connectivity** on the **Access Edge Configuration** page.

You can configure external user access settings, including any policies that you want to use to control external user access, even if you have not enabled external user access for your organization. However, the policies and other settings that you configure are in effect only when you have external user access enabled for your organization. External users cannot communicate with users of your organization when external user access is disabled or if no external user access policies are configured to support it.

Your edge deployment authenticates the types of external users (except for anonymous users, who are authenticated by the conference ID and a passkey that is sent to the anonymous participant when you create the conference and invite participants) and controls access based on how you configure your edge support. In order to control communications, you can configure one or more policies and configure settings that define how users inside and outside your deployment communicate with each other. The policies and settings include the default global policy for external user access, in addition to site and user policies that you can create and configure to enable one or more types of external user access for specific sites or users.

- Configure Policies to Control Remote User Access
- Enable or Disable Remote User Access
- Enable or Disable Anonymous User Access
- Assign Conferencing Policies to Support Anonymous Users

Configure Policies to Control Remote User Access

Deployment > Deploying External User Access > Configuring Support for External User Access >

Topic Last Modified: *2012-10-18*

You configure one or more external user access policies to control whether remote users can collaborate with internal Lync Server users. To control remote user access, you can configure policies at the global, site, and user level. Site policies override the global policy, and user policies override site and global policies. For details about the types of policies that you can configure, see Managing Federation and External Access to Lync Server 2013. Lync Server policy settings that are applied at one policy level can override settings that are applied at another policy level. Lync Server policy precedence is: User policy (most influence) overrides a Site policy, and then a Site policy overrides a Global policy (least influence). This means that the closer the policy setting is to the object that the policy is affecting, the more influence it has on the object.

Note:

You can configure policies to control remote user access, even if you have not enabled remote user access for your organization. However, the policies that you configure are in effect only when you have remote user access enabled for your organization. For details about enabling remote user access, see Enable or Disable Federation and Public IM Connectivity. Additionally, if you specify a user policy to control remote user access, the policy applies only to users that are enabled for Lync Server and configured to use the policy. For details about specifying users that can sign in to Lync Server from remote locations, see Assign an External User Access Policy to a Lync Enabled User.

Use the following procedure to configure each external access policy that you want to use to control remote user access.

Note:

This procedure describes how to configure a policy only to enable communications with remote users, but each policy that you configure to support remote user access can also configure federated user access and public user access. For details about configuring policies to support federated users, see Configure Policies to Control Federated User Access. For details about configuring policies to support public users, see Create or Edit Public SIP Federated Providers.

⊟To configure an external access policy to support remote user access

1. From a user account that is a member of the RTCUniversalServerAdmins group (or has equivalent user rights), or is assigned to the CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **External User Access**, and then click **External Access Policy**.
4. On the **External Access Policy** page, do one of the following:
   - To configure the global policy to support remote user access, click the global policy, click **Edit**, and then click **Show details**.
   - To create a new site policy, click **New**, and then click **Site policy**. In **Select a Site**, click the appropriate site from the list and then click **OK**.
   - To create a new user policy, click **New**, and then click **User policy**. In **New External Access Policy**, create a unique name in the **Name** field that indicates what the user policy covers (for example, **EnableRemoteUsers** for a user policy that enables communications for remote users).
   - To change an existing policy, click the appropriate policy listed in the table,

click **Edit**, and then click **Show details**.

5. (Optional) If you want to add or edit a description, specify the information for the policy in **Description**.
6. Do one of the following:
   - To enable remote user access for the policy, select the **Enable communications with remote users** check box.
   - To disable remote user access for the policy, clear the **Enable communications with remote users** check box.
7. Click **Commit**.

To enable remote user access, you must also enable support for remote user access in your organization. For details, see Enable or Disable Federation and Public IM Connectivity in the Deployment documentation or the Operations documentation.

If this is a user policy, you must also apply the policy to users that you want to be able to connect remotely. For details, see Assign an External User Access Policy to a Lync Enabled User in the Deployment documentation or the Operations documentation.

1.4.2.8.2 Enable or Disable Remote User Access

Enable or Disable Remote User Access

Deployment > Deploying External User Access > Configuring Support for External User Access >

Topic Last Modified: *2013-02-23*

Remote users are users in your organization who have a persistent Active Directory identity within the organization. Remote users often sign in to Lync Server from outside your network by using a virtual private network (VPN) when they are not connected to your organization’s network. Remote users include employees working at home or on the road and other remote workers, such as trusted vendors, who have been granted enterprise credentials. If you enable remote user access for remote users, supported remote users connect over the Internet and do not have to connect using a VPN in order to collaborate with internal users using Lync Server.

To support remote user access, you must enable remote user access. When you enable remote user access, you enable it for your entire organization. If you later want to temporarily or permanently prevent remote user access, you can disable it for your organization. Use the procedure in this section to enable or disable remote user access for your organization.

Note:

Enabling remote user access only specifies that your servers running the Access Edge service support communications with remote users, but remote users cannot participate in instant messaging (IM) or conferences in your organization until you also configure at least one policy to manage the use of remote user access. Lync Server policy settings that are applied at one policy level can override settings that are applied at another policy level. Lync Server policy precedence is: User policy (most influence) overrides a Site policy, and then a Site policy overrides a Global policy (least influence). This means that the closer the policy setting is to the object that the policy is affecting, the more influence it has on the object. For details about configuring policies for the use of remote user access, see Configure Policies to Control Remote User Access.

⊟To enable or disable remote user access for your organization

1. From a user account that is a member of the RTCUniversalServerAdmins group (or has equivalent user rights), or is assigned to the CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync

Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.

3. In the left navigation bar, click **Federation and External Access**, and then click **Access Edge Configuration**.
4. On the **Access Edge Configuration** page, click **Global**, click **Edit**, and then click **Show details**.
5. In **Edit Access Edge Configuration**, do one of the following:
   - To enable remote user access for your organization, select the **Enable remote user access** check box.
   - To disable remote user access for your organization, clear the **Enable remote user access** check box.
6. Click **Commit**.

To enable remote users to sign in to your servers running Lync Server, you must also configure at least one external access policy to support remote user access. For details, see Configure Policies to Control Remote User Access in the Deployment documentation or the Operations documentation.

Enabling or Disabling Remote User Access by Using Windows PowerShell Cmdlets

Remote user access can be managed by using Windows PowerShell and the Set-CsAccessEdgeConfiguration cmdlet. This cmdlet can be run either from the Lync Server 2013 Management Shell or from a remote session of Windows PowerShell. For details about using remote Windows PowerShell to connect to Lync Server, see the Lync Server Windows PowerShell blog article "Quick Start: Managing Microsoft Lync Server 2010 Using Remote PowerShell" at http://go.microsoft.com/fwlink/p/?linkId=255876.

To enable remote user access

- To enable remote user access, set the value of the **AllowOutsideUsers** property to True ($True):

```
Set-CsAccessEdgeConfiguration -AllowOutsideUsers $True
```

To disable remote user access

- To disable remote user access, set the value of the **AllowOutsideUsers** property to False ($False):

```
Set-CsAccessEdgeConfiguration -AllowOutsideUsers $False
```

1.4.2.8.3 Enable or Disable Anonymous User Access

Enable or Disable Anonymous User Access

See Also

Deployment > Deploying External User Access > Configuring Support for External User Access >

Topic Last Modified: *2013-02-23*

Anonymous users are users who do not have a user account in your organization's Active Directory Domain Services (AD DS) or in a supported federated domain, but can be invited to participate remotely in an on-premises conference. By allowing anonymous participation in meetings you enable anonymous users (that is, users whose identity is verified through the meeting or conference key only) to join meetings. Allowing anonymous participation requires enabling it for your organization.

If you later want to temporarily or permanently prevent access by anonymous users, you can disable it for your organization. Use the procedure in this section to enable or disable anonymous user access for your organization.

Note:

By enabling anonymous user access for your organization you are only specifying that your servers running the Access Edge service support access by anonymous users. Anonymous users cannot participate in any meetings in your organization until you also configure at least one conferencing policy and apply it to one or more users or user groups. The only users that can invite anonymous users to meetings are those users that are assigned a conferencing policy that is configured to support anonymous users. For details about configuring conferencing policies to support inviting anonymous users, see Conferencing Policies.

⊟To enable or disable anonymous user access for your organization

1. From a user account that is a member of the RTCUniversalServerAdmins group (or has equivalent user rights), or is assigned to the CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **External User Access**, and then click **Access Edge Configuration**.
4. On the **Access Edge Configuration** page, click **Global**, click **Edit**, and then click **Show details**.
5. In **Edit Access Edge Configuration**, do one of the following:
   - To enable anonymous user access for your organization, select the **Enable communications with anonymous users** check box.
   - To disable anonymous user access for your organization, clear the **Enable communications with anonymous users** check box.
6. Click **Commit**.

Enabling or Disabling Anonymous User Access by Using Windows PowerShell Cmdlets

You can manage anonymous user access by using Windows PowerShell and the **Set-CsAccessEdgeConfiguration** cmdlet. You can run this cmdlet either from the Lync Server 2013 Management Shell or from a remote session of Windows PowerShell. For details about using remote Windows PowerShell to connect to Lync Server, see the Lync Server Windows PowerShell blog article "Quick Start: Managing Microsoft Lync Server 2010 Using Remote PowerShell" at http://go.microsoft.com/fwlink/p/?linkId=255876.

⊟To enable anonymous user access

- To enable anonymous user access, set the value of the **AllowAnonymousUsers** property to True ($True):

```
Set-CsAccessEdgeConfiguration -AllowAnonymousUsers $True
```

⊟To disable anonymous user access

- To disable anonymous user access, set the value of the **AllowAnonymousUsers** property to False ($False):

```
Set-CsAccessEdgeConfiguration -AllowAnonymousUsers $False
```

1.4.2.8.4 Assign Conferencing Policies to Support Anonymous Users

Assign Conferencing Policies to Support Anonymous Users

Deployment > Deploying External User Access > Configuring Support for External User Access >

Topic Last Modified: *2012-10-19*

By default, all users are prevented from inviting anonymous users to participate in a meeting. You control who can invite anonymous users by configuring a conferencing policy to support anonymous users, and applying that conferencing policy to specific users. For details about how to configure a conferencing policies to support anonymous users, see Create or Modify a Conferencing Policy and Managing Federation and External Access to Lync Server 2013.

Use the procedure in this section to apply a conferencing policy that you have already created to one or more users or user groups.

Note:

In addition to configuring and applying a policy to enable users to invite anonymous users, you must also enable support for anonymous users for your organization. For details, see Configure Policies to Control Public User Access.

⊟To configure a user policy for anonymous participation in meetings

1. From a user account that is a member of the RTCUniversalServerAdmins group (or has equivalent user rights), or is assigned to the CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Conferencing**, and then do one of the following:
   3.a. To create a new user policy, click **New**, and then click **User policy**. Create a unique name in the **Name** field that indicates what the user policy covers (for example, **EnableAnonymous** for a user policy that enables communications with anonymous users).
   3.b. To configure an existing user policy, click the appropriate policy listed in the table, click **Edit**, and then click **Show details**.
4. In the **Conferencing Policies** dialog box, select the **Allow participants to invite anonymous users** check box.
5. Click **Commit**.
6. In the left navigation bar, click **Users**, search on the user account that you want to configure.
7. In the table that lists the search results, click the user account, click **Edit**, and then click **Show details**.
8. In **Edit Lync Server User** under **Conferencing policy**, select the user policy with the anonymous user access configuration that you want to apply to this user.

   Note:

   The **<Automatic>** settings apply the default server installation settings and are applied automatically by the server.

To enable users to invite anonymous users to conferences, you must also enable support for anonymous users in your organization. For details, see Configure Policies to Control Public User Access in the Deployment documentation or the Operations documentation.

1.4.2.9 Configuring Support for Autodiscover

Configuring Support for Autodiscover

Microsoft Lync Server 2013 > Deployment > Deploying External User Access >

Topic Last Modified: *2013-01-21*

The Lync Server web services **Autodiscover service** first appeared in the Lync Server 2010 Cumulative Update: November 2011. This update was accompanied by the initial release of Lync Mobile clients. The autodiscover service exposed the mobility services, known as the Mcx service.

The autodiscover service acts as a single location for all clients to request information on what services and features are available, and how to contact the services – either by a fully qualified domain name or a web uniform resource locator reference. Autodiscover exposes a number of features, and each client will make requests based on the features that the client can use. For example, a desktop Lync 2013 client will use autodiscvoer to determine the external web services, but will not use the mobility (Mcx) services. To properly define and enable your clients to use the features available to them, the scenarios that allow a client to effectively find and use autodiscover entries should be defined. To use autodoscover, your deployment requires that a reverse proxy publishes the Lync Server web services, that DNS records are configured to resolve DNS queries for the Lync Server autodiscover service and Lync Server web services, and that certificate services are properly configured for your specific scenario.

Tip:
For technical details on what the elements within the autodiscover request/response do, see Understanding Autodiscover.

The following information and tables define, per scenario, what configurations (if any) you need to implement to provide the full and effective use of the autodiscover service. The information in the following topics is specific to Microsoft Lync Server 2013. If you are looking for guidance on how to plan Mobility for Lync Server 2010, see http://go.microsoft.com/fwlink/?LinkId=275113. To deploy Mobility for Lync Server 2010, see http://go.microsoft.com/fwlink/?LinkId=275114

1.4.2.9.1 Configuring DNS for Autodiscover

Configuring DNS for Autodiscover

Deployment > Deploying External User Access > Configuring Support for Autodiscover >

Topic Last Modified: *2012-12-12*

To support autodiscovery for Lync clients, you need to create the following Domain Name System (DNS) records:

- An internal DNS record to support Lync clients who connect from within your organization's network

- An external, or public, DNS record to support Lync clients who connect from the Internet

You must create an internal DNS record and an external DNS record for each SIP domain.

The DNS records can be either A (host) records or CNAME records, based on your ability to create new certificates with the additional subject alternate name (SAN). If you are not able to request and deploy a new external (public) certificate with the lyncdiscover.<domain name> SAN, use the procedure for using HTTP/TCP port 80. The following procedures describe how to create internal and external DNS records.

⊟To create DNS CNAME records

1. Log on to a DNS server as follows:
   - To create an internal DNS record, log on to a DNS server in your network as a member of the Domain Admins group or a member of the DnsAdmins group.
   - To create an external DNS record, connect to your public DNS provider.
2. Open the DNS administrative snap-in: Click **Start**, click **Administrative Tools**, and then click **DNS**.
3. Do one of the following:
   - For an internal DNS record, in the console tree of the DNS server, expand **Forward Lookup Zones** for your Active Directory domain (for example, contoso.local).

     Note:
     This domain is the Active Directory domain where your Lync Server 2013 Director pool and Front End pool are installed.

   - For an external DNS record, in the console tree of the DNS server, expand **Forward Lookup Zones** for your SIP domain (for example, contoso.com).
4. Verify that a host A record exists for your Director pool as follows:
   - For an internal DNS record, a host A record should exist for the internal Web Services fully qualified domain name (FQDN) for your Director pool (for example, lyncwebdir01.contoso.local).
   - For an external DNS record, a host A record should exist for the external web services FQDN for your Director pool (for example, lyncwebextdir.contoso.com).
5. Verify that a host A record exists for your Front End pool as follows:
   - For an internal DNS record, a host A record should exist for the internal Web Services FQDN for your Front End pool (for example, lyncwebpool01.contoso.local).
   - For an external DNS record, a host A record should exist for the external Web Services FQDN for your Front End pool (for example, lyncwebextpool01.contoso.com).
6. For an internal DNS record, in the console tree of your DNS server, expand **Forward Lookup Zones** for your SIP domain (for example, contoso.com).

   Note:
   If you are creating an external DNS record, **Forward Lookup Zones** is already expanded for your SIP domain from step 3.

7. Right-click the SIP domain name, and then click **New Alias (CNAME)**.
8. In **Alias name**, type one of the following:
   - For an internal DNS record, type lyncdiscoverinternal as the host name for the internal Autodiscover Service URL.
   - For an external DNS record, type lyncdiscover as the host name for the external Autodiscover Service URL.
9. In **Fully qualified domain name (FQDN) for target host**, do one of the following:
   - For an internal DNS record, type or browse to the internal Web Services

FQDN for your Director pool (for example, lyncwebdir01.contoso.local), and then click **OK**.

- For an external DNS record, type or browse to the external Web Services FQDN for your Director pool (for example, lyncwebextdir.contoso.com), and then click **OK**.

Note:
If you do not use a Director, use the internal and external Web Services FQDN for the Front End pool, or, for a single server, the FQDN for the Front End Server or Standard Edition server.

Important:
You must create a new Autodiscover CNAME record in the forward lookup zone of each SIP domain that you support in your Lync Server 2013 environment.

To create DNS A records

1. Log on to a DNS server as follows:
   - To create an internal DNS record, log on to a DNS server in your network as a member of the Domain Admins group or a member of the DnsAdmins group.
   - To create an external DNS record, connect to your public DNS provider or external DNS server.
2. Open the DNS administrative snap-in: Click **Start**, click **Administrative Tools**, and then click **DNS**.
3. Do one of the following:
   - For an internal DNS record, in the console tree of the DNS server, expand **Forward Lookup Zones** for your Active Directory domain (for example, contoso.local).

     Note:
     This domain is the Active Directory domain where your Lync Server 2013 Director pool and Front End pool are installed.
   - For an external DNS record, in the console tree of the DNS server, expand **Forward Lookup Zones** for your SIP domain (for example, contoso.com).
4. Verify that a host A (for IPv6, AAAA) record exists for your Director pool as follows:
   - For an internal DNS record, a host A (for IPv6, AAAA) record should exist for the internal Web Services FQDN for your Director pool (for example, lyncwebdir01.contoso.local).
   - For an external DNS record, a host A (for IPv6, AAAA) record should exist for the external Web Services FQDN for your Director pool (for example, lyncwebextdir.contoso.com).
5. Verify that a host A (for IPv6, AAAA) record exists for your Front End pool as follows:
   - For an internal DNS record, a host A (for IPv6, AAAA) record should exist for the internal Web Services FQDN for your Front End pool (for example, lyncwebpool01.contoso.local).
   - For an external DNS record, a host A (for IPv6, AAAA) record should exist for the external Web Services FQDN for your Front End pool (for example, lyncwebextpool01.contoso.com).
6. For an internal DNS record, in the console tree of your DNS server, expand **Forward Lookup Zones** for your SIP domain (for example, contoso.com).

   Note:
   If you are creating an external DNS record, **Forward Lookup Zones** is already expanded for your SIP domain from step 3.
7. Right-click the SIP domain name, and then click **New Host (A or AAAA)**.
8. In **Name**, type the host name as follows:

- For an internal DNS record, type lyncdiscoverinternal as the host name for the internal Autodiscover Service URL.
- For an external DNS record, type lyncdiscover as the host name for the external Autodiscover Service URL.

Note:
The domain name is assumed from the zone in which the record is defined and, therefore, does not need to be entered as part of the A record.

9. In **IP Address**, type the IP address as follows:
   - For an internal DNS record, type the internal Web Services IP address of the Director (or, if you use a load balancer, type the virtual IP (VIP) of the Director load balancer).

     Note:
     If you do not use a Director, type the IP address of the Front End Server or Standard Edition server, or, if you use a load balancer, type the VIP of the Front End pool load balancer.

   - For an external DNS record, type the external or public IP address of the reverse proxy.
10. Click **Add Host**, and then click **OK**.
11. To create an additional A record, repeat steps 8 through 10.

Important:
You must create a new lyncdiscover and lyncdiscoverinternal A records in the forward lookup zone of each SIP domain that you support in your Lync Server 2013 environment.

12. When you are finished creating A (for IPv6, AAAA) records, click **Done**.

1.4.2.9.2 Configuring Certificates for Autodiscover

Configuring Certificates for Autodiscover

Deployment > Deploying External User Access > Configuring Support for Autodiscover >

Topic Last Modified: *2012-12-12*

The certificates for your Director pool, Front End pool, and reverse proxy require additional subject alternative name entries to support secure connections with Lync clients.

Note:
You can use the **Get-CsCertificate** cmdlet to view information about the currently assigned certificates. However, the default view truncates the properties of the certificate and does not display all values in the SubjectAlternativeNames property. You can use the **Get-CsCertificate** , **Request-**CsCertificate and the **Set-CsCertificate** cmdlets to view some information and to request and assign certificates. However, it’s not the best method to use if you are unsure of the properties of the subject alternative names (SAN) on the current certificate. To view the certificate and all property members, it is suggested to use the Certificates snap-in the *Microsoft Management Console (MMC)* or to use the Lync Server Deployment Wizard. In the Lync Server Deployment Wizard, you can use the Certificate Wizard to view the certificate properties. The procedures for viewing, requesting and assigning a certificate using the Lync Server Management Shell and the *Microsoft Management Console (MMC)* are detailed in the following procedures. To use the Lync Server Deployment Wizard, see details here if you have deployed the optional Director or Director pool: Configure Certificates for the Director. For the Front End Server or Front End pool, see the details here: Configure Certificates for Servers.
The initial steps in this procedure are preparation steps, to orient you as to what role the current certificates play. By default, the certificates will not have a lyncdiscover.<sipdomain> or lyncdiscoverinternal.<internal domain name> entry unless you have previously installed Mobility Services or have prepared your certificates in

advance. This procedure uses the example SIP domain name 'contoso.com' and the example internal domain name 'contoso.net'.
The default certificate configuration for Lync Server 2013 and Lync Server 2010 is to use a single certificate (named 'Default') with the purposes Default (for all purposes except for the web services), WebServicesExternal and WebServicesInternal. An optional configuration is to use separate certificates for each purpose. Certificates can be managed by using the Lync Server Management Shell and Windows PowerShell cmdlets, or by using the Certificate Wizard in the Lync Server Deployment Wizard.

To update certificates with new subject alternative names using the Lync Server Management Shell

1. Log on to the computer using an account that has local administrator rights and permissions.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Find out what certificates have been assigned to the server and for which type of use. You need this information in the next step to assign the updated certificate. At the command line, type:

```
Get-CsCertificate
```

4. Look in the output from the previous step to see whether a single certificate is assigned for multiple uses or whether a different certificate is assigned for each use. Look in the Use parameter to find out how a certificate is used. Compare the Thumbprint parameter for the displayed certificates to see if the same certificate has multiple uses.
5. Update the certificate. At the command line, type:

```
Set-CsCertificate -Type <type of certificate as displayed in the Use p
```

For example, if the **Get-CsCertificate** cmdlet displayed a certificate with Use of Default, another with a Use of WebServicesInternal, and another with a Use of WebServicesExternal, and they all had the same Thumbprint value, at the command line, type:

```
Set-CsCertificate -Type Default,WebServicesInternal,WebServicesExterna
```

Important:
If a separate certificate is assigned for each use (the Thumbprint value is different for each certificate), it is important that you do not run the **Set-CsCertificate** cmdlet with multiple types. In this case, run the **Set-CsCertificate** cmdlet separately for each use. For example:

```
Set-CsCertificate -Type Default -Thumbprint <Certificate Thumbprint>
Set-CsCertificate -Type WebServicesInternal -Thumbprint <Certificate T
Set-CsCertificate -Type WebServicesExternal -Thumbprint <Certificate T
```

6. To view the certificate, click **Start**, click **Run...**. Type MMC to open the Microsoft Management Console.
7. From the MMC menu, select **File**, select **Add/Remove snap-in...**, select Certificates. Click **Add**. When prompted, select **Computer account**, then click **Next**.
8. If the certificate is located on this computer, select **Local computer**. If the certificate is located on another computer, select **Another computer**, type in the fully qualified domain name of the computer or click **Browse** In **Enter the object name to select**, type the name of the computer. Click **Check Names**. When the name of the computer is resolved, it will be underlined. Click **OK**, then click **Finish**. Click **OK** to commit the selection and close the **Add or Remove Snap-ins** dialog.

Important:
If the certificate does not show up in the console, ensure that you have not selected User or Service. You must select Computer, or you will not be able

to locate the probper certificate.

9. To view the properties of the certificate, expand **Certificates**, expand **Personal**, and select **Certificates**. Select the certificate to view, right-click on the certificate and select **Open**.
10. In the **Certificate** view, select **Details**. From here, you can select the certificate subject name by selecting **Subject** and the assigned subject name and associated properties are displayed.
11. To view the assigned subject alternative names, select **Subject Alternative Name**. All assigned subject alternative names are displayed. The subject alternative names that are found in the property are of type **DNS Name** by default. You should see the following members (all of which should be fully qualified domain names as represented in DNS host (A or, if IPv6 AAAA) records:
    - Pool name for this pool, or the single server name if this is not a pool
    - Server name that the certificate is assigned to
    - Simple URL records, typically meet and dialin
    - Web services internal and Web services external names (for example, webpool01.contoso.net, webpool01.contoso.com), based on choices made in Topology Builder and over-ridden web services selections.
    - If already assigned, the lyncdiscover.<sipdomain> and lyncdiscoverinternal.<sipdomain> records.

    The last item is what you are most interested in – if there is a lyncdiscover and lyncdiscoverinternal SAN entry.

    Once you have this information, you can close the certificate view and the MMC.
12. If an Autodiscover Service, meaning the lyncdiscover.>domain name> and lyncdiscoverinternal.<domain name> (based on if this is an external or internal certificate) subject alternative name is missing, and you are using a single Default certificate for the Default, WebServicesInternal and WebServiceExternal types, do the following:
    - At the Lync Server Management Shell command line prompt, type:

      ```
      Request-CsCertificate -New -Type Default,WebServicesInterna
      ```

      If you have many SIP domains, you cannot use the new AllSipDomain parameter. Instead, you must use DomainName parameter. When you use the DomainName parameter, you must define the FQDN for the lyncdiscoverinternal and lyncdiscover records. For example:

      ```
      Request-CsCertificate -New -Type Default,WebServicesInterna
      ```

    - To assign the certificate, type the following:

      ```
      Set-CsCertificate -Type Default,WebServicesInternal,WebServi
      ```

      Where “Thumbprint” is the thumbprint displayed for the newly issued certificate.

13. For a missing internal Autodiscover subject alternative names when using separate certificates for Default, WebServicesInternal, and WebServicesExternal, do the following:
    - At the Lync Server Management Shell command line prompt, type:

      ```
      Request-CsCertificate -New -Type WebServicesInternal -Ca dc\
      ```

      If you have many SIP domains, you cannot use the new AllSipDomain parameter. Instead, you must use DomainName parameter. When you use the DomainName parameter, you must use an appropriate prefix for the SIP domain FQDN. For example:

      ```
      Request-CsCertificate -New -Type WebServicesInternal -Ca dc\
      ```

    - For a missing external Autodiscover subject alternative name, at the command line, type:

```
Request-CsCertificate -New -Type WebServicesExternal -Ca dc\
```

If you have many SIP domains, you cannot use the new AllSipDomain parameter. Instead, you must use DomainName parameter. When you use the DomainName parameter, you must use an appropriate prefix for the SIP domain FQDN. For example:

```
Request-CsCertificate -New -Type WebServicesExternal -Ca dc\
```

- To assign the individual certificate types, type the following:

```
Set-CsCertificate -Type Default -Thumbprint <Certificate Thu
Set-CsCertificate -Type WebServicesInternal -Thumbprint <Cer
Set-CsCertificate -Type WebServicesExternal -Thumbprint <Cer
```

Where "Thumbprint" is the thumbprint displayed for the newly issued individual certificates.

1.4.2.9.3 Configuring a Reverse Proxy for Autodiscover

Configuring a Reverse Proxy for Autodiscover

See Also

Deployment > Deploying External User Access > Configuring Support for Autodiscover >

Topic Last Modified: *2012-12-12*

Autodiscover and the support of clients using autodiscover requires modification of an existing web publishing rule or creating a new web publishing rule for the reverse proxy. The modification or creation of a new publishing rule is not dependent on the decision to update or not update the subject alternative name lists on the reverse proxy certificates.

If you decide to use HTTPS for initial Lync Server 2013 Autodiscover Service requests and update the subject alternative names lists on the reverse proxy certificates, you need to assign the updated public certificate to the Secure Sockets Layer (SSL) Listener on your reverse proxy. The required update to the external (public) certificate will include the subject alternate name (SAN) entry for lyncdiscover.<domain name>. You then need to modify the existing listener for the external web services or create a new web publishing rule for the external Autodiscover Service URL, for example **lyncdiscover.contoso.com**. If you do not already have a web publishing rule for the external Lync Server 2013 Web Services URL for your Front End pool and Director pool (if you have deployed Directors), you also need to publish a rule for that.

Note:

The reverse proxy publishing rule and listener can service both the external web services and the Autodiscover Service, as long as the certificate assigned to the listener contains the necessary subject name and subject alternative names for both. For details on the default configuration of the web listener and publishing rule, see Setting Up Reverse Proxy Servers for more details.

If you decide to use HTTP for initial Autodiscover Service requests so that you do not need to update subject alternative names for the reverse proxy, you need to create or modify a web publishing rule for port 80.

The procedures in this section describe how to create or modify the web publishing rules in Microsoft Forefront Threat Management Gateway 2010 for automatic discovery.

Note:

These procedures assume that you have installed the Standard Edition of Forefront Threat Management Gateway (TMG) 2010. If you are using another reverse proxy, the procedures are similar, but will need to be mapped to the documentation for the third-party product.

⊟To create a web publishing rule for the external Autodiscover URL

1. Click **Start**, point to **Programs**, point to **Microsoft Forefront TMG**, and then click **Forefront TMG Management**.
2. In the left pane, expand **ServerName**, right-click **Firewall Policy**, point to **New**, and then click **Web Site Publishing Rule**.
3. On the **Welcome to the New Web Publishing Rule** page, type a display name for the new publishing rule (for example, LyncDiscoveryURL).
4. On the **Select Rule Action** page, select **Allow**.
5. On the **Publishing Type** page, select **Publish a single Web site or load balancer**.
6. On the **Server Connection Security** page, select **Use SSL to connect to the published Web server or server farm**.
7. On the **Internal Publishing Details** page, in **Internal Site name**, type the fully qualified domain name (FQDN) of your Director pool (for example, lyncdir01.contoso.local). If you are creating a rule for the external Web Services URL on the Front End pool, type the FQDN of the Front End pool (for example, lyncpool01.contoso.local).
8. On the **Internal Publishing Details** page, in **Path (optional)**, type **/*** as the path of the folder to be published, and then select **Forward the original host header**.
9. On the **Public Name Details** page, do the following:
   - Under **Accept Requests for**, select **This domain name**.
   - In **Public Name**, type **lyncdiscover.**<*sipdomain*> (the external Autodiscover Service URL). If you are creating a rule for the external Web Services URL on the Front End pool, type the FQDN for the external Web Services on your Front End pool (for example, lyncwebextpool01.contoso.com).
   - In **Path**, type **/***.
10. On **Select Web Listener** page, in **Web Listener**, select your existing SSL Listener with the updated public certificate.
11. On the **Authentication Delegation** page, select **No delegation, but client may authenticate directly**.
12. On the **User Set** page, select **All Users**.
13. On the **Completing the New Web Publishing Rule Wizard** page, verify that the web publishing rule settings are correct, and then click **Finish**.
14. In the Forefront TMG list of web publishing rules, double-click the new rule you just added to open **Properties**.
15. On the **To** tab, do the following:
    - Select **Forward the original host header instead of the actual one**.
    - Select **Requests appear to come from the Forefront TMG computer**.
16. On the **Bridging** tab, configure the following:
    - Select **Web server**.
    - Select **Redirect requests to HTTP port**, and type **8080** for the port number.
    - Select **Redirect requests to SSL port**, and type **4443** for the port number.
17. Click **OK**.
18. Click **Apply** in the details pane to save the changes and update the configuration.
19. Click **Test Rule** to verify that your new rule is set up correctly.

⊟To modify an existing web publishing rule to add the external Autodiscover SAN and URL

1. Click **Start**, point to **Programs**, point to **Microsoft Forefront TMG**, and then click **Forefront TMG Management**.

   Important:

You will repeat the modification for each publishing rule and listener that you have. Typically, this will be one rule and listener for the Front End pools and one for the optional Directors or Director pools, if you have deployed them.

2. In the left pane, expand **ServerName**, right-click **Firewall Policy**, click the applicable rule. On the **Tasks** tab, click **Edit Selected rule**.
3. On the **Public Name** tab, in **This rule applies to**, select **Requests for the following Web sites**.
4. Click **Add**, type the name of the new Autodiscover site (for example, "lyncdiscover.contoso.com"), and then click **OK**.
5. On the **Listener** tab, click **Select Certificate** and assign the new certificate with the added Autodiscover SAN entries. Close the Listener and Web Publishing properties.
6. Click **Apply** in the details pane to save the changes and update the configuration.
7. Click **Test Rule** to verify that your new rule is set up correctly.

⊟To create a web publishing rule for port 80

1. Click **Start**, point to **Programs**, point to **Microsoft Forefront TMG**, and then click **Forefront TMG Management**.
2. In the left pane, expand **ServerName**, right-click **Firewall Policy**, point to **New**, and then click **Web Site Publishing Rule**.
3. On the **Welcome to the New Web Publishing Rule** page, type a display name for the new publishing rule (for example, Lync Autodiscover (HTTP)).
4. On the **Select Rule Action** page, select **Allow**.
5. On the **Publishing Type** page, select **Publish a single Web site or load balancer**.
6. On the **Server Connection Security** page, select **Use non-secured connections to connect to the published Web server or server farm**.
7. On the **Internal Publishing Details** page, in **Internal Site name**, type the internal Web Services FQDN for your Front End pool (for example, lyncpool01.contoso.local).
8. On the **Internal Publishing Details** page, in **Path (optional)**, type **/*** as the path of the folder to be published, and then select **Forward the original host header instead of the one specified in the Internal site name field**.
9. On the **Public Name Details** page, do the following:
   - Under **Accept Requests for**, select **This domain name**.
   - In **Public Name**, type **lyncdiscover.**<*sipdomain*> (the external Autodiscover Service URL).
   - In **Path**, type **/***.
10. On **Select Web Listener** page, in **Web Listener**, select a Web Listener or use the New Web Listener Definition Wizard to create a new one.
11. On the **Authentication Delegation** page, select **No delegation, and client cannot authenticate directly**.
12. On the **User Set** page, select **All Users**.
13. On the **Completing the New Web Publishing Rule Wizard** page, verify that the web publishing rule settings are correct, and then click **Finish**.
14. In the Forefront TMG list of web publishing rules, double-click the new rule you just added to open **Properties**.
15. On the **Bridging** tab, configure the following:
    - Select **Web server**.
    - Select **Redirect requests to HTTP port**, and type **8080** for the port number.
    - Verify that **Redirect requests to SSL port** is not selected.
16. Click **OK**.
17. Click **Apply** in the details pane to save the changes and update the configuration.
18. Click **Test Rule** to verify that your new rule is set up correctly.
19. Verify that the external Autodiscover Service URL is not defined on any other web publishing rule.

Setting Up Reverse Proxy Servers

1.4.2.9.4 Configuring Autodiscover for Hybrid Deployments

Configuring Autodiscover for Hybrid Deployments

See Also

Deployment > Deploying External User Access > Configuring Support for Autodiscover >

***Topic Last Modified:** 2012-12-12*

Hybrid Deployments are configurations that use both the Microsoft Lync Online cloud service and the on premises deployment. In this type of configuration, the Autodiscover service must be able to locate where the user is actually located. That is to say, Autodiscover aids in finding the user account and where the server that hosts the user's account is, regardless if it is in the on premises deployment or in the Lync Online deployment.

For example, if a user's account is hosted on a server in Lync Online, the attempt to locate the user will happen as follows, in a process known as *discoverability*:

- User initiates a connection attempt to the on premises deployment, **contoso.com**.
- The attempt is sent to lyncdiscover.contoso.com, the DNS name associated with the Autodiscover service.
- Autodiscover refers to the assumed registrar pool at the contoso.com on premises deployment and is given information on the user's actual home server hosted in Lync Online. Autodiscover then sends the user a referral to the **lync.com** online Autodiscover service.
- The user initiates a connection attempt to the lync.com online Autodiscover service and is able to locate the user's account and the user's home server.

To enable clients to discover the deployment where the user home server is located, you must configure the Autodiscover service with a new uniform resource locator (URL). Do the following to configure the Autodiscover service.

⊟Configuring Autodiscover for Hybrid Deployments

1. In the topic, Autodiscover Service Requirements, you use Get-CsHostingProvider to retrieve the value of the attribute ProxyFQDN.
2. From the Lync Server Management Shell, type

```
Set-CsHostingProvider -Identity [identity] -AutodiscoverUrl https://we
```

Where [identity] is replaced with the domain name of the shared SIP address space.

Set-CsHostingProvider

1.4.2.10 Publishing Office Web Apps Server Using a Reverse Proxy Server

Publishing Office Web Apps Server Using a Reverse Proxy Server

Microsoft Lync Server 2013 > Deployment > Deploying External User Access >

Topic Last Modified: *2013-02-25*

If you want external users (that is, users logging on from outside your organization’s firewall) to have access to Office Web Apps Server PowerPoint presentations then you will need to use Office Web Apps Server and a reverse proxy server such as Microsoft Forefront Threat Management Gateway. That also means that you will need to create and configure a website publishing rule; that rule will help ensure that users are able to connect to the server. If you do not need to provide access to external users then you do not need to configure a website publishing rule.

To configure a website publishing rule in Forefront Threat Management Gateway complete the following procedure:

1. Click **Start**, click **All Programs**, click **Microsoft Forefront TMG**, and then click **Forefront TMG Management**.
2. In Forefront TMG, right-click **Firewall Policy**, point to **New**, and then click **Web Site Publishing Rule**.
3. In the New Web Publishing Rule Wizard, on the **Welcome to the New Web Publishing Rule Wizard** page, type a name for your new rule in the **Web publishing rule name** box (for example, **Office Web Apps Server Rule**) and then click **Next**.
4. On the **Specify Rule Action** page, select **Allow** and then click **Next**.
5. On the **Publishing Type** page, select **Publish a single Web site or load balancer** and then click **Next**.
6. On the **Server Connection Security** page, select **Use SSL to connect to the published Web server or server farm** and then click **Next**.
7. On the **Internal Publishing Details** page, type the FQDN of your Office Web Apps server (for example, **officewebapps01.contoso.com**) in the **Internal site name** box and then click **Next**. The name entered in the **Internal site name** box must appear in the Subject field or the Subject Alternative Name field of the certificate you have assigned to Office Web Apps Server.
8. On the **Internal Publishing Details** page, type **/*** in the **Path (optional)** box and then click **Next**. The /* syntax will help ensure that all the folders and subfolders for the site are published.
9. On the **Public Name Details** page, select **This domain name (type below)** from the **Accept requests for** drop-down list and then type the fully qualified for your Office Web Apps Server in the Public name box. This name should be the name used to access your website. For example, if your site is accessed using the URL http://officewebapps01.contoso.com then you should enter **officewebapps01.contoso.com** in the **Public name** box.
10. Click **Next**.
11. On the **Select Web Listener** page, click **New**.
12. In the New Web Listener Definition Wizard, type a name for the new Web listener (for example, **SSL**) in the **Web listener name** box and then click **Next**.
13. On the **Client Connection Security** page, select **Require SSL secured connections with clients** and then click **Next**.
14. On the **Web Listener IP Addresses** page, select **External**, select **Internal**, and then click **Next**.
15. On the **Listener SSL Certificates** page, select **Use a single certificate for this Web Listener** and then click **Select Certificate**.
16. In the **Select Certificate** dialog box, select the certificate to be used for this Web Listener and then click **Select**.
17. On the **Listener SSL Certificates** page, click **Next**.
18. On the **Authentication Settings** page, select **No Authentication** from the **Select how clients will provide credentials to Forefront TMG** drop-down list, and then click **Next**.
19. On the **Single Sign On Settings** page, click **Next**.
20. On the **Completing the New Web Listener Wizard** page, review the summary of the configuration choices you have made. When ready, click

Finish.

21. On the **Select Web Listener** page, click **Next**.
22. On the **Authentication Delegation** page, select **No delegation, but client may authenticate directly** from the **Select the method used by Forefront TMG to authenticate to the published Web server** drop-down list and then click **Next**.
23. On the **User Sets** page, confirm that the appropriate user sets are listed. By default, this is the **All Users** user set. Click **Add** to add other user sets you may have defined. When complete, click **Next**.
24. On the **Completing the New Web Publishing Rule Wizard** page, click **Finish**.

Note that clicking **Finish** does not mean that you completed the process; that is, this does not automatically apply and enable the new rule. Instead, you will need to click the **Apply** button that will appear in the Forefront TMG user interface. When you click **Apply** the **Configuration Change Description** dialog box will appear. Click **Apply** in that dialog box to enable the new publishing rule.

After your new rule has been applied, you will then need to make some minor modifications to the rule to make sure that users can use the new PowerPoint presentation capabilities. To do that, complete the following procedure:

1. In Forefront TMG, right-click the name of the new publishing rule and then click **Properties**.
2. In the **Properties** dialog box, on the **To** tab, select the option **Forward the original host header instead of the actual one**.
3. On the **Traffic** tab, click **Filtering** and then click **Configure HTTP**.
4. In the **Configuring HTTP policy for rule** dialog box, clear the **Verify normalization** check box and then click **OK**.
5. In the **Properties** dialog box, click **OK**.
6. In Forefront TMG, click **Apply** to enable the changes. When the **Configuration Change Description** dialog box appears, click **Apply**.

After completing the installation you can test your Office Web Apps Server using the procedures in the topic Validating the Configuration of Office Web Apps Server.

1.4.2.11 Configuring SIP Federation, XMPP Federation and Public Instant Messaging

Configuring SIP Federation, XMPP Federation and Public Instant Messaging

Microsoft Lync Server 2013 > Deployment > Deploying External User Access >

Topic Last Modified: *2012-10-16*

Federation, public instant messaging connectivity and Extensible Messaging and Presence Protocol (XMPP) define a different class of external users – Federated users. Users of a federated Lync Server deployment or XMPP deployment have access to a limited set of services and are authenticated by the external deployment. Remote users are members of your Lync Server deployment and have access to all services offered by your deployment.

Public instant messaging connectivity is a special type of federation that allows a Lync Server client to access configured public Instant Messaging partners using the Lync 2013. The current public instant messaging connectivity partners are:

- America Online
- Windows Live
- Yahoo!

A public instant messaging connectivity configuration allows Lync users access to public instant messaging connectivity users by:

- IM and Presence
- Visibility of public instant messaging connectivity contacts in Lync client
- Person to person IM conversations with contacts
- Audio and video calls with Windows Live users

Lync Server federation defines an agreement between your Lync Server deployment and other Office Communications Server 2007 R2 or Lync Server deployments. A Lync Server federated configuration allows Lync users access to federated users by:

- IM and Presence
- Creation of federated contacts in the Lync client

XMPP federation defines an external deployment based on the eXtensible Messaging and Presence Protocol. An XMPP configuration allows Lync users access to allowed XMPP domain users by:

- IM and Presence – person to person only
- Creation of XMPP federated contacts in the Lync client

Important:

The XMPP capability of Lync Server 2013 is tested and supported by Microsoft for instant messaging federation with Google Talk. For any other XMPP systems contact the third-party vendor to verify that they support federation with Lync Server 2013, and for any deployment or troubleshooting recommendations.

Edge Server External Federation, Public Instant Messaging Connectivity and XMPP Users Deployment Process

Phase	Steps	Permissions	Documentation
Determine the options to add to the existing Edge deployment	Run Topology Builder to edit Edge Server settings and create and publish the topology. Your existing Edge topology will replicate changes from the Central Management store to the Edge Server.	Domain Admins group and RTCUniversalServerAdmins group **Note:** You can edit a topology using an account that is a member of the local users group, but publishing a topology requires an account that is a member of the Domain Admins group and the RTCUniversalServerAdmins group	Building an Edge and Director Topology
Prepare for setup	1. Ensure that system prerequisites are met. 2. Configure internal and external DNS records, to support public instant	As appropriate to your organization, as these roles are typically split amongst numerous work groups	Scenarios for Federation, Public Instant Messaging Connectivity, and XMPP Federation

	messaging connectivity, Lync Federation and XMPP Federation 3. Configure ports and protocols at the firewall to support the types of federation that you are deploying 4. Obtain and install public certificates. The time required to obtain certificates depends on which certification authority (CA) issues the certificate. This step is optional at this point in the deployment. If you do not perform this step at this point, you must do it during Edge Server configuration. The Edge Server service cannot be started until certificates are obtained		
Set up Edge Servers for Federation Scenarios	1. Transport the exported topology configuration file to each Edge Server or allow replication to complete 2. Re-Run the Deployment Wizard to install supporting components for Federation 3. Configure the Edge Servers 4. Request and install certificates for each Edge Server 5. 	3. Configure SIP Federated Domains to Allow or Block domains 4. Enable SIP Federated Providers for public instant messaging connectivity providers 5. Configure XMPP Federated Partners per XMPP domain		
Verify your Edge Server configuration	Verify server connectivity and replication of configuration data from internal servers	For verification of replication, RTCUniversalServerAdmins group or user account that is assigned to the CSAdministrator roleFor verification of user connectivity, a user for each type of Federated user	Verifying Your Edge Deployment Example XMPP Configuration – XMPP Federation with Google Talk

1.4.2.11.1 Setting Up Lync Federation

Setting Up Lync Federation

See Also

Deployment > Deploying External User Access > Configuring SIP Federation, XMPP Federation and Public Instant Messaging >

Topic Last Modified: *2013-01-11*

If you have already deployed you Edge server or servers, adding the federated scenarios features is straight forward. If you have not set up Edge Servers, you must do that first. For details, see: Planning for External User Access in the Planning documentation and Deploying External User Access in the Deployment documentation.

Note:

If you intend to setup any combination of XMPP federation, Lync Federation, or public instant messaging connectivity, you can deploy them concurrently or one at a time. If you configure the options through the Topology Builder and the Lync Server Management shell, then run the Deployment Wizard at the Edge server after configuring the options for one, two or all three federation types, you can reduce the number of steps required.

Setting Up Lync Federation in Topology Builder and the Deployment Wizard

1. On a Front End server, open Topology Builder. Expand Edge pools, then right click your Edge server or Edge server pool. Select Edit properties.
2. In Edit Properties under General, select Enable federation for this Edge pool (Port 5061). Click OK.
3. Click Action, select Topology, select Publish. When prompted on Publish the topology, click Next. When the Publish is finished, click Finish.
4. On the Edge server, open the Lync Server Deployment wizard. Click Install or Update Lync Server System, then click Setup or Remove Lync Server Components. Click Run Again.

5. At Setup Lync Server components, click Next. The summary screen will show actions as they are executed. Once the deployment is done, click View Log to view available log files. Click Finish to complete the deployment.

Important:

You can select this option, but only one Edge pool or Edge Server in your organization can be published externally for federation. All access by federated users, including public instant messaging (IM) users, go through the same Edge pool or single Edge Server. For example, if your deployment includes an Edge pool or single Edge Server deployed in New York and one deployed in London and you enable federation support on the New York Edge pool or single Edge Server, signal traffic for federated users will go through the New York Edge pool or single Edge Server. This is true even for communications with London users, although a London internal user calling a London federated user uses the London pool or Edge Server for A/V traffic.

Configuring Federation with Partners

1. To setup a successful federation with another Microsoft Lync Server 2013, Lync Server 2010, Office Communications Server 2007 R2, or Office Communicator 2007, select the type of federation from the following table and define DNS SRV records, DNS host (A or AAAA for IPv6) and configure policies applicable to the type of federation:

Federation type	DNS Records	Policy Definition	Notes
Discovered Partner Domain	Configure SRV record of the format _sipfederationtls._tcp.<external domain name>Where the port value for the SRV record is TCP 5061 and the **Host offering this service** is defined as sip.<external domain name> – the FQDN of your Access Edge service. See Configure DNS for Edge Support for details on creating the SRV record	Enable or Disable Federation and Public IM Connectivity Enable or Disable Discovery of Federation Partners	Previous versions referred to this type of federation as **Open Enhanced Federation**. The creation of the SRV record is required for this type of federation and is to allow other partners to discover your federation.
Allowed Partner Domain	Configure SRV record of the format _sipfederationtls._tcp.<external domain name>Where the port value for the SRV	Enable or Disable Federation and Public IM Connectivity	Previous versions referred to this type of federation as **Enhanced Federation**. The creation of the SRV record is optional for this type of federation and is to allow other partners to discover your federation. Of course, this is then an **Open Enhanced**

	record is TCP 5061 and the **Host offering this service** is defined as sip.<external domain name> – the FQDN of your Access Edge service. See Configure DNS for Edge Support for details on creating the SRV record		**Federation**, or **Discovered Partner Domain**
Allowed Partner Server	Configure the SIP domain name and the partner Edge Server FQDN as a federation partner in Policies	Enable or Disable Federation and Public IM Connectivity Configure Support for Allowed External Domains Configure Support for Blocked External Domains	This federation type is the definition of a one to one relationship and does not allow for discovery of other federation partners. Each federation partner is configured explicitly. In previous versions, this was known as **Direct Federation**
Hosting Provider and Public IM Provider	No specific DNS requirements are defined for this type of federation	Enable or Disable Federation and Public IM Connectivity Create or Edit Public SIP Federated Providers Create or Edit Hosted SIP Federated Providers	This federation type defines services and hosting providers that you want to configure for your users. Typical uses include configuration for public IM providers like Windows Live Messenger, Yahoo! and AOL, as well as hosting providers such as Lync Online and Office 365 **Important:** • As of September 1st, 2012, the Microsoft Lync Public IM Connectivity User Subscription License (“PIC USL”) is no longer available for purchase for new or renewing agreements. Customers with active licenses will be able to

			continue to federate with Yahoo! Messenger until the service shut down date (exact date TBD, but no sooner than June 2013). • The PIC USL is a per-user per-month subscription license that is required for Lync Server or Office Communications Server to federate with Yahoo! Messenger. Microsoft’s ability to provide this service has been contingent upon support from Yahoo!, the underlying agreement for which is winding down. • More than ever, Lync is a powerful tool for connecting across organizations and with individuals around the world. Federation with Windows Live Messenger requires no additional user/device licenses beyond the Lync Standard CAL. Skype federation will be added to this list, enabling Lync users to reach hundreds of millions of people with IM and voice.

1. Define and configure any required DNS host (A or AAAA for IPv6) and DNS SRV records

2. Define and configure any policies using the Lync Server Control Panel or by using the Lync Server Management Shell and the appropriate cmdlets. For details on the Lync Server Management Shell cmdlets, see Federation and External Access Cmdlets

Scenarios for Federation, Public Instant Messaging Connectivity, and XMPP Federation
Managing Federation and External Access to Lync Server 2013

1.4.2.11.1.1 Configure Policies to Control Federated User Access

Configure Policies to Control Federated User Access

See Also

Deploying External User Access > Configuring SIP Federation, XMPP Federation and Public Instant Messaging > Setting Up Lync Federation >

Topic Last Modified: *2012-11-01*

When you configure policies to support communications with federated partners, the policies apply to users of federated domains. You can configure one or more external user access policies to control whether users of federated domains can collaborate with your Lync Server 2013 users. To control federated user access, you can configure policies at the global, site, and user level. Lync Server policy settings that are applied at one policy level can override settings that are applied at another policy level. Lync Server policy precedence is: User policy (most influence) overrides a Site policy, and then a Site policy overrides a Global policy (least influence). This means that the closer the policy setting is to the object that the policy is affecting, the more influence it has on the object.

Note:

You can configure policies to control federated user access, even if you have not enabled federation for your organization. However, the policies that you configure are in effect only when you have federation enabled for your organization. For details about enabling federation, see Enable or Disable Remote User Access in the Deployment documentation or the Operations documentation. Additionally, if you specify a user policy to control federated user access, the policy applies only to users that are enabled for Lync Server 2013 and configured to use the policy. For details about specifying federated users that can sign in to Lync Server 2013, see Assign an External User Access Policy to a Lync Enabled User in the Deployment documentation or the Operations documentation.

To configure a policy to support access by users of federated domains

1. From a user account that is a member of the RTCUniversalServerAdmins group (or has equivalent user rights), or is assigned to the CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **External User Access**, and then click **External Access Policy**.
4. On the **External Access Policy** page, do one of the following:
   - To configure the global policy to support federated user access, click the global policy, click **Edit**, and then click **Show details**.
   - To create a new site policy, click **New**, and then click **Site policy**. In **Select a Site**, click the appropriate site from the list and then click **OK**.
   - To create a new user policy, click **New**, and then click **User policy**. In **New External Access Policy**, create a unique name in the **Name** field that indicates what the user policy covers (for example, **EnableFederatedUsers** for a user policy that enables communications for federated domain users).

- To change an existing policy, click the appropriate policy listed in the table, click **Edit**, and then click **Show details**.

5. (Optional) If you want to add or edit a description, specify the information for the policy in **Description**.
6. Do one of the following:
    - To enable federated user access for the policy, select the **Enable communications with federated users** check box.
    - To disable federated user access for the policy, clear the **Enable communications with federated users** check box.
7. Click **Commit**.

To enable federated user access, you must also enable support for federation in your organization. For details, see Enable or Disable Federation and Public IM Connectivity.

If this is a user policy, you must also apply the policy to users that you want to be able to collaborate with federated users. For details, see Assign an External User Access Policy to a Lync Enabled User.

To configure an existing policy using Windows PowerShell to support access by users of federated domains

1. From a user account that is a member of the RTCUniversalServerAdmins group (or has equivalent user rights), or is assigned to the CsAdministrator role, log on to any computer in your internal deployment.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Type the following in the Lync Server Management Shell:

```
Set-CsExternalAccessPolicy -Identity <name of global, site or user pol
```

An example command that will set the global policy for Federated user access to enabled, XMPP domain access to enabled, Remote user access to enabled, Public provider access to enabled, and grant the ability to use audio and video for public providers that support it:

```
Set-CsExternalAccessPolicy -Identity global -EnableFederationAccess $t
```

Tip:

The parameter "EnablePublicCloudAudioVideoAccess" does not have a corresponding selection in the Lync Server Control Panel

To create a new policy using Windows PowerShell to support access by users of federated domains

1. From a user account that is a member of the RTCUniversalServerAdmins group (or has equivalent user rights), or is assigned to the CsAdministrator role, log on to any computer in your internal deployment.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Type the following in the Lync Server Management Shell:

```
New-CsExtenalAccessPolicy -Identity <name of site or user policy - you
```

An example of creating a new site policy:

```
New-CsExternalAccessPolicy -Identity site:Redmond -EnableFederationAcc
```

To delete or reset a policy using Windows PowerShell to support access by users of federated domains

1. From a user account that is a member of the RTCUniversalServerAdmins

group (or has equivalent user rights), or is assigned to the CsAdministrator role, log on to any computer in your internal deployment.

2. Type the following in the Lync Server Management Shell

```
Remove-CsExternalAccessPolicy -Identity <name of global, site or user
```

An example of resetting the global policy (The global policy can only have its setting removed. The policy cannot be deleted):

```
Remove-CsExternalAccessPolicy -Identity global
```

To remove a site policy, type:

```
Remove-CsExternalAccessPolicy -Identity site:Redmond
```

Deletes the site policy Redmond. To delete a user policy named UserEAPPolicy, type:

```
Remove-CsExternalAccessPolicy -Identity UserEAPPolicy
```

1.4.2.11.2 Setting Up Public Instant Messaging Connectivity

Setting Up Public Instant Messaging Connectivity

Deployment > Deploying External User Access > Configuring SIP Federation, XMPP Federation and Public Instant Messaging >

Topic Last Modified: *2012-09-08*

If your organization wants to support public instant messaging (IM) connectivity with AOL, you cannot use the Lync Server Deployment Wizard to request the certificate. Instead, perform the steps in the following procedure.

Setting Up Public Instant Messaging Connectivity

1. On a Front End server, open Topology Builder. Expand Edge pools, then right click your Edge server or Edge server pool. Select Edit properties.
2. In Edit Properties under General, select Enable federation for this Edge pool (Port 5061). Click OK.
3. Click Action, select Topology, select Publish. When prompted on Publish the topology, click Next. When the Publish is finished, click Finish.
4. On the Edge server, open the Lync Server Deployment wizard. Click Install or Update Lync Server System, then click Setup or Remove Lync Server Components. Click Run Again.
5. At Setup Lync Server components, click Next. The summary screen will show actions as they are executed. Once the deployment is done, click View Log to view available log files. Click Finish to complete the deployment.

To create a certificate request for the external interface of the Edge Server to support public IM connectivity with AOL

1. When the required template is available to the CA, use the following

Windows PowerShell cmdlet from at the Edge Server to request the certificate

```
Request-CsCertificate -New -Type AccessEdgeExternal  -Output C:\ <cert
```

The default certificate name of the template used for Lync Server is Web Server. Only specify the <template name> if you need to use a template that is different from the default template.

Important:

If your organization wants to support public IM connectivity with AOL, you must use Windows PowerShell instead of the Certificate Wizard to request the certificate to be assigned to the external edge for the Access Edge service. This is because the Certificate Authority (CA) Web Server template that the Certificate Wizard uses to request a certificate does not support client EKU configuration. Before using Windows PowerShell to create the certificate, the CA administrator must create and deploy a new template that supports client EKU.

1.4.2.11.2.1 Configure Media Encryption for Public Providers

Configure Media Encryption for Public Providers

Deploying External User Access > Configuring SIP Federation, XMPP Federation and Public Instant Messaging > Setting Up Public Instant Messaging Connectivity >

***Topic Last Modified:** 2012-12-23*

For details about licensing requirements and how to complete the provisioning process, see the "Public IM Connectivity Provisioning Guide for Microsoft Lync Server, Office Communications Server, and Live Communications Server" at http://go.microsoft.com/fwlink/p/?linkId=155970

If you are implementing audio/video (A/V) federation with Windows Live Messenger, there are two parameters that you need to modify: the Lync Server encryption level and the EnablePublicCloudAccess policy. By default, the encryption level is set to Required. You must change this setting to Supported. If the EnablePublicCloudAccess policy is set to false, this needs to be set to **True**. You can do this from the Lync Server Management Shell.

Important:

More than ever, Lync is a powerful tool for connecting across organizations and with individuals around the world. Federation with Windows Live Messenger requires no additional user/device licenses beyond the Lync Standard Client Access License (CAL). Next year, Skype federation will be added to this list, enabling Lync users to reach hundreds of millions of people with IM and voice.

Configure Federation for Windows Live

1. Start the Lync Server Management Shell on the Front End server: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. From the command prompt, type the following commands:

```
Set-CsMediaConfiguration -EncryptionLevel SupportEncryption
```

```
Set-CsExternalAccessPolicy Global -EnablePublicCloudAccess $true -Enab
```

Note:

This is required step because Windows Live Messenger does not support encryption of audio/video. The command sets your global policy to a support encryption setting instead of requiring encryption of the audio/video data. Clients that support encryption will still use encryption, such as Lync 2013.

1.4.2.11.2.2 Configure Policies to Control Public User Access

Configure Policies to Control Public User Access

See Also

Deploying External User Access > Configuring SIP Federation, XMPP Federation and Public Instant Messaging > Setting Up Public Instant Messaging Connectivity >

Topic Last Modified: *2013-01-11*

Public instant messaging (IM) connectivity enables users in your organization to use IM to communicate with users of IM services provided by public IM service providers, including the Windows Live network of Internet services, Yahoo!, and AOL. You configure one or more external user access policies to control whether public users can collaborate with internal Lync Server users. Public instant messaging connectivity is an added feature that relies on configuration of your deployment and users. It also depends on the provisioning of the service at the public IM provider. For information on how to provision your deployment to use the public providers, see the "Public IM Connectivity Provisioning Guide for Microsoft Lync Server, Office Communications Server, and Live Communications Server" guide: http://go.microsoft.com/fwlink/?LinkId=269821

◆Important:

- As of September 1st, 2012, the Microsoft Lync Public IM Connectivity User Subscription License ("PIC USL") is no longer available for purchase for new or renewing agreements. Customers with active licenses will be able to continue to federate with Yahoo! Messenger until the service shut down date (exact date TBD, but no sooner than June 2013).
- The PIC USL is a per-user per-month subscription license that is required for Lync Server or Office Communications Server to federate with Yahoo! Messenger. Microsoft's ability to provide this service has been contingent upon support from Yahoo!, the underlying agreement for which is winding down.
- More than ever, Lync is a powerful tool for connecting across organizations and with individuals around the world. Federation with Windows Live Messenger requires no additional user/device licenses beyond the Lync Standard CAL. Skype federation will be added to this list, enabling Lync users to reach hundreds of millions of people with IM and voice.

To access the Microsoft Lync Server Public IM Connectivity Provisioning site, use the following link: http://go.microsoft.com/fwlink/p/?linkId=212638

To control public user access, you can configure policies at the global, site, and user level. For details about the types of policies that you can configure, see Configuring Support for External User Access in the Deployment documentation or the Planning documentation. Lync Server policy settings that are applied at one policy level can override settings that are applied at another policy level. Lync Server policy precedence is: User policy (most influence) overrides a Site policy, and then a Site policy overrides a Global policy (least influence). This means that the closer the policy setting is to the object that the policy is affecting, the more influence it has on the object.

In the case of IM invitations, the response depends on the client software. The request is accepted unless external senders are explicitly blocked by a user-configured rule (that is, the settings in the user's client **Allow** and **Block** lists). Additionally, IM invitations can be blocked if a user elects to block all IM from users who are not on his or her **Allow** list.

Note:
You can configure policies to control public user access, even if you have not enabled federation for your organization. However, the policies that you configure are in effect only when you have federation enabled for your organization. For details about enabling federation, see Enable or Disable Remote User Access in the Deployment documentation or the Operations documentation. Additionally, if you specify a user policy to control public user access, the policy applies only to users that are enabled for Lync Server and configured to use the policy. For details about specifying public users that can sign in to Lync Server, see Assign an External User Access Policy to a Lync Enabled User in the Deployment documentation or the Operations documentation.

Use the following procedure to configure a policy to support access by users of one or more public IM providers.

⊟To configure an external access policy to support public user access

1. From a user account that is a member of the RTCUniversalServerAdmins group (or has equivalent user rights), or is assigned to the CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **External User Access**, and then click **External Access Policy**.
4. On the **External Access Policy** page, do one of the following:
   - To configure the global policy to support public user access, click the global policy, click **Edit**, and then click **Show details**.
   - To create a new site policy, click **New**, and then click **Site policy**. In **Select a Site**, click the appropriate site from the list and then click **OK**.
   - To create a new user policy, click **New**, and then click **User policy**. In **New External Access Policy**, create a unique name in the **Name** field that indicates what the user policy covers (for example, **EnablePublicUsers** for a user policy that enables communications for public users).
   - To change an existing policy, click the appropriate policy listed in the table, click **Edit**, and then click **Show details**.
5. (Optional) If you want to add or edit a description, specify the information for the policy in **Description**.
6. Do one of the following:
   - To enable public user access for the policy, select the **Enable communications with public users** check box.
   - To disable public user access for the policy, clear the **Enable communications with public users** check box.
7. Click **Commit**.

To enable public user access, you must also enable support for federation in your organization. For details, see Configure Policies to Control Federated User Access.

If this is a user policy, you must also apply the policy to public users that you want to be able to collaborate with public users. For details, see Assigning Per-User Policies.

1.4.2.11.3 Setting Up XMPP Federation

Setting Up XMPP Federation

See Also

Deployment > Deploying External User Access > Configuring SIP Federation, XMPP Federation and Public Instant Messaging >

Topic Last Modified: *2012-12-03*

To deploy the XMPP Proxy on the Edge Server, you must configure the Edge Server for XMPP federation. To do this, you do the following steps.

⊟Setting Up XMPP Federation

1. Log on to the computer where the Lync Server Deployment Wizard is installed as a member of the Domain Admins group and the RTCUniversalServerAdmins group.
2. On the Front End server, open the Lync Server Deployment wizard. Click Install or Update Lync Server System, then click Setup or Remove Lync Server Components. Click Run Again.
3. At Setup Lync Server components, click Next. The summary screen will show actions as they are executed. Once the deployment is done, click View Log to view available log files. Click Finish to complete the deployment.
4. On the Edge server, open the Lync Server Deployment wizard. Click Install or Update Lync Server System, then click Setup or Remove Lync Server Components. Click Run Again.
5. At Setup Lync Server components, click Next. The summary screen will show actions as they are executed. Once the deployment is done, click View Log to view available log files. Click Finish to complete the deployment.
6. On the Edge Server, in the Deployment Wizard, next to Step 3: Request, Install, or Assign Certificates, click Run again.

   Tip:

   If you are deploying the Edge Server for the first time, you will see Run instead of Run Again.

7. On the Available Certificate Tasks page, click Create a new certificate request.
8. On the Certificate Request page, click External Edge Certificate.
9. On the Delayed or Immediate Request page, select the Prepare the request now, but send it later check box.
10. On the Certificate Request File page, type the full path and file name of the file to which the request is to be saved (for example, c:\cert_exernal_edge.cer).
11. On the Specify Alternate Certificate Template page, to use a template other than the default WebServer template, select the Use alternative certificate template for the selected certification authority check box.
12. On the Name and Security Settings page, do the following:
    12.a. In Friendly name, type a display name for the certificate
    12.b. In Bit length, specify the bit length (typically, the default of 2048)
    12.c. Verify that the Mark certificate private key as exportable check box is selected
13. On the Organization Information page, type the name for the organization and the organizational unit (for example, a division or department)
14. On the Geographical Information page, specify the location information
15. On the Subject Name/Subject Alternate Names page, the information to be automatically populated by the wizard is displayed. If additional subject alternative names are needed, you specify them in the next two steps
16. On the SIP Domain Setting on Subject Alternate Names (SANs) page, select the domain check box to add a sip.<sipdomain> entry to the subject alternative names list.

17. On the Configure Additional Subject Alternate Names page, specify any additional subject alternative names that are required

> **Tip:**
>
> If the XMPP proxy is installed, by default the domain name (such as contoso.com) is populated in the SAN entries. If you require more entries, add them in this step.

18. On the Request Summary page, review the certificate information to be used to generate the request.
19. After the commands finish running, you can View Log, or click Next to continue.
20. On the Certificate Request File page, you can view the generated certificate signing request (CSR) file by clicking View or exit the Certificate Wizard by clicking Finish.
21. Copy the request file and submit to your public certification authority.
22. After receiving, importing and assigning the public certificate, you must stop and restart the Edge Server services. You do this by typing in the Lync Server Management console:

```
Stop-CsWindowsService
```

```
Start-CsWindowsService
```

23. To configure DNS for XMPP federation, you add the following SRV record to external DNS:_xmpp-server._tcp.<domain name> The SRV record will resolve to the access edge FQDN of the Edge server, with a port value of 5269. Additionally, you configure an 'A' host record (for example, xmpp.contoso.com) that points to the IP address of the Access Edge Server.

> **Important:**
>
> If you have Edge pools in multiple sites, we recommend that you add multiple SRV records for XMPP federation. Add a SRV record for every Edge pool in your organization, and give each of those SRV records a different priority. When all Edge pools are running, XMPP requests will all be handled by the Edge pool with the first priority, but if that Edge pool goes down you won't then have to add a new SRV record to regain XMPP federation functionality.

24. Configure a new External Access Policy to enable all users by opening the Lync Server Management Shell on the Front End and typing:

```
New-CsExternalAccessPolicy -Identity <name of policy to create.  If si
```

```
New-CsExternalAccessPolicy -Identity FedPic -EnableFederationAcces $tr
```

```
Get-CsUser | Grant-CsExternalAccessPolicy -PolicyName FedPic
```

Enable XMPP Access for External Users by typing:

```
Set-CsExternalAccessPolicy -Identity <name of the policy being used> E
```

```
Set-CsExternalAccessPolicy -Identity FedPic -EnableXmppAccess $true
```

25. On the Edge Server where the XMPP Proxy is deployed, open a Command Prompt or a Windows PowerShell™ command-line interface and type the following:

```
Netstat -ano | findstr 5269
```

```
Netstat -ano | findstr 23456
```

The command **netstat –ano** is a network statistics command, the parameters **–ano** request that netstat display all connections and listening ports, address and ports are displayed in a numerical form, and that the owning process ID is associated with each connection. The character **|** defines a pipe to the next command, **findstr**, or find string. The number 5269 and 23456 that is passed to findstr as a parameter instructs findstr to search the output of netstat for the strings 5269 and 23456. If XMPP is correctly configured, the result of the commands should result in listening and established connections, both on the external (port 5269) and the internal (port 23456) interfaces of the Edge Server.

If the commands do not return established or listening ports on 5269 and 23456, check the following:

⊟Troubleshooting XMPP Federation

1. To determine if the XMPP Proxy is running, do the following:
2. Log on to the Edge server that is running the XMPP Proxy service as a member of the local administrator’s group.
3. Click **Start**, click **All Programs**, click **Administrative Tools**, click **Services**
4. In Services, locate Lync Server XMPP Translating Gateway Proxy. The service should be in the **Started** state. If it is not started, click the **Start** icon in the toolbar. The icon appears as a green, right-pointing arrow.
5. Confirm that the service has changed to **Started**. If it has successfully started, close **Services** and continue.

   If ther service has not successfully started, from Administrative Tools, open Event Viewer and refer to the errors and warnings in the **Lync Server** portion under **Applications and Services Logs**.
6. Once the **Lync Server XMPP Translating Gateway** service is running, recheck the netstat commands used previously. If you are not seeing established or listening sessions, check and ensure that the **XMPP Federation Route** is correctly configured in Topology Builder
7. Log on to the computer where Topology Builder is installed as a member of the Domain Admins group and the RTCUniversalServerAdmins group.
8. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
9. In Topology Builder, select the site for the XMPP federation route and review to confirm that the **Site federation route assignment** for **XMPP federation** shows your Edge Server or Edge pool as the selected XMPP federation route assignment.

   If the route assignment is incorrect or is not set, right-click the site, click **Edit Properties**. Select the XMPP federation check box and then select the correct Edge Server or Edge pool.
10. Publish the topology. For details, see Publish Your Topology

Tip:
Though not required and typically not necessary, you may find that you will need to restart the Edge Servers

11. Using the netstat process used previously, confirm that the Edge Server is now listening or has established sessions on port 5269 and port 23456.
12. If you still are not seeing the expected sessions, check the Event Viewer for possible contributing causes for the communication problem.

Tasks

Manage XMPP Federated Partners for Your Organization

1.4.2.11.3.1 Configure Policies to Control XMPP Federated User Access

Configure Policies to Control XMPP Federated User Access

See Also

Deploying External User Access > Configuring SIP Federation, XMPP Federation and Public Instant Messaging > Setting Up XMPP Federation >

Topic Last Modified: *2012-11-01*

This is preliminary documentation and is subject to change. Blank topics are included as placeholders.

When you configure policies for support of extensible messaging and presence protocol (XMPP) federated partners, the policies apply to users of XMPP federated domains, but not to users of session initiation protocol (SIP) instant messaging (IM) service providers (for example, Windows Live), or SIP federated domains. You configure an **XMPP Federated Partner** for each XMPP federated domain that you want to allow your users to add contacts and communicate with. XMPP federated partners policies are only available in a single scope, though it is not defined as a global policy, acts as a global policy. To define a global, site or user policy for XMPP Federation Partners, you configure the policy scope by first creating and configuring the External Access Policy for the scope you require. For details about the types of policies that you can configure for external access and federation, see Managing Federation and External Access to Lync Server 2013 in the Operations documentation.

Note:

All **Federation and External Access** policies are applied through in-band provisioning. The policies that apply to the user, belong to a site, or are global in scope are communicated to the client during login. You can configure policies to control XMPP federated partner access, even if you have not enabled XMPP federation for your organization. However, the policies that you configure take effect only when you have XMPP partner federation deployed, enabled and configured for your organization. For details about deploying and configuring XMPP partner federation, see Configuring SIP Federation, XMPP Federation and Public Instant Messaging in the Deployment documentation. Additionally, if you specify a user policy in External Access Policy to control XMPP federated partners, the policy applies only to users that are enabled for Lync Server 2013 and configured to use the policy.

⊟To edit a global policy for XMPP federated partners

1. From a user account that is a member of the RTCUniversalServerAdmins group (or has equivalent user rights), or is assigned to the CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **External User Access**, and then click **External Access Policy**.
4. On the **External Access Policy** page, do the following for the global policy:
5. Click the global policy, click **Edit**, and then click Show details.
6. Provide a description for the Global policy (optional).
7. Select **Enable communications with federated users**.
8. Select **Enable communications with XMPP federated users**.
9. Click **Commit** to save your changes to the Global policy.

⊟To create a site or user policy for XMPP federated partners

1. Click **New**, and then click **Site policy** or **User policy**. In **Select a Site**, click the appropriate site from the list and then click **OK**.
2. Provide a description for the Site policy (optional).
3. In the site or user policy, select **Enable communications with federated users**.
4. Select **Enable communications with XMPP federated users**.
5. Click **Commit** to save your changes to the site or user policy.

⊟To edit an existing policy for XMPP federated partners

1. To change an existing policy, select the appropriate policy in the list, click

Edit, and then click **Show details**.

2. Change or update the description for the policy (optional).
3. Select or unselect **Enable communications with federated users**.
4. Select or unselect **Enable communications with XMPP federated users**.
5. Click **Commit** to save your changes to the policy.

⊟To edit an existing policy for XMPP federated partners by using Windows PowerShell

1. From a user account that is a member of the RTCUniversalServerAdmins group (or has equivalent user rights), or is assigned to the CsAdministrator role, log on to any computer in your internal deployment.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Type the following in the Lync Server Management Shell:

   ```
   Set-CsExternalAccessPolicy -Identity <name of global, site or user pol
   ```

   An example command that will set the global policy for Federated user access to True (enabled) and XMPP domain access to True (enabled):

   ```
   Set-CsExternalAccessPolicy -Identity global -EnableFederationAccess $t
   ```

⊟To create a site or user policy for XMPP federated partners using Windows PowerShell

1. From a user account that is a member of the RTCUniversalServerAdmins group (or has equivalent user rights), or is assigned to the CsAdministrator role, log on to any computer in your internal deployment.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Type the following in the Lync Server Management Shell:

   ```
   New-CsExternalAccessPolicy -Identity <name of global, site or user pol
   ```

   An example command that will set a site policy for the Redmond site for Federated user access to enabled and XMPP domain access to enabled:

   ```
   New-CsExternalAccessPolicy -Identity site:Redmond -EnableFederationAcc
   ```

⊟To delete an existing policy for XMPP federated partners by using Windows PowerShell

1. From a user account that is a member of the RTCUniversalServerAdmins group (or has equivalent user rights), or is assigned to the CsAdministrator role, log on to any computer in your internal deployment.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Type the following in the Lync Server Management Shell:

   ```
   Remove-CsExternalAccessPolicy -Identity <name of global, site or user
   ```

   An example command that will delete a user policy:

   ```
   Remove-CsExternalAccessPolicy -Identity EAPUserPolicySetXMPP
   ```

4. An example command that will reset the global policy to defaults:

   ```
   Remove-CsExternalAccessPolicy -Identity global
   ```

1.4.2.12 Deploying Mobility

Deploying Mobility

Microsoft Lync Server 2013 > Deployment > Deploying External User Access >

Topic Last Modified: *2012-09-08*

When you deploy the Lync Server 2013 mobility feature, mobile users can use supported mobile devices for Lync functionality such as instant messaging (IM), presence, and contacts.

For details about requirements for deploying the mobility feature, see Planning for Mobility.

This section guides you through the steps for deploying and verifying the mobility and automatic discovery features.

- Creating DNS Records for the Autodiscover Service
- Modifying Certificates for Mobility
- Configuring the Reverse Proxy for Mobility
- Configuring Autodiscover for Mobility with Hybrid Deployments
- Verifying Your Mobility Deployment
- Configuring for Push Notifications
- Configuring Mobility Policy

1.4.2.12.1 Creating DNS Records for the Autodiscover Service

Creating DNS Records for the Autodiscover Service

Deployment > Deploying External User Access > Deploying Mobility >

Topic Last Modified: *2012-10-05*

To support autodiscovery for Lync Mobile users, you need to create the following Domain Name System (DNS) records:

- An internal DNS record to support mobile users who connect from within your organization's network
- An external, or public, DNS record to support mobile users who connect from the Internet

Or

- An external, or public, DNS record to support mobile users who connect from the Internet

You must create an internal DNS record and an external DNS record for each SIP domain.

The DNS records can be either A (host) records or CNAME records. The following procedures describe how to create internal and external DNS records. For more details about the DNS requirements for mobile users, see Technical Requirements for Mobility.

⊟To create DNS CNAME records

1. Log on to a DNS server as follows:
   - To create an internal DNS record, log on to a DNS server in your network as a member of the Domain Admins group or a member of the DnsAdmins group.
   - To create an external DNS record, connect to your public DNS provider.
2. Open the DNS administrative snap-in: Click **Start**, click **Administrative Tools**, and then click **DNS**.
3. Do one of the following:
   - For an internal DNS record, in the console tree of the DNS server, expand **Forward Lookup Zones** for your Active Directory domain (for example, contoso.local).

     > **Note:**
     > This domain is the Active Directory domain where your Lync Server 2013 Director pool and Front End pool are installed.

   - For an external DNS record, in the console tree of the DNS server, expand **Forward Lookup Zones** for your SIP domain (for example, contoso.com).
4. Verify that a host A record exists for your Director pool as follows:
   - For an internal DNS record, a host A record should exist for the internal Web Services fully qualified domain name (FQDN) for your Director pool (for example, lyncwebdir01.contoso.local).
   - For an external DNS record, a host A record should exist for the external web services FQDN for your Director pool (for example, lyncwebextdir.contoso.com).
5. Verify that a host A record exists for your Front End pool as follows:
   - For an internal DNS record, a host A record should exist for the internal Web Services FQDN for your Front End pool (for example, lyncwebpool01.contoso.local).
   - For an external DNS record, a host A record should exist for the external Web Services FQDN for your Front End pool (for example, lyncwebextpool01.contoso.com).
6. For an internal DNS record, in the console tree of your DNS server, expand **Forward Lookup Zones** for your SIP domain (for example, contoso.com).

   > **Note:**
   > If you are creating an external DNS record, **Forward Lookup Zones** is already expanded for your SIP domain from step 3.

7. Right-click the SIP domain name, and then click **New Alias (CNAME)**.
8. In **Alias name**, type one of the following:
   - For an internal DNS record, type lyncdiscoverinternal as the host name for the internal Autodiscover Service URL.
   - For an external DNS record, type lyncdiscover as the host name for the external Autodiscover Service URL.
9. In **Fully qualified domain name (FQDN) for target host**, do one of the following:
   - For an internal DNS record, type or browse to the internal Web Services FQDN for your Director pool (for example, lyncwebdir01.contoso.local), and then click **OK**.
   - For an external DNS record, type or browse to the external Web Services FQDN for your Director pool (for example, lyncwebextdir.contoso.com), and then click **OK**.

   > **Note:**
   > If you do not use a Director, use the internal and external Web Services FQDN for the Front End pool, or, for a single server, the FQDN for the Front End Server or Standard Edition server.

Important:
You must create a new Autodiscover CNAME record in the forward lookup zone of each SIP domain that you support in your Lync Server 2013 environment.

To create DNS A records

1. Log on to a DNS server as follows:
   - To create an internal DNS record, log on to a DNS server in your network as a member of the Domain Admins group or a member of the DnsAdmins group.
   - To create an external DNS record, connect to your public DNS provider.
2. Open the DNS administrative snap-in: Click **Start**, click **Administrative Tools**, and then click **DNS**.
3. Do one of the following:
   - For an internal DNS record, in the console tree of the DNS server, expand **Forward Lookup Zones** for your Active Directory domain (for example, contoso.local).

     Note:
     This domain is the Active Directory domain where your Lync Server 2013 Director pool and Front End pool are installed.
   - For an external DNS record, in the console tree of the DNS server, expand **Forward Lookup Zones** for your SIP domain (for example, contoso.com).
4. Verify that a host A (for IPv6, AAAA) record exists for your Director pool as follows:
   - For an internal DNS record, a host A (for IPv6, AAAA) record should exist for the internal Web Services FQDN for your Director pool (for example, lyncwebdir01.contoso.local).
   - For an external DNS record, a host A (for IPv6, AAAA) record should exist for the external Web Services FQDN for your Director pool (for example, lyncwebextdir.contoso.com).
5. Verify that a host A (for IPv6, AAAA) record exists for your Front End pool as follows:
   - For an internal DNS record, a host A (for IPv6, AAAA) record should exist for the internal Web Services FQDN for your Front End pool (for example, lyncwebpool01.contoso.local).
   - For an external DNS record, a host A (for IPv6, AAAA) record should exist for the external Web Services FQDN for your Front End pool (for example, lyncwebextpool01.contoso.com).
6. For an internal DNS record, in the console tree of your DNS server, expand **Forward Lookup Zones** for your SIP domain (for example, contoso.com).

   Note:
   If you are creating an external DNS record, **Forward Lookup Zones** is already expanded for your SIP domain from step 3.
7. Right-click the SIP domain name, and then click **New Host (A or AAAA)**.
8. In **Name**, type the host name as follows:
   - For an internal DNS record, type lyncdiscoverinternal as the host name for the internal Autodiscover Service URL.
   - For an external DNS record, type lyncdiscover as the host name for the external Autodiscover Service URL.

   Note:
   The domain name is assumed from the zone in which the record is defined and, therefore, does not need to be entered as part of the A record.
9. In **IP Address**, type the IP address as follows:
   - For an internal DNS record, type the internal Web Services IP address of the Director (or, if you use a load balancer, type the virtual IP (VIP) of the

Director load balancer).

Note:
If you do not use a Director, type the IP address of the Front End Server or Standard Edition server, or, if you use a load balancer, type the VIP of the Front End pool load balancer.

- For an external DNS record, type the external or public IP address of the reverse proxy.

10.Click **Add Host**, and then click **OK**.
11.To create an additional A record, repeat steps 8 through 10.

Important:
You must create a new Autodiscover A record in the forward lookup zone of each SIP domain that you support in your Lync Server 2013 environment.

12.When you are finished creating A (for IPv6, AAAA) records, click **Done**.

1.4.2.12.2 Modifying Certificates for Mobility

Modifying Certificates for Mobility

Deployment > Deploying External User Access > Deploying Mobility >

Topic Last Modified: *2012-10-18*

The certificates for your Director pool, Front End pool, and reverse proxy require additional subject alternative name entries to support secure connections with mobile clients. For details about certificate requirements for mobility, see Technical Requirements for Mobility.

Note:
You can use the **Get-CsCertificate** cmdlet to view information about the currently assigned certificates. However, the default view truncates the properties of the certificate and does not display all values in the SubjectAlternativeNames property. You can use the **Get-CsCertificate** , **Request-**CsCertificate and the **Set-CsCertificate** cmdlets to view some information and to request and assign certificates. However, it’s not the best method to use if you are unsure of the properties of the subject alternative names (SAN) on the current certificate. To view the certificate and all property members, it is suggested to use the Certificates snap-in the *Microsoft Management Console (MMC)* or to use the Lync Server Deployment Wizard. In the Lync Server Deployment Wizard, you can use the Certificate Wizard to view the certificate properties. The procedures for viewing, requesting and assigning a certificate using the Lync Server Management Shell and the *Microsoft Management Console (MMC)* are detailed in the following procedures. To use the Lync Server Deployment Wizard, see details here if you have deployed the optional Director or Director pool: Configure Certificates for the Director. For the Front End Server or Front End pool, see the details here: Configure Certificates for Servers
The initial steps in this procedure are preparation steps, to orient you as to what role the current certificates play. By default, the certificates will not have a lyncdiscover.<sipdomain> or lyncdiscoverinternal.<internal domain name> entry unless you have previously installed Mobility Services or have prepared your certificates in advance. This procedure uses the example SIP domain name ‘contoso.com’ and the example internal domain name ‘contoso.net’.
The default certificate configuration for Lync Server 2013 and Lync Server 2010 is to use a single certificate (named ‘Default’) with the purposes Default (for all purposes except for the web services), WebServicesExternal and WebServicesInternal. An optional configuration is to use separate certificates for each purpose. Certificates can be managed by using the Lync Server Management Shell and Windows PowerShell cmdlets, or by using the Certificate Wizard in the Lync Server Deployment Wizard.

⊟To update certificates with new subject alternative names using the Lync

Server Management Shell

1. Log on to the computer using an account that has local administrator rights and permissions.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Find out what certificates have been assigned to the server and for which type of use. You need this information in the next step to assign the updated certificate. At the command line, type:

   ```
   Get-CsCertificate
   ```

4. Look in the output from the previous step to see whether a single certificate is assigned for multiple uses or whether a different certificate is assigned for each use. Look in the Use parameter to find out how a certificate is used. Compare the Thumbprint parameter for the displayed certificates to see if the same certificate has multiple uses.
5. Update the certificate. At the command line, type:

   ```
   Set-CsCertificate -Type <type of certificate as displayed in the Use p
   ```

   For example, if the **Get-CsCertificate** cmdlet displayed a certificate with Use of Default, another with a Use of WebServicesInternal, and another with a Use of WebServicesExternal, and they all had the same Thumbprint value, at the command line, type:

   ```
   Set-CsCertificate -Type Default,WebServicesInternal,WebServicesExterna
   ```

   Important:

   If a separate certificate is assigned for each use (the Thumbprint value is different for each certificate), it is important that you do not run the **Set-CsCertificate** cmdlet with multiple types. In this case, run the **Set-CsCertificate** cmdlet separately for each use. For example:

   ```
   Set-CsCertificate -Type Default -Thumbprint <Certificate Thumbprint>
   Set-CsCertificate -Type WebServicesInternal -Thumbprint <Certificate T
   Set-CsCertificate -Type WebServicesExternal -Thumbprint <Certificate T
   ```

6. To view the certificate, click **Start**, click **Run...**. Type MMC to open the Microsoft Management Console.
7. From the MMC menu, select **File**, select **Add/Remove snap-in...**, select Certificates. Click **Add**. When prompted, select **Computer account**, then click **Next**.
8. If this is the computer where the certificate is located, select **Local computer**. If the certificate is located on another computer, select **Another computer**, type in the fully qualified domain name of the computer or click **Browse** In **Enter the object name to select**, type the name of the computer. Click **Check Names**. When the name of the computer is resolved, it will be underlined. Click **OK**, then click **Finish**. Click **OK** to commit the selection and close the **Add or Remove Snap-ins** dialog.
9. To view the properties of the certificate, expand **Certificates**, expand **Personal**, and select **Certificates**. Select the certificate to view, right-click on the certificate and select **Open**.
10. In the **Certificate** view, select **Details**. From here, you can select the certificate subject name by selecting **Subject** and the assigned subject name and associated properties are displayed.
11. To view the assigned subject alternative names, select **Subject Alternative Name**. All assigned subject alternative names are displayed. The subject alternative names that are found in the property are of type **DNS Name** by default. You should see the following members (all of which should be fully qualified domain names as represented in DNS host (A or, if IPv6 AAAA) records:
    - Pool name for this pool, or the single server name if this is not a pool
    - Server name that the certificate is assigned to

- Simple URL records, typically meet and dialin
- Web services internal and Web services external names (for example, webpool01.contoso.net, webpool01.contoso.com), based on choices made in Topology Builder and over-ridden web services selections.
- If already assigned, the lyncdiscover.<sipdomain> and lyncdiscoverinternal.<sipdomain> records.

The last item is what you are most interested in – if there is a lyncdiscover and lyncdiscoverinternal SAN entry.

Once you have this information, you can close the certificate view and the MMC.

12. If an Autodiscover Service subject alternative name is missing, and you are using a single Default certificate for the Default, WebServicesInternal and WebServiceExternal types, do the following:
    - At the Lync Server Management Shell command line prompt, type:

      ```
      Request-CsCertificate -New -Type Default,WebServicesInternal
      ```

      If you have many SIP domains, you cannot use the new AllSipDomain parameter. Instead, you must use DomainName parameter. When you use the DomainName parameter, you must define the FQDN for the lyncdiscoverinternal and lyncdiscover records. For example:

      ```
      Request-CsCertificate -New -Type Default,WebServicesInternal
      ```

    - To assign the certificate, type the following:

      ```
      Set-CsCertificate -Type Default,WebServicesInternal,WebServi
      ```

      Where "Thumbprint" is the thumbprint displayed for the newly issued certificate.

13. For a missing internal Autodiscover subject alternative names when using separate certificates for Default, WebServicesInternal, and WebServicesExternal, do the following:
    - At the Lync Server Management Shell command line prompt, type:

      ```
      Request-CsCertificate -New -Type WebServicesInternal -Ca dc\
      ```

      If you have many SIP domains, you cannot use the new AllSipDomain parameter. Instead, you must use DomainName parameter. When you use the DomainName parameter, you must use an appropriate prefix for the SIP domain FQDN. For example:

      ```
      Request-CsCertificate -New -Type WebServicesInternal -Ca dc\
      ```

    - For a missing external Autodiscover subject alternative name, at the command line, type:

      ```
      Request-CsCertificate -New -Type WebServicesExternal -Ca dc\
      ```

      If you have many SIP domains, you cannot use the new AllSipDomain parameter. Instead, you must use DomainName parameter. When you use the DomainName parameter, you must use an appropriate prefix for the SIP domain FQDN. For example:

      ```
      Request-CsCertificate -New -Type WebServicesExternal -Ca dc\
      ```

    - To assign the individual certificate types, type the following:

      ```
      Set-CsCertificate -Type Default -Thumbprint <Certificate Thu
      Set-CsCertificate -Type WebServicesInternal -Thumbprint <Cer
      Set-CsCertificate -Type WebServicesExternal -Thumbprint <Cer
      ```

      Where "Thumbprint" is the thumbprint displayed for the newly issued individual certificates.

Configuring the Reverse Proxy for Mobility

See Also

Deployment > Deploying External User Access > Deploying Mobility >

Topic Last Modified: *2012-09-08*

If you want to use automatic discovery for mobile device clients, you need to modify an existing or create a new web publishing rule for the reverse proxy whether or not you update the subject alternative name lists on the reverse proxy certificates.

If you decide to use HTTPS for initial Lync Server 2013 Autodiscover Service requests and update the subject alternative names lists on the reverse proxy certificates, you need to assign the updated public certificate to the Secure Sockets Layer (SSL) Listener on your reverse proxy. For details about the required subject alternative name entries, see Technical Requirements for Mobility. You then need to modify the existing listener for the external web services or create a new web publishing rule for the external Autodiscover Service URL. If you do not already have a web publishing rule for the external Lync Server 2013 Web Services URL for your Front End pool, you also need to publish a rule for that.

Note:

The reverse proxy publishing rule and listener can service both the external web services and the Autodiscover Service, as long as the certificate assigned to the listener contains the necessary subject name and subject alternative names for both. For details on the default configuration of the web listener and publishing rule, see Setting Up Reverse Proxy Servers for more details.

If you decide to use HTTP for initial Autodiscover Service requests so that you do not need to update subject alternative names for the reverse proxy, you need to create or modify a web publishing rule for port 80.

The procedures in this section describe how to create or modify the web publishing rules in Microsoft Forefront Threat Management Gateway 2010 for automatic discovery.

Note:

These procedures assume that you have installed the Standard Edition of Forefront Threat Management Gateway (TMG) 2010. If you are using another reverse proxy, the procedures are similar, but will need to be mapped to the documentation for the third-party product.

⊟To create a web publishing rule for the external Autodiscover URL

1. Click **Start**, point to **Programs**, point to **Microsoft Forefront TMG**, and then click **Forefront TMG Management**.
2. In the left pane, expand **ServerName**, right-click **Firewall Policy**, point to **New**, and then click **Web Site Publishing Rule**.
3. On the **Welcome to the New Web Publishing Rule** page, type a display name for the new publishing rule (for example, LyncDiscoveryURL).
4. On the **Select Rule Action** page, select **Allow**.
5. On the **Publishing Type** page, select **Publish a single Web site or load balancer**.
6. On the **Server Connection Security** page, select **Use SSL to connect to the published Web server or server farm**.
7. On the **Internal Publishing Details** page, in **Internal Site name**, type the fully qualified domain name (FQDN) of your Director pool (for example, lyncdir01.contoso.local). If you are creating a rule for the external Web Services URL on the Front End pool, type the FQDN of the Front End pool (for example, lyncpool01.contoso.local).

8. On the **Internal Publishing Details** page, in **Path (optional)**, type **/*** as the path of the folder to be published, and then select **Forward the original host header**.
9. On the **Public Name Details** page, do the following:
   - Under **Accept Requests for**, select **This domain name**.
   - In **Public Name**, type **lyncdiscover.**<*sipdomain*> (the external Autodiscover Service URL). If you are creating a rule for the external Web Services URL on the Front End pool, type the FQDN for the external Web Services on your Front End pool (for example, lyncwebextpool01.contoso.com).
   - In **Path**, type **/***.
10. On **Select Web Listener** page, in **Web Listener**, select your existing SSL Listener with the updated public certificate.
11. On the **Authentication Delegation** page, select **No delegation, but client may authenticate directly**.
12. On the **User Set** page, select **All Users**.
13. On the **Completing the New Web Publishing Rule Wizard** page, verify that the web publishing rule settings are correct, and then click **Finish**.
14. In the Forefront TMG list of web publishing rules, double-click the new rule you just added to open **Properties**.
15. On the **To** tab, do the following:
    - Select **Forward the original host header instead of the actual one**.
    - Select **Requests appear to come from the Forefront TMG computer**.
16. On the **Bridging** tab, configure the following:
    - Select **Web server**.
    - Select **Redirect requests to HTTP port**, and type **8080** for the port number.
    - Select **Redirect requests to SSL port**, and type **4443** for the port number.
17. Click **OK**.
18. Click **Apply** in the details pane to save the changes and update the configuration.
19. Click **Test Rule** to verify that your new rule is set up correctly.

To modify an existing web publishing rule to add the external Autodiscover SAN and URL

1. Click **Start**, point to **Programs**, point to **Microsoft Forefront TMG**, and then click **Forefront TMG Management**.

   > **Important:**
   >
   > You will repeat the modification for each publishing rule and listener that you have. Typically, this will be one rule and listener for the Front End pools and one for the optional Directors or Director pools, if you have deployed them.

2. In the left pane, expand **ServerName**, right-click **Firewall Policy**, click the applicable rule. On the **Tasks** tab, click **Edit Selected rule**.
3. On the **Public Name** tab, in **This rule applies to**, select **Requests for the following Web sites**.
4. Click **Add**, type the name of the new Autodiscover site (for example, “lyncdiscover.contoso.com”), and then click **OK**.
5. On the **Listener** tab, click **Select Certificate** and assign the new certificate with the added Autodiscover SAN entries. Close the Listener and Web Publishing properties.
6. Click **Apply** in the details pane to save the changes and update the configuration.
7. Click **Test Rule** to verify that your new rule is set up correctly.

To create a web publishing rule for port 80

1. Click **Start**, point to **Programs**, point to **Microsoft Forefront TMG**, and then click **Forefront TMG Management**.
2. In the left pane, expand **ServerName**, right-click **Firewall Policy**, point to **New**, and then click **Web Site Publishing Rule**.

3. On the **Welcome to the New Web Publishing Rule** page, type a display name for the new publishing rule (for example, Lync Autodiscover (HTTP)).
4. On the **Select Rule Action** page, select **Allow**.
5. On the **Publishing Type** page, select **Publish a single Web site or load balancer**.
6. On the **Server Connection Security** page, select **Use non-secured connections to connect to the published Web server or server farm**.
7. On the **Internal Publishing Details** page, in **Internal Site name**, type the internal Web Services FQDN for your Front End pool (for example, lyncpool01.contoso.local).
8. On the **Internal Publishing Details** page, in **Path (optional)**, type **/*** as the path of the folder to be published, and then select **Forward the original host header instead of the one specified in the Internal site name field**.
9. On the **Public Name Details** page, do the following:
   - Under **Accept Requests for**, select **This domain name**.
   - In **Public Name**, type **lyncdiscover.**<*sipdomain*> (the external Autodiscover Service URL).
   - In **Path**, type **/***.
10. On **Select Web Listener** page, in **Web Listener**, select a Web Listener or use the New Web Listener Definition Wizard to create a new one.
11. On the **Authentication Delegation** page, select **No delegation, and client cannot authenticate directly**.
12. On the **User Set** page, select **All Users**.
13. On the **Completing the New Web Publishing Rule Wizard** page, verify that the web publishing rule settings are correct, and then click **Finish**.
14. In the Forefront TMG list of web publishing rules, double-click the new rule you just added to open **Properties**.
15. On the **Bridging** tab, configure the following:
    - Select **Web server**.
    - Select **Redirect requests to HTTP port**, and type **8080** for the port number.
    - Verify that **Redirect requests to SSL port** is not selected.
16. Click **OK**.
17. Click **Apply** in the details pane to save the changes and update the configuration.
18. Click **Test Rule** to verify that your new rule is set up correctly.
19. Verify that the external Autodiscover Service URL is not defined on any other web publishing rule.

Technical Requirements for Mobility

1.4.2.12.4 Configuring Autodiscover for Mobility with Hybrid Deployments

Configuring Autodiscover for Mobility with Hybrid Deployments

See Also

Deployment > Deploying External User Access > Deploying Mobility >

Topic Last Modified: *2013-01-24*

Hybrid Deployments are configurations that use both the Microsoft Lync Online cloud service and the on premises deployment. In this type of configuration, the Autodiscover service must be able to locate where the user is actually located. That is to say, Autodiscover aids in finding the user account and where the server that hosts the user’s account is, regardless if it is in the on premises deployment or in the Lync Online deployment.

For example, if a user’s account is hosted on a server in Lync Online, the attempt to locate the user will happen as follows, in a process known as *discoverability*:

- User initiates a connection attempt to the on premises deployment, **contoso.com**.
- The attempt is sent to lyncdiscover.contoso.com, the DNS name associated with the Autodiscover service.
- Autodiscover refers to the assumed registrar pool at the contoso.com on premises deployment and is given information on the user’s actual home server hosted in Lync Online. Autodiscover then sends the user a referral to the **lync.com** online Autodiscover service.
- The user initiates a connection attempt to the lync.com online Autodiscover service and is able to locate the user’s account and the user’s home server.

To enable mobile clients to discover the deployment where the user home server is located, you must configure the Autodiscover service with a new uniform resource locator (URL). Do the following to configure the Autodiscover service.

Configuring Autodiscover for Hybrid Deployments

1. You use Get-CsHostingProvider to retrieve the value of the attribute ProxyFQDN.
2. From the Lync Server Management Shell, type

   ```
   Set-CsHostingProvider -Identity [identity] -AutodiscoverUrl https://we
   ```

   Where [identity] is replaced with the domain name of the shared SIP address space.

1.4.2.12.5 Verifying Your Mobility Deployment

Verifying Your Mobility Deployment

See Also

Deployment > Deploying External User Access > Deploying Mobility >

Topic Last Modified: *2013-02-12*

```
Some information in this topic pertains to Cumulative Updates for Lync Server 201
```

After you deploy the Lync Server Mobility Service and Lync Server Autodiscover Service, run a test transaction to verify that your deployment works correctly. You can run **Test-CsUcwaConference** to test the ability of two users who are using Lync 2013 Mobile clients to create, join and communicate in a conference. To use this test transaction, you need two actual users or test users, and their full credentials.

You use **Test-CsMcxP2PIM** to test sending an instant message between two users who are using Lync 2010 Mobile. Similar to **Test-CsUcwaConference**, you use two actual users or two predefined test users.

To test conferencing for Lync 2013 Mobile clients

1. Log on as a member of the CsAdministrator role on any computer where Lync Server Management Shell and Ocscore are installed.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.

3. At the command line, type:

   ```
   Test-CsUcwaConference -TargetFqdn <FQDN of Front End pool> -Authentica
   ```

   You can set credentials in a script and pass them to the test cmdlet. For example:

   ```
   $passwd1 = ConvertTo-SecureString "Password01" -AsPlainText -Force
   $passwd2 = ConvertTo-SecureString "Password02" -AsPlainText -Force
   $testuser1 = New-Object Management.Automation.PSCredential("contoso\Us
   $testuser2 = New-Object Management.Automation.PSCredential("contoso\Us
   Test-CsUcwaConference -TargetFqdn pool01.contoso.com -Authentication N
   ```

To test person-to-person instant messaging (IM) for Lync 2010 Mobile

1. Log on as a member of the CsAdministrator role on any computer where Lync Server Management Shell and Ocscore are installed.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. At the command line, type:

   ```
   Test-CsMcxP2PIM -TargetFqdn <FQDN of Front End pool> -Authentication <
   ```

   You can set credentials in a script and pass them to the test cmdlet. For example:

   ```
   $passwd1 = ConvertTo-SecureString "Password01" -AsPlainText -Force
   $passwd2 = ConvertTo-SecureString "Password02" -AsPlainText -Force
   $tuc1 = New-Object Management.Automation.PSCredential("contoso\UserNam
   $tuc2 = New-Object Management.Automation.PSCredential("contoso\UserNam
   Test-CsMcxP2PIM -TargetFqdn pool01.contoso.com -Authentication Negotia
   ```

1.4.2.12.6 Configuring for Push Notifications

Configuring for Push Notifications

See Also

Deployment > Deploying External User Access > Deploying Mobility >

Topic Last Modified: *2013-02-12*

Push notifications, in the form of badges, icons, or alerts, can be sent to a mobile device even when the mobile application is inactive. Push notifications notify a user of events such as a new or missed IM invitation and voice mail. The Lync Server 2013 Mobility Service sends the notifications to the cloud-based Lync Server Push Notification Service, which then sends the notifications to the Apple Push Notification Service (APNS) (for an Apple device running the Lync 2010 Mobile client) or the Microsoft Push Notification Service (MPNS) (for a Windows Phone device running the Lync 2010 Mobile or the Lync 2013 Mobile client).

Important:

If you use Windows Phone with Lync 2010 Mobile or Lync 2013 Mobile client, push notification is an important consideration.
If you use Lync 2010 Mobile on Apple devices, push notification is an important consideration.
If you use Lync 2013 Mobile on Apple devices, you no longer need push notification.

Configure your topology to support push notifications by doing the following:

- If your environment has a Lync Server 2010 or Lync Server 2013 Edge Server,

you need to add a new hosting provider, Microsoft Lync Online, and then set up hosting provider federation between your organization and Lync Online.
- If your environment has a Office Communications Server 2007 R2 Edge Server, you need to set up direct SIP federation with push.lync.com.

> **Note:**
>
> Push.lync.com is a Microsoft Office 365 domain for Push Notification Service.

- To enable push notifications, you need to run the **Set-CsPushNotificationConfiguration** cmdlet. By default, push notifications are turned off.
- Test the federation configuration and push notifications.

To configure for push notifications with Lync Server 2013 or Lync Server 2010 Edge Server

1. Log on to a computer where Lync Server Management Shell and Ocscore are installed as a member of the RtcUniversalServerAdmins group.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Add a Lync Server online hosting provider. At the command line, type:

   ```
   New-CsHostingProvider -Identity <unique identifier for Lync Online hos
   ```

   For example:

   ```
   New-CsHostingProvider -Identity "LyncOnline" -Enabled $True -ProxyFqdn
   ```

   > **Note:**
   >
   > You cannot have more than one federation relationship with a single hosting provider. That is, if you have already set up a hosting provider that has a federation relationship with sipfed.online.lync.com, do not add another hosting provider for it, even if the identity of the hosting provider is something other than LyncOnline.

4. Set up hosting provider federation between your organization and the Push Notification Service at Lync Online. At the command line, type:

   ```
   New-CsAllowedDomain -Identity "push.lync.com"
   ```

To configure for push notifications with Office Communications Server 2007 R2 Edge Server

1. Log on to the Edge Server as a member of the RtcUniversalServerAdmins group.
2. Click **Start**, click **All Programs**, click **Administrative Tools**, and then click **Computer Management**.
3. In the console tree, expand **Services and Applications**, right-click **Microsoft Office Communications Server 2007 R2**, and then click **Properties**.
4. On the **Allow** tab, click **Add**.
5. In the **Add Federated Partner** dialog box, do the following:
   - In **Federated partner domain name**, type **push.lync.com**.
   - In **Federated partner Access Edge Server**, type **sipfed.online.lync.com**.
   - Click **OK**.

To enable push notifications

1. Log on to a computer where Lync Server Management Shell and Ocscore are installed as a member of the CsAdministrator role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Enable push notifications. At the command line, type:

```
Set-CsPushNotificationConfiguration -EnableApplePushNotificationServic
```

4. Enable federation. At the command line, type:

```
Set-CsAccessEdgeConfiguration -AllowFederatedUsers $True
```

⊟To test federation and push notifications

1. Log on to a computer where Lync Server Management Shell and Ocscore are installed as a member of the CsAdministrator role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Test the federation configuration. At the command line, type:

```
Test-CsFederatedPartner -TargetFqdn <FQDN of Access Edge server used f
```

For example:

```
Test-CsFederatedPartner -TargetFqdn accessproxy.contoso.com -Domain pu
```

4. Test push notifications. At the command line, type:

```
Test-CsMcxPushNotification -AccessEdgeFqdn <Access Edge service FQDN>
```

For example:

```
Test-CsMcxPushNotification -AccessEdgeFqdn accessproxy.contoso.com
```

1.4.2.12.7 Configuring Mobility Policy

Configuring Mobility Policy

See Also

Deployment > Deploying External User Access > Deploying Mobility >

Topic Last Modified: *2013-02-13*

```
Some information in this topic pertains to Cumulative Updates for Lync Server 201
```

Lync Server 2013 provides mobility policies that determine who can use mobility features, Call via Work, voice over IP (VoIP) or video, and whether WiFi will be required for either VoIP or video. The Call via Work feature enables a mobile user to make and receive calls on a mobile phone by using a work phone number instead of the mobile phone number. This feature prevents the called party from seeing the caller's mobile phone number and enables a user to avoid outbound calling charges. Configuring VoIP and video makes it possible for users to receive and make VoIP calls and video. Settings for WiFi usage define if a user’s device will be required to use a WiFi network over a cellular data network.

By default, mobility, Call via Work, and the VoIP and video features are enabled. The settings to require WiFi for VoIp and video are disabled. Administrators can determine who has access to these features by running a cmdlet. You can turn options off globally, by site, or by user.

To be able to use mobility features and Call via Work, users must meet the following prerequisites:

- Users must be enabled for Lync Server 2013.
- Users must be enabled for Enterprise Voice.
- Users must be assigned a mobility policy that has the **EnableMobility** option set to True.

For users to be able to use Call via Work, they must meet the following two additional prerequisites:

- Users must be assigned a voice policy that has the **Enable simultaneous ringing of phones** option selected.
- Users must be assigned a mobility policy that has the **EnableOutsideVoice** option set to True.

Note:

Users who are not enabled for Enterprise Voice can use their mobile devices to make Lync to Lync Voice over IP (VoIP) calls, or can join conferences by using the Click to Join link on their mobile devices, if you assign those users the appropriate options for voice policy. For details, see Defining Your Mobility Requirements.

For details about enabling users for Lync Server 2013, see Disable or Re-Enable User Account for Lync Server. For details about enabling users for Enterprise Voice, see Enable Users for Enterprise Voice. For details about setting voice policy options, see Modify a Voice Policy and Configure PSTN Usage Records.

To modify global mobility policy

1. Log on to any computer where Lync Server Management Shell and Ocscore are installed as a member of the CsAdministrator role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Turn off access to mobility and Call via Work globally. At the command line, type:

```
Set-CsMobilityPolicy -EnableMobility $False -EnableOutsideVoice $False
```

Note:

You can turn off Call via Work without turning off access to mobility. However, you cannot turn off mobility without also turning off Call via Work.

To modify mobility policy by site

1. Log on to any computer where Lync Server Management Shell and Ocscore are installed as a member of the CsAdministrator role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Create a site-level policy, and turn off VoIP and video, and enable Require WiFi for IP Audio and for IP Video by site. At the command line, type:

```
New-CsMobilityPolicy -Identity site:<site identifier> -EnableIPAudioVi
```

To modify mobility policy by user

1. Log on to any computer where Lync Server Management Shell and Ocscore are installed as a member of the CsAdministrator role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Create user level mobility policies and turn off mobility and Call via Work by user. At the command line, type:

```
New-CsMobilityPolicy -Identity <policy name> -EnableMobility $False -E
Grant-CsMobilityPolicy -Identity <user identifier> -PolicyName <policy
```

You can turn off Call via Work without turning off access to mobility. However, you cannot turn off mobility without also turning off Call via Work.

For example:

```
New-CsMobilityPolicy "tag:disableOutsideVoice" -EnableOutsideVoice $Fa
Grant-CsMobilityPolicy -Identity -MobileUser1@contoso.com -PolicyName
```

1.4.2.13 Verifying Your Edge Deployment

Verifying Your Edge Deployment

Microsoft Lync Server 2013 > Deployment > Deploying External User Access >

Topic Last Modified: *2010-11-07*

After completing the installation and configuration of your edge components, you need to verify the configuration and connectivity of servers and to verify connectivity for each type of external user that you support.

- Verify Connectivity Between Internal Servers and Edge Servers
- Verify Connectivity for External Users

1.4.2.13.1 Verify Connectivity Between Internal Servers and Edge Servers

Verify Connectivity Between Internal Servers and Edge Servers

Deployment > Deploying External User Access > Verifying Your Edge Deployment >

Topic Last Modified: *2012-09-08*

In Lync Server 2013, a separate validation wizard was available to help validate connectivity between Edge Servers and internal servers. In Lync Server 2013 validation of connectivity is done automatically when you install your Edge Servers.

You can validate the replication of configuration information to the edge by running the Windows PowerShell **Get-CsManagementStoreReplicationStatus** cmdlet on the internal computer on which the Central Management store is located (or any domain joined computer on which Lync Server 2013 Core Components (OcsCore.msi) is installed. Initial results may indicate the status as "False" instead of "True" for replication. If so, run the **Invoke-CsManagementStoreReplication** cmdlet and allow time for the replication to complete before running the **Get-CsManagementStoreReplicationStatus** again.

You can verify external user connectivity separately, including using the Office Communications Server Remote Connectivity Analyzer to verify remote user connectivity. For details, see Verify Connectivity for External Users.

1.4.2.13.2 Verify Connectivity for External Users

Verify Connectivity for External Users

Deployment > Deploying External User Access > Verifying Your Edge Deployment >

Topic Last Modified: *2012-10-19*

Validating connectivity for external users requires ensuring connectivity from users to the server and port for the Access Edge service.

A valuable resource for confirming your configuration and the ability to connect, send and receive the correct messages for the scenarios that external user access requires is the Remote Connectivity Analyzer site (http://www.testocsconnectivity.com). The site is managed and maintained by Microsoft Support. To reach the Remote Connectivity Analyzer, open the Web site in a browser and follow the instructions to select the scenario.

Test Connectivity of External Users and External access

Tests for external user access should include each type of external user that your organization supports, including any or all of the following:

- Users from at least one federated domain, and test IM, presence, A/V and desktop sharing.
- Users of each public IM service provider that your organization supports (and for which provisioning has been completed).
- Anonymous users.
- Users within your organization who are logged into Lync remotely, but not using VPN.

These tests determine whether your Edge Server is:

- Listening on the necessary ports by using a telnet client from outside your network.
  - Example: telnet sip.contoso.com 443
  - Perform the preceding test on ports you are using on the Edge Server or Edge Server pool depending on your deployment.
- Performing accurate external DNS resolution.
  - From outside your network ping each of the external FQDN's of your Edge or Edge pool. Even if the ping fails you will see the IP addresses, which you can compare to the ones you have assigned.

1.4.3 Deploying Enterprise Voice

Deploying Enterprise Voice

See Also

Microsoft Lync Server 2013 > Deployment >

Topic Last Modified: *2012-10-03*

Lync Server 2013, Enterprise Voice is part of the Lync Server 2013 infrastructure.

Deploying Enterprise Voice requires that you:

1. Review the Planning for Enterprise Voice section of the Planning documentation.

2. Finalize plans for features and components to deploy with this workload.
3. Run Planning Tool to design a topology that reflects your deployment decisions.
4. Open the topology design in Topology Builder, as described in Defining and Configuring the Topology in the Deployment documentation.

Note:
Installation of Topology Builder is part of the deployment process for the internal pool. For details, see Install Lync Server Administrative Tools in the Deployment documentation.

Additionally, you must have already deployed Lync Server, Enterprise Edition at central sites and branch sites that correspond to the reference topology that you choose to deploy. You can't deploy Enterprise Voice components until you have defined, published, and installed files for at least one internal pool, and you must use Topology Builder to define and publish an internal pool.

To view reference topologies with examples of where Enterprise Voice server roles can be deployed (and their relationship to one another and other Lync Server 2013 server roles), see Reference Topologies in the Planning documentation.

To view a reference topology that illustrates and explains a sample call admission control deployment, including network regions, network sites, and subnets, see Example: Gathering Your Organization's Requirements for Call Admission Control in the Planning documentation.

Important:
To deploy Enterprise Voice at a central site, continue reading the topics in this section. To deploy Enterprise Voice at a branch site, skip to Deploying Branch Sites in the Deployment documentation.

This section includes procedures for deployments in which a Mediation Server is collocated on each Front End Server or Standard Edition server, as recommended, and also for deployments with a stand-alone Mediation Server pool.

You can skip the following content if you used Topology Builder to define and publish a topology that collocates a Mediation Server on each Front End Server or Standard Edition server, because Deployment Wizard already automatically installed the files for Mediation Server when you installed files for your Front End Server pool or Standard Edition server:

- Configuring Trunks

If you used Topology Builder to define and publish a Mediation Server in a stand-alone pool, you can use the following content:

- Verify that your topology meets the software and environment prerequisites, as described in Enterprise Voice Prerequisites.

In This Section

- Enterprise Voice Prerequisites
- Deploying Mediation Servers and Defining Peers
- Configuring Trunks
- Configuring Dial Plans
- Configuring Voice Policies, PSTN Usage Records, and Voice Routes
- Exporting and Importing Voice Routing Configuration
- Test Voice Routing
- Publish Pending Changes to the Voice Routing Configuration
- Deploying On-Premises Exchange UM to Provide Lync Server 2013 Voice Mail
- Providing Lync Server 2013 Users Voice Mail on Hosted Exchange UM
- Configuring On-premises Lync Server 2013 Integration with Exchange Online

- Deploying Advanced Enterprise Voice Features
  - About Network Regions, Sites, and Subnets
  - Create or Modify a Network Region
  - Create or Modify a Network Site
  - Associate a Subnet with a Network Site
  - Configure Call Admission Control
  - Configure Enhanced 9-1-1
  - Configure Media Bypass
- Enable Users for Enterprise Voice

1.4.3.1 Enterprise Voice Prerequisites

Enterprise Voice Prerequisites

Microsoft Lync Server 2013 > Deployment > Deploying Enterprise Voice >

Topic Last Modified: *2012-08-06*

For the best experience when deploying Enterprise Voice, be sure that your IT infrastructure, network, and systems meet the prerequisites described in the topics in this section.

- Software Prerequisites for Enterprise Voice
- Security and Configuration Prerequisites for Enterprise Voice

1.4.3.1.1 Software Prerequisites for Enterprise Voice

Software Prerequisites for Enterprise Voice

Deployment > Deploying Enterprise Voice > Enterprise Voice Prerequisites >

Topic Last Modified: *2012-10-03*

Verify that the infrastructure in which you intend to deploy Enterprise Voice meets the following software prerequisites:

- Lync Server 2013 Standard Edition or Enterprise Edition is installed and operational on your network.
- All Edge Servers are deployed and operational in your perimeter network, including Edge Servers running Access Edge service, A/V Edge service, Web Conferencing Edge service, and a reverse proxy.
- Either Microsoft Exchange Server 2007 Service Pack 3 (SP3), Microsoft Exchange Server 2010 or Microsoft Exchange Server 2013 is required for integrating Exchange Unified Messaging with Lync Server and to provide rich notifications and call log information to the Lync endpoints.
- One or more users have been created and enabled for Lync Server.
- Lync clients and devices have been successfully deployed.
- Topology Builder is installed on a server on your network.

Next Steps: Verify Security and

Configuration Prerequisites

After verifying software prerequisites for Enterprise Voice, you can use the documentation to continue preparing for deploying Enterprise Voice:

1. Verify security, user configuration, and hardware perquisites, as described in Security and Configuration Prerequisites for Enterprise Voice.
2. Install the Mediation Server, as described in Install the Files for Mediation Server, but *only* if you want to deploy a stand-alone Mediation Server or pool because Mediation Servers are installed as part of the Front End pool or Standard Edition server deployment process when collocated.
3. Configure trunk connections to provide PSTN connectivity for users, as described in Configuring Trunks.

1.4.3.1.2 Security and Configuration Prerequisites for Enterprise Voice

Security and Configuration Prerequisites for Enterprise Voice

Deployment > Deploying Enterprise Voice > Enterprise Voice Prerequisites >

Topic Last Modified: *2012-10-18*

Verify that your infrastructure meets the following security, user configuration, and scenario-specific hardware prerequisites.

Administrative Rights and Certificate Infrastructure

Be sure that your environment is configured with the following administrative user groups and certificate infrastructure for use during the Enterprise Voice deployment process.

- Administrators deploying Enterprise Voice should be members of the RTCUniversalServerAdmins group.
- Administrators performing the configuration tasks must have adequate rights:
  - **CsVoiceAdministrator:** This administrator role can perform voice configuration tasks, manage voice applications, and assign voice policies to end users.
  - **CsUserAdministrator:** This administrator role can manage user properties, such as enabling Enterprise Voice for a user. This administrator role can also assign per-user policies, with the exception of the archiving policy; move users; and manage common area phones and analog devices.
  - **CsAdministrator:** This administrator role can perform all of the tasks of CsVoiceAdministrator and CsUserAdministrator.

  Note:

  Delegation enables more administrators to participate in your Lync Server deployment without opening up unnecessary access to resources.
- Managed key infrastructure (MKI) is deployed and configured, by using either a Microsoft or a third-party certification authority (CA) infrastructure.

  Note:

  For details about certificate requirements in Lync Server, see Certificate Infrastructure Requirements in the Planning documentation.

User Configuration

If you collocated the Mediation Server with each Front End pool or Standard Edition server during Front End deployment, user settings necessary for Enterprise Voice were configured automatically during installation of the files for those server roles.

If you are newly deploying the Enterprise Voice workload at this time, before you begin the deployment process, designate a primary phone number for each user who you plan to enable for Enterprise Voice. As the administrator, you are responsible for ensuring that this number is unique. Before implementation, all primary phone numbers must be normalized (correctly formatted) and copied to each user's **Line URI** property using Lync Server Control Panel.

Note:

For examples of primary phone numbers required for Enterprise Voice deployment, see the Dial Plans and Normalization Rules section of Dial Plans and Normalization Rules in the Planning documentation.

Next Steps: Install Files or Configure PSTN Connectivity

After verifying software and environmental prerequisites for Enterprise Voice, you can use the following content to either:

- Install the Mediation Server, as described in Install the Files for Mediation Server, but only if you want to deploy a stand-alone Mediation Server or pool because Mediation Servers are installed as part of the Front End pool or Standard Edition server deployment process when collocated.
- Or, begin configuring settings to route calls for Enterprise Voice users, as described in Configuring Trunks.

1.4.3.2 Deploying Mediation Servers and Defining Peers

Deploying Mediation Servers and Defining Peers

Microsoft Lync Server 2013 > Deployment > Deploying Enterprise Voice >

Topic Last Modified: *2012-09-21*

The Enterprise Voice workload, dial-in conferencing, and advanced Enterprise Voice applications (Response Group application, Call Park application, call admission control (CAC), and so on), are available in Front End pools. With Lync Server 2013, the functionality of the Mediation Server is built into the Front End Server. A separate stand-alone Mediation Server is no longer necessary. Front End pools can communicate directly with supported gateways (a public switched telephone network (PSTN) gateway or an IP-PBX), removing the need for a Mediation Server to serve as an intermediary.

The only exception is if you configure a SIP trunk to connect to a Session Border Controller for an Internet Telephony Service Provider. To connect your Enterprise Voice infrastructure to your SIP trunk provider, a separate Mediation Server must be deployed.

The connection between Lync Server (the Mediation Server component on a Front End pool or stand-alone Mediation Server) and a gateway is defined as a logical association called a *trunk*. The topics in this section describe how to define a trunk and how to deploy a stand-alone Mediation Server, if you connect to a SIP trunk.

- Define a Mediation Server in Topology Builder
- Define a Gateway in Topology Builder
- Install the Files for Mediation Server
- Define additional Trunks in Topology Builder

⊟Related Sections

Configuring Dial-in Conferencing

1.4.3.2.1 Define a Mediation Server in Topology Builder

Define a Mediation Server in Topology Builder

Deployment > Deploying Enterprise Voice > Deploying Mediation Servers and Defining Peers >

Topic Last Modified: *2013-02-24*

Follow the steps in this topic to use Topology Builder to define a stand-alone Mediation Server or pool collocated with a Front End pool at a site for which you did not previously deploy Enterprise Voice.

You can define a topology using an account that is a member of the Administrators group.

Define Mediation Server collocated to a Front End pool

Follow the steps in this topic to use Topology Builder to define a Mediation Server collocated to a Front End pool in a site where Enterprise Voice has not been previously deployed.

⊟To Add a Mediation Server to a Front End pool

1. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
2. In Topology Builder, in the console tree, expand the name of the site for which you want to define a Front End pool.
3. In the console tree, right-click the type of Front End pool you want, and then click **New Front End pool...**.
4. Navigate through the **Define New Front End Pool** wizard until you reach the **Select collocated server roles** page.
5. In **Select collocated server roles**, check the option **Collocate Mediation Server**.

Note:

- If the type of Front End pool you selected is the Enterprise Edition, then the Mediation Server component will be installed on all the Front End Servers of that Front End pool.
- The **Next hop pool** used by the Mediation Server will be the Front End pool where the Mediation Server is collocated on.
- The **Edge pool** used by the Mediation Server will be the same Edge pool associated with the Front End pool where the Mediation Server is collocated on.

1. Click **Make Default** to use this Front End pool to route calls from Microsoft Office Communications Server 2007 R2 to the PSTN.
2. Click **Finish** when you are finished associating one or more peers to the Front End pool.

Note:

Before you proceed to the next step in the Enterprise Voice deployment process, make sure that the Mediation Server pool (i.e. Front End pool with the Mediation Server component collocated) is using the FQDNs that you specified.

3. Next, follow the procedures in Publish the Topology in the Deployment Guide documentation to add the Mediation Server to your topology before proceeding to the next step of modifying the listening ports of the Mediation Server if needed. You must publish your topology each time you use Topology Builder to define or modify your topology.

Define stand-alone Mediation Server

Follow the steps in this topic to use Topology Builder to define a stand-alone Mediation Server or pool at a site where Enterprise Voice has not been previously deployed.

If you already deployed Mediation Servers collocated to Front End pools at this site, you can skip this section and Install the Files for Mediation Server before proceeding to Configuring Trunks.

Note:

This section assumes that you have already setup at least one Front End pool, as described in Define and Configure a Front End Pool or Standard Edition Server and Publish the Topology in the Deployment Guide documentation.

To Add a Mediation Server

1. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
2. In Topology Builder, in the console tree, expand the name of the site for which you want to define a Mediation Server.
3. In the console tree, right-click the **Mediation pools** node, and then click **Mediation Server pool**.
4. In **Define New Mediation Pool**, type the Mediation Server pool fully qualified domain name (FQDN).
5. Next, do one of the following:
   - If you want to deploy multiple Mediation Servers in the pool to provide high availability, then select **Multiple computer pool**.

     Note:

     You must deploy DNS load balancing to support Mediation Server pools that have multiple Mediation Servers. For details, see the Using DNS Load Balancing on Mediation Server Pools section of DNS Load Balancing in the Planning documentation.

   - If you want to deploy only one Mediation Server in the pool because you do not require high availability, then select **Single computer pool**. Skip the following step.
6. If you selected **Multiple computer pool** in the previous step, on the **Define the computers in this pool** item, click **Computer FQDN**, type the FQDN of each server in the pool, and then click **Add**. Repeat this step for all other Mediation Servers that you want to add to the pool. When you have defined all the computers in the pool, click **Next**.
7. On the **Select the next hop** page, click **Next hop pool**, click the FQDN of the Front End pool that will use this Mediation Server pool, and then click **Next**.
8. On the **Select an Edge Server** page, do one of the following:
   - If you want to provide PSTN connectivity to external users enabled for Enterprise Voice, under **Select Edge Pool used by this Mediation Server**, click the FQDN of the Edge Server pool that will use this Mediation Server pool to provide PSTN connectivity to those external users, and then click **Next**.
   - If you do not plan to enable external users for Enterprise Voice, or if you do not want to provide PSTN connectivity to users when they are outside the internal network, click **Next**.
9. Next, follow the procedures in Publish the Topology in the Deployment documentation to add the Mediation Server to the topology. You must publish

your topology each time you use Topology Builder to build or modify your topology so that the data can be used to install the files for servers that are running Lync Server. Then continue to the next steps to modify the listening ports on the Mediation Server, if necessary.

Define the Mediation Server Listening Ports

Follow the steps in this topic to use Topology Builder to define the listening ports a Mediation Server or pool will accept incoming connections from a gateway peer.

⊟To Modify the Mediation Server Listening Ports

1. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
2. In Topology Builder, in the console tree, expand the **Mediation pools** node, and right-click the Mediation Server previously created.
3. By default, the SIP listening ports on the Mediation Server are 5070 for TLS traffic from Lync Server, 5067 for TLS traffic from peers (gateways, PBXes, or SBCs). TCP port is disabled by default. You must enable TCP port if you have gateways that do not support TLS.
4. Specify the desired TLS or TCP listening port range the Mediation Server will accept incoming connections from PSTN gateways.

Note:

Entering a TCP port range is not required if **Enable TCP port** is not checked. This setting is optional.

Next, Define a Gateway in Topology Builder and install the files on each Mediation Server in the pool by following the procedures in Install the Files for Mediation Server.

1.4.3.2.2 Define a Gateway in Topology Builder

Define a Gateway in Topology Builder

See Also

Deployment > Deploying Enterprise Voice > Deploying Mediation Servers and Defining Peers >

Topic Last Modified: *2012-10-04*

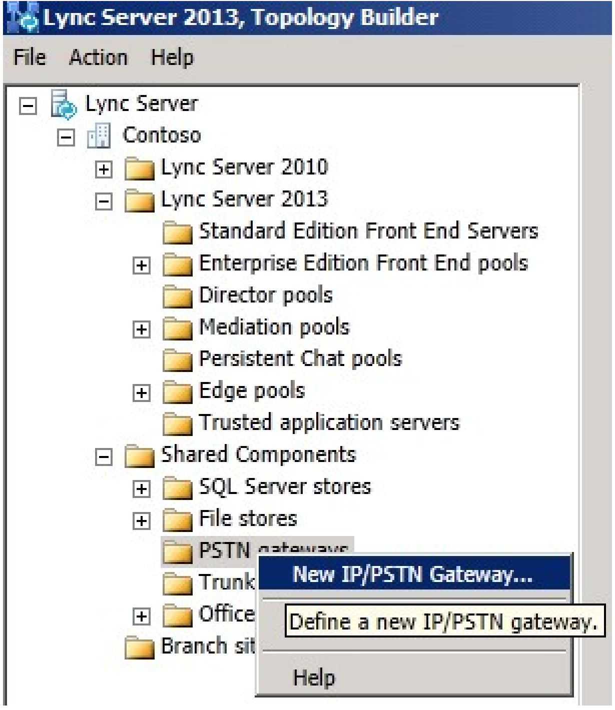
Follow these steps to use Topology Builder to define a *peer* with which you can associate a Mediation Server to provide connectivity to the public switched telephone network (PSTN) for users enabled for Enterprise Voice. A peer to the Mediation Server can be a PSTN gateway, an IP-PBX, or a Session Border Controller (SBC) for an Internet Telephony Service Provider (ITSP) to which you connect by configuring a SIP trunk.

Note:

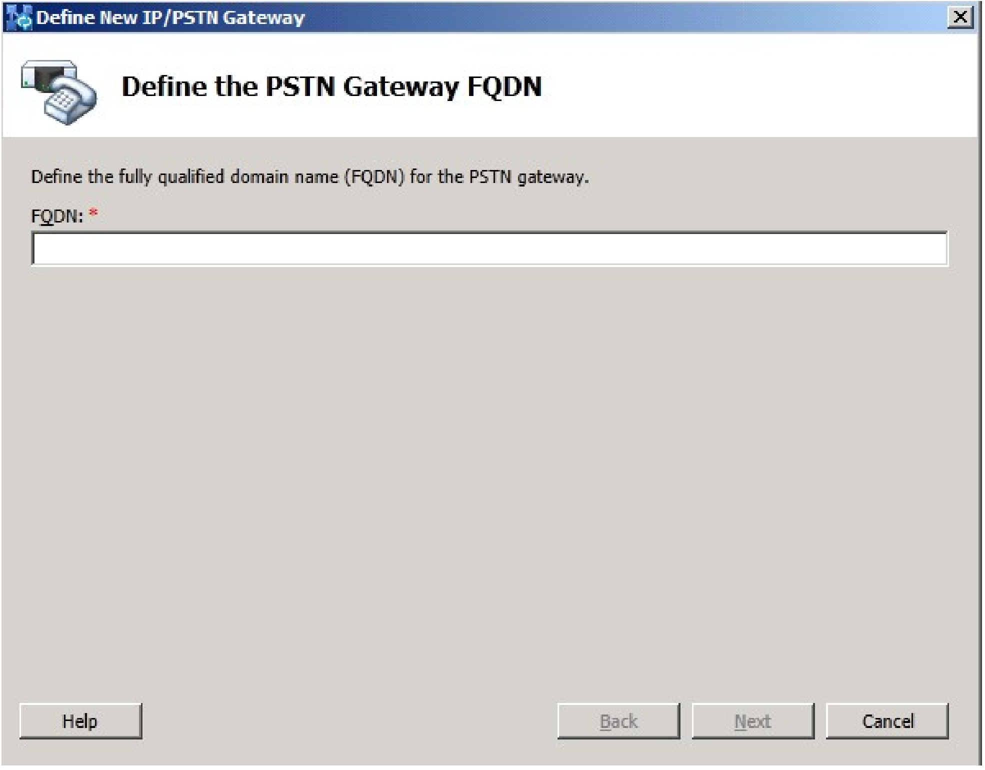
This topic assumes that you have set up at least one internal Front End pool or Standard Edition server in at least one central site with a collocated or stand-alone Mediation Server, as described in Define and Configure a Front End Pool or Standard Edition Server and Publish the Topology in the Deployment documentation. This topic also assumes that you have verified that your infrastructure meets the prerequisites described in Software Prerequisites for Enterprise Voice and Security and Configuration Prerequisites for Enterprise Voice.

⊟To Define a Peer for the Mediation Server

1. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
2. Under Lync Server 2013, your site name, Shared Components, right-click the **PSTN Gateways** node, and then click **New PSTN Gateway**.



3. In **Define New IP/PSTN Gateway**, type the fully qualified domain name (FQDN) or IP address of the peer, and click **Next**.



Define the PSTN Gateway FQDN

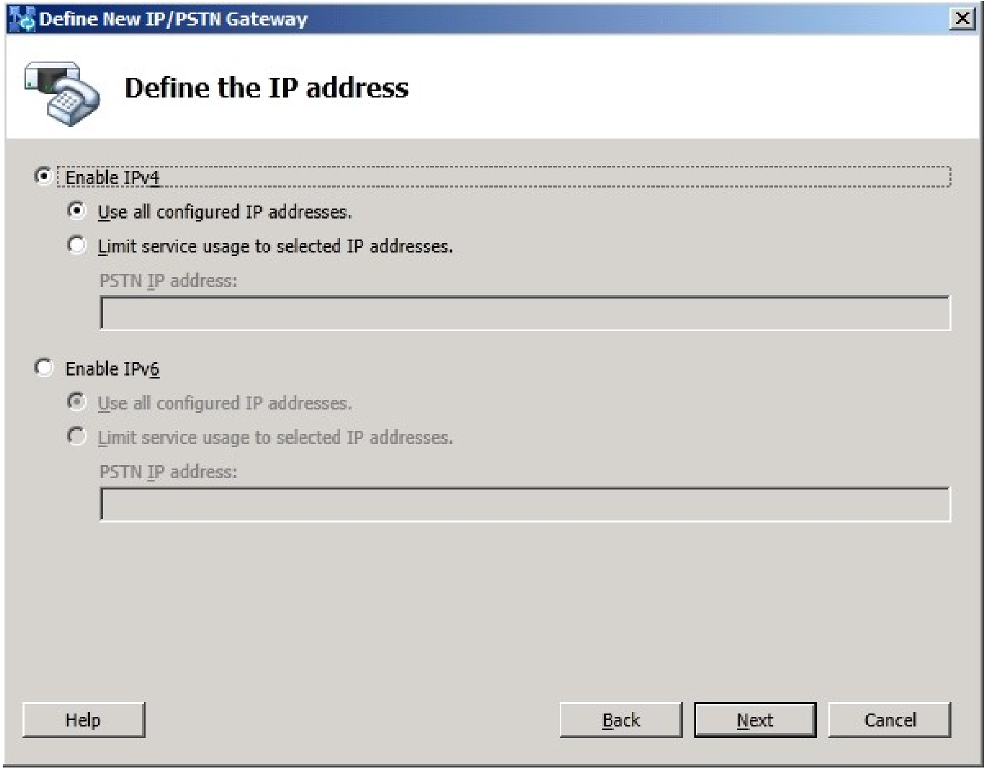
Define the fully qualified domain name (FQDN) for the PSTN gateway.

FQDN: *

Note:

If you specify Transport Layer Security (TLS) as the transport type, you must specify the FQDN instead of the IP address of the peer of the Mediation Server.

4. Define the listening mode (IPv4 or IPv6) of the IP address of your new PSTN gateway, and click **Next**.



Define New IP/PSTN Gateway

Define the IP address

● Enable IPv4

● Use all configured IP addresses.

○ Limit service usage to selected IP addresses.

PSTN IP address:

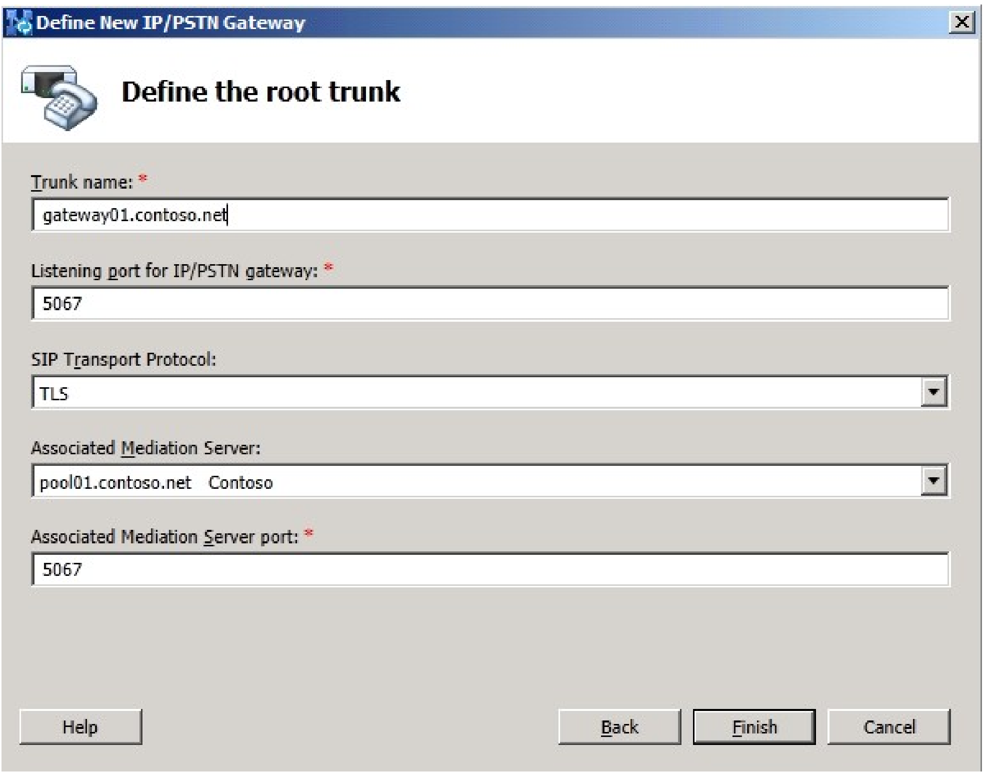
○ Enable IPv6

● Use all configured IP addresses.

○ Limit service usage to selected IP addresses.

PSTN IP address:

5. Define a *root trunk* for the PSTN gateway. A trunk is a logical connection between a Mediation Server and a gateway uniquely identified by the tuple. {Mediation Server FQDN, Mediation Server listening port (TLS or TCP) : gateway IP and FQDN, gateway listening port}
   - When defining a PSTN gateway in Topology Builder, you must define a root trunk to successfully add the PSTN gateway to your topology.
   - The root trunk cannot be removed until the associated PSTN gateway is removed.



Trunk name: *
gateway01.contoso.net

Listening port for IP/PSTN gateway: *
5067

SIP Transport Protocol:
TLS

Associated Mediation Server:
pool01.contoso.net Contoso

Associated Mediation Server port: *
5067

6. Under **Listening Port for IP/PSTN Gateway**, type the listening port that the gateway, PBX, or SBC will use for SIP messages from the Mediation Server that will be associated with the root trunk of the PSTN gateway. (By default, the ports are 5066 for Transmission Control Protocol (TCP) and 5067 for Transport Layer Security (TLS) on a PSTN gateway, PBX or SBC. On a Survivable Branch Appliance at a branch site, the default ports are 5081 for TCP and 5082 for TLS.)
7. Under **SIP Transport Protocol**, click the transport type that the peer uses, and then click **OK**.

Note:
For security reasons, we strongly recommend that you deploy a peer to the Mediation Server that can use TLS.

8. Under **Associated Mediation Server**, select the Mediation Server pool to associate with the root trunk of this this PSTN Gateway.
9. Under **Associated Mediation Server port**, type the listening port that the Mediation Server will use for SIP messages from the gateway.

Note:
With multiple trunk support in Lync Server 2013, multiple SIP signaling ports can be defined on the Mediation Server to be used for communication with multiple PSTN gateways. When defining a trunk, the **Associated Mediation Server port** must be within the range of the listening ports for the respective protocol allowed by the Mediation Server. This port range is defined under Lync Server 2013 and Mediation Pools. Right-click the Mediation Server pool of interest, and select **Edit Properties**. Specify the port range in the **Listening ports** field.

10. Click **Finish**.

Important:
Before you finish this step, be sure that the peer that you defined is running and using the FQDN or IP address that you specified.

Next, to add the peer to the topology, follow the procedures in Publish the Topology in the Deployment documentation. You must publish your topology each time that you use Topology Builder to build or modify your topology, so that the data can be used to install the files for servers that are running Lync Server.

Tasks

Modify a Trunk in Topology Builder

1.4.3.2.2.1 Modify a Trunk in Topology Builder

Modify a Trunk in Topology Builder

Deploying Enterprise Voice > Deploying Mediation Servers and Defining Peers > Define a Gateway in Topology Builder >

Topic Last Modified: *2012-09-21*

Follow these steps to modify the alternate media IP address and alternate bypass identifier of a trunk.

To Modify the Alternate Media IP Address of a Trunk

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the Set-CsPstnGateway cmdlet and modify the AlternateBypassId field in the Lync Server Management Shell.

```
Set-CsPstnGateway -Identity "PstnGateway:<peer FQDN> -RepresentativeMe
```

To Modify the Alternate BypassID of a Trunk

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the Set-CsPstnGateway cmdlet and modify the AlternateBypassId field in the Lync Server Management Shell.

```
Set-CsPstnGateway -Identity "PstnGateway:<peer FQDN> -AlternateBypassI
```

1.4.3.2.3 Define additional Trunks in Topology Builder

Define additional Trunks in Topology Builder

See Also

Deployment > Deploying Enterprise Voice > Deploying Mediation Servers and Defining Peers >

Topic Last Modified: *2012-10-04*

Follow these steps to use Topology Builder to define an additional trunk to which you can associate a *peer* with a Mediation Server. A peer provides users enabled for Enterprise Voice with connectivity to the public switched telephone network (PSTN). A peer can be a PSTN gateway, an IP-PBX, or a Session Border Controller (SBC) for an Internet Telephony Service Provider (ITSP). The trunk defines this connection between the Mediation Server and peer. Multiple trunks can be defined per Mediation Server. A Mediation Server can be associated with multiple peers.

A trunk is a logical connection between a Mediation Server and a gateway uniquely identified by the tuple:

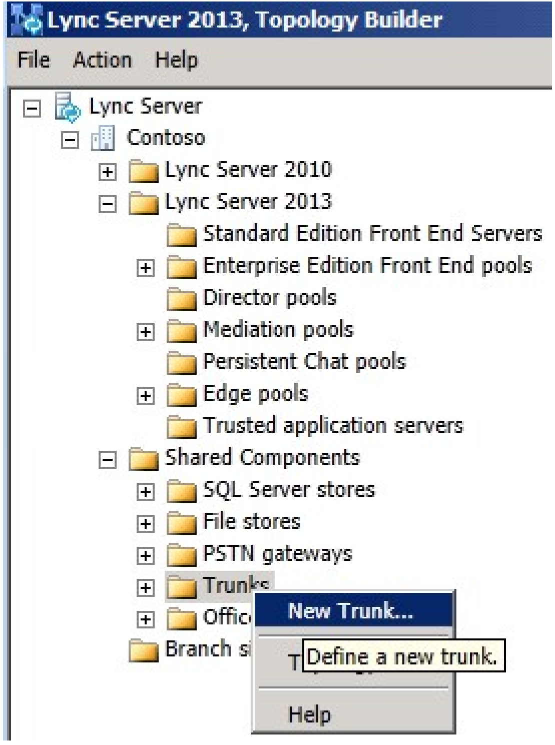
{Mediation Server FQDN, Mediation Server listening port (TLS or TCP) : gateway IP and FQDN, gateway listening port}

Note:
This topic assumes that you have setup a PSTN gateway and root trunk with at least one collocated or stand-alone Mediation Server or pool as described in Define a Gateway in Topology Builder in the Deployment documentation.

Note:
This topic assumes that you have set up at least one Front End pool or Standard Edition server in at least one central site, as described in Define and Configure a Front End Pool or Standard Edition Server and Publish the Topology in the Deployment documentation.

⊟To Define an additional Trunk between a Mediation Server and a Gateway Peer

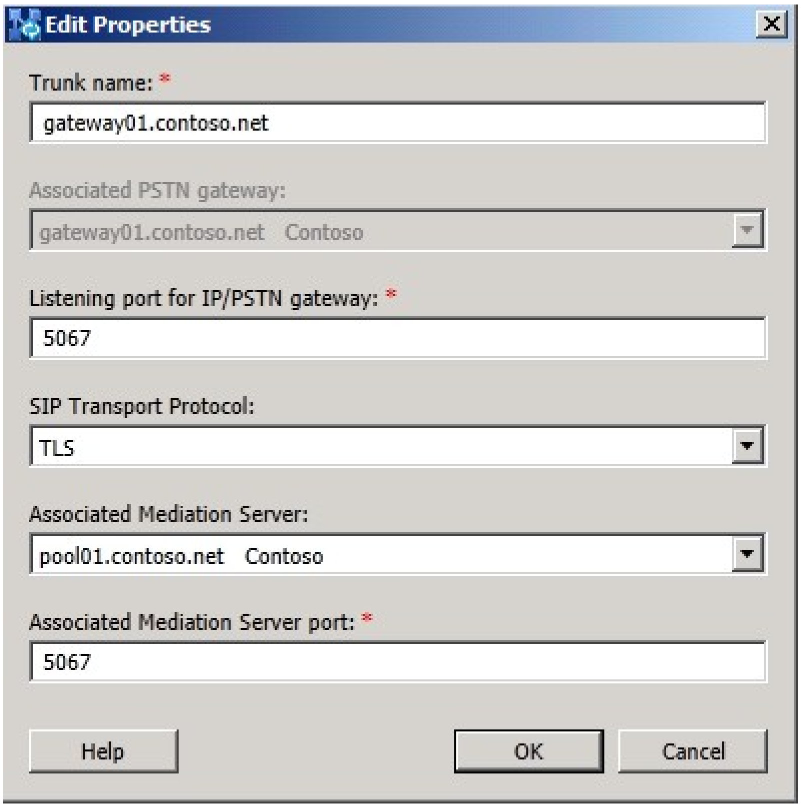
1. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
2. Under Lync Server 2013, your site name, **Shared Components**, right-click the **Trunks** node, and then click **New Trunk**.



3. In **Define New Trunk**, specify a friendly name to uniquely identify the trunk. You cannot have two trunks with the same name.

Note:
If you specify Transport Layer Security (TLS) as the transport type, you must specify the FQDN instead of the IP address of the peer of the Mediation Server.

4. Under **Associated PSTN gateway**, select the PSTN gateway peer to associate with this trunk.



Trunk name: *
gateway01.contoso.net

Associated PSTN gateway:
gateway01.contoso.net Contoso

Listening port for IP/PSTN gateway: *
5067

SIP Transport Protocol:
TLS

Associated Mediation Server:
pool01.contoso.net Contoso

Associated Mediation Server port: *
5067

5. Under **Listening Port for PSTN gateway**, type the listening port that the peer (PSTN gateway, IP-PBX, or SBC) will receive SIP messages from the Mediation Server that is to be associated with this trunk. The default peer ports are 5066 for Transmission Control Protocol (TCP) and 5067 for Transport Layer Security (TLS). The default Survivable Branch Appliance ports are 5081 for TCP and 5082 for TLS.
6. Under **SIP Transport Protocol**, click the transport type that the peer uses.

Note:
For security reasons, we strongly recommend that you deploy a peer to the Mediation Server that can use TLS.

7. Under **Associated Mediation Server**, select the Mediation Server pool to associate with the root trunk of this peer
8. Under **Associated Mediation Server port**, type the listening port that the Mediation Server will receive SIP messages from the peer.

Note:
With multiple trunk support in Lync Server 2013, two trunks with different trunk names cannot be configured with the same **Associated Mediation Server port** and **Listening Port for IP/PSTN gateway**

Note:
With multiple trunk support in Lync Server 2013, multiple SIP signaling ports can be defined on the Mediation Server for communication with multiple peers. When defining a trunk, the **Associated Mediation Server port** number must be within the range of the listening ports for the respective protocol allowed by the Mediation Server. This port range is defined under Lync Server 2013 and Mediation Server pools. Right-click the relevant Mediation Server pool, and select **Edit Properties**. Specify the port range in the **Listening ports** field.

9. Click **OK**.

Tasks

Modify a Trunk in Topology Builder

1.4.3.2.3.1 Modify a Trunk in Topology Builder

Modify a Trunk in Topology Builder

Deploying Enterprise Voice > Deploying Mediation Servers and Defining Peers > Define a Gateway in Topology Builder >

Topic Last Modified: *2012-09-21*

Follow these steps to modify the alternate media IP address and alternate bypass identifier of a trunk.

To Modify the Alternate Media IP Address of a Trunk

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the Set-CsPstnGateway cmdlet and modify the AlternateBypassId field in the Lync Server Management Shell.

```
Set-CsPstnGateway -Identity "PstnGateway:<peer FQDN> -RepresentativeMe
```

To Modify the Alternate BypassID of a Trunk

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the Set-CsPstnGateway cmdlet and modify the AlternateBypassId field in the Lync Server Management Shell.

```
Set-CsPstnGateway -Identity "PstnGateway:<peer FQDN> -AlternateBypassI
```

1.4.3.2.4 Install the Files for Mediation Server

Install the Files for Mediation Server

See Also

Deployment > Deploying Enterprise Voice > Deploying Mediation Servers and Defining Peers >

Topic Last Modified: *2012-08-06*

To successfully complete this procedure, you should be logged on to the server, at the minimum, as a local administrator and a domain user who has membership in at least the RTCUniversalReadOnlyAdmins group.

Use the steps in this topic to run Lync Server 2013 Deployment Wizard to install the files for Mediation Server on a computer that you added to a Mediation Server pool when you used Topology Builder to define and publish the pool. When installing files Mediation Server, you also install and assign the certificate required by each computer in a Mediation Server pool.

At this site, if you have already deployed Mediation Servers collocated on the Front End pools or Standard Edition server, you can skip this topic and, instead, continue to Configuring Trunks.

Note:
This topic assumes that you have already defined and published a stand-alone Mediation Server pool as described in Define a Mediation Server in Topology Builder and Publish the Topology in the Deployment documentation, and that you have verified that the computers in the Mediation Server pool meet the prerequisites described in Software Prerequisites for Enterprise Voice and Security and Configuration Prerequisites for Enterprise Voice.

To install the files for a stand-alone Mediation Server pool

1. From the installation media, right-click <*installation media*>**\Setup\amd64\Setup.exe**, and then click **Run as Administrator**.
2. On the **Installation Location** page, click **OK**.
3. On the **End User License Agreement** page, click **I accept**, and then click **OK**. (Required to continue.)
4. On the **Lync Server 2010 Deployment Wizard** page, click **Install or Update Lync Server System**.
5. Next to **Step 1: Install Local Configuration Store**, click **Run**, and then follow the instructions on the screen.
6. On the **Configure Local Replica of Central Management Store** page, accept the default **Retrieve directly from the Central Management Store**, and then click **Next**.
7. On the **Executing Commands** page, when the task status is shown as **Completed**, click **Finish**.
8. Next to **Step 2: Setup or Remove Lync Server Components**, click **Run**, and then click **Next**.
9. On the **Executing Commands** page, when the task status is shown as **Completed**, click **Finish**.
10. Next to **Step 3: Request, Install or Assign Certificates**, click **Run**. Follow the instructions on the screen, accepting the default settings. The Mediation Server requires one certificate, and so you will run **Step 3** twice: once to issue the required certificate, and once more to assign it.
11. When the certificate has been issued and assigned correctly, beside **Step 4: Start Services**, click **Run**, and then follow the instructions on the screen.
12. When **Step 4** has completed successfully, restart the server, and log on to the server as a member of the DomainAdmins group.
13. On the computer where you are running Lync Server Control Panel, verify on the **Topology** page of Lync Server Control Panel that the service status of the Mediation Server is shown as a green check mark. If a red X appears instead, select the Mediation Server. On the **Action** menu, click **Start All Services**.

If you added more than one computer to the Mediation Server pool, perform the steps in this procedure on all other computers in the Mediation Server pool. If you do not need to install files for Mediation Server for any other computers, then follow the procedures in Configuring Trunks to configure settings for the trunk connection between this Mediation Server pool (or all Mediation Servers at a site) and its peer.

Microsoft Lync Server 2013 > Deployment > Deploying Enterprise Voice >

Topic Last Modified: *2012-11-01*

As part of Enterprise Voice deployment, you can configure a trunk between a Mediation Server and one or more of the following peers to provide public switched telephone network (PSTN) connectivity for Enterprise Voice clients and devices in your organization:

- SIP trunk connection to an Internet telephony service provider (ITSP)
- PSTN gateway
- Private branch exchange (PBX)

For details, see Planning for PSTN Connectivity in the Planning documentation.

Important:

Before you begin trunk configuration, verify that the topology has been created and that the Mediation Server and its peer have been configured and associated with one another. For details, see Define a Gateway in Topology Builder in the Deployment documentation.

Note:

As a part of trunk configuration, you can enable the Lync Server 2013 media bypass feature, which enables media to bypass the Mediation Server. Trunks can be configured either with or without media bypass enabled, but we strongly recommend that you enable it. For details, see Planning for Media Bypass in the Planning documentation.

1.4.3.3.1 Multiple Trunk Support

Multiple Trunk Support

Deployment > Deploying Enterprise Voice > Configuring Trunks >

Topic Last Modified: *2012-11-01*

Lync Server 2013 functionality supports multiple associations between gateways and Mediation Servers. These associations are made by defining a trunk, which is a logical association between a Mediation Server pool and a public switched telephone network (PSTN) gateway, Session Border Controller (SBC), or IP-PBX. Use the Topology Builder to associate gateways with Mediation Servers (that is, trunks).

- To assign or remove a trunk in Lync Server 2013, you must first define a trunk in Topology Builder. A trunk consists of the following association: Mediation Server fully qualified domain name (FQDN), the Mediation Server listening port, the gateway FQDN, and the gateway listening port.
- To configure multiple trunks, you can create multiple associations between the same gateway and the Mediation Server. This provides additional resiliency to

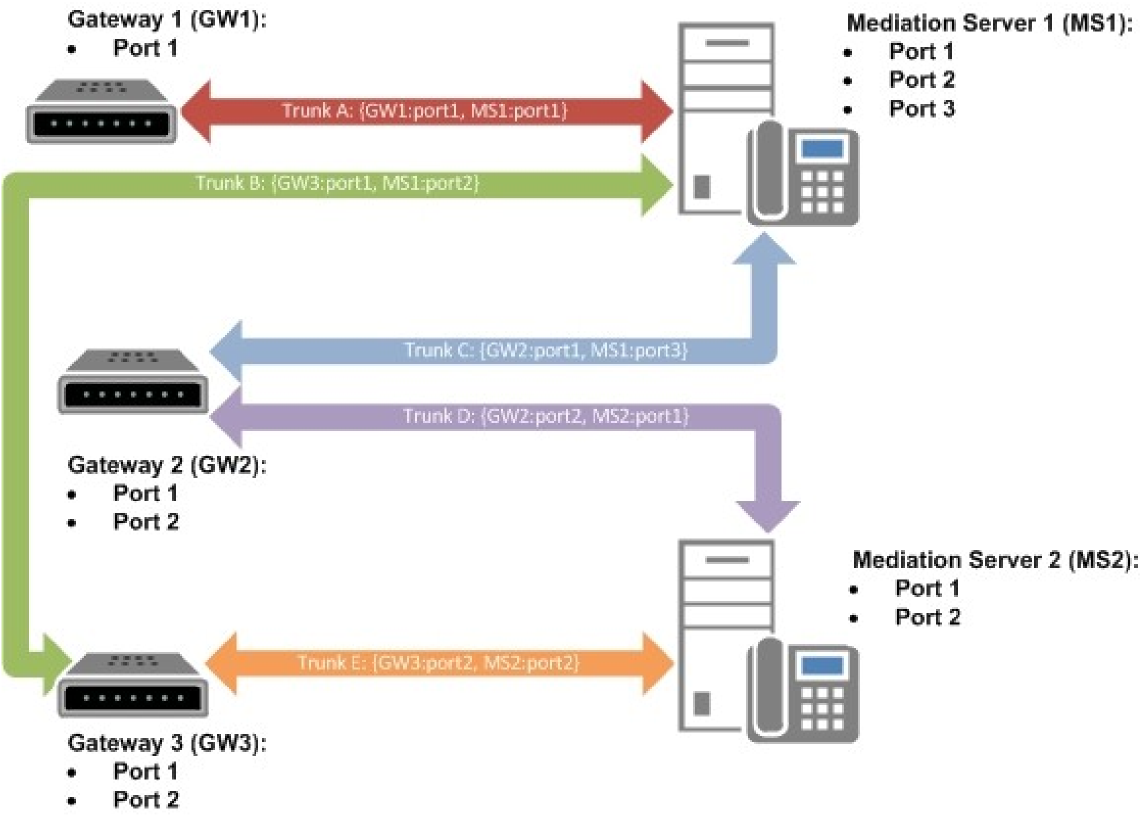
the Enterprise Voice infrastructure, which is especially useful in private branch exchange (PBX) interoperational scenarios.

When a trunk is defined, it must be associated to a route. To associate a trunk to a route, you define a simple name for the trunk in Topology Builder. This simple name is used as the trunk name in the Lync Server Control Panel, where trunks can be associated with routes. The simple trunk name is used as the gateway name from the Lync Server Management Shell.

```
New-CsVoiceRoute -Identity <RouteId> -NumberPattern <String> -PstnUsages @{add="<
```

The administrator must select a default trunk associated with a Mediation Server. From the Topology Builder, right-click the associated Mediation Server, and then click **Properties**. Specify the default gateway for the Mediation Server.

The following diagram illustrates the multiple trunks that are defined for each Mediation Server and gateway.



Gateway 1 (GW1):
• Port 1
Mediation Server 1 (MS1):
• Port 1
• Port 2
• Port 3
Trunk A: {GW1:port1, MS1:port1}
Trunk B: {GW3:port1, MS1:port2}
Trunk C: {GW2:port1, MS1:port3}
Trunk D: {GW2:port2, MS2:port1}
Gateway 2 (GW2):
• Port 1
• Port 2
Mediation Server 2 (MS2):
• Port 1
• Port 2
Trunk E: {GW3:port2, MS2:port2}
Gateway 3 (GW3):
• Port 1
• Port 2

1.4.3.3.2 Configure a Trunk w ith Media Bypass

Configure a Trunk with Media Bypass

See Also

Deployment > Deploying Enterprise Voice > Configuring Trunks >

Topic Last Modified: *2013-02-24*

Follow these steps to configure a trunk with media bypass enabled. To configure a trunk with media bypass disabled, see Configure a Trunk without Media Bypass.

We strongly recommend that you enable media bypass. However, before you enable media bypass on a SIP trunk, confirm that your qualified SIP trunk provider supports media bypass and is able to accommodate the requirements for successfully enabling the scenario. Specifically, the provider must have the IP addresses of servers in your organization's internal network. If the provider cannot support this scenario, media bypass will not succeed. For details, see Planning for Media Bypass in the Planning documentation.

Note:
Media bypass will not interoperate with every public switched telephone network (PSTN) gateway, IP-PBX, and Session Border Controller (SBC). Microsoft has tested a set of PSTN gateways and SBCs with certified partners and has done some testing with Cisco IP-PBXs. Media bypass is supported only with products and versions that are listed on Unified Communications Open Interoperability Program – Lync Server at http://go.microsoft.com/fwlink/p/?linkId=214406.

A trunk configuration as described below groups a set of parameters that are applied to trunks assigned this trunk configuration. A particular trunk configuration can be scoped globally (to all trunks that do not have more specific site or pool configuration), or to a site, or to a pool. The pool-level trunk configuration is used to scope a specific trunk configuration to a single trunk.

⊟To configure a trunk with media bypass

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing**, and then click **Trunk Configuration**.
4. On the **Trunk Configuration** page, use one of the following methods to configure a trunk:
   - Double-click an existing trunk (for example, the **Global** trunk) to display the **Edit Trunk Configuration** dialog box.
   - Click **New**, and then select a scope for the new trunk configuration:
     - **Site trunk:** Choose the site for this trunk configuration from **Select a Site**, and then click **OK**. Note that if a trunk configuration has already been created for a site, the site does not appear in **Select a Site**. This trunk configuration will be applied to all trunks in the site.
     - **Pool trunk:** Choose the name of the trunk that this trunk configuration applies to. This trunk can be the root trunk or any additional trunks defined in Topology Builder. From **Select a Service**, click **OK**. Note that if a trunk configuration has already been created for a specific trunk, the trunk does not appear in **Select a Service**.

   Note:
   After you select the scope of the trunk configuration, it cannot be changed. The **Name** field is prepopulated with the name of the trunk configuration's associated site or service and cannot be changed.
5. Specify a value in **Maximum early dialogs supported**. This is the maximum number of forked responses a public switched telephone network (PSTN) gateway, IP-PBX, or ITSP Session Border Controller (SBC) can receive to an INVITE that it sent to the Mediation Server. The default value is 20.

   Note:

Before you change this value, consult your service provider or equipment manufacturer for details about the capabilities of your system.

6. Select one of the following **Encryption support level** options:
   - **Required:** Secure real-time transport protocol (SRTP) encryption must be used to help protect traffic between the Mediation Server and the gateway or private branch exchange (PBX).
   - **Optional:** SRTP encryption will be used if the service provider or equipment manufacturer supports it.
   - **Not Supported:** SRTP encryption is not supported by the service provider or equipment manufacturer and therefore will not be used.
7. Select the **Enable media bypass** check box if you want media to bypass the Mediation Server for processing by the trunk peer.

   Important:

   For media bypass to work successfully, the PSTN gateway, IP-PBX, or ITSP Session Border Controller must support certain capabilities. For details, see Planning for Media Bypass in the Planning documentation.
8. Select the **Centralized media processing** check box if there is a well-known media termination point (for example, a PSTN gateway where the media termination has the same IP as the signaling termination). Clear this check box if the trunk does not have a well-known media termination point.
9. If the trunk peer supports receiving SIP REFER requests from the Mediation Server, select the **Enable sending refer to the gateway** check box.

   Note:

   If you disable this option while the **Enable media bypass** option is selected, additional settings are required. If the trunk peer does not support receiving SIP REFER requests from the Mediation Server and media bypass is enabled, you must also run the **Set-CsTrunkConfiguration** cmdlet to disable RTCP for active and held calls in order to support proper conditions for media bypass. For details, see the Lync Server Management Shell documentation. Alternatively, you can select **Enable refer using third-party-call control** if you want transferred calls to be media bypassed, and the gateway does not support SIP REFER requests.
10. (Optional) To enable inter-trunk routing, associate and configure PSTN usage records to this trunk configuration. The PSTN usages associated to this trunk configuration will be applied for all incoming calls through the trunk that is not originating from a Lync endpoint. To manage PSTN usage records associated to a trunk configuration, use one of the following methods:
    - To select one or more records from a list of all PSTN usage records available in your Enterprise Voice deployment, click **Select**. Highlight the records you want to associate with this trunk configuration and then click **OK**.
    - To remove a PSTN usage record from this trunk configuration, select the record and click **Remove**.
    - To define a new PSTN usage record and associate it with this trunk configuration, do the following:
      - Click **New**.
      - In the **Name** field, specify a descriptive name for the record that is unique.

        Note:

        The PSTN usage record name must be unique within the Enterprise Voice deployment. After the record is saved, the **Name** field cannot be edited.
      - Use one of the following methods to associate and configure routes for this PSTN usage record:
        - To select one or more routes from the list of all available routes in your Enterprise Voice deployment, click **Select**. Highlight the routes you want to associate with this PSTN usage record, and click **OK**.

        - To remove a route from the PSTN usage record, select the route, and click **Remove**.
        - To define a new route and associate it to this PSTN usage record, click **New**. For details, see Create a Voice Route.
        - To edit a route that is associated with this PSTN usage record, select the route, and click **Show details**. For details, see Modify a Voice Route.
    - Click **OK**.
- To edit a PSTN usage record that is already associated with this trunk configuration, do the following:
    - Select the PSTN usage record you want to edit, and click **Show details**.
    - Use one of the following methods to associate and configure routes for this PSTN usage record:
        - To select one or more routes from the list of all available routes in your Enterprise Voice deployment, click **Select**. Highlight the routes you want to associate with this PSTN usage record, and click **OK**.
        - To remove a route from the PSTN usage record, select the route, and click **Remove**.
        - To define a new route and associate it to this PSTN usage record, click **New**. For details, see Create a Voice Route.
        - To edit a route that is associated with this PSTN usage record, select the route, and click **Show details**. For details, see Modify a Voice Route.
    - Click **OK**.

> **Important:**
>
> It important to associate PSTN usage records according to the Mediation Server peer that is associated to the trunk being configured. If the Mediation Server peer is a PSTN gateway or a Session Border Controller (SBC), it is strongly recommended that the trunk configuration is not associated to a PSTN usage record that routes to a PSTN destination or any other downstream systems connected via Lync Server.

11. Arrange the PSTN usage records for optimum performance. To change a record’s position in the list, select the PSTN usage record, and click the up or down arrows.

> **Important:**
>
> The order in which PSTN usage records are listed in the trunk configuration is significant. Lync Server traverses the list from top to down.

12. **Enable RTP Latching** should be selected to enable bypass media for clients behind a network address translation (NAT) or firewall and an SBC that supports latching.
13. **Enable forward call history** should be selected to enable sending of call history information to the gateway peer of the Mediation Server.
14. **Enable forward P-Asserted-Identity data** should be selected to enable the P-Asserted-Identity (PAI) call originator information to be forwarded between the Mediation Server side and gateway side (and vice versa), when present.
15. **Enable outbound routing failover timer** should be selected to enable fast failover. The gateway associated with this trunk can give notification within 10 seconds that it is processing an outbound call. Rerouting to another trunk will occur if this notification is not received by the Mediation Server. On networks where latency may delay the response time or the gateway takes longer than 10 seconds to respond, the fast failover should be disabled.
16. (Optional) Associate and configure **calling number translation rules** for the trunk. These translation rules apply to the calling number for outbound calls
    - To choose one or more rules from a list of all translation rules that are available in your Enterprise Voice deployment, click **Select**. In **Select Translation Rules**, click the rules that you want to associate with the trunk, and then click **OK**.
    - To define a new translation rule and associate it with the trunk, click **New**. For details about defining a new rule, see Defining Translation Rules in the

Deployment documentation.
- To edit a translation rule that is already associated with the trunk, click the rule name, and then click **Show details**. For details, see Defining Translation Rules in the Deployment documentation.
- To copy an existing translation rule to use as a starting point for defining a new rule, click the rule name and click **Copy**, and then click **Paste**. For details, see Defining Translation Rules.
- To remove a translation rule from the trunk, highlight the rule name and click **Remove**.

> ⚠**Warning:**
>
> Do not associate translation rules with a trunk if you have configured translation rules on the associated trunk peer, because the two rules might conflict.

17.(Optional) Associate and configure **called number translation rules** for the trunk. The translation rules apply to the called number in an outbound call.
- To choose one or more rules from a list of all translation rules that are available in your Enterprise Voice deployment, click **Select**. In **Select Translation Rules**, click the rules that you want to associate with the trunk, and then click **OK**.
- To define a new translation rule and associate it with the trunk, click **New**. For details about defining a new rule, see Defining Translation Rules in the Deployment documentation.
- To edit a translation rule that is already associated with the trunk, click the rule name, and then click **Show details**. For details, see Defining Translation Rules in the Deployment documentation.
- To copy an existing translation rule to use as a starting point for defining a new rule, click the rule name and click **Copy**, and then click **Paste**. For details, see Defining Translation Rules.
- To remove a translation rule from the trunk, highlight the rule name and click **Remove**.

> ⚠**Warning:**
>
> Do not associate translation rules with a trunk if you have configured translation rules on the associated trunk peer, because the two rules might conflict.

18.Make sure that the trunk’s translation rules are arranged in the correct order. To change a rule’s position in the list, highlight the rule name and then click the up or down arrow.

> **Important:**
>
> Lync Server 2013 traverses the translation rule list from the top down and uses the first rule that matches the dialed number. If you configure a trunk so that a dialed number can match more than one translation rule, be sure that the more restrictive rules are sorted above the less restrictive rules. For example, if you have included a translation rule that matches any 11-digit number and a translation rule that matches only 11-digit numbers that start with +1425, be sure that the rule that matches any 11-digit number is sorted *below* the more restrictive rule.

19.When you are finished configuring the trunk, click **OK**.
20.On the **Trunk Configuration** page, click **Commit**, and then click **Commit all**.

> **Note:**
>
> Whenever you create or modify a trunk configuration, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

After you have configured the trunk, continue configuring media bypass by choosing between global media bypass options, as described in Global Media Bypass Options in the Deployment documentation.

Topic Last Modified: *2013-02-24*

If you want to configure a trunk with media bypass disabled, follow these steps. If you want to configure a trunk with media bypass enabled, see Configure a Trunk with Media Bypass.

A trunk configuration, as described below, groups a set of parameters that are applied to trunks assigned this trunk configuration. A particular trunk configuration can be scoped globally (to all trunks that do not have more specific site or pool configuration), or to a site, or to a pool. The pool-level trunk configuration is used to scope a specific trunk configuration to a single trunk.

⊟To configure a trunk without media bypass

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing**, and then click **Trunk Configuration**.
4. On the **Trunk Configuration** page, use one of the following methods to configure a trunk:
   - Double-click an existing trunk (for example, the **Global** trunk) to display the **Edit Trunk Configuration** dialog box.
   - Click **New**, and then select a scope for the new trunk configuration:
     - **Site trunk:** Choose the site for this trunk configuration in **Select a Site** , and then click **OK**. Note that if a trunk configuration has already been created for a site, the site does not appear in **Select a Site**. This trunk configuration will be applied to all trunks in the site.
     - **Pool trunk:** Choose the name of the trunk that this trunk configuration applies to in **Select a Service** and click **OK**. This trunk can be the root trunk, or any additional trunks defined in Topology Builder. Note that if a trunk configuration has already been created for a specific trunk, the trunk does not appear in **Select a Service**.

   Note:

After you select the scope of the trunk configuration, it cannot be changed. The **Name** field is prepopulated with the name of the trunk configuration’s associated site or service and cannot be changed.

5. Select one of the following **Encryption support level** options:
   - **Required:** Secure real-time transport protocol (SRTP) encryption must be used to help protect traffic between the Mediation Server and the gateway or private branch exchange (PBX).
   - **Optional:** SRTP encryption will be used if the service provider or equipment manufacturer supports it.
   - **Not Supported:** SRTP encryption is not supported by the service provider or equipment manufacturer and therefore will not be used.
6. Be sure that the **Enable media bypass** check box is cleared.
7. Select the **Centralized media processing** check box if there is a well-known media termination point (for example, a public switched telephone network (PSTN) gateway where the media termination has the same IP as the signaling termination). Clear this check box if the trunk does not have a well-known media termination point.
8. If the trunk peer supports receiving SIP REFER requests from the Mediation Server, select the **Enable sending refer to the gateway** check box.
9. (Optional) To enable inter-trunk routing, associate and configure PSTN usage records to this trunk configuration. The PSTN usages associated to this trunk configuration will be applied for all incoming calls through the trunk that is not originating from a Lync endpoint. To manage PSTN usage records associated to a trunk configuration, use one of the following methods:
   - To select one or more records from a list of all PSTN usage records available in your Enterprise Voice deployment, click **Select**. Highlight the records you want to associate with this trunk configuration and then click **OK**.
   - To remove a PSTN usage record from this trunk configuration, select the record and click **Remove**.
   - To define a new PSTN usage record and associate it with this trunk configuration, do the following:
     - Click **New**.
     - In the **Name** field, specify a descriptive name for the record that is unique.

       Note:

       The PSTN usage record name must be unique within the Enterprise Voice deployment. After the record is saved, the **Name** field cannot be edited.

     - Use one of the following methods to associate and configure routes for this PSTN usage record:
       - To select one or more routes from the list of all available routes in your Enterprise Voice deployment, click **Select**. Highlight the routes you want to associate with this PSTN usage record, and click **OK**.
       - To remove a route from the PSTN usage record, select the route, and click **Remove**.
       - To define a new route and associate it to this PSTN usage record, click **New**. For details, see Create a Voice Route.
       - To edit a route that is associated with this PSTN usage record, select the route, and click **Show details**. For details, see Modify a Voice Route.
     - Click **OK**.
   - To edit a PSTN usage record that is already associated with this trunk configuration, do the following:
     - Select the PSTN usage record you want to edit, and click **Show details**.
     - Use one of the following methods to associate and configure routes for this PSTN usage record:
       - To select one or more routes from the list of all available routes in your Enterprise Voice deployment, click **Select**. Highlight the routes you

want to associate with this PSTN usage record, and click **OK**.

- To remove a route from the PSTN usage record, select the route, and click **Remove**.
- To define a new route and associate it to this PSTN usage record, click **New**. For details, see Create a Voice Route.
- To edit a route that is associated with this PSTN usage record, select the route, and click **Show details**. For details, see Modify a Voice Route.

- Click **OK**.

> ◆**Important:**
>
> It important to associate PSTN usage records according to the Mediation Server peer that is associated to the trunk being configured. If the Mediation Server peer is a PSTN gateway or a Session Border Controller (SBC), it is strongly recommended that the trunk configuration is not associated to a PSTN usage record that routes to a PSTN destination or any other downstream systems connected via Lync Server.

10. Arrange the PSTN usage records for optimum performance. To change a record’s position in the list, select the PSTN usage record, and click the up or down arrows.

> ◆**Important:**
>
> The order in which PSTN usage records are listed in the trunk configuration is significant. Lync Server traverses the list from top to down.

11. **Enable RTP Latching** should be selected to enable bypass media for clients behind a NAT or firewall and an SBC that supports latching.
12. **Enable forward call history** should be selected to enable sending of call history information to the gateway peer of the Mediation Server.
13. **Enable forward P-Asserted-Identity data** should be selected to enable PAI call originator information to be forwarded between the Mediation Server side and gateway side (and vice versa), when present.
14. **Enable outbound routing failover timer** should be selected to enable fast failover. The gateway associated with this trunk can give notification within 10 seconds that it is processing an outbound call. Rerouting to another trunk will occur if this notification is not received by the Mediation Server. On networks where latency may delay the response time or the gateway takes longer than 10 seconds to respond, the fast failover should be disabled.
15. (Optional) Associate and configure **calling number translation rules** for the trunk. These translation rules apply to the calling number for outbound calls
    - To choose one or more rules from a list of all translation rules that are available in your Enterprise Voice deployment, click **Select**. In **Select Translation Rules**, click the rules that you want to associate with the trunk, and then click **OK**.
    - To define a new translation rule and associate it with the trunk, click **New**. For details about defining a new rule, see Defining Translation Rules in the Deployment documentation.
    - To edit a translation rule that is already associated with the trunk, click the rule name, and then click **Show details**. For details, see Defining Translation Rules in the Deployment documentation.
    - To copy an existing translation rule to use as a starting point for defining a new rule, click the rule name and click **Copy**, and then click **Paste**. For details, see Defining Translation Rules.
    - To remove a translation rule from the trunk, highlight the rule name and click **Remove**.

> 🔒**Security Note:**
>
> Do not associate translation rules with a trunk if you have configured translation rules on the associated trunk peer, because the two rules might conflict.

16. (Optional) Associate and configure **called number translation rules** for the trunk. The translation rules apply to the called number in an outbound call.

- To choose one or more rules from a list of all translation rules that are available in your Enterprise Voice deployment, click **Select**. In **Select Translation Rules**, click the rules that you want to associate with the trunk, and then click **OK**.
- To define a new translation rule and associate it with the trunk, click **New**. For details about defining a new rule, see Defining Translation Rules in the Deployment documentation.
- To edit a translation rule that is already associated with the trunk, click the rule name, and then click **Show details**. For details, see Defining Translation Rules in the Deployment documentation.
- To copy an existing translation rule to use as a starting point for defining a new rule, click the rule name and click **Copy**, and then click **Paste**. For details, see Defining Translation Rules.
- To remove a translation rule from the trunk, highlight the rule name and click **Remove**.

Caution:
Do not associate translation rules with a trunk if you have configured translation rules on the associated trunk peer, because the two rules might conflict.

17. Make sure that the trunk's translation rules are arranged in the correct order. To change a rule's position in the list, highlight the rule name, and then click the up or down arrow.

Important:
Lync Server traverses the translation rule list from the top down and uses the first rule that matches the dialed number. If you configure a trunk so that a dialed number can match more than one translation rule, be sure that the more restrictive rules are sorted above the less restrictive rules. For example, if you have included a translation rule that matches any 11-digit number and a translation rule that matches only 11-digit numbers that start with +1425, be sure that the rule that matches any 11-digit number is sorted *below* the more restrictive rule.

18. When you are finished configuring the trunk, click **OK**.
19. On the **Trunk Configuration** page, click **Commit**, and then click **Commit all**.

Note:
Whenever you create or modify a trunk configuration, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

Tasks

Defining Translation Rules

1.4.3.3.4 Defining Translation Rules

Defining Translation Rules

See Also

Deployment > Deploying Enterprise Voice > Configuring Trunks >

Topic Last Modified: *2013-02-22*

Lync Server 2013 Enterprise Voice routes calls based on phone numbers normalized to E.164 format. This means that all dialed strings must be normalized to E.164 format for the purpose of performing reverse number lookup (RNL) so they can be translated to their matching SIP URI. Lync Server 2013 provides the ability to manipulate the called ID and the caller ID presentation.

This section discusses how to manipulate the called ID and caller ID.

- Caller ID Presentation
- Called ID Presentation

Defining Normalization Rules

1.4.3.3.4.1 Caller ID Presentation

Caller ID Presentation

Deploying Enterprise Voice > Configuring Trunks > Defining Translation Rules >

Topic Last Modified: *2013-02-22*

With Lync Server 2010, the called party’s phone number (that is, the phone number called) can be translated from E.164 format to the local dialing format that is required by the *trunk peer* (that is, the associated gateway, private branch exchange (PBX), or SIP trunk). To do this, you must define one or more translation rules to translate the Request URI before routing it to the trunk peer.

Lync Server 2013 introduces the option to also translate the calling party’s phone number (that is, the phone number that the caller is calling from) from E.164 format to the local dialing format that is required by the trunk peer. For example, you can write a translation rule to remove +44 from the beginning of a dial string and replace it with 0144.

To configure Caller ID by using Lync Server Control Panel

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing**, and then click **Trunk Configuration**.
4. On the **Trunk Configuration** page, double-click an existing trunk (for example, the **Global** trunk) to display the **Edit Trunk Configuration** dialog box.
5. To configure caller ID presentation:
   - To choose one or more rules from a list of all translation rules available in your Enterprise Voice deployment, click **Select**. In **Calling number translation rules**, click the rules that you want to associate with the trunk, and then click **OK**.
   - To define a new translation rule and associate it with the trunk, click **New**. For details about defining a new rule, see Defining Translation Rules in the Deployment documentation.
   - To edit a translation rule that is already associated with the trunk, click the rule name, and then click **Show details**. For details, see Defining Translation Rules in the Deployment documentation.
   - To copy an existing translation rule to use as a starting point for defining a new rule, click the rule name and click **Copy**, and then click **Paste**. For details, see Defining Translation Rules.
   - To remove a translation rule from the trunk, highlight the rule name and click **Remove**.

⚠Warning:

Do not associate translation rules with a trunk if you have configured translation rules on the associated trunk peer, because the two rules might conflict.

1.4.3.3.4.2 Called ID Presentation

Called ID Presentation

Deploying Enterprise Voice > Configuring Trunks > Defining Translation Rules >

Topic Last Modified: *2012-09-21*

With Lync Server 2010, the called party's phone number (that is, the phone number called) can be translated from E.164 format to the local dialing format that is required by the *trunk peer* (that is, the associated gateway, private branch exchange (PBX), or SIP trunk). To do this, you must define one or more translation rules to translate the Request URI before routing it to the trunk peer.

Important:

The ability to associate one or more translation rules with an Enterprise Voice trunk configuration is intended to be used as an *alternative* to configuring translation rules on the trunk peer. Do not associate translation rules with an Enterprise Voice trunk configuration if you have configured translation rules on the trunk peer because the two rules might conflict.

You can use either of the following methods to create or modify a translation rule:

- Use the **Build a Translation Rule** tool to specify values for the starting digits, length, digits to remove and digits to add, and then let Lync Server Control Panel generate the corresponding matching pattern and translation rule for you.
- Write regular expressions manually to define the matching pattern and translation rule.

Note:

For information about how to write regular expressions, see ".NET Framework Regular Expressions" at http://go.microsoft.com/fwlink/p/?linkId=140927.

- Create or Modify a Translation Rule by Using the Build a Translation Rule Tool
- Create or Modify a Translation Rule Manually

Create or Modify a Translation Rule by Using the Build a Translation Rule Tool

See Also

Configuring Trunks > Defining Translation Rules > Called ID Presentation >

Topic Last Modified: *2012-10-05*

Follow these steps if you want to define a translation rule by entering a set of values in the **Build a Translation Rule** tool and enabling Lync Server Control Panel to generate the corresponding matching pattern and translation rule for you. Alternatively, you can a write regular expression manually to define the matching pattern and translation rule. For details, see Create or Modify a Translation Rule Manually.

⊟To define a rule by using the Build a Translation Rule tool

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. To begin defining a translation rule, follow the steps in Configure a Trunk with Media Bypass through step 10 or Configure a Trunk without Media Bypass through step 9.
4. Under **Name** on the **New Translation Rule** or **Edit Translation Rule** page, type a name that describes the number pattern being translated.
5. (Optional) Under **Description**, type a description of the translation rule, for example **US International long-distance dialing**.
6. In the **Build a Translation Rule** section of the dialog box, enter values in the following fields:
   - **Starting digits**: (Optional) Specify the leading digits of numbers you want the pattern to match. For example, enter **+** in this field to match numbers in E.164 format (which begin with +).
   - **Length**: Specify the number of digits in the matching pattern and select whether you want the pattern to match numbers that are this length exactly, at least this length, or any length. For example, enter **11** and select **At least** in the drop-down list to match numbers that are at least 11 digits in length.
   - **Digits to remove**: (Optional) Specify the number of starting digits to be removed. For example, enter **1** to strip out the **+** from the beginning of the number.
   - **Digits to add**: (Optional) Specify digits to be prepended to the translated numbers. For example, enter **011** if you want 011 to be prepended to the translated numbers when the rule is applied.

   The values you enter in these fields are reflected in the **Pattern to match** and **Translation rule** fields. For example, if you specify the preceding example values, the resulting regular expression in the **Pattern to match** field is:

   ^\+(\d{9}\d+)$

   The **Translation rule** field specifies a pattern for the format of translated numbers. This pattern has two parts:
   - A value (for example, **$1**) that represents the number of digits in the matching pattern
   - (Optional) A value that you can prepend by entering it in the **Digits to add** field

   Using the preceding example values, **011$1** appears in the **Translation rule** field.

   When this translation rule is applied, +441235551010 becomes 011441235551010.
7. Click **OK** to save the translation rule.
8. Click **OK** to save the trunk configuration.
9. On the **Trunk Configuration** page, click **Commit**, and then click **Commit all**.

> **Note:**
>
> Whenever you create or modify a translation rule, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

Follow these steps if you want to define a translation rule by writing a regular expression for the matching pattern and translation rule. Alternatively, you can enter a set of values in the **Build a Translation Rule** tool and enable Lync Server Control Panel to generate the corresponding matching pattern and translation rule for you. For details, see Create or Modify a Translation Rule by Using the Build a Translation Rule Tool.

⊟To define a translation rule manually

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. To begin defining a translation rule, follow the steps in Configure a Trunk with Media Bypass through step 10 or Configure a Trunk without Media Bypass through step 9.
4. In the **Name** field on the **New Translation Rule** or **Edit Translation Rule** page, type a name that describes the number pattern being translated.
5. (Optional) In **Description**, type a description of the translation rule, for example **US International long-distance dialing**.
6. Click **Edit** at the bottom of the **Build a Translation Rule** section.
7. Enter the following in **Type a Regular Expression**:
   - In **Match this pattern**, specify the pattern that will be used to match the numbers to be translated.
   - In **Translation rule**, specify a pattern for the format of translated numbers.

   For example, if you enter **^\+(\d{9}\d+)$** in **Match this pattern** and **011$1** in **Translation rule**, the rule will translate +441235551010 to 011441235551010.
8. Click **OK** to save the translation rule.
9. Click **OK** to save the trunk configuration.
10. On the **Trunk Configuration** page, click **Commit**, and then click **Commit all**.

Note:
Whenever you create or modify a translation rule, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

1.4.3.3.5 Inter-Trunk Routing

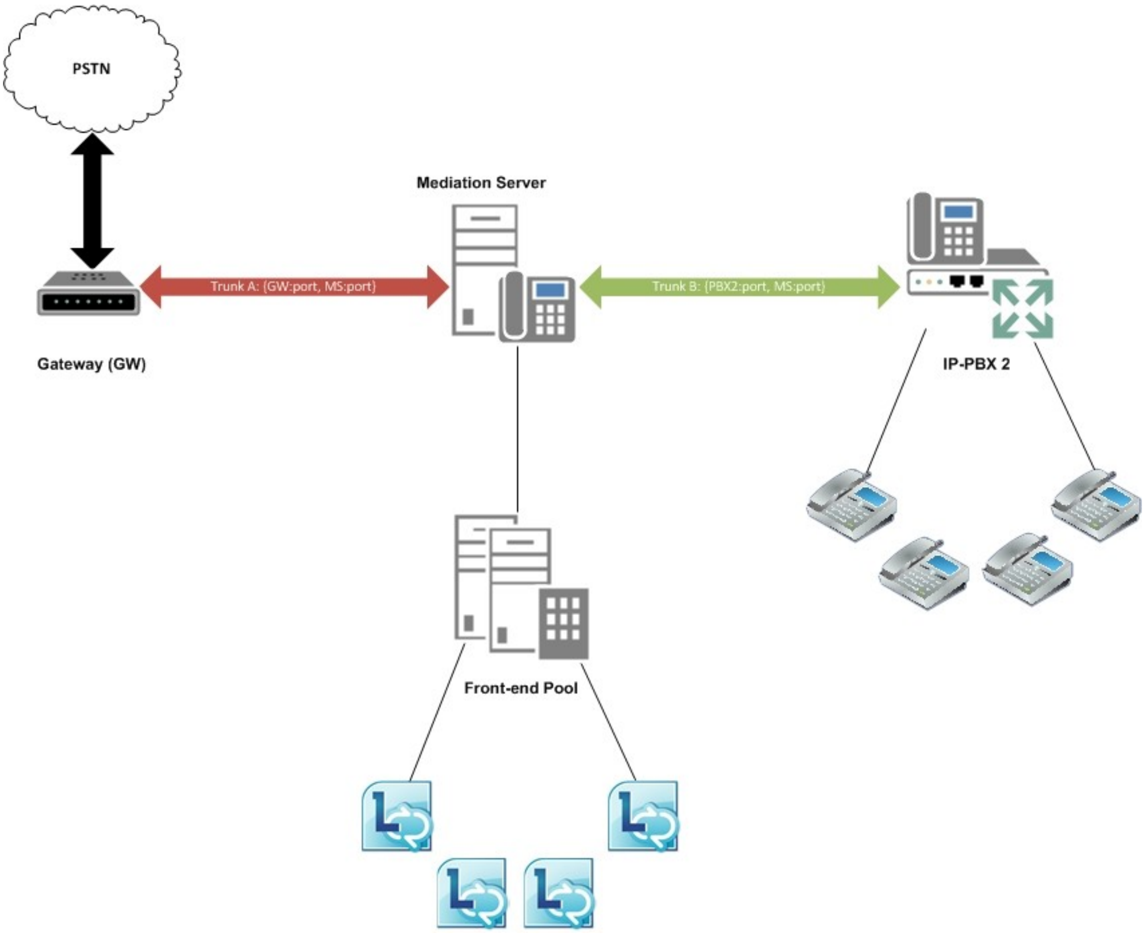
Inter-Trunk Routing

Planning > Planning for Enterprise Voice > Planning for PSTN Connectivity >

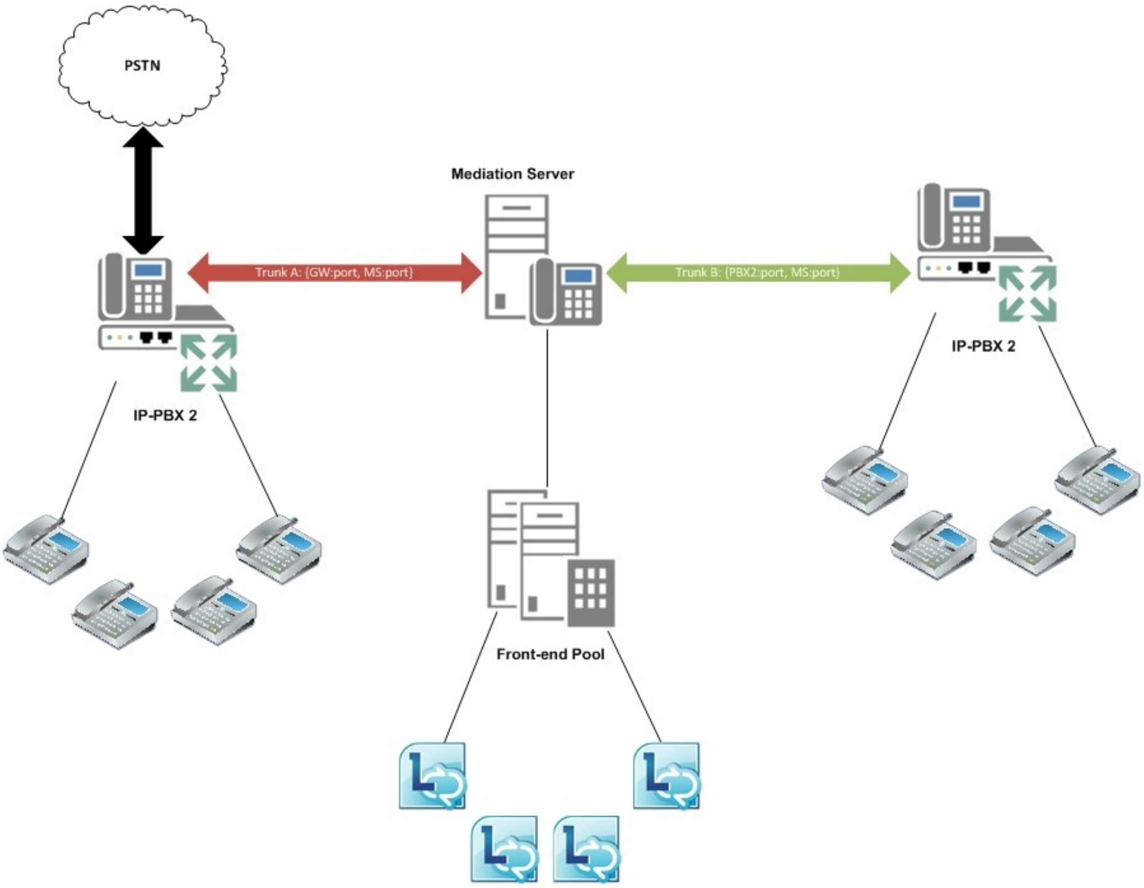
Topic Last Modified: *2012-10-08*

Lync Server 2013 provides basic session management through the support of intertrunk routing. This new capability enables Lync Server to provide call control functionalities to downstream telephony systems. Intertrunk routing can interconnect an IP-PBX to a public switched telephone network (PSTN) gateway so that calls from a private branch exchange (PBX) phone can be routed to the PSTN, and incoming PSTN calls can be routed to a PBX phone. Similarly, Lync Server can interconnect two or more IP-PBX systems so that calls can be placed and received between PBX phones from the different IP-PBX systems.

The following figure illustrates Lync Server 2013 providing interconnectivity between a PSTN gateway and an IP-PBX.



The next figure illustrates Lync Server 2013 connecting two IP-PBX systems.



1.4.3.4 Configuring Dial Plans

Configuring Dial Plans

1.4.3.4.1 View Dial Plan Information

View Dial Plan Information

See Also

Deployment > Deploying Enterprise Voice > Configuring Dial Plans >

Topic Last Modified: *2012-11-01*

To view information for an existing dial plan, perform the steps in the following procedure. If you want to create a new dial plan, see Create a Dial Plan.

⊟To view information about a dial plan from Lync Server Control Panel

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing** and then click **Dial Plan**.
4. On the **Dial Plan** page, double-click a dial plan name.

> **Note:**
> You can view information for only one dial plan at a time.

⊟To view dial plans by using Windows PowerShell cmdlets

- Dial plans can be viewed by using the Windows PowerShell command-line interface and the **Get-CsDialPlan** cmdlet. This cmdlet can be run either from the Lync Server 2013 Management Shell or from a remote session of Windows PowerShell. For details about using remote Windows PowerShell to connect to Lync Server, see the Lync Server Windows PowerShell blog article "Quick Start: Managing Microsoft Lync Server 2010 Using Remote PowerShell" at http://go.microsoft.com/fwlink/p/?linkId=255876.

  To view information about all your dial plans, type the following command in the Lync Server Management Shell, and then press ENTER:

  ```
  Get-CsDialPlan
  ```

  That command will return information similar to this:

  ```
  Identity                   : Global
  Description                :
  DialinConferencingRegion   :
  NormalizationRules         : {Description=;
                               Pattern=^(\d+)$;Translation=$1;Name=
                               KeepAll;IsInternalExtension=False}
  CountryCode                :
  State                      :
  City                       :
  ExternalAccessPrefix       :
  SimpleName                 : DefaultProfile
  OptimizeDeviceDialing      : False
  ```

Deployment > Deploying Enterprise Voice > Configuring Dial Plans >

Topic Last Modified: *2012-10-06*

To create a new dial plan, perform the steps in the following procedure. If you want to edit a dial plan, see Modify a Dial Plan.

⊟To create a dial plan

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing** and then click **Dial Plan**.
4. On the **Dial Plan** page, click **New** and select a scope for the dial plan:
   - **Site dial plan** applies to an entire site, except any users or groups that are assigned to a user dial plan. If you select **Site** for a dial plan's scope, you must choose the site from the **Select a Site** dialog box. If a dial plan has already been created for a site, the site does not appear in the **Select a Site** dialog box.
   - **Pool dial plan** can apply to a public switched telephone network (PSTN) gateway or a Registrar. If you select **Pool** for a dial plan's scope, choose the PSTN gateway or Registrar from the **Select a Service** dialog box. If a dial plan has already been created for a service (PSTN gateway or Registrar), the service does not appear in the list.
   - **User dial plan** can be applied to specified users or groups.

Note:
After you select the dial plan scope, it cannot be changed.

5. If you are creating a user dial plan, enter a descriptive name in the **Name** field on the **New Dial Plan** dialog box. After this name is saved, it cannot be changed.

Note:
For site dial plans, the **Name** field is prepopulated with the site name and cannot be changed. For pool dial plans, the **Name** field is prepopulated with the PSTN gateway or Registrar name and cannot be changed.

6. The **Simple name** field is prepopulated with the same name that appears in the **Name** field. You can optionally edit this field to specify a more descriptive name that reflects the site, service, or user to which the dial plan applies.

Important:
The **Simple name** must be unique among all dial plans within the Lync Server deployment. It cannot exceed 256 Unicode characters, each of which can be an alphabetic or numeric character, a hyphen (-), a period (.), a plus sign (+), or an underscore (_). Spaces are not allowed in the **Simple name**.

7. (Optional) In the **Description** field, you can type additional descriptive information about the dial plan.
8. (Optional) If you want to use this dial plan as a region for dial-in access numbers, specify a **Dial-in conferencing region**. If you do not want to use this dial plan for dial-in access numbers, leave this field empty.

> **Note:**
> Dial-in conferencing regions are required to associate dial-in conferencing access numbers with one or more dial plans.

9. (Optional) In the **External access prefix** field, specify a value only if users need to dial one or more additional leading digits (for example, 9) to get an external line. You can type in a prefix value of up to four characters (#, *, and 0-9).

> **Note:**
> If you specify an external access prefix, you do not need to create a new normalization rule to accommodate the prefix.

10. Associate and configure normalization rules for the dial plan as follows:
    - To choose one or more rules from a list of all normalization rules available in your Enterprise Voice deployment, click **Select**. In **Select Normalization Rules**, highlight the rules you want to associate with the dial plan and then click **OK**.
    - To define a new normalization rule and associate it with the dial plan, click **New**. For details about defining a new rule, see Defining Normalization Rules.
    - To edit a normalization rule that is already associated with the dial plan, highlight the rule name and click **Show details**. For details about editing the rule, see Defining Normalization Rules.
    - To copy an existing normalization rule to use as a starting point for defining a new rule, highlight the rule name and click **Copy**, and then click **Paste**. For details about editing the copy, see Defining Normalization Rules.
    - To remove a normalization rule from the dial plan, highlight the rule name and click **Remove**.

> **Note:**
> Each dial plan must have at least one associated normalization rule. For information about how to determine all of the normalization rules a dial plan requires, see Dial Plans and Normalization Rules in the Planning documentation.

11. Verify that the dial plan’s normalization rules are arranged in the correct order. To change a rule’s position in the list, highlight the rule name and then click the up or down arrow.

> **Important:**
> Lync Server traverses the normalization rule list from the top down and uses the first rule that matches the dialed number. If you configure a dial plan so that a dialed number can match more than one normalization rule, make sure the more restrictive rules are sorted above the less restrictive ones.
> The default **Keep All** normalization rule **^(\d{11})$** matches any 11-digit number. For example, if you add a normalization rule that matches 11-digit numbers that start with 1425, make sure that **Keep All** is sorted below the more restrictive **^(1425\d{7})$** rule.

12. (Optional) Enter a number to test the dial plan and then click **Go**. The test results are displayed under **Enter a number to test**.

> **Note:**
> You can save a dial plan that does not yet pass the test and then reconfigure it later. For details, see Test Voice Routing.

13. Click **OK**.
14. On the **Dial Plan** page, click **Commit**, and then click **Commit all**.

> **Note:**
> Any time you create a dial plan, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

Deployment > Deploying Enterprise Voice > Configuring Dial Plans >

Topic Last Modified: *2012-11-01*

To modify an existing dial plan, perform the steps in the following procedure. If you want to create a new dial plan, see Create a Dial Plan.

⊟To modify a dial plan

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing** and then click **Dial Plan**.
4. On the **Dial Plan** page, double-click a dial plan name.

   Note:
   The dial plan scope and name were set when the dial plan was created. They cannot be changed.

5. (Optional) In **Edit Dial Plan**, edit the **Simple name** field, which is prepopulated with the same name that appears in the **Name** field to specify a more descriptive name that reflects the site, service, or user to which the dial plan applies.

   Important:
   The **Simple name** must be unique among all dial plans within the Lync Server 2013 deployment. It cannot exceed 256 Unicode characters, each of which can be an alphabetic or numeric character, a hyphen (-), a period (.), a plus sign (+), or an underscore (_).
   Spaces are not allowed in the **Simple name** field.

6. (Optional) In the **Description** field, type descriptive information about the dial plan.
7. (Optional) If you want to use this dial plan as a region for dial-in access numbers, specify a **Dial-in conferencing region**. If you do not want to use this dial plan for dial-in access numbers, leave this field empty.

   Note:
   Dial-in conferencing regions are required to associate dial-in conferencing access numbers with one or more dial plans.

8. (Optional) In the **External access prefix** field, specify a value only if users need to dial one or more additional leading digits to get an external line (for example, 9). You can type in a prefix value of up to four characters (that is, #, *, and 0-9).

   Note:
   If you specify an external access prefix, you do not need to create a new

normalization rule to accommodate the prefix.

9. Associate and configure normalization rules for the dial plan:
   - To choose one or more rules from a list of all normalization rules available in your Enterprise Voice deployment, click **Select**. In the **Select Normalization Rules** dialog box, highlight the rules that you want to associate with the dial plan and then click **OK**.
   - To define a new normalization rule and associate it with the dial plan, click **New**. For details about defining a new rule, see Defining Normalization Rules.
   - To edit a normalization rule that is already associated with the dial plan, highlight the rule name and click **Show details**. For details about editing the rule, see Defining Normalization Rules.
   - To copy an existing normalization rule to use as a starting point for defining a new rule, highlight the rule name and click **Copy**, and then click **Paste**. For details about editing the copy, see Defining Normalization Rules.
   - To remove a normalization rule from the dial plan, highlight the rule name and click **Remove**.

Note:

Each dial plan must have at least one associated normalization rule. For details about how to determine all of the normalization rules a dial plan requires, see Dial Plans and Normalization Rules in the Planning documentation.

10. Verify that the dial plan’s normalization rules are arranged in the correct order. To change a rule’s position in the list, highlight the rule name and then click the up or down arrow.

Important:

Lync Server traverses the normalization rule list from the top down and uses the first rule that matches the dialed number. If you configure a dial plan so that a dialed number can match more than one normalization rule, make sure the more restrictive rules are sorted above the less restrictive ones.

The default **Keep All** normalization rule **^(\d{11})$** matches any 11-digit number. If, for example, you add a normalization rule that matches 11-digit numbers that start with 1425, make sure that **Keep All** is sorted below the more restrictive **^(1425\d{7})$** rule.

11. (Optional) Enter a number to test the dial plan and then click **Go**. The test results are displayed under **Enter a number to test**.

Note:

You can save a dial plan that does not yet pass the test and then reconfigure it later. For details, see Test Voice Routing.

12. Click **OK**.
13. On the **Dial Plan** page, click **Commit**, and then click **Commit all**.

Note:

Any time you create or modify a dial plan, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

Deployment > Deploying Enterprise Voice > Configuring Dial Plans >

Topic Last Modified: *2012-09-23*

Lync Server 2013 normalization rules use .NET Framework regular expressions to translate dialed phone numbers to E.164 format. Each dial plan must be assigned one or more normalization rules.

For details about normalization rules, see Dial Plans and Normalization Rules in the Planning documentation.

For details about how to write regular expressions, see ".NET Framework Regular Expressions" at http://go.microsoft.com/fwlink/p/?linkId=140927.

You can use either of the following methods to define or edit a normalization rule:

- Use the **Build a Normalization Rule** tool to specify values for the starting digits, length, digits to remove and digits to add, and then let Lync Server Control Panel generate the corresponding matching pattern and translation rule for you.
- Write regular expressions manually to define the matching pattern and translation rule.
- Create or Modify a Normalization Rule by Using Build a Normalization Rule
- Create or Modify a Normalization Rule Manually

Topic Last Modified: *2012-11-01*

Complete the following steps if you want to create or modify a normalization rule in Lync Server Control Panel. Alternatively, if you want to create or modify a normalization rule manually, see Create or Modify a Normalization Rule Manually.

⊟To define a rule by using Build a Normalization Rule

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. (Optional) Follow the steps in Create a Dial Plan through step 11 or Modify a Dial Plan through step 10.

4. In **New Normalization Rule** or **Edit Normalization Rule**, type a name that describes the number pattern being normalized in **Name** (for example, **5DigitExtension**).
5. (Optional) In **Description**, type a description of the normalization rule (for example, "Translates 5-digit extensions").
6. In **Build a Normalization Rule**, enter values in the following fields:
   - **Starting digits** (Optional) Specify the leading digits of dialed numbers you want the pattern to match. For example, type **425** if you want the pattern to match dialed numbers beginning with 425.
   - **Length** Specify the number of digits in the matching pattern and select whether you want the pattern to match this length exactly, match dialed numbers that are at least this length, or match dialed numbers of any length.
   - **Digits to remove** (Optional) Specify the number of starting digits to be removed from dialed numbers you want the pattern to match.
   - **Digits to add** (Optional) Specify digits to be added to dialed numbers you want the pattern to match.

   The values you enter in these fields are reflected in **Pattern to match** and **Translation rule**. For example, if you leave **Starting digits** empty, type **7** into the **Length** field and select **Exactly**, and specify **0** in **Digits to remove**, the resulting regular expression in the **Pattern to match** is:

   ^(\d{7})$
7. In **Translation rule**, specify a pattern for the format of translated E.164 phone numbers as follows:
   - A value that represents the number of digits specified in the matching pattern. For example, if the matching pattern is **^(\d{7})$** then **$1** in the translation rule represents 7-digit dialed numbers.
   - (Optional) Type a value into the **Digits to add** field to specify digits to be prepended to the translated number (for example, **+1425**).

   For example, if **Pattern to match** contains **^(\d{7})$** as the pattern for dialed numbers and **Translation rule** contains **+1425$1** as the pattern for E.164 phone numbers, the rule normalizes 5550100 to +14255550100.
8. (Optional) If the normalization rule results in a phone number that is internal to your organization, select **Internal extension**.
9. (Optional) Enter a number to test the normalization rule, and then click **Go**. The test results are displayed under **Enter a number to test**.

   Note:
   You can save a normalization rule that does not yet pass the test and then reconfigure it later. For details, see Test Voice Routing.
10. Click **OK** to save the normalization rule.
11. Click **OK** to save the dial plan.
12. On the **Dial Plan** page, click **Commit**, and then click **Commit all**.

    Note:
    Whenever you create or change a normalization rule, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

Topic Last Modified: *2012-09-22*

Complete the following steps if you want to create or modify a normalization rule manually. If you want to create or modify a normalization rule by using Build a Normalization Rule in Lync Server Control Panel, see Create or Modify a Normalization Rule by Using Build a Normalization Rule.

⊟To define a normalization rule manually

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. (Optional) Follow the steps in Create a Dial Plan or Modify a Dial Plan.
4. In **New Normalization Rule** or **Edit Normalization Rule**, type a name that describes the number pattern being normalized in **Name** (for example, name the normalization rule **5DigitExtension**).
5. (Optional) In **Description** field, type a description of the normalization rule (for example, "Translates 5-digit extensions").
6. In **Build a Normalization Rule**, click **Edit**.
7. Enter the following in **Type a Regular Expression**:
   - In **Match this pattern**, specify the pattern that you want to use to match the dialed phone number.
   - In **Translation rule**, specify a pattern for the format of translated E.164 phone numbers.

   For example, if you enter **^(\d{7})$** in **Match this pattern** and **+1425$1** in **Translation rule**, the rule normalizes 5550100 to +14255550100.
8. (Optional) If the normalization rule results in a phone number that is internal to your organization, select **Internal extension**.
9. (Optional) Enter a number to test the normalization rule and then click **Go**. The test results are displayed under **Enter a number to test**.

   > **Note:**
   >
   > You can save a normalization rule that does not yet pass the test and then reconfigure it later. For details, see Test Voice Routing.
10. Click **OK** to save the normalization rule.
11. Click **OK** to save the dial plan.
12. On the **Dial Plan** page, click **Commit**, and then click **Commit all**.

   > **Note:**
   >
   > Whenever you create or change a normalization rule, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

1.4.3.5 Configuring Voice Policies, PSTN Usage Records, and Voice Routes

Configuring Voice Policies, PSTN Usage Records, and Voice Routes

Microsoft Lync Server 2013 > Deployment > Deploying Enterprise Voice >

Topic Last Modified: *2012-10-10*

Voice policies, PSTN usage records, and voice routes are integrally related. You configure voice policies by selecting a set of calling features and then assigning the policy a set of PSTN usage records, which specify what rights are authorized for the users or groups who are assigned the voice policy. Voice routes are also assigned PSTN usage records, which serve to match routes with the users who are authorized to use them. That is, users can only place calls that use the routes for which they have a matching PSTN usage record.

The recommended workflow for a new Enterprise Voice deployment is to start by configuring a voice policy that includes the appropriate PSTN usage records, and then associate the appropriate routes to each PSTN usage record.

Note:

You can also create voice policies with *user* scope and assign them to individual users or groups.

For the detailed steps to perform each of these tasks, see the procedures in this section.

- Configuring Voice Policies and PSTN Usage Records to Authorize Calling Features and Privileges
- View PSTN Usage Records
- Configuring Voice Routes for Outbound Calls
- Exporting and Importing Voice Routing Configuration
- Publish Pending Changes to the Voice Routing Configuration
- Test Voice Routing

1.4.3.5.1 Configuring Voice Policies and PSTN Usage Records to Authorize Calling Features and Privileges

Configuring Voice Policies and PSTN Usage Records to Authorize Calling Features and Privileges

Deployment > Deploying Enterprise Voice > Configuring Voice Policies, PSTN Usage Records, and Voice Routes >

Topic Last Modified: *2012-10-10*

A *voice policy* enables a set of calling features and associates one or more PSTN usage records to define the calling features and permissions of users who are assigned the policy.

Voice policy scope can be either *Site* (which defines the default features and permissions for a network site) or *User* (which defines the features and permissions to be assigned on a per-user or group basis). Users not assigned to a voice policy will automatically be assigned to the global policy, which is the default voice policy that is installed with the product.

Note:
For details, see Voice Policies in the Planning documentation.

- Create a Voice Policy and Configure PSTN Usage Records
- Modify a Voice Policy and Configure PSTN Usage Records
- Configuring Voice Mail Escape

1.4.3.5.1.1 Create a Voice Policy and Configure PSTN Usage Records

Create a Voice Policy and Configure PSTN Usage Records

See Also

Deploying Enterprise Voice > Configuring Voice Policies, PSTN Usage Records, and Voice Routes > Configuring Voice Policies and PSTN Usage Records to Authorize Calling Features and Privileges >

Topic Last Modified: *2012-11-01*

Follow these steps if you want to create a new voice policy. If you want to edit a voice policy, see Modify a Voice Policy and Configure PSTN Usage Records for the procedure.

Note:
Each voice policy must have at least one associated public switched telephone network (PSTN) usage record. To see a listing of all PSTN usage records available in your Enterprise Voice deployment and view their properties, see View PSTN Usage Records.

⊟To create a voice policy

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing** and then click **Voice Policy**.
4. On the **Voice Policy** page, click **New** and then select a scope for the new policy:
   - **Site policy** applies to an entire site, except any users or groups that are assigned to a user policy. If you select Site for a policy scope, choose the site from the **Select a Site** dialog box. If a voice policy has already been created for a site, the site does not appear in the **Select a Site** dialog box.
   - **User policy** can be applied to specified users or groups.
5. If the voice policy scope is User, enter a descriptive name for the policy in the **Name** field.

   Note:
   If the voice policy scope is Site, the **Name** field in **New Voice Policy** is prepopulated with the site name and cannot be changed.
6. (Optional) Enter additional descriptive information for the voice policy.
7. Select or clear the following check boxes to enable or disable each of the **Calling features** for this voice policy:
   - **Voice mail escape** prevents calls from being immediately routed to the user's mobile phone voice mail system when simultaneous ringing is configured and the phone is turned off, out of battery, or out of range.

     Note:
     This feature is only configurable through the Lync Server

Management Shell

- **Call forwarding** enables users to forward calls to other phones and client devices. Lync Server 2013 provides a significantly wider range of configuration options for call forwarding. For example, if an organization does not want to allow incoming calls to be forwarded externally to the PSTN, an administrator can apply a special voice policy to deploy this restriction. Enabled by default.
- **Delegation** enables users to specify other users to send and receive calls on their behalf. In Lync Server 2013, a delegate can configure simultaneous ringing that enables incoming calls to his or her manager to ring all of the delegate's simultaneous ringing targets. This provides the delegate with greater flexibility in responding to calls directed to the manager. Enabled by default.
- **Call transfer** enables users to transfer calls to other users. Enabled by default.
- **Call park** enables users to park calls on hold and then pick up the call from a different phone or client. Disabled by default.
- **Simultaneous ringing** enables incoming calls to ring on additional phones (for example, a mobile phone) or other endpoint devices. Lync Server 2013 provides a significantly wider range of configuration options for simultaneous ringing. Enabled by default.
- **Team call** enables users on a defined team to answer calls for other members of the team. Enabled by default.
- **PSTN re-route** enables calls made by users who are assigned this policy to other enterprise users to be rerouted on the public switched telephone network (PSTN) if the WAN is congested or unavailable. Enabled by default.
- **Bandwidth policy override** enables administrators to override call admission control policy decisions for a particular user. Disabled by default.

Note:

The policy will be overridden only for incoming calls to the user and not for outgoing calls that are placed by the user. After the session is established, the bandwidth consumption will be accurately recorded. This setting should be used sparingly and should be reserved for appropriate call admission control decisions.

- **Malicious call tracing** enables users to report malicious calls (such as bomb threats) by using the client UI, which in turn flags the calls in the call detail records (CDRs). Disabled by default.

8.To associate and configure PSTN usage records for this voice policy, do any of the following:

- To choose one or more records from a list of all PSTN usage records available in your Enterprise Voice deployment, click **Select**. Highlight the records that you want to associate with this voice policy, and then click **OK**.
- To remove a PSTN usage record from this voice policy, highlight the record and click **Remove**.
- To define a new PSTN usage record and associate it with this voice policy, do the following:

  8..a.Click **New**.

  8..b.In the **Name** field, enter a unique descriptive name for the record. For example, you may want to create a PSTN usage record named **Redmond** for full-time employees located in Redmond, and another named **RedmondTemps** for temporary employees.

  Note:

  The PSTN usage record name must be unique within the Enterprise Voice deployment. After the record is saved, the **Name** field cannot be edited.

  8..c.Use any of the following methods to associate and configure routes for this PSTN usage record:

- To choose one or more routes from the list of all available routes in your Enterprise Voice deployment, click **Select**, highlight the routes that you want to associate with this PSTN usage record, and then click **OK**.
- To remove a route from the PSTN usage record, highlight the route, and then click **Remove**.
- To define a new route and associate it with this PSTN usage record, click **New**. For details, see Create a Voice Route.
- To edit a route that is already associated with this PSTN usage record, highlight the route and click **Show details**. For details, see Modify a Voice Route.

8..d.Click **OK**.

- To edit a PSTN usage record that is already associated with this voice policy, do the following:

  8..a.Highlight the PSTN usage record that you want to edit, and then click **Show details**.

  8..b.Use any of the following methods to associate and configure routes for this PSTN usage record:

  - To choose one or more routes from the list of all available routes in your Enterprise Voice deployment, click **Select**, highlight the routes you want to associate with this PSTN usage record, and then click **OK**.
  - To remove a route from this PSTN usage record, highlight the route, and then click **Remove**.
  - To define a new route and associate it with this PSTN usage record, click **New**. For details, see Create a Voice Route.
  - To edit a route that is already associated with this PSTN usage record, highlight the route and lick **Show details**. For details, see Modify a Voice Route.

  8..c.Click **OK**.

9.Arrange the PSTN usage records for optimum performance. To change a record’s position in the list, highlight the record name and click the up or down arrow.

> **Important:**
>
> The order in which PSTN usage records are listed in the voice policy is significant. Lync Server traverses the list from the top down. We recommend that you organize the list by frequency of use, for example: RedmondLocal, RedmondLongDist, RedmondInternational, RedmondBackup.

10.To associate and configure PSTN usage records for call forwarding and simultaneous ringing in this voice policy, do any of the following:

- To use the same PSTN usage records for call forwarding and simultaneous ringing as this voice policy, select the option **Route using the call PSTN usages** from the drop-down menu.
- To allow call forwarding and simultaneous ringing to internal Lync users only, select the option **Route to internal Lync users only** from the drop-down menu. Calls will not be forwarded to external PSTN numbers.
- To specify different PSTN usage records for call forwarding and simultaneous ringing than used for this voice policy, select the option **Route using custom PSTN usages** from the drop-down menu. This option displays a control to select existing PSTN usage records or create new PSTN usage records specifically for call forwarding and simultaneous ringing.

  10..a.To choose one or more records from a list of PSTN usage records for call forwarding and simultaneous ringing, click **Select**. Highlight the records that you want to associate with this call forwarding and simultaneous ringing policy, and then click **OK**.

  10..b.To remove a PSTN usage record from this call forwarding and simultaneous ringing policy, highlight the record and click **Remove**.

  10..c.To define a new PSTN usage record and associate it with this call forwarding and simultaneous ringing policy, do the following:

  - Click **New**.

- In the **Name** field, enter a unique descriptive name for the record.

> **Note:**
> The PSTN usage record name must be unique within the Enterprise Voice deployment. After the record is saved, the **Name** field cannot be edited.

- Use any of the following methods to associate and configure routes for this PSTN usage record:
  - To choose one or more routes from the list of all available routes in your Enterprise Voice deployment, click **Select**, highlight the routes that you want to associate with this PSTN usage record, and then click **OK**.
  - To remove a route from the PSTN usage record, highlight the route and click **Remove**.
  - To define a new route and associate it with this PSTN usage record, click **New**. For details, see Create a Voice Route.
  - To edit a route that is already associated with this PSTN usage record, highlight the route and click **Show details**. For details, see Modify a Voice Route.
- Click **OK**.

10..d.To edit a PSTN usage record that is already associated with this voice policy, do the following:

- Highlight the PSTN usage record you want to edit and click **Show details**.
- Use any of the following methods to associate and configure routes for this PSTN usage record:
  - To choose one or more routes from the list of all available routes in your Enterprise Voice deployment, click **Select**, highlight the routes that you want to associate with this PSTN usage record, and then click **OK**.
  - To remove a route from this PSTN usage record, highlight the route and click **Remove**.
  - To define a new route and associate it with this PSTN usage record, click **New**. For details, see Create a Voice Route.
  - To edit a route that is already associated with this PSTN usage record, highlight the route and click **Show details**. For details, see Modify a Voice Route.
- Click **OK**.

11.(Optional) Enter a number to test the voice policy and click **Go**. The test results are displayed under **Translated number to test**.

> **Note:**
> You can save a voice policy that does not yet pass the test and then reconfigure it later. For details, see Test Voice Routing.

12.Click **OK**.

13.On the **Voice Policy** page, click **Commit**, and then click **Commit all**.

> **Note:**
> Any time you create or modify a voice policy, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

14.(Optional) Voicemail Escape detects that a call was immediately answered by the user’s mobile phone voice mail, and disconnects the call to the mobile phone voice mail. This allows the call to continue to ring on the user’s other endpoints giving the user the opportunity to answer the call. For details on how to configure a voice mail policy, see Configuring Voice Mail Escape.

Topic Last Modified: *2012-11-01*

Follow these steps if you want to modify a voice policy. If you want to create a new voice policy, see Create a Voice Policy and Configure PSTN Usage Records for the procedure.

Note:
If a user is assigned to a voice policy has no associated public switched telephone network (PSTN) usage records, the user cannot place outbound calls. For a listing of all PSTN usage records available in your Enterprise Voice deployment and view their properties, see View PSTN Usage Records.

⊟To modify a voice policy

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing**, and then click **Voice Policy**.
4. On the **Voice Policy** page, double-click a voice policy name.

   Note:
   The scope and name were set when the voice policy was created. They cannot be changed.
5. (Optional) In **Edit Voice Policy**, enter additional descriptive information for the voice policy.
6. Select or clear the following check boxes to enable or disable each of the **Calling features**:
   - **Voice mail escape** prevents calls from being immediately routed to the user's mobile phone voice mail system when simultaneous ringing is configured and the phone is turned off, out of battery, or out of range.

     Note:
     This feature is only configurable through the Lync Server Management Shell
   - **Call forwarding** enables users to forward calls to other phones and client devices. Lync Server 2013 provides a significantly wider range of configuration options for call forwarding. For example, if an organization does not want to allow incoming calls to be forwarded externally to the PSTN, an administrator can apply a special voice policy to deploy this

restriction. Enabled by default.

- **Delegation** enables users to specify other users to send and receive calls on their behalf. In Lync Server 2013, a delegate can configure simultaneous ringing that enables incoming calls to his or her manager to ring all of the delegate's simultaneous ringing targets. This provides the delegate with greater flexibility in responding to calls directed to the manager. Enabled by default.
- **Call transfer** enables users to transfer calls to other users. Enabled by default.
- **Call park** enables users to park calls on hold, and then pick up the call from a different phone or client. Disabled by default.
- **Simultaneous ringing** enables incoming calls to ring on additional phones (for example, a mobile phone) or other endpoint devices. Lync Server 2013 provides a significantly wider range of configuration options for simultaneous ringing. Enabled by default.
- **Team call** enables users on a defined team to answer calls for other members of the team. Enabled by default.
- **PSTN re-route** enables calls made by users who are assigned this policy to other enterprise users to be rerouted on the public switched telephone network (PSTN) if the WAN is congested or unavailable. Enabled by default.
- **Bandwidth policy override** enables administrators to override call admission control (CAC) policy decisions for a particular user. Disabled by default.

> **Note:**
>
> The policy will be overridden only for incoming calls to the user and not for outgoing calls that are placed by the user. After the session is established, the bandwidth consumption will be accurately recorded. This setting should be used sparingly.

- **Malicious call tracing** enables users to report malicious calls (such as bomb threats) using the client UI, which in turn flags the calls in the call detail records (CDRs). Disabled by default.

7.To associate and configure PSTN usage records for this voice policy, do any of the following:

- To choose one or more records from a list of all PSTN usage records available in your Enterprise Voice deployment, click **Select**. Highlight the records that you want to associate with this voice policy, and then click **OK**.
- To remove a PSTN usage record from this voice policy, highlight the record and click **Remove**.
- To define a new PSTN usage record and associate it with this voice policy, do the following:

  7..a.Click **New**.

  7..b.In the **Name** field, enter a unique descriptive name for the record. For example, you may want to create a PSTN usage record named **Redmond** for full-time employees located in Redmond, and another record named **RedmondTemps** for temporary employees.

  > **Note:**
  >
  > The PSTN usage record name must be unique within the Enterprise Voice deployment. After the record is saved, the **Name** field cannot be edited.

  7..c.Use any of the following methods to associate and configure routes for this PSTN usage record:

  - To choose one or more routes from the list of all available routes in your Enterprise Voice deployment, click **Select**, highlight the routes that you want to associate with this PSTN usage record, and then click **OK**.
  - To remove a route from the PSTN usage record, highlight the route and click **Remove**.
  - To define a new route and associate it with this PSTN usage record,

click **New**. For details, see Create a Voice Route.

- To edit a route that is already associated with this PSTN usage record, highlight the route and click **Show details**. For details, see Modify a Voice Route.

7..d.Click **OK**.

- To edit a PSTN usage record that is already associated with this voice policy, do the following:

7..a.Highlight the PSTN usage record that you want to edit and click **Show details**.

7..b.Use any of the following methods to associate and configure routes for this PSTN usage record:

- To choose one or more routes from the list of all available routes in your Enterprise Voice deployment, click **Select**, highlight the routes that you want to associate with this PSTN usage record, and then click **OK**.
- To remove a route from this PSTN usage record, highlight the route and click **Remove**.
- To define a new route and associate it with this PSTN usage record, click **New**. For details, see Create a Voice Route.
- To edit a route that is already associated with this PSTN usage record, highlight the route and click **Show details**. For details, see Modify a Voice Route.

7..c.Click **OK**.

8.Arrange the PSTN usage records for optimum performance. To change a record’s position in the list, highlight the record name and click the up or down arrow.

Note:

The order in which PSTN usage records are listed in the voice policy is significant. Lync Server traverses the list from the top down. We recommend that you organize the list by frequency of use, for example: RedmondLocal, RedmondLongDist, RedmondInternational, RedmondBackup.

9.To associate and configure PSTN usage records for call forwarding and simultaneous ringing in this voice policy, do any of the following:

- To use the same PSTN usage records for call forwarding and simultaneous ringing as this voice policy, select the option **Route using the call PSTN usages** from the drop-down menu.
- To allow call forwarding and simultaneous ringing to internal Lync users only, select **Route to internal Lync users only** from the drop-down menu. Calls will not be forwarded to external PSTN numbers.
- To specify different PSTN usage records for call forwarding and simultaneous ringing than those used for this voice policy, select the option **Route using custom PSTN usages** from the drop-down menu. This option displays a control to select existing PSTN usage records or to create new PSTN usage records, specifically for call forwarding and simultaneous ringing.

9..a.To choose one or more records from a list of PSTN usage records for call forwarding and simultaneous ringing, click **Select**. Highlight the records that you want to associate with this call forwarding and simultaneous ringing policy, and then click **OK**.

9..b.To remove a PSTN usage record from this call forwarding and simultaneous ringing policy, highlight the record and click **Remove**.

9..c.To define a new PSTN usage record and associate it with this call forwarding and simultaneous ringing policy, do the following:

- Click **New**.
- In the **Name** field, enter a unique descriptive name for the record.

Note:

The PSTN usage record name must be unique within the Enterprise Voice deployment. After the record is saved, the **Name** field cannot be edited.

- Use any of the following methods to associate and configure routes for this PSTN usage record:
  - To choose one or more routes from the list of all available routes in your Enterprise Voice deployment, click **Select**, highlight the routes that you want to associate with this PSTN usage record, and then click **OK**.
  - To remove a route from the PSTN usage record, highlight the route and click **Remove**.
  - To define a new route and associate it with this PSTN usage record, click **New**. For details, see Create a Voice Route.
  - To edit a route that is already associated with this PSTN usage record, highlight the route, and then click **Show details**. For details, see Modify a Voice Route.
- Click **OK**.

9..d.To edit a PSTN usage record that is already associated with this voice policy, do the following:

- Highlight the PSTN usage record that you want to edit and click **Show details**.
- Use any of the following methods to associate and configure routes for this PSTN usage record:
  - To choose one or more routes from the list of all available routes in your Enterprise Voice deployment, click **Select**, highlight the routes you want to associate with this PSTN usage record, and then click **OK**.
  - To remove a route from this PSTN usage record, highlight the route and click **Remove**.
  - To define a new route and associate it with this PSTN usage record, click **New**. For details, see Create a Voice Route.
  - To edit a route that is already associated with this PSTN usage record, highlight the route and click **Show details**. For details, see Modify a Voice Route.
- Click **OK**.

10.(Optional) Enter a number to test the voice policy and click **Go**. The test results are displayed under **Translated number to test**.

> **Note:**
>
> You can save a voice policy that does not yet pass the test and then reconfigure it later. For details, see Test Voice Routing.

11.Click **OK**.

12.On the **Voice Policy** page, click **Commit**, and then click **Commit all**.

> **Note:**
>
> Whenever you create or modify a voice policy, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

13.(Optional) Voicemail Escape detects that a call was immediately answered by the user's mobile phone voice mail, and disconnects the call to the mobile phone voice mail. This allows the call to continue to ring on the user's other endpoints giving the user the opportunity to answer the call. For details about how to configure a voice mail policy, see Configuring Voice Mail Escape.

Configuring Voice Mail Escape

See Also Example

Deploying Enterprise Voice > Configuring Voice Policies, PSTN Usage Records, and Voice Routes > Configuring Voice Policies and PSTN Usage Records to Authorize Calling Features and Privileges >

Topic Last Modified: *2013-02-22*

When a user configures simultaneous ringing to a mobile phone, a caller will typically be routed to the user’s personal voice mail if the mobile phone is turned off, out of battery power, or out of range. With Lync Server 2013, users can opt to have business-related calls routed to their corporate voice mail system. Specifically, a timer can be configured, and if the call is answered by the carrier’s voice mail within the range of time defined, Lync Server will disconnect from the carrier’s voice mail system (and the user’s personal voice mail), while the user’s remaining endpoints in the corporate system continue to ring. This way, the caller is automatically routed to the user’s corporate voice mail.

This configuration is performed using the Lync Server Management Shell cmdlet, **Set-CsVoicePolicy**, at the voice policy level, with the following parameters.

To configure voice mail escape

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Specify the following parameters to **Set-CsVoicePolicy**:
   - **EnableVoicemailEscapeTimer** - Enables or disables the escape timer.
   - **PSTNVoicemailEscapeTimer** - Specifies the timeout value in milliseconds. The default value is 1500 milliseconds, and the value can range from 0 milliseconds to 8000 milliseconds.

```
Set-CsVoicePolicy UserVoicePolicy -EnableVoiceMailEscapeTimer $true - PSTNVoicema
Set-CsVoicePolicy -Identity site:SitePolicy -EnableVoiceMailEscapeTimer $true -PS
```

Topic Last Modified: *2013-02-22*

A public switched telephone network (PSTN) usage record specifies a class of call (such as internal, local, or long distance) that can be made by various users or groups of users in an organization. For details, see PSTN Usage Records in the Planning documentation.

To view a PSTN usage record by using Lync Server Control Panel

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing** and then click **PSTN Usage**.
4. On the **PSTN Usage** page, highlight the PSTN usage record you want to view, click **Edit** and then click **Show details**.

Note:
A read-only page of the selected PSTN usage record shows the associated routes and associated voice policies.

Viewing PSTN Usage Information by Using Windows PowerShell Cmdlets

You can also view PSTN usages by using Windows PowerShell and the **Get-CsPstnUsage** cmdlet. This cmdlet can be run either from the Lync Server 2013 Management Shell or from a remote session of Windows PowerShell. For details about using remote Windows PowerShell to connect to Lync Server, see the Lync Server Windows PowerShell blog article "Quick Start: Managing Microsoft Lync Server 2010 Using Remote PowerShell" at http://go.microsoft.com/fwlink/p/?linkId=255876.

To view PSTN usage information by using Windows PowerShell cmdlets

- To view information about all of your PSTN usages, type the following command in the Lync Server Management Shell, and then press ENTER:

```
Get-CsPstnUsage
```

This command returns information similar to the following:

```
Identity : Global
Usage    : {Internal, Local, Long Distance}
```

For details, see Get-CsPstnUsage.

Deployment > Deploying Enterprise Voice > Configuring Voice Policies, PSTN Usage Records, and Voice Routes >

Topic Last Modified: *2012-11-01*

A Lync Server 2013 voice route associates destination phone numbers with one or more public switched telephone network (PSTN) gateways or SIP trunks and one or more PSTN usage records.

To view voice routes by using Lync Server Control Panel

1. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
2. Click **Voice Routing**.
3. Click **Route**.
4. Double-click a voice route to view additional properties from the list of voice routes, or select the route and click **Edit**. Then click **Show details**.

> **Note:**
> You can only view detailed information for a single route at a time.

To view voice routes by using Windows PowerShell

- Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**. Voice routes can be viewed by using Windows PowerShell and the **Get-CsVoiceRoute** cmdlet. This cmdlet can be run either from the Lync Server 2013 Management Shell or from a remote session of Windows PowerShell. For details about using remote Windows PowerShell to connect to Lync Server, see the Lync Server Windows PowerShell blog article "Quick Start: Managing Microsoft Lync Server 2010 Using Remote PowerShell" at http://go.microsoft.com/fwlink/p/?linkId=255876.
  To view information about all of your voice routes, type the following command in the Lync Server Management Shell, and then press ENTER:

```
Get-CsVoiceRoute
```

  That will return information similar to this:

```
Identity           : global
Priority           : -1
Description        :
NumberPattern      : ^(\+1[0-9]{10})$
PstnUsages         : {}
PstnGatewayList    : {}
Name               : global
SuppressCallerId   :
AlternateCallerId  :
```

> **Note:**
> For details, see Voice Routes in the Planning documentation.

Topic Last Modified: *2012-11-01*

The following procedure explains how to create a new voice route by using the Lync Server 2013 Control Panel. To edit an existing route, see Modify a Voice Route for the procedure.

⊟To create a voice route by using the Lync Server Control Panel

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the **CsVoiceAdministrator**, **CsServerAdministrator**, or **CsAdministrator** administrative role.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing**.
4. Click **Route**.
5. Click **New** to display the **New Voice Route** dialog box.
6. In **Name**, type a descriptive name for the voice route.
7. (Optional) In **Description**, type additional descriptive information for the voice route.
8. To specify the patterns that you want this route to accommodate, you can either use the **Build a pattern to match** tool to generate a regular expression, or write the regular expression manually.
   - To use the **Build a pattern to match** tool to generate a regular expression, enter values as follows. You can specify two types of pattern matching:
     - **Starting digits for numbers that you want to allow:** Enter prefix values that this route must accommodate (including the leading + if needed). For example, type **+425**, and then click **Add**. Repeat this for each prefix value that you want to include in the route.
     - **Exceptions:** If you want to specify one or more exceptions for a prefix value, highlight the prefix and click **Exceptions**. Type in one or more values for the matching patterns that you do *not* want this route to accommodate. For example, to exclude numbers starting with +425237 from the route, enter a value of **+425237** in the **Exceptions** field, and then click **OK**.
   - To define the matching pattern manually, click **Edit** in the **Build a pattern to match** tool and then type in a .NET Framework regular expression to specify the matching pattern for destination phone numbers to which the route is applied. For details about how to write regular expressions, see ".NET Framework Regular Expressions" at http://go.microsoft.com/fwlink/p/?linkId=140927.
9. Select **Suppress caller ID** if you do not want the ID of the phone making the outbound call to appear to the call recipient. If you select this option, you must specify an **Alternate caller ID** that will appear on the recipient's caller ID display.
10. To associate one or more trunks with the voice route, click **Add** and then select a trunk from the list.

Note:
If your deployment includes any Microsoft Office Communications Server 2007 R2 Mediation Servers, they will also be available in the list.

11. To associate one or more public switched telephone network (PSTN) usages with the voice route, click **Select** and choose a record from the list of PSTN usage records that have been defined for your Enterprise Voice deployment.

Note:
To view the properties of each of the available PSTN usage records, see View PSTN Usage Records. To create or edit PSTN usage records, see Create a Voice Policy and Configure PSTN Usage Records or Modify a Voice Policy and Configure PSTN Usage Records.

12. Arrange the PSTN usage records for optimum performance. To change a record's position in the list, highlight the record name and click the up or down arrow.

Note:
In contrast to a voice policy, where the order in which PSTN usage records are listed is important, the order in which PSTN usage records are listed in the voice route is insignificant. However, we recommend that you organize the list by frequency of use. For example: RedmondLocal, RedmondLongDist, RedmondInternational, RedmondBackup. (Lync Server traverses the list from the top down.)

13. (Optional) Type a value into the **Enter a translated number to test** field and click **Go**. The test results are displayed under the field.

Note:
You can save a voice route that does not yet pass the test and then reconfigure it later. For details, see Test Voice Routing.

14. Click **OK** to save the voice route.

Important:
Whenever you create a voice route, you must run the **Commit All** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration.

Topic Last Modified: *2012-11-01*

This topic explains how to edit a voice route. To create a new route, see Create a Voice Route.

To modify a voice route

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing**, and then click **Route**.
4. On the **Route** page, use either of the following methods to modify a voice route:
   - Click a voice route name, click **Edit**, and then click **Show details**.
   - Click a voice route name, click **Edit**, click **Copy**, and then click **Paste**. Click the new copy of the voice route that you just created, click **Edit**, and then click **Show details**.
5. In the **Name** field on the **Edit Voice Route** page, type a descriptive name for the voice route.
6. (Optional) In the **Description** field, type in additional descriptive information

for the voice route.

7. To specify the patterns you want this route to accommodate, you can either use the **Build a pattern to match** tool to generate a regular expression, or write the regular expression manually.
   - To use the **Build a pattern to match** tool to generate a regular expression, enter values as follows. You can specify two types of pattern matching:
     - **Starting digits for numbers that you want to allow:** Enter prefix values that this route must accommodate (including the leading + if needed). For example, type **+425** and then click **Add**. Repeat this for each prefix value that you want to include in the route.
     - **Exceptions:** If you want to specify one or more exceptions for a prefix value, highlight the prefix and click **Exceptions**. Type in one or more values for the matching patterns that you do *not* want this route to accommodate. For example, to exclude numbers starting with +425237 from the route, enter a value of **+425237** in the **Exceptions** field, and then click **OK**.
   - To define the matching pattern manually, click **Edit** in the **Build a pattern to match** tool and then type in a .NET Framework regular expression to specify the matching pattern for destination phone numbers to which the route is applied. For information about how to write regular expressions, see ".NET Framework Regular Expressions" at http://go.microsoft.com/fwlink/p/?linkId=140927.
8. Select **Suppress caller ID** if you do not want the ID of the phone that is making the outbound call to appear to the call recipient. If you select this option, you must specify an **Alternate caller ID** that will appear on the recipient’s caller ID display.
9. To associate one or more public switched telephone network (PSTN) trunks with the voice route, click **Add**, and then select a trunk from the list.

   > **Note:**
   >
   > If your deployment includes any Microsoft Office Communications Server 2007 R2 Mediation Servers, they will also be available in the list.

10. To associate one or more PSTN usages with the voice route, click **Select** and choose a record from the list of PSTN usage records that have been defined for your Enterprise Voice deployment.

1.4.3.6 Exporting and Importing Voice Routing Configuration

Exporting and Importing Voice Routing Configuration

Microsoft Lync Server 2013 > Deployment > Deploying Enterprise Voice >

Topic Last Modified: *2012-11-01*

If you want to save your voice routing configuration without publishing it, follow these steps to use the Lync Server Control Panel configuration export and import commands to save and retrieve a snapshot of your voice routing configuration. When you import a voice routing configuration file (.vcfg), but changes have been made to the voice routing configuration on the server in the meantime, the pages in the **Voice Routing** group in Lync Server Control Panel will indicate that there are uncommitted changes to voice routing. Those uncommitted changes are the differences between the two configurations that require reconciliation.

Important:
If you have made any uncommitted changes to the settings on any page within the **Voice Routing** group, the changes are saved in the exported voice configuration file (.vcfg). This enables you to make voice routing configuration changes during multiple Lync Server Control Panel sessions before you publish the changes.

1.4.3.7 Test Voice Routing

Test Voice Routing

Microsoft Lync Server 2013 > Deployment > Deploying Enterprise Voice >

Topic Last Modified: *2013-02-24*

You can use the Lync Server Control Panel **Test Voice Routing** tab to configure test case scenarios. To define a test case, you specify the dial plan, voice policy, PSTN usage, and voice route against which to test a specified phone number.

Before you actually deploy your voice routing configuration, we recommend that you test it on various phone numbers to make sure that the results are what you're expecting.

Tip:
You can use the **Export test cases** and **Import test cases** commands to save voice routing test cases and import them for use on another computer.

Caution:
If you delete any part of your voice routing configuration, such as a dial plan, voice policy, voice route, or phone usage, you should review and update your voice routing test cases. The Lync Server Control Panel will not alert you to test cases that are no longer valid due to changed configurations.

- Export Voice Routing Test Cases
- Import Voice Routing Test Cases
- Running Voice Routing Tests

1.4.3.7.1 Create a Voice Routing Test Case

Create a Voice Routing Test Case

See Also

Deployment > Deploying Enterprise Voice > Test Voice Routing >

Topic Last Modified: *2012-10-10*

To create a test case

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to

start Lync Server Control Panel, see Open Lync Server Administrative Tools.

3. In the left navigation bar, click **Voice Routing** and then click **Test Voice Routing**.
4. On the **Test Voice Routing** page, click **New** to create a new test case.
5. In **Name**, type in a unique name for the test case.

   The name must be unique among all voice routing test cases in your Enterprise Voice deployment. It can be up to 32 characters in length and may contain any alphanumeric characters, in addition to the backslash (\), period (.), or underscore (_).
6. In **Dialed number to test**, type in the dialed number that you want to use to test the routing configuration that you specify for this test case. Based on the dial plan, route, and voice policy, this number will be normalized and displayed as output.
7. In the **Dial Plan** list, select the dial plan to use when running the test. Default is the Global dial plan.
8. In the **Voice Policy** list, select the voice policy to use when running the test. Default is the Global voice policy.
9. In **Expected translation**, type in the phone number in the format you expect to see it after translation. This is the value of the phone number that you are testing after it has been translated by the first normalization rule that matches in the selected dial plan. When you run the test case, if the number you are testing does not result in the value in **Expected translation**, the test fails.
10. (Optional) In the **Expected PSTN usage** list, you can select the public switched telephone network (PSTN) usage record that you expect to be used when you run the test case, based on the specified dial plan and voice policy. If a different PSTN usage record is used, the test fails.
11. (Optional) In the **Expected route** list, you can select the voice route that you expect to be used when you run the test case, based on the specified dial plan and voice policy. If a different voice route is used, the test fails.
12. (Optional) Click **Run** to run the test case. The results are shown in the right panel of the page.
13. Click **OK**.
14. Click **Commit**, and then click **Commit all**.

> **Note:**
>
> Whenever you create a voice routing test case, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

Test cases provide a way for you to test voice routes in your organization: you define such things as the number to be dialed and the dial plan and voice policy to be employed, and Lync Server can then verify that that, given those conditions, the supplied number can successfully be routed to the PSTN network.

Test cases, which can be created by using Lync Server Control Panel, are typically saved only on the server where the case was originally created and run. However, these test cases can be exported as XML files (with the .vtest extension) and then imported on other servers. This enables you to run the same tests on different computers located at different points in your topology.

⊟To export a voice routing test case

1. In Lync Server Control Panel, click **Voice Routing** and then click **Test Voice Routing**.
2. On the **Test Voice Routing** tab, select the test case (or test cases) to be exported. To select multiple test cases, click the first case to be exported, then hold down the Ctrl key and select the additional cases to be exported.
3. Click **Action**, then click **Export test cases**.
4. In the **Save As** dialog box, select a folder to store the exported test cases and type a name for the resulting XML file in the **File name** box. Note that if you are exporting multiple tests cases all of these test cases will be saved to a single XML file.
5. To save the test cases, click **Save**.

1.4.3.7.4 Running Voice Routing Tests

Running Voice Routing Tests

Deployment > Deploying Enterprise Voice > Test Voice Routing >

Topic Last Modified: *2013-02-21*

Lync Server 2013 provides two different methods for testing voice routes: you can do informal, ad hoc testing against any phone number and any voice route; or you can do more formal testing using voice route test cases. With formal testing, you define such things as the number to be dialed and the dial plan and voice policy to be employed, and Lync Server can then verify that that, given those conditions, the supplied number can successfully be routed to the PSTN network. Both of these methods are described in subsequent sections of this documentation.

- Run Informal Voice Routing Tests
- Run Voice Routing Test Cases

1.4.3.7.4.1 Run Informal Voice Routing Tests

Run Informal Voice Routing Tests

See Also

Deploying Enterprise Voice > Test Voice Routing > Running Voice Routing Tests >

Topic Last Modified: *2012-08-07*

You can use the **Create voice routing test case information** dialog box to run informal tests before creating an actual test case. When you are satisfied with the outcome of a test, you have the option of saving it as a formal test case.

⊟To run an informal voice routing test

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing**, and then click **Test Voice Routing**.
4. On the **Test Voice Routing** page, click **Create voice routing test case information**.
5. In the **Dialed number** field, type in the phone number you want to use for this test. This number will be normalized and displayed in the **Normalized number** field of the **Results** pane.
6. In the **Dial plan** list, select the dial plan to use for testing the dialed number. Default is the Global dial plan.

   When you run the test, the first normalization rule in this dial plan that matches the dialed number will be displayed in the **Normalization rule** field of the **Results** pane.

7.In the **Voice Policy** list, select the voice policy to use for testing the dialed number. Default is the Global voice policy.

When you run the test, the first matching PSTN usage record in this voice policy will be displayed in the **First PSTN usage** field of the **Results** pane. Also, the first matching voice route that is associated with this PSTN usage record will be displayed in the **First route** field.

8.(Optional) Select the **Populate from user** check box if you want to test the dialed number against the voice policy assigned to a particular user.

8.a.Click **Browse** to display the **Select Enterprise Voice Users** dialog box.

8.b.Click **Find** to display the list of users who are enabled for Enterprise Voice.

8.c.Double-click the user name whose assigned voice policy you want to use for this test. The **Policy** field is now populated with the voice policy assigned to the selected user.

When you run the test, the first matching public switched telephone network (PSTN) usage record in this voice policy will be displayed in the **First PSTN usage** field of the **Results** pane. Also, the first matching voice route that is associated with this PSTN usage record will be displayed in the **First route** field.

9.Click **Run** to run the test case. The results are shown in the right panel of the dialog box.

10.(Optional) Click **Save as** if you want to save this test configuration as a formal test case.

10.a.In the **Name** field of the **Save Voice Routing Test Case Information** dialog box, type a unique name for the test case.

The name must be unique among all voice routing test cases in your Enterprise Voice deployment. It can be up to 32 characters in length and may contain any alphanumeric characters, in addition to the backslash (\), period (.), or underscore (_).

10.b.Note that the remaining fields on the **Save Voice Routing Test Case Information** dialog box are read-only, and are prepopulated from the informal test configuration *and* results. Verify that this is the configuration that you want to save for the test case.

> **Note:**
>
> Values from the test results are used to prepopulate fields on the **Save Voice Routing Test Case Information** dialog box as follows:
>
> - **Expected translation** is prepopulated with the value in the **Normalized number** field.
> - **Expected route** is prepopulated with the value in the **First route** field.
> - **Expected PSTN usage record** is prepopulated with the value in the **First PSTN usage** field.
>
> If matches for any of these values were not found during the test run, the corresponding field is empty on the **Save Voice Routing Test Case Information** dialog box.

1.a.Click **Ok** to save the test case, or click **Cancel** to return to return to the **View voice routing test case information** dialog box to further develop the test before saving it.

2.Click **Commit**, and then click **Commit all**.

> **Note:**
>
> Whenever you create a voice routing test case, you must run the **Commit all** command to publish the test case. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

1.4.3.7.4.2 Run Voice Routing Test Cases

Run Voice Routing Test Cases

See Also

Deploying Enterprise Voice > Test Voice Routing > Running Voice Routing Tests >

Topic Last Modified: *2013-02-24*

You can run all of the test cases in your voice routing test case suite, or you can run one or more selected test cases.

⊟To run all voice routing test cases

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing** and then click **Test Voice Routing**.
4. On the **Test Voice Routing** page, click **Action** and then click **Run all**.

   The pass or fail status of each test case is shown in the **Pass/fail** column. If a test case has not yet been run, N/A is shown in the **Pass/fail** column.
5. (Optional) To see detailed results for each test case, double-click the test case name. Results are shown in the shaded area on the right side of the **Edit Test Case** page:

   5.a. **Test result:** Overall pass or fail status of the test case run.

   5.b. **Normalization rule:** The first normalization rule in the dial plan selected for this test case that matches the dialed number (the value in the **Number to test** field).

   5.c. **Normalized number:** The value of the dialed number after the normalization rule has translated it.

   5.d. **First PSTN usage:** The first public switched telephone network (PSTN) usage record in the voice policy selected for this test case that matches the dialed number.

   5.e. **First route:** The first voice route in the first PSTN usage record that matches the dialed number.

> **Note:**
> The **Expected PSTN usage record** and **Expected route** fields are optional in voice routing test case configuration. If the test case does not specify these values, the corresponding field in the test results will be empty.

⊟To run one or more selected voice routing test cases

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync

Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.

3. In the left navigation bar, click **Voice Routing**, and then click **Test Voice Routing**.
4. On the **Test Voice Routing** page, click the names of the test cases that you want to run.
5. On the **Action** menu, click **Run selected**.

   The pass or fail status of each test case is shown in the **Pass/fail** column. If a test case has not yet been run, N/A is shown in the **Pass/fail** column.
6. (Optional) To see detailed results for each test case, double-click the test case name. Results are shown in the shaded area on the right side of the **Edit Test Case** page:
   - 6.a. **Test result:** Overall pass or fail status of the test case run.
   - 6.b. **Normalization rule:** The first normalization rule in the dial plan selected for this test case that matches the dialed number (the value in the **Number to test** field).
   - 6.c. **Normalized number:** The value of the dialed number after the normalization rule has translated it.
   - 6.d. **First PSTN usage:** The first PSTN usage record in the voice policy selected for this test case that matches the dialed number.
   - 6.e. **First route:** The first voice route in the first PSTN usage record that matches the dialed number.

> **Note:**
> The **Expected PSTN usage record** and **Expected route** fields are optional in voice routing test case configuration. If the test case does not specify these values, the corresponding field in the test results will be empty.

1.4.3.8 Publish Pending Changes to the Voice Routing Configuration

Publish Pending Changes to the Voice Routing Configuration

Microsoft Lync Server 2013 > Deployment > Deploying Enterprise Voice >

Topic Last Modified: *2012-08-07*

After you make changes to any of the configuration settings in pages in the **Voice Routing** group, perform this procedure to review, publish, or cancel the pending changes.

> **Important:**
> Be sure that only one user at a time modifies the Voice Routing configuration settings. All pending changes must be published at the same time by running the **Commit all** command. You cannot selectively publish pending changes. Before you publish pending changes, run the **Review uncommitted changes** command and cancel any configuration changes that you do not want to publish.
> If you navigate away from the pages in the **Voice Routing** group before committing pending changes, all pending changes will be lost. However, you can export the current configuration (including any pending changes) to a voice configuration file, and then import and publish the updated configuration. For details, see Export a Voice Route Configuration File.

⊟To review, publish, or cancel voice routing configuration changes

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator,

or CsAdministrator role. For details, see Delegate Setup Permissions.

2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing**.
4. Make the configuration changes you want to the settings on each page of the **Voice Routing** group.
5. To review pending changes without publishing them, select **Review uncommitted changes** from the **Commit** menu.
6. If you want to cancel any of the pending changes, do one of the following:
   - Select **Cancel all uncommitted changes** from the **Commit** menu.
   - Navigate to the tab of the **Voice Routing** page that has pending changes you want to cancel, select the item with the pending changes, click **Commit**, and then click **Cancel selected changes**.
7. After you have reviewed all pending changes and canceled any that you do not want to publish, click **Commit**, and then click **Commit all**.
8. In the **Uncommitted Voice Configuration Settings** dialog box, which displays a list of all of the pending changes, click **OK**.

   When Lync Server Control Panel has committed the changes, the **Successfully published voice routing configuration** message appears.

1.4.3.9 Deploying On-Premises Exchange UM to Provide Lync Server 2013 Voice Mail

Deploying On-Premises Exchange UM to Provide Lync Server 2013 Voice Mail

Microsoft Lync Server 2013 > Deployment > Deploying Enterprise Voice >

Topic Last Modified: *2012-09-26*

If you have deployed or plan to deploy Microsoft Exchange Server in your organization, you can use Exchange Unified Messaging (UM) features to provide voice mail to Enterprise Voice users.

In This Section

- Configuring Unified Messaging on Microsoft Exchange Server to Work with Lync Server 2013
- Configure Lync Server 2013 to Work with Unified Messaging on Microsoft Exchange Server

1.4.3.9.1 Configuring Unified Messaging on Microsoft Exchange Server to Work with Lync Server 2013

Configuring Unified Messaging on Microsoft Exchange Server to Work with Lync Server 2013

Deployment > Deploying Enterprise Voice > Deploying On-Premises Exchange UM to Provide Lync Server 2013 Voice Mail >

Topic Last Modified: *2012-10-11*

Important:

If you want to use Exchange Unified Messaging (UM) to provide call answering, Outlook Voice Access, or auto-attendant services for Enterprise Voice users, read Planning for Exchange Unified Messaging Integration in the Planning documentation, and then follow the instructions in this section.

To configure Exchange Unified Messaging (UM) to work with Enterprise Voice, you'll need to perform the following tasks:

- Configure certificates on the server running Exchange Unified Messaging (UM) services

  > **Note:**
  > Add all Client Access and Mailbox servers to all UM SIP URI dial plans. If not, outbound call routing won't work as expected.

- Create one or more UM SIP URI dial plans, along with the subscriber access phone numbers, as needed, and then create corresponding Lync Server dial plans.
- Use the **exchucutil.ps1** script to:
  - Create UM IP gateways.
  - Create UM hunt groups.
  - Grant Lync Server 2013 permission to read UM Active Directory Domain Services (AD DS) objects.
- Create a UM auto-attendant object.
- Create a subscriber access object.
- Create a SIP URI for each user and associating users with a UM SIP URI dial plan.

Requirements and Recommendations

Before you begin, the documentation in this section assumes that you have deployed the following Exchange 2013 roles: Client Access and Mailbox. In Microsoft Exchange Server 2013, Exchange UM runs as a service on these servers.

For details about deploying Exchange 2013, see the Exchange 2013 TechNet Library at http://go.microsoft.com/fwlink/p/?LinkId=266637

Also note the following:

- If Exchange UM is installed in multiple forests, the Exchange Server integration steps must be performed for each UM forest. In addition, each UM forest must be configured to trust the forest in which Lync Server 2013 is deployed, and the forest in which Lync Server 2013 is deployed must be configured to trust each UM forest.
- Integration steps are performed on both the Exchange Server roles where Unified Messaging services are running, and on the server running Lync Server 2013. You should perform the Exchange Server Unified Messaging integration steps before you perform the Lync Server 2013 integration steps.

  > **Note:**
  > To see which integration steps are performed on which servers and by which administrator roles, see Deployment Process for Integrating On-Premises Unified Messaging and Lync Server 2013.

The following tools must be available on each server running Exchange UM:

- Exchange Management Shell
- The script **exchucutil.ps1**, which performs the following tasks:
  - Creates a UM IP gateway for each Lync Server 2013.
  - Creates a hunt group for each gateway. The pilot identifier of each hunt group specifies the UM SIP URI dial plan used by the Front End pool or Standard Edition server that is associated with the gateway.
  - Grants Lync Server 2013 permission to read Exchange UM objects in Active Directory Domain Services (AD DS).

In This Section

1.4.3.9.1.1 Configure Certificates on the Server Running Microsoft Exchange Server Unified Messaging

Configure Certificates on the Server Running Microsoft Exchange Server Unified Messaging

Deploying Enterprise Voice > Deploying On-Premises Exchange UM to Provide Lync Server 2013 Voice Mail > Configuring Unified Messaging on Microsoft Exchange Server to Work with Lync Server 2013 >

Topic Last Modified: *2012-09-26*

If you have deployed Exchange Unified Messaging (UM), as described in Planning for Exchange Unified Messaging Integration in the Planning documentation, and you want to provide Exchange UM features to Enterprise Voice users in your organization, you can use the following procedures to configure the certificate on the server running Exchange UM.

Important:
For internal certificates, both the servers running Lync Server 2013 and the servers running Microsoft Exchange must have trusted root authority certificates that are mutually trusted. The certification authority (CA) can either be the same, or a different certification authority, as long as the servers have the certification authority’s root certificate registered in their trusted root authority certificate store.

The Exchange Server must be configured with a server certificate in order to connect to Lync Server 2013:

1. Download the CA certificate for the Exchange Server.
2. Install the CA certificate for the Exchange Server.
3. Verify that the CA is in the list of trusted root CAs of the Exchange Server.
4. Create a certificate request for the Exchange Server and install the certificate.
5. Assign the certificate for the Exchange Server.

⊟To download the CA certificate

1. On the server running Exchange UM, click **Start**, click **Run**, type **http://<name of your Issuing CA Server>/certsrv**, and then click **OK**.
2. Under **Select a task**, click **Download a CA certificate, certificate chain, or CRL**.
3. Under **Download a CA Certificate, Certificate Chain, or CRL**, select **Encoding Method to Base 64**, and then click **Download CA certificate**.

Note:
You can also specify Distinguished Encoding Rules (DER) encoding at this step. If you select DER encoding, the file type in the next step of this procedure and in step 10 of **To Install the CA certificate** is .p7b rather than .cer.

4. In the **File Download** dialog box, click **Save**, and then save the file to the hard disk on the server. (The file will have either a .cer or a .p7b file extension, depending on the encoding that you selected in the previous step.)

⊟To install the CA certificate

1. On the server running Exchange UM, open Microsoft Management Console (MMC) by clicking **Start**, clicking **Run**, typing **mmc** in the **Open** box, and then clicking **OK**.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. In the **Add Standalone Snap-ins** box, click **Certificates**, and then click **Add**.
4. In the **Certificate snap-in** dialog box, click **Computer account**, and then click **Next**.
5. In the **Select Computer** dialog box, verify that the **Local computer: (the computer this console is running on)** check box is selected, and then click **Finish**.
6. Click **Close**, and then click **OK**.
7. In the console tree, expand **Certificates (Local Computer)**, expand **Trusted Root Certification Authorities**, and then click **Certificates**.
8. Right-click **Certificates**, click **All Tasks**, and click **Import**.
9. Click **Next**.
10. Click **Browse** to locate the file, and then click **Next**. (The file will have either a .cer or a .p7b file extension, depending on the encoding that you selected in step 3 of **To download the CA certificate**.
11. Click **Place All Certificates in the following store**.
12. Click **Browse**, and then select **Trusted Root Certification Authorities**.
13. Click **Next** to verify the settings, and then click **Finish**.

⊟To verify that the CA is in the list of trusted root CAs

1. On the server running Exchange UM, in MMC expand **Certificates (Local Computer)**, expand **Trusted Root Certification Authorities**, and then click **Certificates**.
2. In the details pane, verify that your CA is on the list of trusted CAs.

⊟To configure Exchange Server 2013 UM with Lync Server

1. For details, see "Integrate Exchange 2013 UM with Lync Server" in the Exchange Server documentation at http://go.microsoft.com/fwlink/p/?LinkId=265372.

⊟To create a certificate request and install the certificate on Exchange Server 2007 (SP1)

1. On the server running Exchange UM, click **Start**, click **Run**, type **http://<***name of your Issuing CA Server***>/certsrv**, and then click **OK**.
2. Under **Select a task**, click **Request a Certificate**.
3. Under **Request a Certificate**, click **Advanced certificate request**.
4. Under **Advanced Certificate Request**, click **Create and submit a request to this CA**.
5. Under **Advanced Certificate Request**, select **Web server** or another server certificate template configured for server authentication.
6. Under **Identifying Information for Offline Template**, in the **Name** box, type the fully qualified domain name (FQDN) of the Exchange Server.

   Note:
   You must enter the FQDN of the Exchange Server for communications to work.

7. Under **Key Options**, click the **Store certificate in the local computer certificate store** check box.
8. Click the **Submit** button in the bottom of the webpage.
9. In the dialog box that opens asking for confirmation, click **Yes**.
10. On the Certificate Issued page, under **Certificate Issued**, click **Install this certificate**.
11. In the dialog box that opens asking for confirmation, click **Yes**.

12. Verify that the message "Your new certificate has been successfully installed" appears.

⊟To create a certificate on Exchange Server 2010

1. Log on to the server running Exchange UM with appropriate user rights. For details, see "Client Access Permissions" at http://go.microsoft.com/fwlink/p/?linkId=195499.
2. Refer to the following procedures to create the certificate:
   - 2.a. "Create a New Exchange Certificate" at http://go.microsoft.com/fwlink/p/?linkId=195494
   - 2.b. "Import an Exchange Certificate" at http://go.microsoft.com/fwlink/p/?linkId=195496

Note:
For the certificate **Subject Name**, you must enter the FQDN of the Exchange Server for communications to work.

⊟To assign the certificate on Exchange Server 2007 (SP1)

1. On the server running Exchange UM, open MMC.
2. In the console tree, expand **Personal** and then click **Certificates**.
3. In the details pane, verify that personal certificate is displayed.
4. Double-click the certificate to read its details and verify that it is valid.

Note:
It may take a few minutes before the certificate displays as valid.

5. Restart the Microsoft Exchange Unified Messaging service.

Note:
The server running Exchange Server 2007 SP1 Unified Messaging automatically retrieves the correct certificate.

6. Open Event Viewer and look for Event ID 1112, which specifies what certificate the server running Exchange Server 2007 SP1 Unified Messaging has retrieved.

⊟To assign the certificate on Exchange Server 2010

1. Log on to the server running Exchange UM with appropriate user rights. For details, see "Client Access Permissions" at http://go.microsoft.com/fwlink/p/?linkId=195499.
2. For the procedure to assign the certificate, see "Assign Services to a Certificate" at http://go.microsoft.com/fwlink/p/?linkId=195497.

1.4.3.9.1.2 Configure Unified Messaging on Microsoft Exchange

Configure Unified Messaging on Microsoft Exchange

Deploying Enterprise Voice > Deploying On-Premises Exchange UM to Provide Lync Server 2013 Voice Mail > Configuring Unified Messaging on Microsoft Exchange Server to Work with Lync Server 2013 >

Topic Last Modified: *2013-02-24*

This topic describes how to configure Exchange Unified Messaging (UM) on a Microsoft Exchange Server for use with Enterprise Voice.

Note:
The cmdlet examples in this topic provide syntax for the Exchange 2007 version of Exchange Management Shell. If you are running Exchange 2010 or Exchange 2013, see the appropriate documentation as referenced.

To configure a server running Exchange Server UM

1. Create a UM Session Initiation Protocol (SIP) Uniform Resource Identifier (URI) dial plan for each of your Enterprise Voice location profiles. If you choose to use the Exchange Management Console, create a new dial plan with the security setting **Secured (preferred)**.

   > **Warning:**
   > If you set your security setting value to **SIP Secured** to require encryption for SIP traffic only, as previously recommended, note that this security setting on a dial plan is insufficient if the Front End pool is configured to require encryption, which means the pool requires encryption for both SIP and RTP traffic. When the dial plan and pool security settings are not compatible, all calls to Exchange UM from the Front End pool will fail, resulting in an error indicating that you have an "Incompatible security setting."

   If you use the Exchange Management Shell, type:

   ```
   New-UMDialPlan -Name <dial plan name> -UriType "SipName" -VoipSecurity
   ```

   For details, see:

   - For Office Communications Server 2007, see "How to Create a Unified Messaging SIP URI Dial Plan" at http://go.microsoft.com/fwlink/p/?LinkId=268632 and "New-UMDialplan: Exchange 2007 Help" at http://go.microsoft.com/fwlink/p/?LinkId=268666.
   - For Exchange 2010, see "Create a UM Dial Plan" at http://go.microsoft.com/fwlink/p/?LinkId=268674 and "New-UMDialplan: Exchange 2010 Help" at http://go.microsoft.com/fwlink/p/?LinkId=268680.
   - For Exchange 2013, see "Unified Messaging" at http://go.microsoft.com/fwlink/p/?LinkID=266579.

   > **Note:**
   > Whether you select a security level of **SIPSecured** or **Secured** depends on whether secure real-time transport protocol (SRTP) is activated or deactivated for media encryption. For the Lync Server 2010 integration with Exchange UM, this should correspond to the encryption level in the Lync Server media configuration. The Lync Server media configuration can be viewed by running the **Get-CsMediaConfiguration** cmdlet. For details, see Get-CsMediaConfiguration in the Lync Server Management Shell documentation.
   > For details about selecting the appropriate VoIP Security setting, see Deployment Process for Integrating On-Premises Unified Messaging and Lync Server 2013.

2. Run the following cmdlet to obtain the fully qualified domain name (FQDN) for each UM dial plan:

   ```
   (Get-UMDialPlan <dialplanname>).PhoneContext
   ```

   For details, see:

   - For Exchange 2007, see "Get-UMDialplan: Exchange 2007 Help" at http://go.microsoft.com/fwlink/p/?LinkId=268678.
   - For Exchange 2010, see "Get-UMDialplan: Exchange 2010 Help" at http://go.microsoft.com/fwlink/p/?LinkId=268679.
   - For Exchange 2013, see "Unified Messaging" at http://go.microsoft.com/fwlink/p/?LinkID=266579.

3. Record the dial plan name of each UM dial plan. Depending on your version of Exchange Server, you may need to use the FQDN of each dial plan name later as the name of each UM dial plan’s corresponding Lync Server dial plan so that the dial plan names match.

   > **Note:**
   > Lync Server dial plan names must match UM dial plan names only if the UM

dial plan is running on a version of Exchange *earlier* than Exchange 2010 SP1.

4. Add the dial plan to the server running Exchange UM as follows:
   - If you choose to use the Exchange Management Console, you can add the dial plan from the property sheet for the server. For specific instructions, see the Exchange Server product documentation.

     For Exchange 2007, see "How to Add Unified Messaging Server to a Dial Plan" at http://go.microsoft.com/fwlink/p/?LinkId=268681.

     For Exchange 2010, see "View or Configure the Properties of a UM Server" at http://go.microsoft.com/fwlink/p/?LinkId=268682.

     For Exchange 2013, see "Unified Messaging" at http://go.microsoft.com/fwlink/p/?LinkID=266579.
   - If you use the Exchange Management Shell, run the following for each of your Exchange UM servers:

```
$ums=get-umserver;
$dp=get-umdialplan -id <name of dial-plan created in step 1>
$ums[0].DialPlans +=$dp.Identity;
set-umservice -instance $ums[0]
```

Note:

Before you perform the following step, make sure that all Enterprise Voice users have been configured with an Exchange Server mailbox.

For Exchange 2007, see the Exchange Server 2007 TechNet Library at http://go.microsoft.com/fwlink/p/?LinkId=268685.

For Exchange 2010, see the Exchange Server 2010 TechNet Library at http://go.microsoft.com/fwlink/p/?LinkId=268686.

When specifying a mailbox policy for each dial plan that you created in step 1, select either the default policy or one that you have created.

5. Navigate to <*Exchange installation directory*>\Scripts, and then if Exchange is deployed in a single forest, type:

```
exchucutil.ps1
```

Or, if Exchange is deployed in multiple forests, type:

```
exchucutil.ps1 -Forest:"<forest FQDN>"
```

where *forest FQDN* specifies the forest in which Lync Server is deployed.

If you have one or more UM dial plans that are associated with multiple IP gateways, continue to step 6. If your dial plans are each associated with only a single IP gateway, skip step 6.

Important:

Be sure to restart the **Lync Server Front-End** service (rtcsrv.exe) *after* you run exchucutil.ps1. Otherwise, Lync Server will not detect Unified Messaging in the topology.

6. Using either the Exchange Management Shell or Exchange Management Console, disable outbound calling for all but one of the IP gateways associated with each of your dial plans.

Note:

This step is necessary to make sure that outbound calls by the server running Exchange Server Unified Messaging to external users (for example, as is the case with play-on-phone scenarios) reliably traverse the corporate firewall.

Important:

When selecting the UM IP gateway through which to allow outgoing calls, choose the one that is likely to handle the most traffic. Do not allow outgoing traffic through an IP gateway that connects to a pool of Lync Server

Directors. Also avoid pools in another central site or a branch site. You can use either of the following methods to block outgoing calls from passing through an IP gateway:

- If you use the Exchange Management Shell, disable each IP gateway by running the following command:

  ```
  Set-UMIPGateway <gatewayname> -OutcallsAllowed $false
  ```

  For Exchange 2007, see "Set-UMIPGateway: Exchange 2007 Help" at http://go.microsoft.com/fwlink/p/?LinkId=268687.
  For Exchange 2010, see "Set-UMIPGateway: Exchange 2010 Help" at http://go.microsoft.com/fwlink/p/?LinkId=268688.
- If you use the Exchange Management Console, clear the **Allow outgoing calls through this IP gateway** check box.

Important:
If your UM SIP URI dial plan is associated with only a single IP gateway, do not disallow outgoing calls through this gateway.

7. Create a UM auto-attendant for each Lync Server dial plan.

Important:
Do not include any spaces in the name of the auto attendant.

```
New-umautoattendant -name <auto attendant name> -umdialplan < name of
```

For details, see:

- For Exchange 2007, see "New-UMAutoAttendant: Exchange 2007 Help" at http://go.microsoft.com/fwlink/p/?LinkId=268689.
- For Exchange 2010, see "New-UMAutoAttendant: Exchange 2010 Help" at http://go.microsoft.com/fwlink/p/?LinkId=268690.

The following step should be performed for each user after you have enabled Lync Server users for Enterprise Voice and know their SIP URIs.

8. Associate Exchange UM users (each of whom should be configured with an Exchange mail box) with the UM dial plan and create a SIP URI for each user.

Note:
The **SIPResourceIdentifier** in the following sample must be the SIP address of the Lync Server user.

```
enable-ummailbox -id <user name> -ummailboxpolicy <name of the mailbox
```

For details, see:

- For Exchange 2007, see "Enable-UMMailbox: Exchange 2007 Help" at http://go.microsoft.com/fwlink/p/?LinkId=268691.
- For Exchange 2010, see "Enable-UMMailbox: Exchange 2010 Help" at http://go.microsoft.com/fwlink/p/?LinkId=268692.

1.4.3.9.2 Configure Lync Server 2013 to Work with Unified Messaging on Microsoft Exchange Server

Configure Lync Server 2013 to Work with Unified Messaging on Microsoft Exchange Server

Deployment > Deploying Enterprise Voice > Deploying On-Premises Exchange UM to Provide Lync Server 2013 Voice Mail >

Topic Last Modified: *2012-09-26*

This step requires the Exchange UM Integration Utility (OcsUmUtil.exe). This tool is located on the Lync Server 2013 in the %CommonProgramFiles%\Microsoft Lync Server 2013 \Support folder.

Running the Exchange UM Integration Utility

The Exchange UM Integration Utility must be run from a user account with the following characteristics:

- Membership in the RTCUniversalServerAdmins and RtcUniversalUserAdmins groups (which includes permission to read Exchange Server Unified Messaging settings).
- User rights within the domain to create contact objects in the specified organizational unit (OU) container.

When you run the Exchange UM Integration Utility, it performs the following tasks:

- Creates contact objects for each auto-attendant and subscriber access number to be used by Enterprise Voice users.
- Verifies that the name of each Enterprise Voice dial plan matches its corresponding unified messaging (UM) dial plan phone context. This matching is necessary only if the UM dial plan is running on a version of Exchange *earlier* than Exchange 2010 Service Pack 1 (SP1).

> **Important:**
>
> Before running the Exchange UM Integration Utility, be sure that you have done the following:
>
> - Create one or more Exchange UM dial plans, as described in the Exchange product documentation.
>   For Microsoft Exchange Server 2010, see "Create a UM Dial Plan" at http://go.microsoft.com/fwlink/p/?linkId=186177.
>   For Microsoft Exchange Server 2007 Service Pack 1 (SP1), see "How to Create a Unified Messaging SIP URI Dial Plan" at http://go.microsoft.com/fwlink/p/?linkId=185771.
> - Create one or more corresponding Lync Server dial plans, as described in Create a Dial Plan.
>
>   > **Important:**
>   >
>   > If you are using a version of Exchange that is earlier than Microsoft Exchange Server 2010 SP1, you must enter the fully qualified domain name (FQDN) of the corresponding Exchange Unified Messaging (UM) SIP dial plan in the Lync Server 2013 dial plan **Simple name** field. If you are using Microsoft Exchange Server 2010 SP1 or latest service pack, this dial plan name matching is not necessary.
>
> - Create an auto-attendant and make sure that both the subscriber access number and auto-attendant number are in E.164 format.

To run the Exchange UM Integration Utility

1. On a Front End Server, open a command prompt and type **cd %CommonProgramFiles%\Microsoft Lync Server 2013\Support**, and then press ENTER.
2. Type **OcsUmUtil.exe**, and then press ENTER.
3. Click **Load Data** to find all trusted Exchange forests.
4. In the **SIP Dial Plans** list, select a UM SIP dial plan for which you want to create contact objects, and then click **Add**.
5. In the **Contact** box, accept the default organizational unit, or click **Browse** to start the **OU Picker**. In the **OU Picker** box, you can select an OU and click **OK**, or you can click **Make New OU** to create a new organizational unit under the root or any other OU in the domain (for example, "OU=RTC Special Accounts,DC=fourthcoffee,DC=com"), and then click **OK**.

   > **Note:**

The distinguished name (DN) of the OU that you have selected or created is now displayed in the **Organizational Unit** box.

6. In the **Name** box, either accept the default dial plan name or type a new display name for the contact object that you are creating.

   Note:
   For example, if you are creating a subscriber access contact object, you might simply name it Subscriber Access.

7. In the **SIP Address** box, either accept the default SIP address or type a new SIP address.

   Note:
   If you type a new SIP address, it must begin with **SIP:** (that is, "SIP:" including the colon).

8. In the **Server or Pool** list, select the Standard Edition server or Front End pool in which the contact object is to be enabled.

   Note:
   Preferably, the pool you select is the same one pool where users enabled for Enterprise Voice and Exchange UM are deployed.

9. In the **Phone Number** list, select either **Enter phone number** or **Use this pilot number from Exchange UM** and then enter a phone number.
10. In the **Contact Type** list, select the contact type that you want to create, and then click **OK**.
11. Repeat steps 1 through 10 for additional contact objects that you want to create.

   Note:
   You should create at least one contact for each auto attendant. If you want external access, you also need a Subscriber Access contact and to specify Direct Inward Dial (DID) numbers.

To verify that the contact objects have been created, open Active Directory Users and Computers and select the OU in which the objects were created. The contact objects should appear in the details pane.

1.4.3.10 Providing Lync Server 2013 Users Voice Mail on Hosted Exchange UM

Providing Lync Server 2013 Users Voice Mail on Hosted Exchange UM

Microsoft Lync Server 2013 > Deployment > Deploying Enterprise Voice >

Topic Last Modified: *2012-09-24*

This section guides you through the process of providing users in an on-premises Lync Server 2013 deployment with voice mail on a hosted Exchange Unified Messaging (UM) service.

- Create a DNS SRV Record for Integration with Hosted Exchange UM
- Configure the Edge Server for Integration with Hosted Exchange UM
- Manage Hosted Voice Mail Policies
- Enable Users for Hosted Voice Mail
- Create Contact Objects for Hosted Exchange UM

Create a DNS SRV Record for Integration with Hosted Exchange UM

See Also

Deployment > Deploying Enterprise Voice > Providing Lync Server 2013 Users Voice Mail on Hosted Exchange UM >

Topic Last Modified: *2013-02-20*

This topic describes how to configure the Domain Name System (DNS) SRV record that is required for a Lync Server 2013 Edge Server to route to a hosted Exchange service such as Microsoft Exchange Online.

⊟To create an external DNS SRV record for the hosted Exchange service

1. Log on to the external DNS server as a member of the DnsAdmins group.
2. Click **Start**, click **Administrative Tools**, and then click **DNS**.
3. In the console tree for your SIP domain, expand **Forward Lookup Zones**, and select the SIP domain in which Lync Server 2013 will be installed.

   Important:

   You must create the DNS SRV record in the SIP domain in which Lync Server is or will be installed. When you create the SRV record, the FQDN used for the Host offering this service field must be the external FQDN of the Edge pool. For example, if the external FQDN of your Edge pool is edge01.contoso.net, enter that value. This must also be in the same domain as the DNS Hosts (A) record.

4. Right-click the selected domain, and then click **Other New Records**.
5. In **Resource Record Type**, click **Service Location (SRV)**, and then click **Create Record**.
6. In **New Resource Record**, click **Service**, and then type **_sipfederationtls**.
7. Click **Protocol**, and then type **_tcp**.
8. Click **Port Number**, and then type **5061**.
9. Click **Host offering this service**, and then type the fully qualified domain name (FQDN) of the Lync Server 2013 Edge pool that provides access to your Lync Server 2013 system for trusted external clients.

   Note:

   The domain must also be set up as an authoritative, accepted domain in your Exchange Online settings. For details, see Create Accepted Domains at http://go.microsoft.com/fwlink/p/?linkId=229762.

10. Click **OK**, and then click **Done**.

⊟To verify that the DNS SRV record was created successfully

1. Log on to a client computer in the domain.
2. Click **Start**, and then click **Run**.
3. At the command prompt, run the following command:

   ```
   nslookup <FQDN Lync Edge Pool>
   ```

4. Verify that you receive a reply that resolves to the appropriate IP address for the FQDN.

Concepts

Create DNS Records for Reverse Proxy Servers

1.4.3.10.2 Configure the Edge Server for Integration with Hosted Exchange UM

Configure the Edge Server for Integration with Hosted Exchange UM

See Also

Deployment > Deploying Enterprise Voice > Providing Lync Server 2013 Users Voice Mail on Hosted Exchange UM >

Topic Last Modified: *2012-10-10*

To provide your Lync Server 2013 users with voice mail capabilities on hosted Exchange Unified Messaging (UM), you must perform the following configuration tasks on the Edge Server:

- Configure the Edge Server for federation.
- Replicate Central Management store data to the Edge Server and verify the replication.
- Create a hosting provider on the Edge Server.

For details, see the Lync Server Management Shell documentation for the following cmdlets:

- Set-CsAccessEdgeConfiguration
- New-CsHostingProvider

Important:

You must create an external DNS SRV record for the hosting Exchange service before you perform these steps. For details, see Create a DNS SRV Record for Integration with Hosted Exchange UM.

To configure the Edge Server for federation

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the Set-CsAccessEdgeConfiguration cmdlet to configure the server for federation. For example, run:

   ```
   Set-CsAccessEdgeConfiguration -UseDnsSrvRouting -AllowFederatedUsers 1
   ```

   The preceding example sets the following parameters:

   - **UseDnsSrvRouting** specifies that Edge Servers will rely on DNS SRV records when sending and receiving federation requests.
   - **AllowFederatedUsers** specifies whether internal users are allowed to communicate with users from federated domains. This property also determines whether internal users can communicate with users in a split domain scenario.
   - **EnablePartnerDiscovery** specifies whether Lync Server will use DNS records to try to discover partner domains not listed in the Active Directory allowed domains list. If False, Lync Server 2013 will only federate with domains found on the allowed domains list. This parameter is required if you use DNS service routing. In most deployments, the value is set to false to avoid opening up federation to all partners.

To replicate data to the Edge Server and verify the replication

- Verify that the replication to the Edge Server is complete. For the procedure, see Verify Connectivity Between Internal Servers and Edge Servers.

To create a hosting provider on the Edge Server

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click

Microsoft Lync Server 2013, and then click **Lync Server Management Shell**.

2. Run the **New-CsHostingProvider** cmdlet to configure the hosting provider. For example, run:

```
New-CsHostingProvider -Identity Fabrikam.com -Enabled $True -EnabledSh
```

The preceding example sets the following parameters:

- **Identity** specifies a unique string value identifier for the hosting provider you are creating, in this example, **Fabrikam.com**. Note that the command will fail if an existing provider has already been configured with that Identity.
- **Enabled** indicates whether the network connection between your domain and the hosting provider is enabled. Messages cannot be exchanged between the two organizations until this value is set to **True**.
- **EnabledSharedAddressSpace** indicates whether the hosting provider is being used in a shared SIP address space (split domain) scenario.
- **HostsOCSUsers** indicates whether the hosting provider is used to host Lync Server 2013 accounts. If **False**, the provider hosts other account types, such as Microsoft Exchange accounts.
- **ProxyFQDN** specifies the fully qualified domain name (FQDN) for the proxy server used by the hosting provider, in this example, **proxyserver.fabrikam.com**. This value cannot be modified. If the hosting provider changes its proxy server you will need to delete and then recreate the entry for that provider.
- **IsLocal** indicates whether the proxy server used by the hosting provider is contained within your Lync Server 2013 topology.
- **VerficationLevel** indicates the allowed verification level for messages sent to and from the hosted provider. Specify **UseSourceVerification**, which relies on the verification level included in messages sent from the hosting provider. If this level is not specified, then the message will be rejected as being unverifiable.

Tasks

Export Your Topology and Copy It to External Media for Edge Installation

Concepts

Verify Connectivity Between Internal Servers and Edge Servers

New-CsHostingProvider

1.4.3.10.3 Manage Hosted Voice Mail Policies

Manage Hosted Voice Mail Policies

Deployment > Deploying Enterprise Voice > Providing Lync Server 2013 Users Voice Mail on Hosted Exchange UM >

Topic Last Modified: *2012-09-20*

A *hosted voice mail policy* provides information to the Lync Server 2013 ExUM Routing application about where to route calls for users whose mailboxes are located on a hosted Exchange service.

Note:

Typically, only one hosted voice mail policy is required. In many cases, you can modify the global policy to meet all your needs. If you create a policy with site scope, it is assigned automatically to all users homed at the specified site. If you create a policy with per-user scope, you must explicitly assign it to users, groups, and contact objects. It is possible to deploy multiple hosted voice mail policies, but in that case the policies must be assigned on a per-user basis.

For details about planning hosted voice mail policies, see Hosted Voice Mail Policies in the Planning documentation.

- Modify the Global Hosted Voice Mail Policy
- Create a Site-Level Hosted Voice Mail Policy
- Create a Per-User Hosted Voice Mail Policy
- Assign a Per-User Hosted Voice Mail Policy

1.4.3.10.3.1 Modify the Global Hosted Voice Mail Policy

Modify the Global Hosted Voice Mail Policy

Deploying Enterprise Voice > Providing Lync Server 2013 Users Voice Mail on Hosted Exchange UM > Manage Hosted Voice Mail Policies >

***Topic Last Modified:** 2012-09-24*

The *global* hosted voice mail policy is installed with Lync Server 2013. You can modify it to meet your needs, but you cannot rename or delete it. To modify the global policy, you use the Set-CsHostedVoicemailPolicy cmdlet to set the parameters to appropriate values for your specific deployment.

For details about the Set-CsHostedVoicemailPolicy cmdlet, see the Lync Server Management Shell documentation.

To modify the global hosted voice mail policy

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the Set-CsHostedVoicemailPolicy cmdlet to set the global policy parameters for your environment. For example, run:

```
Set-CsHostedVoicemailPolicy -Destination ExUM.fabrikam.com -Organizati
```

Because this command does not specify the policy’s Identity parameter, Windows PowerShell command-line interface sets the following values on the global hosted voice mail policy:

- **Destination** specifies the fully qualified domain name (FQDN) of the hosted Exchange UM service. This parameter is optional, but if you attempt to enable a user for hosted voice mail and the user’s assigned policy does not have a Destination value, the enable will fail.
- **Organization** specifies a comma-separated list of the Exchange tenants that home Lync Server users. Each tenant must be specified as the FQDN of that tenant on the hosted Exchange UM service.

Note:

In the previous example cmdlet, the value “corp1.litwareinc.com” replaces any value that might already be present in the Organization parameter. For example, if the policy already contains a comma-separated list of organizations, the full list would be replaced. If you want to add an organization to the list rather than replace the entire list, run a command similar to the following.

```
$a = Get-CsHostedVoicemailPolicy
$a.Organization += ",corp3.litwareinc.com"
Set-CsHostedVoicemailPolicy -Organization $a.Organization
```

1.4.3.10.3.2 Create a Site-Level Hosted Voice Mail Policy

Create a Site-Level Hosted Voice Mail Policy

Deploying Enterprise Voice > Providing Lync Server 2013 Users Voice Mail on Hosted Exchange UM > Manage Hosted Voice Mail Policies >

***Topic Last Modified:** 2012-09-24*

A *site* policy can impact all users that are homed on the site for which the policy is defined. If a user is configured for hosted Exchange UM access and has not been assigned a Per-user policy, the site policy applies. If you have not deployed a site policy, the global policy applies.

For details about configuring site policies, see the Lync Server Management Shell documentation for the following cmdlets:

- New-CsHostedVoicemailPolicy
- Set-CsHostedVoicemailPolicy
- Get-CsHostedVoicemailPolicy

To create a site hosted voice mail policy

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the New-CsHostedVoicemailPolicy cmdlet to create the policy. For example, run:

```
New-CsHostedVoicemailPolicy -Identity site:Redmond -Destination ExUM.f
```

   This example creates a hosted voice mail policy with site scope, and sets the following parameters:

   - **Identity** specifies a unique identifier for the policy, which includes the scope. For a policy with site scope, the Identity parameter value must be specified in the format `site:`<*name*>, for example, `site:Redmond`.
   - **Destination** specifies the fully qualified domain name (FQDN) of the hosted Exchange UM service. This parameter is optional, but if you attempt to enable a user for hosted voice mail and the user’s assigned policy does not have a Destination value, the enable will fail.
   - **Description** provides optional descriptive information about the policy.
   - **Organization** specifies a comma-separated list of the Exchange tenants that home Lync Server 2013 users. Each tenant must be specified as the FQDN of that tenant on the hosted Exchange UM service.

1.4.3.10.3.3 Create a Per-User Hosted Voice Mail Policy

Create a Per-User Hosted Voice Mail Policy

See Also

Deploying Enterprise Voice > Providing Lync Server 2013 Users Voice Mail on Hosted Exchange UM > Manage Hosted Voice Mail Policies >

***Topic Last Modified:** 2012-09-24*

A *per-user* policy can only impact individual users, groups, and contact objects. To deploy a per-user policy, you must explicitly assign the policy to one or more users, groups, or contact objects. For details, see Assign a Per-User Hosted Voice Mail Policy.

For details about working with per-user hosted voice mail policies, see the Lync Server

Management Shell documentation for the following cmdlets:

- New-CsHostedVoicemailPolicy
- Set-CsHostedVoicemailPolicy
- Get-CsHostedVoicemailPolicy

To create a per-user hosted voice mail policy

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the New-CsHostedVoicemailPolicy cmdlet to create the policy. For example, run:

```
New-CsHostedVoicemailPolicy -Identity ExRedmond -Destination ExUM.fabr
```

The previous example creates a hosted voice mail policy with per-user scope, and sets the following parameters:

- **Identity** specifies a unique identifier for the policy, which includes the scope. For a policy with per-user scope, this parameter value is specified as a simple string, for example, ExRedmond.
- **Destination** specifies the fully qualified domain name (FQDN) of the hosted Exchange UM service. This parameter is optional, but if you attempt to enable a user for hosted voice mail and the user’s assigned policy does not have a Destination value, the enable will fail.
- **Description** provides optional descriptive information about the policy.
- **Organization** specifies a comma-separated list of the Exchange tenants that home Lync Server 2013 users. Each tenant must be specified as the FQDN of that tenant on the hosted Exchange UM service.

Tasks

Assign a Per-User Hosted Voice Mail Policy

1.4.3.10.3.4 Assign a Per-User Hosted Voice Mail Policy

Assign a Per-User Hosted Voice Mail Policy

Deploying Enterprise Voice > Providing Lync Server 2013 Users Voice Mail on Hosted Exchange UM > Manage Hosted Voice Mail Policies >

***Topic Last Modified:** 2010-11-07*

Deploying one or more per-user hosted voice mail policies is optional. If you do deploy per-user policies, you must explicitly assign them to users, groups, or contact objects.

For details about assigning or removing the assignment of per-user hosted voice mail policies, see the Lync Server Management Shell documentation for the following cmdlets:

- Grant-CsHostedVoicemailPolicy
- Remove-CsHostedVoicemailPolicy

To assign a per-user hosted voice mail policy

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the Grant-CsHostedVoicemailPolicy cmdlet to assign the per-user hosted voice mail policy to individual users, groups, and contact objects. For example, run:

```
Grant-CsHostedVoicemailPolicy -Identity "Ken Myer" -PolicyName ExRedmo
```

This example assigned the ExRedmond hosted voice mail policy to user Ken

Myer.

Identity specifies the user account to be modified. The Identity value can be specified using any of the following formats:

- The user's SIP address
- The user's Active Directory User-Principal-Name
- The user's domain\logon name (for example, contoso\kenmyer)
- The user's Active Directory Domain Services Display-Name (for example, Ken Myer). If using the Display-Name as the Identity value, you can use the asterisk (*) wildcard character. For example, the Identity "* Smith" returns all the users who have a Display-Name that ends with the string value "Smith".

Note:

The user’s Active Directory SAM-Account-Name cannot be used as the Identity value because the SAM-Account-Name is not necessarily unique in the forest.

1.4.3.10.4 Enable Users for Hosted Voice Mail

Enable Users for Hosted Voice Mail

Deployment > Deploying Enterprise Voice > Providing Lync Server 2013 Users Voice Mail on Hosted Exchange UM >

Topic Last Modified: *2012-09-24*

Follow the procedure to enable Lync Server 2013 users for voice mail on a hosted Exchange Unified Messaging (UM) service.

For details, see Hosted Exchange User Management in the Planning documentation.

For details about the Set-CsUser cmdlet, see the Lync Server Management Shell documentation.

Important:

Before a Lync Server 2013 user can be enabled for hosted voice mail, a hosted voice mail policy that applies to their user account must be deployed. For details, see Hosted Voice Mail Policies.

⊟To enable users for hosted voice mail

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the Set-CsUser cmdlet to configure the user account for hosted voice mail. For example, run:

```
Set-CsUser -HostedVoiceMail $True -Identity "contoso\kenmyer"
```

The preceding example sets the following parameters:

- **HostedVoiceMail** enables a user’s voice mail calls to be routed to hosted Exchange UM. It also signals Microsoft Lync 2013 to light up the “call voice mail” indicator.
- **Identity** specifies the user account to be modified. The Identity value can be specified using any of the following formats:
    - The user's SIP address
    - The user's Active Directory User-Principal-Name
    - The user's domain\logon name (for example, contoso\kenmyer)
    - The user's Active Directory Domain Services Display-Name (for example, Ken Myer). If using the Display-Name as the Identity value, you can use

the asterisk (*) wildcard character. For example, the Identity "* Smith" returns all the users who have a Display-Name that ends with the string value "Smith".

> **Note:**
> The user’s Active Directory SAM-Account-Name cannot be used as the Identity value because the SAM-Account-Name is not necessarily unique in the forest.

1.4.3.10.5 Create Contact Objects for Hosted Exchange UM

Create Contact Objects for Hosted Exchange UM

Deployment > Deploying Enterprise Voice > Providing Lync Server 2013 Users Voice Mail on Hosted Exchange UM >

Topic Last Modified: *2012-09-24*

The following procedure explains how to create Auto Attendant (AA) or Subscriber Access (SA) contact objects for hosted Exchange Unified Messaging (UM).

For details, see Hosted Exchange Contact Object Management in the Planning documentation.

For details about configuring contact objects, see the Lync Server Management Shell documentation for the following cmdlets:

- New-CsExUmContact
- Set-CsExUmContact

> **Important:**
> Before Lync Server 2013 contact objects can be enabled for hosted Exchange UM, a hosted voice mail policy that applies to them must be deployed. For details, see Hosted Voice Mail Policies.

To create AA or SA contact objects for hosted Exchange UM

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the New-CsExUmContact cmdlet to create any contact objects required for your deployment. For example, run the following to create an AA and an SA contact object:

```
New-CsExUmContact -SipAddress "sip:exumaa1@fabrikam.com" -RegistrarPoo
```

```
New-CsExUmContact -SipAddress "sip:exumsa1@fabrikam.com" -RegistrarPoo
```

These examples set the following parameters:

- **SipAddress** specifies the SIP address of the contact object. This must be an address that has not already been used to configure a user or contact object in Active Directory Domain Services. This value must be in the format “sip:<*SIP address*>“ as shown in the previous examples.
- **RegistrarPool** specifies the fully qualified domain name (FQDN) of the pool on which the Registrar service is running.

> **Note:**
> Exchange UM contact objects cannot be moved to pools that are part of Lync Server 2013 deployments prior to Lync Server 2013.

- **OU** specifies the Active Directory organizational unit where this contact object will be located.

- **DisplayNumber** specifies the telephone number of the contact object. The phone number for each contact object must be unique.
- **AutoAttendant** specifies whether the Contact object is an Auto Attendant. Auto Attendant provides a set of voice prompts that allow callers to navigate the phone system and reach the party that they want to contact. A value of **False** (the default) for this parameter indicates a Subscriber Access contact object.

1.4.3.11 Configuring On-premises Lync Server 2013 Integration with Exchange Online

Configuring On-premises Lync Server 2013 Integration with Exchange Online

See Also

Microsoft Lync Server 2013 > Deployment > Deploying Enterprise Voice >

Topic Last Modified: *2012-10-21*

Customers who are using on-premises Lync Server 2013 deployments can configure interoperability with Microsoft Outlook Web App in Microsoft Exchange Online in a hybrid deployment mode. Interoperability features include single sign on and instant messaging (IM) and presence integration with the Outlook Web App interface. To enable this integration, you must configure the Edge Server in your on-premises Lync Server deployment by completing the following tasks:

- Configure a shared SIP address space
- Configure a hosting provider on the Edge Server
- Verify replication of the updated Central Management store

Configure a Shared SIP Address Space

To integrate on-premises Lync Server 2013 with Exchange Online, you must configure a shared SIP address space. The same SIP domain address space is supported by both Lync Server and the Exchange Online service.

Using the Lync Server Management Shell, configure the Edge Server for federation by running the **Set-CSAccessEdgeConfiguration** cmdlet, using the parameters displayed in the following example:

```
Set-CsAccessEdgeConfiguration -AllowFederatedUsers $True
```

- **AllowFederatedUsers** parameter specifies whether internal users are allowed to communicate with users from federated domains. This property also determines whether internal users can communicate with users in a shared SIP address space scenario with Lync Server and Exchange Online.

For details about using the Lync Server Management Shell, see Lync Server Management Shell.

Configure a Hosting Provider on the Edge Server

Using the Lync Server Management Shell, configure a hosting provider on the Edge Server by running the **New-CsHostingProvider** cmdlet, using the parameters in the following example:

```
New-CsHostingProvider -Identity "Exchange Online" -Enabled $True -EnabledSharedAd
```

- **Identity** specifies a unique string value identifier for the hosting provider that you are creating (for example, "Exchange Online"). Values that contain spaces must be in double quotes.

- **Enabled** indicates whether the network connection between your domain and the hosting provider is enabled. This must be set to True.
- **EnabledSharedAddressSpace** indicates whether the hosting provider will be used in a shared SIP address space scenario. This must be set to True.
- **HostsOCSUsers** indicates whether the hosting provider is used to host Office Communications Server or Lync Server. This must be set to False.
- **ProxyFQDN** specifies the fully qualified domain name (FQDN) for the proxy server used by the hosting provider. For Exchange Online, the FQDN is exap.um.outlook.com.
- **IsLocal** indicates whether the proxy server used by the hosting provider is contained within your Lync Server topology. This must be set to False.
- **VerificationLevel** Indicates the verification level allowed for messages that are sent to and from the hosted provider. Specify **UseSourceVerification**, which relies on the verification level included in messages sent from the hosting provider. If this level is not specified, the message will be rejected as being unverifiable.

Verify Replication of the Updated Central Management Store

The changes you made by using the cmdlets in the preceding sections are automatically applied to the Edge Server, and generally take less than a minute to replicate. You can validate replication status, and then confirm that the changes were applied to your Edge Server by using the following cmdlets.

To verify replication updates, on a server internal in your Lync Server deployment, run the following cmdlet:

```
Get-CsManagementStoreReplicationStatus
```

To confirm that the changes were applied, on the Edge Server, run the following cmdlet:

```
Get-CsHostingProvider -LocalStore
```

1.4.3.12 Deploying Advanced Enterprise Voice Features

Deploying Advanced Enterprise Voice Features

Microsoft Lync Server 2013 > Deployment > Deploying Enterprise Voice >

Topic Last Modified: *2012-09-22*

After you have configured basic Enterprise Voice functionality for your organization, you can optionally deploy one or more advanced Enterprise Voice features by following the procedures in this section.

For details about the advanced Enterprise Voice features, see the following sections of the Planning documentation:

- Planning for Call Admission Control
- Planning for Emergency Services (E9-1-1)

- Planning for Media Bypass
- About Network Regions, Sites, and Subnets
- Create or Modify a Network Region
- Create or Modify a Network Site
- Associate a Subnet with a Network Site
- Configure Call Admission Control
- Configure Enhanced 9-1-1
- Configure Media Bypass

1.4.3.12.1 About Network Regions, Sites, and Subnets

About Network Regions, Sites, and Subnets

Deployment > Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features >

***Topic Last Modified:** 2013-02-24*

The advanced Enterprise Voice features described in this section share certain configuration requirements for network regions, network sites, and subnets. For example, all three advanced features require that each subnet in your topology be associated with a specific *network site*, and each network site must be associated with a *network region*.

> ◆**Important:**
>
> Before you begin network configuration for call admission control, E9-1-1, or media bypass, make sure that you reviewed additional information about network settings in the Network Settings for the Advanced Enterprise Voice Features topic in the Planning documentation. For details about network configuration primarily about call admission control, also see Defining Your Organization's Requirements for Call Admission Control in the Planning documentation.

Call admission control and E9-1-1 have additional configuration requirements for network sites:

- Call admission control requires that a *bandwidth policy profile* be specified for each site that is constrained by WAN bandwidth limitations. If you plan to deploy call admission control, you must Create Bandwidth Policy Profiles before you configure your network sites.
- E9-1-1 requires that a *location policy* be specified for each site. If you plan to deploy E9-1-1, you must Create Location Policies before you configure your network sites.

Create or Modify Network Regions, Network Sites, and Subnets

The following topics provide steps to create or modify network regions and network sites, and to associate subnets with network sites. These topics are not specific to any particular advanced Enterprise Voice feature.

- Create or Modify a Network Region
- Create or Modify a Network Site
- Associate a Subnet with a Network Site

1.4.3.12.2 Create or Modify a Network Region

Create or Modify a Network Region

Deployment > Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features >

Topic Last Modified: *2012-10-19*

Network regions are the network hubs or backbones used in the configuration of call admission control, E9-1-1, and media bypass. Use the following procedures to create or modify network regions. For example, if you have already created network regions for one Voice feature, you do not need to create new network regions; other advanced Enterprise Voice features will use those same network regions. You may, however, need to modify an existing network region definition to apply feature-specific settings. For example, if you have created network regions for E9-1-1 (which do not require an associated central site) and you then deploy call admission control, you need to modify the network region definitions to specify a central site. For details, see Configure Network Regions for CAC.

Note:

Any feature-specific requirements for network region definitions are documented in the Deployment topics for the feature.

For details about working with network regions, see the Lync Server Management Shell documentation for the following cmdlets:

- New-CsNetworkRegion
- Get-CsNetworkRegion
- Set-CsNetworkRegion
- Remove-CsNetworkRegion

Create a Network Region

Create a network region that can be used by call admission control, E9-1-1, or media bypass.

To create a network region using Lync Server Management Shell

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the New-CsNetworkRegion cmdlet to create network regions:

   ```
   New-CsNetworkRegion -Identity <String> -CentralSite <String>
   ```

   For example:

   ```
   New-CsNetworkRegion -Identity NorthAmerica -CentralSite CHICAGO -Descr
   ```

   In this example, you created a network region called “NorthAmerica” that is associated with a central site with site ID CHICAGO.
3. To finish creating network regions for your topology, repeat step 2 with settings for each network region.

To create a network region using Lync Server Control Panel

1. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
2. In the left navigation bar, click **Network Configuration**.
3. Click **Region**.
4. Click **New**.
5. On the **New Region** page, click **Name** and then type a name for the network region.
6. Click **Central site**, and then click a central site in the list.
7. Optionally, click **Description**, and then type additional information to describe this network site.
8. Click **Commit**.
9. To finish creating network regions for your topology, repeat steps 4 through

8 with settings for other regions.

Modify a Network Region

Modify settings for an existing network region to accommodate changes to the basic region information or changes required by a new feature.

⊟To modify a network region using Lync Server Management Shell

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the Set-CsNetworkRegion cmdlet to modify an existing network region:

   ```
   Set-CsNetworkRegion -Identity <String> -CentralSite <String>
   ```

   For example:

   ```
   Set-CsNetworkRegion -Identity NorthAmerica -CentralSite CHICAGO -Descr
   ```

   In this example, you modified an existing network region called “NorthAmerica” (created using the procedures earlier in this topic) by changing the description. If a description existed for the “NorthAmerica” region, this command overwrites it with this value; if no description had been set, then this command sets it.
3. To modify other network regions, repeat step 2 with settings for other regions.

⊟To modify a network region using Lync Server Control Panel

1. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
2. In the left navigation bar, click **Network Configuration**.
3. Click the **Region** navigation button.
4. In the table, click the network region that you want to modify.
5. Click **Edit**, and then click **Show details...**.
6. On the **Edit Region** page, change the values for this network region’s settings as appropriate.
7. Click **Commit**.
8. To finish modify network regions, repeat steps 4 through 7 with settings for other regions.

1.4.3.12.3 Create or Modify a Network Site

Create or Modify a Network Site

Deployment > Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features >

Topic Last Modified: *2013-02-24*

Call admission control (CAC), E9-1-1, and media bypass deployments rely on the configuration of *network sites* which are defined within and always associated with a network region. A network site represents a branch office location, a set of buildings, or a campus. Network sites represent collections of subnets with similar bandwidth.

Use the following procedures to create or modify network sites. For example, if you have already created network sites for one Voice feature, you do not need to create new network sites; other Voice features will use those same sites. You may, however, need to modify an existing network site definition to apply feature-specific settings. For example, if you created a network site for E9-1-1, you need to modify the network site during deployment of call admission control to apply a bandwidth policy profile.

Note:

Where they exist, you can find specific examples and requirements for network sites as they pertain to an advanced Voice feature in the Deployment documentation for each feature:

- Configure Network Sites for CAC

For details about working with network sites, see the Lync Server Management Shell documentation for the following cmdlets:

- New-CsNetworkSite
- Get-CsNetworkSite
- Set-CsNetworkSite
- Remove-CsNetworkSite

Create a Network Site

Create a network region that can be used by call admission control, E9-1-1, or media bypass.

To create a network site by using Management Shell

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the New-CsNetworkSite cmdlet to create network sites:

   ```
   New-CsNetworkSite -NetworkSiteID <string>
   ```

   For example:

   ```
   New-CsNetworkSite -NetworkSiteID Chicago -Description "Corporate headq
   ```

   In this example, you created a network site called “Chicago” that is in the “NorthAmerica” network region.

   Note:

   The NorthAmerica network region must already exist for this command to run successfully.
3. To finish creating network sites for your topology, repeat step 2 with settings for other sites.

To create a network site by using Lync Server Control Panel

1. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
2. In the left navigation bar, click **Network Configuration**.
3. Click the **Site** navigation button.
4. Click **New**.
5. On the **New Site** page, click **Name** and then type a name for the network site.
6. Click **Region**, and then click a region in the list.
7. Optionally, click **Bandwidth policy**, and then click a bandwidth policy in the list.

   Note:

   Bandwidth policy is required only if you deploy call admission control at the site.
8. Optionally, click **Location policy**, and then click a location policy in the list.

   Note:

   Location policy is required only if you deploy E9-1-1 at the site.
9. Optionally, click **Description**, and then type additional information to describe

this network site.

10. Click **Commit**.
11. To finish creating network sites for your topology, repeat steps 4 through 10 with settings for other sites.

Modify a Network Site

Modify a network region that can be used by call admission control, E9-1-1, or media bypass.

⊟To modify a network site

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the Set-CsNetworkSite cmdlet to modify network sites:

```
Set-CsNetworkSite -Identity <string>
```

For example:

```
Set-CsNetworkSite -Identity Albuquerque -NetworkRegionID NorthAmerica
```

In this example, the site called “Albuquerque” is moved to the “NorthAmerica” network region. To modify the network site configuration to deploy call admission control, E9-1-1, or media bypass, modify the network site settings by running the Set-CsNetworkSite cmdlet with the BWPolicyProfileID or LocationPolicy parameter, respectively.

> **Note:**
> Although the BypassID parameter exists for media bypass, we strongly recommend that you do not override automatically generated bypass IDs. You do not need to specify additional parameters to configure a network site for media bypass.

3. To finish modifying network sites for your topology, repeat step 2 with settings for other sites.

⊟To modify a network site by using Lync Server Control Panel

1. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
2. In the left navigation bar, click **Network Configuration**.
3. Click the **Site** navigation button.
4. In the table, click the network site that you want to modify.
5. Click **Edit**, and then click **Show details...**.
6. On the **Edit Site** page, change the values for this network site’s settings as appropriate.
7. Click **Commit**.
8. To finish modify network sites, repeat steps 4 through 7 with settings for other sites.

1.4.3.12.4 Associate a Subnet with a Network Site

Associate a Subnet with a Network Site

Deployment > Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features >

Topic Last Modified: *2012-10-19*

Every subnet in your network must be associated with a specific network site, because subnet information is used to determine the network site on which an endpoint is located while a new session is initiated. When the location of each party in a session is known, advanced Enterprise Voice features can apply that information to determine how to handle the call setup or routing.

Important:

All configured public IP addresses of the Audio/Video Edge Servers in your deployment must be added to your network configuration settings. These IP addresses are added as subnets with a mask of 32. The associated network site should correspond to the appropriate configured network site. For example, the public IP address that corresponds to the A/V Edge Server in central site Chicago would be NetworkSiteID Chicago. For details about public IP addresses, see Determine External A/V Firewall and Port Requirements in the Planning documentation.

Note:

A Key Health Indicator (KHI) alert is raised, specifying a list of IP addresses that are present in your network but are either not associated with a subnet, or the subnet that includes the IP addresses is not associated with a network site. This alert will not be raised more than once within an 8-hour period. The relevant alert information and an example are as follows:

Source: CS Bandwidth Policy Service (Core)
Event number: 36034
Level: 2
Description: The subnets for the following IP addresses: <List of IP Addresses> are either not configured or the subnets are not associated to a Network Site.
Cause: The subnets for the corresponding IP addresses are missing from the network configuration settings or the subnets are not associated to a network site.
Resolution: Add subnets corresponding to the list of IP addresses into the network configuration settings and associate every subnet to a network site.

For example, if the IP address list in the alert specifies 10.121.248.226 and 10.121.249.20, either these IP addresses are not associated with a subnet or the subnet they are associated with does not belong to a network site. If 10.121.248.0/24 and 10.121.249.0/24 are the corresponding subnets for these addresses, you can resolve this issue as follows:

1. Be sure that IP address 10.121.248.226 is associated with the 10.121.248.0/24 subnet and IP address 10.121.249.20 is associated with the 10.121.249.0/24 subnet.
2. Be sure that the 10.121.248.0/24 and 10.121.249.0/24 subnets are each associated with a network site.

For details about working with network subnets, see the Lync Server Management Shell documentation for the following cmdlets:

- New-CsNetworkSubnet
- Get-CsNetworkSubnet
- Set-CsNetworkSubnet
- Remove-CsNetworkSubnet

Tip:

If you are working with a large number of subnets, we recommend using a comma-separated values (CSV) file to associate the subnets to sites. The CSV file must have the following four columns: **IPAddress**, **mask**, **description**, **NetworkSiteID**.

To associate a subnet with a network site by using Management Shell

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the **New-CsNetworkSubnet** cmdlet to associate a subnet with a network site:

```
New-CsNetworkSubnet -SubnetID <String> -MaskBits <Int32> -NetworkSiteI
```

For example:

```
New-CsNetworkSubnet -SubnetID 172.11.12.13 - MaskBits 20 -NetworkSiteI
```

In this example, you created an association between the subnet 172.11.12.13 and the network site “Chicago”.

3. Repeat step 2 for all subnets in your topology.

⊟To associate subnets with network sites by importing a CSV file

1. Create a CSV file that includes all of the subnets you want to add. For example, create a file named **subnet.csv** with the following content:
```
IPAddress, mask, description, NetworkSiteID
172.11.12.0, 24, "NA:Subnet in Portland", Portland
172.11.13.0, 24, "NA:Subnet in Reno", Reno
172.11.14.0, 25, "EMEA:Subnet in Warsaw", Warsaw
172.11.15.0, 31, "EMEA:Subnet in Paris", Paris
```
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run the following cmdlet to import **subnet.csv**, and then store its contents in the Lync Server management store:
```
import-csv subnet.csv | foreach {New-CSNCSSubnet  _.IPAddress -MaskBit
```

⊟To associate a subnet with a network site by using Lync Server Control Panel

1. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
2. In the left navigation bar, click **Network Configuration**.
3. Click the **Subnet** navigation button.
4. Click **New**.
5. On the **New Subnet** page, click **Subnet ID**, and then type the first address in the IP address range defined by the subnet you want to associate with a network site.
6. Click **Mask**, and then type the bitmask to apply to the subnet.
7. Click **Network site ID**, and then select the site ID of the site to which you are adding this subnet.

> **Note:**
> If you have not yet created network sites, this list will be empty. For details about the procedure, see Create or Modify a Network Site. You can also retrieve site IDs for your deployment by running the **Get-CsNetworkSite** cmdlet. For details, see the Lync Server Management Shell documentation.

8. Optionally, click **Description**, and then type additional information to describe this subnet.
9. Click **Commit**.

Repeat these steps to add other subnets to a network site.

1.4.3.12.5 Configure Call Admission Control

Configure Call Admission Control

Deployment > Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features >

Topic Last Modified: *2012-09-21*

Call admission control (CAC) is a solution that determines whether a real-time session can be established based on the available bandwidth to help prevent poor audio/video quality for users on congested networks. CAC controls real-time traffic only for audio and video, and does not affect data traffic. CAC may route the call through an Internet path when the default WAN path does not have the required bandwidth. For details, see Planning for Call Admission Control in the Planning documentation.

This section provides a set of example procedures that illustrate how to deploy and manage CAC in your network.

Important:

Before you deploy CAC, you must gather all of the required information for your enterprise network topology, as described in Example: Gathering Your Organization's Requirements for Call Admission Control in the Planning documentation. Also be sure that CAC components have been installed and activated, as described in Define and Configure a Front End Pool or Standard Edition Server in the Deployment documentation.

Note:

All CAC deployment and management examples in this section are performed by using the Lync Server Management Shell. As an alternative, you can also use the **Network Configuration** section of Lync Server Control Panel to manage CAC.

- Configure Network Regions for CAC
- Create Bandwidth Policy Profiles
- Configure Network Sites for CAC
- Associate Subnets with Network Sites for CAC
- Create Network Region Links
- Create Network Interregion Routes
- Create Network Intersite Policies
- Enable Call Admission Control
- Call Admission Control Deployment Checklist

1.4.3.12.5.1 Configure Network Regions for CAC

Configure Network Regions for CAC

Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features > Configure Call Admission Control >

Topic Last Modified: *2012-09-21*

Important:

If you have already created network regions for E9-1-1 or media bypass, you can modify the existing network regions by adding settings specific to call admission control (CAC) by using the **Set-CsNetworkRegion** cmdlet. For an example of how to modify a network region, see Create or Modify a Network Region.

Network regions are the network hubs or backbones that are used in configuring CAC, E9-1-1, and media bypass. Use the following procedure to create network regions that align to network regions in the example network topology for CAC. To view the example network topology, see Example: Gathering Your Organization's Requirements for Call Admission Control in the Planning documentation.

The example network topology for CAC has three regions: North America, EMEA, and APAC. Each region has a specified central site. For the North America region, the designated central site is named CHICAGO. The following procedure shows an example of how you can use the **New-CsNetworkRegion** cmdlet to create the North America region.

Note:

In the following procedure, Lync Server Management Shell is used to create a network region. For details about using Lync Server Control Panel to create a network region, see Create or Modify a Network Region.

To create a network region for call admission control

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. For each region that you need to create, run the **New-CsNetworkRegion** cmdlet. For example, to create the North America region, run:

   ```
   New-CsNetworkRegion -Identity NorthAmerica -CentralSite CHICAGO -Descr
   ```

3. Repeat step 2 to create the network regions, EMEA and APAC.

1.4.3.12.5.2 Create Bandwidth Policy Profiles

Create Bandwidth Policy Profiles

Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features > Configure Call Admission Control >

***Topic Last Modified:** 2012-10-19*

Bandwidth policies define limitations on bandwidth usage for real-time audio and video modalities. Bandwidth policies are applied to *bandwidth policy profiles*, which can be applied to multiple network sites for call admission control.

For guidelines about what bandwidth limits you should set in your CAC deployment, see Defining Your Organization's Requirements for Call Admission Control in the Planning documentation.

For details about working with bandwidth policies and policy profiles, see the Lync Server Management Shell documentation for the following cmdlets:

- New-CsNetworkBandwidthPolicyProfile
- Get-CsNetworkBandwidthPolicyProfile
- Set-CsNetworkBandwidthPolicyProfile
- Remove-CsNetworkBandwidthPolicyProfile

The example policies created in the following procedure set limits for overall audio traffic, individual audio sessions, overall video traffic, and individual video sessions. For example, the 5Mb_Link bandwidth policy profile sets the following limits:

- Audio Limit: 2,000 kbps
- Audio Session Limit: 200 kbps
- Video Limit: 1,400 kbps
- Video Session Limit: 700 kbps

Note:

The minimum Audio Session Limit value is 40 kbps. The minimum Video Session Limit value is 100 kbps.

To create bandwidth policy profiles by using Management Shell

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. For each bandwidth policy profile that you want to create, run the New-CsNetworkBandwidthPolicyProfile cmdlet. For example, run:

```
New-CsNetworkBandwidthPolicyProfile -Identity 5Mb_Link -Description "B
```

```
New-CsNetworkBandwidthPolicyProfile -Identity 10Mb_Link -Description "
```

```
New-CsNetworkBandwidthPolicyProfile -Identity 50Mb_Link -Description "
```

```
New-CsNetworkBandwidthPolicyProfile -Identity 25Mb_Link -Description "
```

To create bandwidth policy profiles by using Lync Server Control Panel

1. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
2. In the left navigation bar, click **Network Configuration**.
3. Click the **Policy Profile** navigation button.
4. Click **New**.
5. On the **New Policy Profile** page, click **Name** and then type a name for the bandwidth policy profile.
6. Click **Audio limit**, and then type in the maximum number of kbps to allow for all audio sessions combined.
7. Click **Audio session limit**, and then type in the maximum number of kbps to allow for each individual audio session.
8. Click **Video limit**, and then type in the maximum number of kbps to allow for all video sessions combined.
9. Click **Video session limit**, and then type in the maximum number of kbps to allow for each individual video session.
10. Optionally, click **Description**, and then type additional information to describe this bandwidth policy profile.
11. Click **Commit**.
12. To finish creating bandwidth policy profiles for your topology, repeat steps 4 through 11 with settings for other bandwidth policy profiles.

1.4.3.12.5.3 Configure Network Sites for CAC

Configure Network Sites for CAC

Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features > Configure Call Admission Control >

Topic Last Modified: *2012-09-05*

Important:

If you have already created network sites for E9-1-1 or media bypass, you can modify the existing network sites to apply a bandwidth policy profile by using the **Set-CsNetworkSite** cmdlet. For an example of how to modify a network site, see Create or Modify a Network Site.

Network sites are the offices or locations within each network region of call admission control (CAC), E9-1-1, and media bypass deployments. Use the following procedures to create network sites that align to network sites in the example network topology for CAC. These procedures show how to create and configure network sites that are constrained by WAN bandwidth and therefore require bandwidth policies that limit real-time audio or video traffic flow.

In the example CAC deployment, the North America region has six sites. Three of these sites are constrained by WAN bandwidth: Reno, Portland, and Albuquerque. The other three sites, which are *not* constrained by WAN bandwidth: New York, Chicago, and Detroit. For an example of how to create or modify those other network sites, see Create or Modify a Network Site.

To view the example network topology, see Example: Gathering Your Organization's Requirements for Call Admission Control in the Planning documentation.

Note:
In the following procedure, Lync Server Management Shell is used to create a network site. For details about using Lync Server Control Panel to create a network site, see Create or Modify a Network Site.

To create network sites for call admission control

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the **New-CsNetworkSite** cmdlet to create network sites and apply an appropriate bandwidth policy profile to each site. For example, run:

   ```
   New-CsNetworkSite -NetworkSiteID Reno -Description "NA:Branch office f
   ```

   ```
   New-CsNetworkSite -NetworkSiteID Portland -Description "NA:Branch offi
   ```

   ```
   New-CsNetworkSite -NetworkSiteID Albuquerque -Description "NA:Branch o
   ```

3. To finish creating network sites for the entire example topology, repeat step 2 for the bandwidth-constrained network sites in the EMEA and APAC regions.

1.4.3.12.5.4 Associate Subnets with Network Sites for CAC

Associate Subnets with Network Sites for CAC

Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features > Configure Call Admission Control >

Topic Last Modified: *2012-10-20*

Every subnet in your network must be associated with a specific network site. This is because subnet information is used to determine the network site on which an endpoint is located. When the locations of both parties in a session are known, call admission control (CAC) can determine if there is sufficient bandwidth to establish a call.

Call admission control does not have any special requirements for associating subnets with network sites. To create an association between the subnets and network sites in your topology, follow the procedures in Associate a Subnet with a Network Site. To view the network sites (and their respective subnets) in the example network topology for call admission control, see Example: Gathering Your Organization's Requirements for Call Admission Control in the Planning documentation.

1.4.3.12.5.5 Create Network Region Links

Create Network Region Links

Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features > Configure Call Admission Control >

Topic Last Modified: *2012-10-19*

Regions within a network are linked through physical WAN connectivity. A *network region link* creates a link between two regions configured for call admission control (CAC) and sets the bandwidth limitations on audio and video traffic between these regions.

For details about working with network region links, see the Lync Server Management Shell documentation for the following cmdlets:

- New-CsNetworkRegionLink
- Get-CsNetworkRegionLink
- Set-CsNetworkRegionLink
- Remove-CsNetworkRegionLink

The example topology has a link between the North America and APAC regions, and a link between the EMEA and APAC regions. Each of these region links is constrained by WAN bandwidth, as described in Region Link Bandwidth Information table in the Example: Gathering Your Organization's Requirements for Call Admission Control section of the Planning documentation.

To create network region links by using Lync Server Management Shell

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the New-CsNetworkRegionLink cmdlet to create the region links and apply appropriate bandwidth policy profiles. For example, run:

```
New-CsNetworkRegionLink -NetworkRegionLinkID NA-EMEA-LINK -NetworkRegi
```

```
New-CsNetworkRegionLink -NetworkRegionLinkID EMEA-APAC-LINK -NetworkRe
```

To create network region links by using Lync Server Control Panel

1. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
2. In the left navigation bar, click **Network Configuration**.
3. Click the **Region Link** navigation button.
4. Click **New**.
5. On the **New Region Link** page, click **Name** and then type a name for the network region link.
6. Click **Network Region #1**, and then click the network region in the list that you want to link to Network Region #2.
7. Click **Network Region #2**, and then click a network region in the list that you want to link to Network Region #1.
8. Optionally, click **Bandwidth policy**, and then select the bandwidth policy profile that you want to apply to the network region link.

> **Note:**
> Apply a bandwidth policy only if the network region link is bandwidth-constrained and you want to use CAC to control media traffic on that link.

9. Click **Commit**.
10. To finish creating network region links for your topology, repeat steps 4 through 9 with settings for other regions.

1.4.3.12.5.6 Create Network Interregion Routes

Create Network Interregion Routes

Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features > Configure Call Admission Control >

Topic Last Modified: *2012-10-20*

A *network interregion route* defines the route between a pair of network regions. Each pair of network regions in your call admission control deployment requires a network interregion route. This enables every network region within the deployment to access every other region.

While region links set bandwidth limitations on the connections between regions, an interregion route determines which linked path the connection will traverse from one region to another.

For details about working with network interregion routes, see the Lync Server Management Shell documentation for the following cmdlets:

- New-CsNetworkInterRegionRoute
- Get-CsNetworkInterRegionRoute
- Set-CsNetworkInterRegionRoute
- Remove-CsNetworkInterRegionRoute

In the example topology, network interregion routes must be defined for each of the three region pairs: North America/EMEA, EMEA/APAC, and North America/APAC.

⊟To create network interregion routes by using Lync Server Management Shell

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the **New-CsNetworkInterRegionRoute** cmdlet to define the required routes. For example, run:

```
New-CsNetworkInterRegionRoute -Identity NorthAmerica_EMEA_Route -Netwo
```

```
New-CsNetworkInterRegionRoute -Identity NorthAmerica_APAC_Route -Netwo
```

```
New-CsNetworkInterRegionRoute -Identity EMEA_APAC_Route -NetworkRegion
```

Note:

The North America/APAC network interregion route requires two network region links because there is no direct network region link between them.

⊟To create network interregion routes by using Lync Server Control Panel

1. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
2. In the left navigation bar, click **Network Configuration**.
3. Click the **Region Route** navigation button.
4. Click **New**.
5. On the **New Region Route** page, click **Name** and then type a name for the network interregion route.
6. Click **Network Region #1**, and then click a network region in the list that you want to route to Network Region #2.
7. Click **Network Region #2**, and then click a network region in the list that you want to route to Network Region #1.
8. Click **Add** beside the **Network Region Links** field, and then add a network region link that will be used in the network interregion route.

Note:

If you are creating a route for two network regions that do not have a direct network region link between them, you must add all the necessary links to complete the route. For example, the North America/APAC network interregion route requires two network region links because there is no direct network region link between them.

9. Click **Commit**.
10. To finish creating network interregion routes for your topology, repeat steps

4 through 9 with settings for other network interregion routes.

1.4.3.12.5.7 Create Network Intersite Policies

Create Network Intersite Policies

Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features > Configure Call Admission Control >

Topic Last Modified: *2012-10-19*

A *network intersite policy* defines bandwidth limitations between sites that have direct WAN links between them.

For details, see the Lync Server Management Shell documentation for the following cmdlets:

- New-CsNetworkInterSitePolicy
- Get-CsNetworkInterSitePolicy
- Set-CsNetworkInterSitePolicy
- Remove-CsNetworkInterSitePolicy

Important:

A network intersite policy is required *only* if there is a direct cross link between two network sites.

In the example topology North America region, there is a direct link between the Reno and Albuquerque sites. These two sites require an intersite policy that applies an appropriate bandwidth policy profile. The following example applies the 20Mb_Link profile.

To create a network intersite policy

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the New-CsNetworkInterSitePolicy cmdlet to create network intersite policies and apply an appropriate bandwidth policy profile for two sites that have a direct cross link. For example, run:

```
New-CsNetworkInterSitePolicy -InterNetworkSitePolicyID Reno_Albuquerqu
```

3. Repeat step 2 as needed to create network intersite policies for all network sites pairs that have a direct cross link.

1.4.3.12.5.8 Enable Call Admission Control

Enable Call Admission Control

Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features > Configure Call Admission Control >

Topic Last Modified: *2012-10-19*

After you have configured your network settings for call admission control deployment, you must enable CAC to put your bandwidth policies into effect.

For details, see the Lync Server Management Shell documentation for the following cmdlets:

- Get-CsNetworkConfiguration
- Set-CsNetworkConfiguration
- Remove-CsNetworkConfiguration

To enable call admission control by using Management Shell

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the Set-CsNetworkConfiguration cmdlet to enable CAC in your network. For example, run:

   ```
   Set-CsNetworkConfiguration -EnableBandwidthPolicyCheck 1
   ```

   If you want to disable CAC in your network, run the following:

   ```
   Set-CsNetworkConfiguration -EnableBandwidthPolicyCheck 0
   ```

To enable call admission control by using Lync Server Control Panel

1. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
2. In the left navigation bar, click **Network Configuration**.
3. Click the **Global** navigation button.
4. Click **Global** in the list, and then select **Show Details** on the **Edit** menu.
5. On the **Edit Global Settings** page, select the **Enable call admission control** check box.

   Note:
   If you want to disable call admission control throughout your deployment, clear this check box.

6. Click **Commit**.

1.4.3.12.5.9 Call Admission Control Deployment Checklist

Call Admission Control Deployment Checklist

Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features > Configure Call Admission Control >

Topic Last Modified: *2012-10-22*

Use the following checklist to verify that you have completed all the necessary configuration tasks to deploy call admission control (CAC).

- If one or more Edge Servers are deployed, each external interface IP address must be added to the subnet list in the network configuration settings, with a bit mask of 32. You should also associate this subnet (IP address) with the network site ID for the geographic location where the A/V Edge service is deployed.

  Note:
  Edge servers are not required to implement CAC.

- Make sure that CAC is enabled, either through Lync Server Control Panel or by running the cmdlet as specified in Enable Call Admission Control.
- Make sure that CAC is enabled in all central sites. This can be done through the Topology Builder. If a warning is generated when you publish, *do not* ignore it.
- Make sure that all the subnets that are managed in the enterprise network are configured in the network configuration settings. It is also essential that every subnet be associated to a network site, as explained in Associate a Subnet with a Network Site.

- Make sure that the subnet or IP addresses of all Front End Servers, Survivable Branch Appliances (SBAs), Audio/Video Conferencing Servers (if in a separate pool), and Mediation Servers are configured in the network configuration settings.

1.4.3.12.6 Configure Enhanced 9-1-1

Configure Enhanced 9-1-1

Deployment > Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features >

Topic Last Modified: *2013-02-24*

Enhanced 9-1-1 (E9-1-1) is an emergency notification feature that associates the calling party's telephone number with a civic or a street address. Using this information, the Public Safety Answering Point (PSAP) can immediately dispatch emergency services to the caller in distress.

To support E9-1-1, Lync Server 2013 must be able to correctly associate a location with a client and to make sure that this information is used to route the emergency call to the nearest PSAP.

For details about planning for an E9-1-1 deployment, see Planning for Emergency Services (E9-1-1).

◆Important:

Lync Server 2013 only supports E9-1-1 within the United States. To deploy E9-1-1, you need to configure a SIP connection to a qualified E9-1-1 service provider, or deploy an emergency location identification number (ELIN) gateway to a public switched telephone (PSTN)-based E9-1-1 service provider. For details, see Enhanced 9-1-1 (E9-1-1) and Mediation Server. For details about configuring trunk connections, see Configure a Trunk with Media Bypass.

- Configure an E9-1-1 Voice Route
- Create Location Policies
- Configure Site Information for E9-1-1
- Configure the Location Database
- Configure Advanced E9-1-1 Features

1.4.3.12.6.1 Configure an E9-1-1 Voice Route

Configure an E9-1-1 Voice Route

Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features > Configure Enhanced 9-1-1 >

Topic Last Modified: *2012-09-17*

To deploy E9-1-1, you first need to configure an emergency call voice route. For details about creating voice routes, see Create a Voice Route. You may define more than one route if, for example, your deployment includes a primary SIP trunk and a secondary SIP trunk.

Note:

To include location information in an E9-1-1 INVITE, you need to configure the SIP trunk that connects to the E9-1-1 service provider to route emergency calls through the gateway. To do this, set the EnablePIDFLOSupport flag on the **Set-CsTrunkConfiguration** cmdlet to True. The default value for EnablePIDFLOSupport is False. For example: `Set-CsTrunkConfiguration`

```
Service:PstnGateway:192.168.0.241 -EnablePIDFLOSupport $true.
```

It is not necessary to enable receiving locations for fallback public switched telephone network (PSTN) gateways and Emergency Location Identification Number (ELIN) gateways.

For details about working with voice routes, see the Lync Server Management Shell documentation for the following cmdlets:

- **Set-CsPstnUsage**
- **Get-CsPstnUsage**
- **New-CsVoiceRoute**
- **Get-CsVoiceRoute**
- **Set-CsVoiceRoute**
- **Remove-CsVoiceRoute**

To configure an E9-1-1 voice route

1. Log on to the computer with an account that is a member of the RTCUniversalServerAdmins groups, or a member of the CsVoiceAdministrator administrative role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run the following cmdlet to create a new PSTN usage record.

   This must be the same name that you will use for the **PSTN** setting in the location policy. Although your deployment will have multiple phone usage records, the following example adds "Emergency Usage" to the current list of available PSTN usages. For details, see Configuring Voice Policies and PSTN Usage Records to Authorize Calling Features and Privileges.

   ```
   Set-CsPstnUsage -Usage @{add='EmergencyUsage'}
   ```

4. Run the following cmdlet to create a new voice route by using the PSTN usage record that you created in the previous step.

   The number pattern must be the same number pattern that is used in the **Emergency Dial String** setting in the location policy. A "+" sign is needed because Lync adds "+" to emergency calls. "Co1-pstngateway-1" is the SIP trunk service ID for the E9-1-1 service provider or for the ELIN gateway service ID. The following example uses "EmergencyRoute" as the name of the voice route.

   ```
   New-CsVoiceRoute -Name "EmergencyRoute" -NumberPattern "^\+911$" -Pstn
   ```

5. Optionally, for SIP trunk connections, we recommend that you run the following cmdlet to create a local route for calls that are not handled by the E9-1-1 service provider's SIP trunk. This route will be used if the connection to the E9-1-1 service provider is not available.

   The following example assumes that user has "Local" usage in their voice policy.

   ```
   New-CsVoiceRoute -Name "LocalEmergencyRoute" -NumberPattern "^\+911$"
   ```

1.4.3.12.6.2 Create Location Policies

Create Location Policies

Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features > Configure Enhanced 9-1-1 >

Topic Last Modified: *2012-09-11*

Lync Server uses a location policy to enable Lync clients for E9-1-1 during client registration. A location policy contains the settings that define how E9-1-1 will be implemented.

You can edit the global location policy and create new tagged location policies. A client obtains a global policy when it is not located within a subnet with an associated location policy, or when the client has not been directly assigned a location policy. Tagged policies are assigned to subnets or users.

To create a location policy, you must use an account that is a member of the RTCUniversalServerAdmins group, or is a member of the CsVoiceAdministrator administrative role, or has equivalent administrator rights and permissions.

For a complete description of Location policies, see Defining the Location Policy. Cmdlets in this procedure use a location policy defined using the following values:

Element	Value
EnhancedEmergencyServicesEnabled	**True**
LocationRequired	**Disclaimer**
EnhancedEmergencyServiceDisclaimer	Your company policy requires you to set a location. If you do not set a location, emergency services will not be able to locate you in an emergency. Please set a location.
UseLocationForE911Only	**False**
PstnUsage	**EmergencyUsage**
EmergencyDialString	**911**
EmergencyDialMask	**112**
NotificationUri	**sip:security@litwareinc.com**
ConferenceUri	**sip:+14255550123@litwareinc.com**
ConferenceMode	**twoway**
LocationRefreshInterval	**2**

For details about working with location policies, see the Lync Server Management Shell documentation for the following cmdlets:

- New-CsLocationPolicy
- Get-CsLocationPolicy
- Set-CsLocationPolicy
- Remove-CsLocationPolicy
- Grant-CsLocationPolicy

To create location policies

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.

Note:
CsLocationPolicy will fail if the setting for **PstnUsage** is not already in the Global list of PstnUsages.

2. Optionally, run the following cmdlet to edit the global Location Policy:

   ```
   Set-CsLocationPolicy -Identity Global -EnhancedEmergencyServicesEnable
   ```

3. Run the following to create a tagged Location Policy.

   ```
   New-CsLocationPolicy -Identity Tag:Redmond - EnhancedEmergencyServices
   ```

4. Run the following cmdlet to apply the tagged Location Policy created in step 3 to a user policy.

   ```
   (Get-CsUser | where { $_.Name -match "UserName" }) | Grant-CsLocationP
   ```

1.4.3.12.6.3 Configure Site Information for E9-1-1

Configure Site Information for E9-1-1

Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features > Configure Enhanced 9-1-1 >

Topic Last Modified: *2012-10-03*

To define a location policy for subnets, you must do the following, in any order:

- Apply a location policy to the network site.
- Add the subnets to the network site.

For details about network sites, see Sites.

Note:
If you create network sites for another voice feature and you want to configure E9-1-1 by using the same sites, then you can modify the sites to be used for E9-1-1.

- Add a Location Policy to a Network Site
- Associate a Subnet with a Network Site

Add a Location Policy to a Network Site

Deploying Advanced Enterprise Voice Features > Configure Enhanced 9-1-1 > Configure Site Information for E9-1-1 >

Topic Last Modified: *2013-02-24*

The following examples show how to add the **Redmond** location policy defined in Create Location Policies to an existing network site and how to create a new network site that uses the **Redmond** location policy.

For details about working with network sites, see the Lync Server Management Shell documentation for the following cmdlets:

- **New-CsNetworkSite**
- **Get-CsNetworkSite**
- **Set-CsNetworkSite**
- **Remove-CsNetworkSite**

To assign a location policy to an existing network site

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the following cmdlets to modify an existing network site.

   Assign the **Redmond** tagged Location policy to an existing network site named **Redmond**.

   ```
   Set-CsNetworkSite -Identity "Redmond" -NetworkRegionID "NorthAmerica"
   ```

To assign a location policy to a new network site

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the following cmdlet to create a new network site.

   Create a new network site in the network region and assign the **Redmond** tagged Location policy.

   ```
   New-CsNetworkSite -Identity "Redmond" -NetworkRegionID "NorthAmerica"
   ```

Associate Subnets with Network Sites for E9-1-1

Deploying Advanced Enterprise Voice Features > Configure Enhanced 9-1-1 > Configure Site Information for E9-1-1 >

Topic Last Modified: *2012-10-02*

Every subnet in your network that you want to enable for E9-1-1 must be associated with a specific network site. This is because subnet information is used to determine the network site on which an endpoint is located.

E9-1-1 does not have any special requirements for associating subnets with network sites. To create an association between the subnets and network sites in your topology, follow the procedures in Associate a Subnet with a Network Site.

1.4.3.12.6.4 Configure the Location Database

Configure the Location Database

Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features > Configure Enhanced 9-1-1 >

Topic Last Modified: *2012-09-17*

To enable clients to automatically detect their location within a network, you first need to configure the location database. If you do not configure a location database, and **Location Required** in the location policy is set to **Yes** or **Disclaimer**, the user will be prompted to manually enter a location.

To configure the location database, you will perform the following tasks:

1. Populate the database with a mapping of network elements to locations. If you use an Emergency Location Identification Number (ELIN) gateway, you need to include the ELIN in the <CompanyName> field.
2. Validate the addresses against the master street address guide (MSAG) that is maintained by the E9-1-1 service provider.
3. Publish the updated database.

> **Note:**
>
> Alternately, you can define a secondary location source database that can be used in placed of the location database. For details, see Configure a Secondary Location Information Service.

- Populate the Location Database
- Validate Addresses
- Publish the Location Database

Populate the Location Database

Deploying Advanced Enterprise Voice Features > Configure Enhanced 9-1-1 > Configure the Location Database >

Topic Last Modified: *2012-09-17*

To automatically locate clients within a network, you first need to populate the location database with a network *wiremap*, which maps network elements to civic (that is, street) addresses. You can use subnets, wireless access points, switches, and ports to define the wiremap.

You can add addresses to the location database individually, or in bulk by using a CSV file that contains the column formats described in the following table.

If you use an Emergency Location Identification Number (ELIN) gateway, include the ELIN in the **CompanyName** field for each location. You can include multiple ELINs for each location, each separated by a semicolon.

Network Element	Required Columns
Wireless access point	<BSSID>,<Description>,<Location>,<CompanyName>,<HouseNumber>,<HouseNumberSuffix>,<PreDirectional>,… …<StreetName>,<StreetSuffix>,<PostDirectional>,<City>,<State>,<PostalCode>,<Country>
Subnet	<Subnet>,<Description>,<Location>,<CompanyName>,<HouseNumber>,<HouseNumberSuffix>,<PreDirectional>,… …<StreetName>,<StreetSuffix>,<PostDirectional>,<City>,<State>,<PostalCode>,<Country>
Port	<ChassisID>,<PortIDSubType>,<PortID>,<Description>,<Location>,<CompanyName>,<HouseNumber>,<HouseNumberSuffix>,… …<PreDirectional>,<StreetName>,<StreetSuffix>,<PostDirectional>,<City>,<State>,<PostalCode>,<Country>
Switch	<ChassisID>,<Description>,<Location>,<CompanyName>,<HouseNumber>,<HouseNumberSuffix>,<PreDirectional>,… …<StreetName>,<StreetSuffix>,<PostDirectional>,<City>,<State>,<PostalCode>,<Country>

If you do not populate the location database, and the **Location Required** in the Location Policy is set to **Yes** or **Disclaimer**, the client will prompt the user to enter a location manually.

For details about populating the location database, see the Lync Server Management Shell documentation for the following cmdlets:

- **Get-CsLisSubnet**
- **Set-CsLisSubnet**
- Remove-CsLisSubnet
- **Get-CsLisWirelessAccessPoint**
- **Set-CsLisWirelessAccessPoint**
- **Remove-CsLisWirelessAccessPoint**
- **Get-CsLisSwitch**
- **Set-CsLisSwitch**
- **Remove-CsLisSwitch**
- **Get-CsLisPort**
- **Set-CsLisPort**
- **Remove-CsLisPort**

To add network elements to the location database

1. Run the following cmdlet to add a subnet location to the location database.

   ```
   Set-CsLisSubnet -Subnet 157.56.66.0 -Description "Subnet 1" -Location
   ```

   For ELIN gateways, put the ELIN in the CompanyName field. You can include more than one ELIN. For example:

   ```
   Set-CsLisSubnet -Subnet 157.56.66.0 -Description "Subnet 1" -Location
   ```

   Alternately, you can run the following cmdlets and use a file named "subnets.csv" to bulk update subnet locations.

   ```
   $g = Import-Csv subnets.csv
   $g | Set-CsLisSubnet
   ```

2. Run the following cmdlet to add wireless locations to the location database.

   ```
   Set-CsLisWirelessAccessPoint -BSSID 0A-23-CD-16-AA-2E -Description "Wi
   ```

   Alternately, you can run the following cmdlets and use a file named "waps.csv" to bulk update wireless locations.

   ```
   $g = Import-Csv waps.csv
   $g | Set-CsLisWirelessAccessPoint
   ```

3. Run the following cmdlet to add switch locations to the location database.

   ```
   Set-CsLisSwitch-ChassisID 0B-23-CD-16-AA-BB -Description "Switch1" -Lo
   ```

   Alternately, you can run the following cmdlets and use a file named "switches.csv" to bulk update switch locations.

   ```
   $g = Import-Csv switches.csv
   $g | Set-CsLisSwitch
   ```

4. Run the following cmdlet to add port locations to the location database

   ```
   Set-CsLisPort -ChassisID 0C-23-CD-16-AA-CC -PortID 0A-abcd -Descriptio
   ```

   The default for PortIDSubType is LocallyAssigned. You can also set it to InterfaceAlias or InterfaceName

   Alternately, you can run the following cmdlets and use a file named "ports.csv" to bulk update port locations.

   ```
   $g = Import-Csv ports.csv

   $g | Set-CsLisPort
   ```

Validate Addresses

Deploying Advanced Enterprise Voice Features > Configure Enhanced 9-1-1 > Configure the Location Database >

Topic Last Modified: *2012-09-17*

Before publishing the location database, you must validate new locations against the Master Street Address Guide (MSAG) that is maintained by your SIP trunk or public switched telephone network (PSTN) E9-1-1 service provider.

For details about SIP trunk E9-1-1 service providers, see Choosing an E9-1-1 Service Provider.

For details about validating addresses, see the Lync Server Management Shell documentation for the following cmdlets:

- **Get-CsLisServiceProvider**
- **Set-CsLisServiceProvider**
- **Remove-CsLisServiceProvider**
- **Get-CsLisCivicAddress**
- **Test-CsLisCivicAddress**

To validate addresses located in the location database

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the following cmdlets to configure the emergency service provider connection.

```
$pwd = Read-Host -AsSecureString <password>
Set-CsLisServiceProvider -ServiceProviderName Provider1 -ValidationSer
```

3. Run the following cmdlet to validate the addresses in the location database.

```
Get-CsLisCivicAddress | Test-CsLisCivicAddress -UpdateValidationStatus
```

You can also use the **Test-CsLisCivicAddress** cmdlet to validate individual addresses.

Publish the Location Database

Deploying Advanced Enterprise Voice Features > Configure Enhanced 9-1-1 > Configure the Location Database >

Topic Last Modified: *2012-10-30*

The new locations that you added to the location database will not be made available to the client until they have been published.

For details, see the Lync Server Management Shell documentation for the following cmdlet:

- **Publish-CsLisConfiguration**

If you use Emergency Location Identification Number (ELIN) gateways, you also need to upload the ELINs to your public switched telephone network (PSTN) carrier's Automatic Location Identification (ALI) database. Your PSTN carrier may require you to use a specific format for the ELIN records. Contact your PSTN carrier for details. You can export the records from the Location Information service database and format them as required.

To publish the location database

- Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
- Run the following cmdlet to publish the location database.

```
Publish-CsLisConfiguration
```

Configure Advanced E9-1-1 Features

Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features > Configure Enhanced 9-1-1 >

Topic Last Modified: *2012-06-06*

Lync Server 2013 includes the following features that you can use to customize your E9-1-1 deployment:

- A web service interface to connect the Location Information Server to an SNMP application.
- A web service interface to connect to a Secondary Location Source database.
- Configure an SNMP Application
- Configure a Secondary Location Information Service

Configure an SNMP Application

Deploying Advanced Enterprise Voice Features > Configure Enhanced 9-1-1 > Configure Advanced E9-1-1 Features >

Topic Last Modified: *2012-10-03*

Lync Server 2013 includes a standard web service interface that you can use to connect the Location Information service to Simple Network Management Protocol (SNMP) applications that match MAC addresses with port and switch information.

If an SNMP application is installed and the Location Information service fails to find a match in the location database, the Location Information service automatically queries the application by using the MAC address provided by the client. The Location Information service then uses the port and switch information returned by the SNMP application to query the location database again.

For details, see Set-CsWebServiceConfiguration.

Note:

MAC addresses are not available on computers running Windows 8.

⊟To configure the SNMP application URL

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the following cmdlet to configure the URL for the SNMP application.

```
Set-CsWebServiceConfiguration -MACResolverUrl "<SNMP application url>"
```

Configure a Secondary Location Information Service

Deploying Advanced Enterprise Voice Features > Configure Enhanced 9-1-1 > Configure Advanced E9-1-1 Features >

Topic Last Modified: *2012-10-30*

Lync Server 2013 provides a web service interface that you can use to point the Location Information service to a Secondary Location Source (SLS) database. The web service interface that connects to the SLS database must conform to Location Information service

WSDL. If both a location database and secondary location database are configured, the Location Information service first queries the location database, and if no match is found, sends the location request from the client to the SLS database. If the location exists in the SLS, the Location Information service then sends the location back to the client.

For details, see the Lync Server Management Shell documentation for the following cmdlet:

- **Set-CsWebServiceConfiguration**

To configure Secondary Location database

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the following cmdlet to configure the URL for the location of the secondary location database.

```
Set-CsWebServiceConfiguration -SecondaryLocationSourceURL "<web servic
```

1.4.3.12.7 Configure Media Bypass

Configure Media Bypass

See Also

Deployment > Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features >

Topic Last Modified: *2013-02-24*

This section assumes that you have already published and configured either at least one or more Mediation Servers (as described in Define a Mediation Server in Topology Builder and Publish the Topology, or in Define and Configure a Front End Pool or Standard Edition Server and Publish the Topology, respectively, all in the Deployment documentation).

This section also assumes that you have defined at least one gateway peer to provide PSTN connectivity, as described in Define a Gateway in Topology Builder. If the peer you connect to is the SBC of a SIP trunking provider, make sure that the provider is a qualified provider and that the provider supports media bypass. For example, many SIP trunking providers will only allow their SBC to receive traffic from the Mediation Server. If so, then bypass must not be enabled for the trunk in question. Also, you cannot enable media bypass unless your organization reveals its internal network IP addresses to the SIP trunking provider.

Note:

Media bypass will not interoperate with every PSTN gateway, IP-PBX, and SBC. Microsoft has tested a set of PSTN gateways and SBCs with certified partners and has done some testing with Cisco IP-PBXs. Media bypass is supported only with products and versions listed on Unified Communications Open Interoperability Program – Lync Server at http://go.microsoft.com/fwlink/p/?linkId=214406.

This section describes how to enable media bypass to reduce the processing required of the Mediation Server. Before you enable media bypass, make sure that your environment meets the conditions required to support media bypass, as described in Planning for Media Bypass in the Planning documentation. Also make sure that you used the information in Planning for Media Bypass to decide whether to enable media bypass global settings to always bypass the Mediation Server or to use site and region information when determining whether to bypass the Mediation Server.

If you have already optionally configured call admission control (CAC), another advanced Enterprise Voice feature, note that the bandwidth reservation performed by call admission control does not apply to any calls for which media bypass is employed. The verification of whether to employ media bypass is performed first, and if media bypass is employed, call admission control is not used for the call; only if the media bypass check fails is the check performed for call admission control. The two features are thus mutually exclusive for any particular call that is routed to the PSTN. This is the logic because media bypass assumes that bandwidth constraints do not exist between the media endpoints on a call; media bypass cannot be performed on links with restricted bandwidth. As a result, one of the following will apply to a PSTN call: a) media bypasses the Mediation Server, and call admission control does not reserve bandwidth for the call; or b) call admission control applies bandwidth reservation to the call, and media is processed by the Mediation Server involved in the call.

Next Steps: Enable Media Bypass on the Trunk Connection

After configuring initial settings for PSTN connectivity (dial plans, voice policies, PSTN usage records, outbound call routes, and translation rules), begin the process of enabling media bypass by using the steps in Configure a Trunk with Media Bypass.

Planning for Media Bypass

1.4.3.12.7.1 Configure a Trunk with Media Bypass

Configure a Trunk with Media Bypass

See Also

Deployment > Deploying Enterprise Voice > Configuring Trunks >

Topic Last Modified: *2013-02-24*

Follow these steps to configure a trunk with media bypass enabled. To configure a trunk with media bypass disabled, see Configure a Trunk without Media Bypass.

We strongly recommend that you enable media bypass. However, before you enable media bypass on a SIP trunk, confirm that your qualified SIP trunk provider supports media bypass and is able to accommodate the requirements for successfully enabling the scenario. Specifically, the provider must have the IP addresses of servers in your organization’s internal network. If the provider cannot support this scenario, media bypass will not succeed. For details, see Planning for Media Bypass in the Planning documentation.

> **Note:**
> Media bypass will not interoperate with every public switched telephone network (PSTN) gateway, IP-PBX, and Session Border Controller (SBC). Microsoft has tested a set of PSTN gateways and SBCs with certified partners and has done some testing with Cisco IP-PBXs. Media bypass is supported only with products and versions that are listed on

Unified Communications Open Interoperability Program – Lync Server at http://go.microsoft.com/fwlink/p/?linkId=214406.

A trunk configuration as described below groups a set of parameters that are applied to trunks assigned this trunk configuration. A particular trunk configuration can be scoped globally (to all trunks that do not have more specific site or pool configuration), or to a site, or to a pool. The pool-level trunk configuration is used to scope a specific trunk configuration to a single trunk.

⊟To configure a trunk with media bypass

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing**, and then click **Trunk Configuration**.
4. On the **Trunk Configuration** page, use one of the following methods to configure a trunk:
   - Double-click an existing trunk (for example, the **Global** trunk) to display the **Edit Trunk Configuration** dialog box.
   - Click **New**, and then select a scope for the new trunk configuration:
     - **Site trunk:** Choose the site for this trunk configuration from **Select a Site**, and then click **OK**. Note that if a trunk configuration has already been created for a site, the site does not appear in **Select a Site**. This trunk configuration will be applied to all trunks in the site.
     - **Pool trunk:** Choose the name of the trunk that this trunk configuration applies to. This trunk can be the root trunk or any additional trunks defined in Topology Builder. From **Select a Service**, click **OK**. Note that if a trunk configuration has already been created for a specific trunk, the trunk does not appear in **Select a Service**.

   Note:
   After you select the scope of the trunk configuration, it cannot be changed. The **Name** field is prepopulated with the name of the trunk configuration's associated site or service and cannot be changed.

5. Specify a value in **Maximum early dialogs supported**. This is the maximum number of forked responses a public switched telephone network (PSTN) gateway, IP-PBX, or ITSP Session Border Controller (SBC) can receive to an INVITE that it sent to the Mediation Server. The default value is 20.

   Note:
   Before you change this value, consult your service provider or equipment manufacturer for details about the capabilities of your system.

6. Select one of the following **Encryption support level** options:
   - **Required:** Secure real-time transport protocol (SRTP) encryption must be used to help protect traffic between the Mediation Server and the gateway or private branch exchange (PBX).
   - **Optional:** SRTP encryption will be used if the service provider or equipment manufacturer supports it.
   - **Not Supported:** SRTP encryption is not supported by the service provider or equipment manufacturer and therefore will not be used.
7. Select the **Enable media bypass** check box if you want media to bypass the Mediation Server for processing by the trunk peer.

   Important:
   For media bypass to work successfully, the PSTN gateway, IP-PBX, or ITSP

> Session Border Controller must support certain capabilities. For details, see Planning for Media Bypass in the Planning documentation.

8. Select the **Centralized media processing** check box if there is a well-known media termination point (for example, a PSTN gateway where the media termination has the same IP as the signaling termination). Clear this check box if the trunk does not have a well-known media termination point.
9. If the trunk peer supports receiving SIP REFER requests from the Mediation Server, select the **Enable sending refer to the gateway** check box.

> **Note:**
>
> If you disable this option while the **Enable media bypass** option is selected, additional settings are required. If the trunk peer does not support receiving SIP REFER requests from the Mediation Server and media bypass is enabled, you must also run the **Set-CsTrunkConfiguration** cmdlet to disable RTCP for active and held calls in order to support proper conditions for media bypass. For details, see the Lync Server Management Shell documentation. Alternatively, you can select **Enable refer using third-party-call control** if you want transferred calls to be media bypassed, and the gateway does not support SIP REFER requests.

10. (Optional) To enable inter-trunk routing, associate and configure PSTN usage records to this trunk configuration. The PSTN usages associated to this trunk configuration will be applied for all incoming calls through the trunk that is not originating from a Lync endpoint. To manage PSTN usage records associated to a trunk configuration, use one of the following methods:
    - To select one or more records from a list of all PSTN usage records available in your Enterprise Voice deployment, click **Select**. Highlight the records you want to associate with this trunk configuration and then click **OK**.
    - To remove a PSTN usage record from this trunk configuration, select the record and click **Remove**.
    - To define a new PSTN usage record and associate it with this trunk configuration, do the following:
        - Click **New**.
        - In the **Name** field, specify a descriptive name for the record that is unique.

        > **Note:**
        >
        > The PSTN usage record name must be unique within the Enterprise Voice deployment. After the record is saved, the **Name** field cannot be edited.

        - Use one of the following methods to associate and configure routes for this PSTN usage record:
            - To select one or more routes from the list of all available routes in your Enterprise Voice deployment, click **Select**. Highlight the routes you want to associate with this PSTN usage record, and click **OK**.
            - To remove a route from the PSTN usage record, select the route, and click **Remove**.
            - To define a new route and associate it to this PSTN usage record, click **New**. For details, see Create a Voice Route.
            - To edit a route that is associated with this PSTN usage record, select the route, and click **Show details**. For details, see Modify a Voice Route.
        - Click **OK**.
    - To edit a PSTN usage record that is already associated with this trunk configuration, do the following:
        - Select the PSTN usage record you want to edit, and click **Show details**.
        - Use one of the following methods to associate and configure routes for this PSTN usage record:
            - To select one or more routes from the list of all available routes in your Enterprise Voice deployment, click **Select**. Highlight the routes you want to associate with this PSTN usage record, and click **OK**.

  - To remove a route from the PSTN usage record, select the route, and click **Remove**.
  - To define a new route and associate it to this PSTN usage record, click **New**. For details, see Create a Voice Route.
  - To edit a route that is associated with this PSTN usage record, select the route, and click **Show details**. For details, see Modify a Voice Route.
- Click **OK**.

> **◆Important:**
> It important to associate PSTN usage records according to the Mediation Server peer that is associated to the trunk being configured. If the Mediation Server peer is a PSTN gateway or a Session Border Controller (SBC), it is strongly recommended that the trunk configuration is not associated to a PSTN usage record that routes to a PSTN destination or any other downstream systems connected via Lync Server.

11.Arrange the PSTN usage records for optimum performance. To change a record's position in the list, select the PSTN usage record, and click the up or down arrows.

> **◆Important:**
> The order in which PSTN usage records are listed in the trunk configuration is significant. Lync Server traverses the list from top to down.

12.**Enable RTP Latching** should be selected to enable bypass media for clients behind a network address translation (NAT) or firewall and an SBC that supports latching.

13.**Enable forward call history** should be selected to enable sending of call history information to the gateway peer of the Mediation Server.

14.**Enable forward P-Asserted-Identity data** should be selected to enable the P-Asserted-Identity (PAI) call originator information to be forwarded between the Mediation Server side and gateway side (and vice versa), when present.

15.**Enable outbound routing failover timer** should be selected to enable fast failover. The gateway associated with this trunk can give notification within 10 seconds that it is processing an outbound call. Rerouting to another trunk will occur if this notification is not received by the Mediation Server. On networks where latency may delay the response time or the gateway takes longer than 10 seconds to respond, the fast failover should be disabled.

16.(Optional) Associate and configure **calling number translation rules** for the trunk. These translation rules apply to the calling number for outbound calls

- To choose one or more rules from a list of all translation rules that are available in your Enterprise Voice deployment, click **Select**. In **Select Translation Rules**, click the rules that you want to associate with the trunk, and then click **OK**.
- To define a new translation rule and associate it with the trunk, click **New**. For details about defining a new rule, see Defining Translation Rules in the Deployment documentation.
- To edit a translation rule that is already associated with the trunk, click the rule name, and then click **Show details**. For details, see Defining Translation Rules in the Deployment documentation.
- To copy an existing translation rule to use as a starting point for defining a new rule, click the rule name and click **Copy**, and then click **Paste**. For details, see Defining Translation Rules.
- To remove a translation rule from the trunk, highlight the rule name and click **Remove**.

> **⚠Warning:**
> Do not associate translation rules with a trunk if you have configured translation rules on the associated trunk peer, because the two rules might conflict.

17.(Optional) Associate and configure **called number translation rules** for the trunk. The translation rules apply to the called number in an outbound call.

- To choose one or more rules from a list of all translation rules that are available in your Enterprise Voice deployment, click **Select**. In **Select Translation Rules**, click the rules that you want to associate with the trunk, and then click **OK**.
- To define a new translation rule and associate it with the trunk, click **New**. For details about defining a new rule, see Defining Translation Rules in the Deployment documentation.
- To edit a translation rule that is already associated with the trunk, click the rule name, and then click **Show details**. For details, see Defining Translation Rules in the Deployment documentation.
- To copy an existing translation rule to use as a starting point for defining a new rule, click the rule name and click **Copy**, and then click **Paste**. For details, see Defining Translation Rules.
- To remove a translation rule from the trunk, highlight the rule name and click **Remove**.

⚠**Warning:**

Do not associate translation rules with a trunk if you have configured translation rules on the associated trunk peer, because the two rules might conflict.

18.Make sure that the trunk’s translation rules are arranged in the correct order. To change a rule’s position in the list, highlight the rule name and then click the up or down arrow.

Important:

Lync Server 2013 traverses the translation rule list from the top down and uses the first rule that matches the dialed number. If you configure a trunk so that a dialed number can match more than one translation rule, be sure that the more restrictive rules are sorted above the less restrictive rules. For example, if you have included a translation rule that matches any 11-digit number and a translation rule that matches only 11-digit numbers that start with +1425, be sure that the rule that matches any 11-digit number is sorted *below* the more restrictive rule.

19.When you are finished configuring the trunk, click **OK**.

20.On the **Trunk Configuration** page, click **Commit**, and then click **Commit all**.

Note:

Whenever you create or modify a trunk configuration, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

After you have configured the trunk, continue configuring media bypass by choosing between global media bypass options, as described in Global Media Bypass Options in the Deployment documentation.

Lync Server 2013 Enterprise Voice routes calls based on phone numbers normalized to E.164 format. This means that all dialed strings must be normalized to E.164 format for the purpose of performing reverse number lookup (RNL) so they can be translated to their matching SIP URI. Lync Server 2013 provides the ability to manipulate the called ID and the caller ID presentation.

This section discusses how to manipulate the called ID and caller ID.

- Caller ID Presentation
- Called ID Presentation

Defining Normalization Rules

Create or Modify a Translation Rule by Using the Build a Translation Rule Tool

See Also

Configuring Trunks > Defining Translation Rules > Called ID Presentation >

Topic Last Modified: *2012-10-05*

Follow these steps if you want to define a translation rule by entering a set of values in the **Build a Translation Rule** tool and enabling Lync Server Control Panel to generate the corresponding matching pattern and translation rule for you. Alternatively, you can a write regular expression manually to define the matching pattern and translation rule. For details, see Create or Modify a Translation Rule Manually.

⊟To define a rule by using the Build a Translation Rule tool

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. To begin defining a translation rule, follow the steps in Configure a Trunk with Media Bypass through step 10 or Configure a Trunk without Media Bypass through step 9.
4. Under **Name** on the **New Translation Rule** or **Edit Translation Rule** page, type a name that describes the number pattern being translated.
5. (Optional) Under **Description**, type a description of the translation rule, for example **US International long-distance dialing**.
6. In the **Build a Translation Rule** section of the dialog box, enter values in the following fields:
   - **Starting digits**: (Optional) Specify the leading digits of numbers you want the pattern to match. For example, enter **+** in this field to match numbers in E.164 format (which begin with +).
   - **Length**: Specify the number of digits in the matching pattern and select whether you want the pattern to match numbers that are this length exactly, at least this length, or any length. For example, enter **11** and select **At least** in the drop-down list to match numbers that are at least 11 digits in length.
   - **Digits to remove**: (Optional) Specify the number of starting digits to be removed. For example, enter **1** to strip out the **+** from the beginning of the

number.

- **Digits to add**: (Optional) Specify digits to be prepended to the translated numbers. For example, enter **011** if you want 011 to be prepended to the translated numbers when the rule is applied.

The values you enter in these fields are reflected in the **Pattern to match** and **Translation rule** fields. For example, if you specify the preceding example values, the resulting regular expression in the **Pattern to match** field is:

^\+(\d{9}\d+)$

The **Translation rule** field specifies a pattern for the format of translated numbers. This pattern has two parts:

- A value (for example, **$1**) that represents the number of digits in the matching pattern
- (Optional) A value that you can prepend by entering it in the **Digits to add** field

Using the preceding example values, **011$1** appears in the **Translation rule** field.

When this translation rule is applied, +441235551010 becomes 011441235551010.

7. Click **OK** to save the translation rule.
8. Click **OK** to save the trunk configuration.
9. On the **Trunk Configuration** page, click **Commit**, and then click **Commit all**.

Note:

Whenever you create or modify a translation rule, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

Follow these steps if you want to define a translation rule by writing a regular expression for the matching pattern and translation rule. Alternatively, you can enter a set of values in the **Build a Translation Rule** tool and enable Lync Server Control Panel to generate the corresponding matching pattern and translation rule for you. For details, see Create or Modify a Translation Rule by Using the Build a Translation Rule Tool.

⊟To define a translation rule manually

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. To begin defining a translation rule, follow the steps in Configure a Trunk with

Media Bypass through step 10 or Configure a Trunk without Media Bypass through step 9.

4. In the **Name** field on the **New Translation Rule** or **Edit Translation Rule** page, type a name that describes the number pattern being translated.
5. (Optional) In **Description**, type a description of the translation rule, for example **US International long-distance dialing**.
6. Click **Edit** at the bottom of the **Build a Translation Rule** section.
7. Enter the following in **Type a Regular Expression**:
   - In **Match this pattern**, specify the pattern that will be used to match the numbers to be translated.
   - In **Translation rule**, specify a pattern for the format of translated numbers.

   For example, if you enter **^\+(\d{9}\d+)$** in **Match this pattern** and **011$1** in **Translation rule**, the rule will translate +441235551010 to 011441235551010.
8. Click **OK** to save the translation rule.
9. Click **OK** to save the trunk configuration.
10. On the **Trunk Configuration** page, click **Commit**, and then click **Commit all**.

> **Note:**
> Whenever you create or modify a translation rule, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

Global Media Bypass Options

1.4.3.12.7.2 Global Media Bypass Options

Global Media Bypass Options

See Also

Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features > Configure Media Bypass >

Topic Last Modified: *2012-10-04*

> **Note:**
> This topic assumes that you have already configured media bypass for any trunks to a peer (a public switched telephone network (PSTN) gateway, an IP-PBX, or a Session Border Controller (SBC) at an Internet Telephony Service Provider) for a specific site or service for which you want media to bypass the Mediation Server.

In addition to enabling media bypass for individual trunk connections associated with a peer, you must also enable media bypass globally. Global media bypass settings can either specify that media bypass is always attempted for calls to the PSTN, or that media bypass is employed by using the mapping of subnets to network sites and network regions—similar to what is done by call admission control, another advanced voice feature. When media bypass and call admission control are both enabled, then the network region, network site, and subnet information that is specified for call admission control is automatically used when determining whether to employ media bypass. This means that you cannot specify that media bypass is always attempted for calls to the PSTN when call admission control is enabled.

This topic describes how to use Lync Server Control Panel and Lync Server Management Shell together to configure global media bypass settings.

Note:

When you use these steps to configure media bypass, the assumption is that you have good connectivity between clients and the Mediation Server peer (for example, a PSTN gateway, an IP-PBX, or an SBC at a SIP trunking provider). If there are any bandwidth limitations on the link, media bypass cannot be applied to the call. Media bypass will not interoperate with every PSTN gateway, IP-PBX, and SBC. Microsoft has tested a set of PSTN gateways and SBCs with certified partners and has done some testing with Cisco IP-PBXs. Media bypass is supported only with products and versions listed on Unified Communications Open Interoperability Program – Lync Server at http://go.microsoft.com/fwlink/p/?linkId=214406.

Next Steps: Choose Global Media Bypass Settings

After you have enabled media bypass on any trunk connections to a peer for specific sites or services, use the following content to either:

- Enable media bypass always, as described in Configure Media Bypass to Always Bypass the Mediation Server.
- Or, configure media bypass to use site and region information, as described in Configure Media Bypass Global Settings to Use Site and Region Information.

Media Bypass and Mediation Server

Configure Media Bypass to Always Bypass the Mediation Server

See Also

Deploying Advanced Enterprise Voice Features > Configure Media Bypass > Global Media Bypass Options >

***Topic Last Modified:** 2013-02-25*

Note:

This topic assumes that you have already configured media bypass for any trunk connections to a peer (a public switched telephone network (PSTN) gateway, an IP-PBX, or a Session Border Controller (SBC) at an Internet Telephony Service Provider (ITSP)) for a specific site or service for which you want media to bypass the Mediation Server.
You cannot configure media to always bypass the Mediation Server while also enabling call admission control. These settings are incompatible and are therefore mutually exclusive settings in the Lync Server Control Panel user interface.

In addition to enabling media bypass for individual trunk connections associated with a peer to the Mediation Server, you must also configure global settings for media bypass. If you use the steps in this topic to configure global settings for media bypass, the assumption is that you have good connectivity between Lync endpoints and any peer for which you configured media bypass on the trunk connection.

If you do not have good connectivity between Lync Server endpoints and all peers to the Mediation Server whose respective trunk connections have been enabled for media bypass, you must configure global media bypass settings to use site and region information when employing media bypass. This allows for more control in determining when media bypasses the Mediation Server. To do this, use the steps in Configure Media Bypass Global Settings to Use Site and Region Information and Associate a Subnet with a Network Site instead.

⊟To Enable Media Bypass Globally to Always Bypass the Mediation Server

1. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
2. In the left navigation bar, click **Network Configuration**.
3. Double-click the **Global** configuration in the list.
4. On the **Edit Global Setting** page, select the **Enable media bypass** check box.
5. Click **Always bypass**.
6. Click **Commit**.

Planning for Media Bypass

Configure Media Bypass Global Settings to Use Site and Region Information

See Also

Deploying Advanced Enterprise Voice Features > Configure Media Bypass > Global Media Bypass Options >

Topic Last Modified: *2012-09-21*

Note:

This topic assumes that you have already configured media bypass for any trunk connections from the Mediation Server to a peer (a public switched telephone network (PSTN) gateway, an IP-PBX, or a Session Border Controller (SBC) at an Internet Telephony Service Provider (ITSP) for a specific site or service for which you want media to bypass the Mediation Server.
This topic also assumes that you have defined all central sites and branch sites in Topology Builder in a way that matches the network region, network site, and subnet configuration that you performed according to the steps in Create or Modify a Network Region, Create or Modify a Network Site, and Associate a Subnet with a Network Site. If they do not match, then media bypass will not succeed.

In addition to enabling media bypass for individual trunk connections associated with a peer, you must also configure global settings. If you use the steps in this topic to configure global settings for media bypass, the assumption is that one or both of the following situations affects your configuration:

- You *do not* have good connectivity between Lync Server endpoints and any peers for which you configured media bypass on the trunk connection.
- Call admission control (CAC) for bandwidth management is enabled.

Note:

For details about the considerations for both call admission control and media bypass, see the "Call Admission Control of PSTN Connections" section in

Media Bypass and Mediation Server in the Planning documentation.

Network region and network site information is shared between call admission control and media bypass advanced Enterprise Voice features when both are enabled. Therefore, if you have already configured call admission control, you are not required to use the following procedure to edit the site and region information specifically for media bypass. Follow the steps in this procedure if you have not yet configured network regions and sites for call admission control, and you want to change media bypass settings.

Or, follow these steps if you want to use site and region information in making the bypass decision, but have no intention of enabling call admission control. In such a case, bandwidth restricted links will still need to be represented through network intersite policies, as described in Create Network Intersite Policies. The actual bandwidth constraints are not as important in this case, because call admission control has not been enabled. Instead, these links are used to partition subnets to specify those that have no bandwidth limits and can, therefore, employ media bypass. Note that this is also true when call admission control and media bypass are both enabled.

Furthermore, for bypass to work properly there must be consistency between a site as defined in Topology Builder and as it is defined when you configure network regions and network sites. For example, if you have a branch site that you defined in Topology Builder as having only a PSTN gateway deployed, then that branch site must be configured with an Enterprise Voice policy that enables branch site users to have their PSTN calls routed through the PSTN gateway at the branch site.

⊟To Configure Site and Region Information for Media Bypass

1. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
2. In the left navigation bar, click **Network Configuration**.
3. Double-click the **Global** configuration in the table.
4. On the **Edit Global Setting** page, select the **Enable media bypass** check box.
5. Click **Use sites and region configuration**.
6. If necessary, select the **Enable bypass for non-mapped sites** check box.

   Note:

   Select this check box only if you have one or more large sites associated with the same region that do not have bandwidth constraints (for example, a large central site), but you also have some branch sites associated with the same region that do have bandwidth constraints. When you enable bypass for non-mapped sites, configuration is streamlined in that you specify only the subnets associated with the branch sites, rather than needing to specify all subnets associated with all sites. We recommend that you do not select this check box if call admission control is enabled.

7. Click **Commit**.

Next, add subnets to the network site, as described in Associate Subnets with Network Sites for Media Bypass. (The actual procedures for associating subnets with network sites are described in Associate a Subnet with a Network Site.) After you associate all subnets with network sites, media bypass deployment is complete.

Important:

If you have not already created network regions and network sites, you must first create those before you can proceed with media bypass deployment. For details, see Create or Modify a Network Region and Create or Modify a Network Site.

Concepts

Associate Subnets with Network Sites for Media Bypass

Associate Subnets with Network Sites for Media Bypass

Configure Media Bypass > Global Media Bypass Options > Configure Media Bypass Global Settings to Use Site and Region Information >

Topic Last Modified: *2012-09-12*

Note:

This topic assumes that you have configured media bypass global settings and that you have configured network region and network sites for media bypass.

Every subnet in your network must be associated with a specific network site. This is because subnet information is used to determine the network site on which an endpoint is located. When the locations of both parties in a session are known, media bypass can determine where to send media for processing.

Media bypass does not have any special requirements for associating subnets with network sites. To create an association between the subnets and network sites in your topology, follow the procedures in Associate a Subnet with a Network Site.

Next Steps: Create Bandwidth Policy Profiles

After you associate subnets with network sites for media bypass, you must create one or more bandwidth policy profiles that will partition subnets into those with good connectivity and those without, for the purposes of media bypass. All subnets within a network region with network sites that do not have bandwidth constraints have good connectivity, and, therefore, those subnets can use media bypass.

For procedures to configure bandwidth policy profiles, see Create Bandwidth Policy Profiles.

1.4.3.12.8 Configuring Location-Based Routing

Configuring Location-Based Routing

See Also

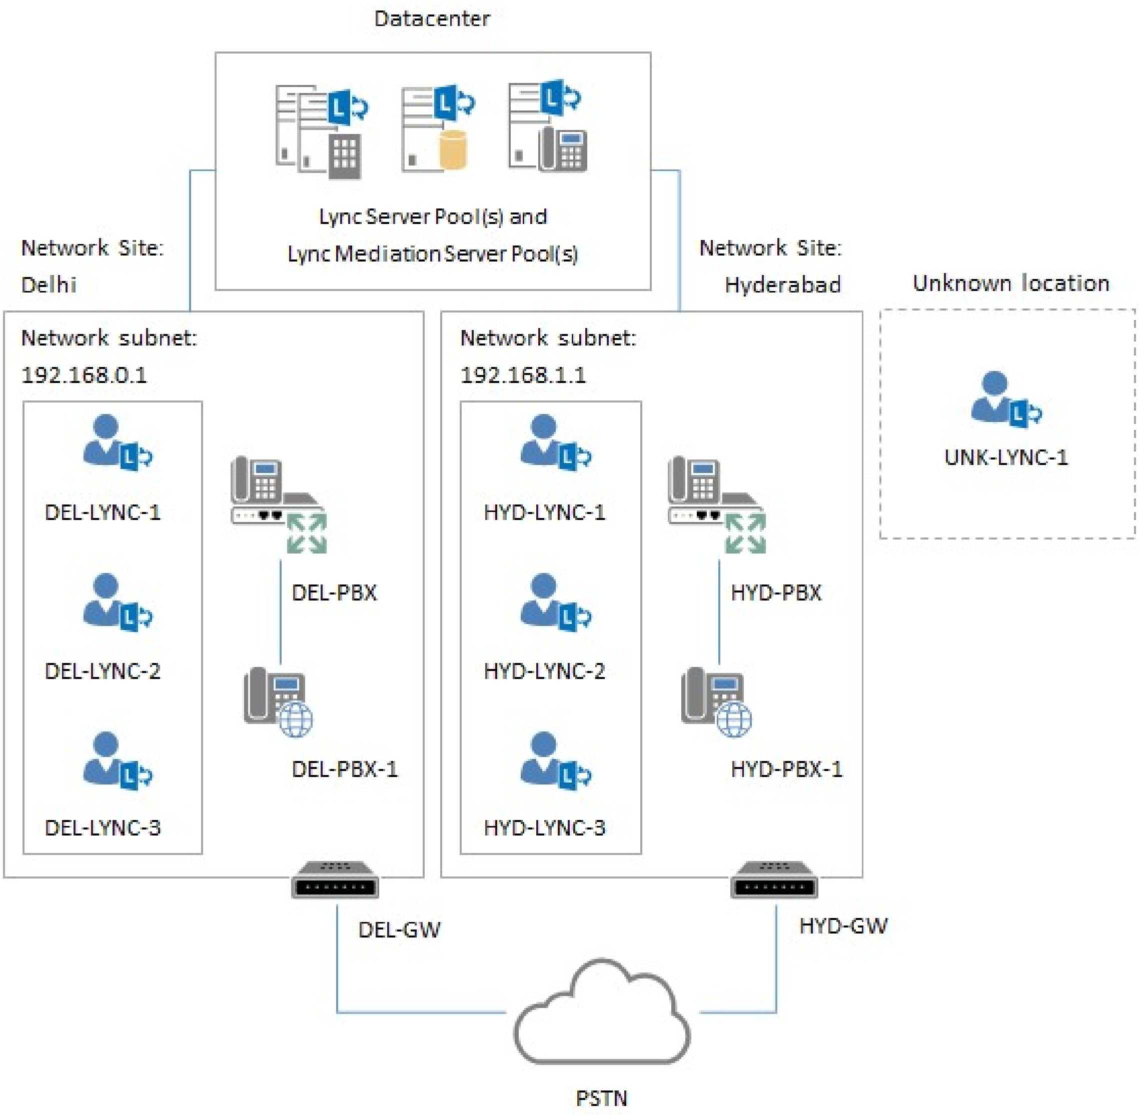
Deployment > Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features >

Topic Last Modified: *2013-03-12*

Lync Server 2013 CU1, Location-Based Routing is a feature of Enterprise Voice. Location-Based Routing is a call management feature that controls how calls are routed by Lync Server 2013 CU1. It enforces restrictions on whether calls can be routed to PBX or PSTN destinations based on the Lync caller's location. Location-Based Routing applies call authorization rules to PSTN calls based on the caller's network location. The caller's location is determined based on the network site associated with the network subnet the caller is connected on. Configuring Location-Based Routing requires first deploying Enterprise Voice, then configuring network regions, sites and subnets. This sets up the foundation for enabling Location-Based Routing.

Before deploying Location-Based Routing, you must first deploy Enterprise Voice, and configure network regions, sites, and associate network subnets to your network sites. Once completed, you can configure Location-Based Routing. For steps on how to configure network regions, sites and subnets, see Deploying Advanced Enterprise Voice Features

This section guides you through the configuration of Location-Based Routing using the following example as illustration.



The following table represents the users defined in this example.

Endpoint type	Location	Users
Lync	Delhi corporate office	DEL-LYNC-1,DEL-LYNC-2,DEL-LYNC-3
Lync	Hyderabad corporate office	HYD-LYNC-1, HYD-LYNC-2, HYD-LYNC-3
Lync	Unknown (i.e. hotel)	UNK-LYNC-1
PBX	Delhi corporate office	DEL-PBX-1, DEL-PBX-2
PBX	Hyderabad corporate office	HYD-PBX-1, HYD-PBX-2

PSTN	Unknown	PSTN-1, PSTN-2, PSTN-3

The following table represents the systems illustrated in this example environment.

System	Location	Name
Lync Server 2013 CU1 pool	any	LS-PL1
Lync Server 2013 CU1, Mediation Server	any	MS-PL1
PSTN gateway 1	Delhi	DEL-GW
PSTN gateway 2	Hyderabad	HYD-GW
PBX 1	Delhi	DEL-PBX
PBX 2	Hyderabad	RED-PBX

Configuring Enterprise Voice

See Also

Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features > Configuring Location-Based Routing >

Topic Last Modified: *2013-03-12*

To deploy Enterprise Voice, you'll need to configure the following:

- Create a Trunk
- Define a Voice Policy
- Define a Voice Route
- Enable Users for Enterprise Voice

Create a Trunk

You must define trunks in your Enterprise Voice deployment. For Location-Based Routing, you must create a trunk configuration per trunk. Use the Lync Server Topology Builder to define your trunks, and use the Lync Server Windows PowerShell command, New-CsTrunkConfiguration, or the Lync Server Control Panel to define the corresponding trunk configurations. More information on how to enable Location-Based Routing on trunk configurations can be found in the section, Enable Location-Based Routing to Trunks, in the topic, Enabling Location-Based Routing. For this example, the following table illustrates the trunks used in this scenario.

For more information, see Define additional Trunks in Topology Builder.

Trunk name	System type	Name	Location	Mediation Server

Trunk 1 DEL-GW	PSTN gateway	DEL-GW	Delhi	MS1
Trunk 2 HYD-GW	PSTN gateway	HYD-GW	Hyderabad	MS1
Trunk 3 DEL-PBX	PBX	DEL-PBX	Delhi	MS1
Trunk 4 HYD-PBX	PBX	HYD-PBX	Hyderabad	MS1

⊟

Defines Voice Policies

You must define voice policies for your Enterprise Voice deployment. Define a Voice Policy to enforce Location-Based Routing restrictions to a subset of users if only a subset of them is required to use Location-Based Routing. For this example, the following table illustrates the voice policies used in this scenario. Only settings that are specific to Location-Based Routing are included in the table for illustration purposes.

For more information, see Configuring Voice Policies and PSTN Usage Records to Authorize Calling Features and Privileges.

	Voice policy 1	**Voice policy 2**
Voice policy ID	Delhi voice policy	Hyderabad voice policy
PSTN usages	Delhi usage, PBX Del usage, PBX Hyd usage	Hyderabad usage, PBX Hyd usage, PBX Del usage
PreventPSTNTollBypass	False	False

⊟

Define Voice Routes

You must define voice routes for your Enterprise Voice deployment. For this example, the following table illustrates the voice routes used in this scenario. Only settings that are specific to Location-Based Routing are included in the table for illustration purposes.

For more information, see Configuring Voice Routes for Outbound Calls.

	Voice route 1	**Voice route 2**	**Voice route 3**	**Voice route 4**
Name	Delhi route	Hyderabad route	PBX Del route	PBX Hyd route
PSTN usages	Delhi usage	Hyderabad usage	PBX Del usage	PBX Hyd usage
Trunk	Trunk 1 DEL-GW	Trunk 2 HYD-GW	Trunk 3 DEL-PBX	Trunk 4 HYD-PBX

⊟

Enable Users for Enterprise Voice

Enable users for Enterprise Voice and assign them a voice policy you’ve previously defined. For this example, the following table illustrates the assignment used in this scenario. Only settings that are specific to Location-Based Routing are included in the table for illustration purposes.

For more information, see Enable Users for Enterprise Voice.

	Users located in Delhi	Users located in Hyderabad
Associated voice policy	Delhi voice policy	Hyderabad voice policy
Sample users	DEL-LYNC-1,DEL-LYNC-2,DEL-LYNC-3	HYD-LYNC-1, HYD-LYNC-2, HYD-LYNC-3

Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features > Configuring Location-Based Routing >

Topic Last Modified: *2013-03-12*

Once Enterprise Voice is deployed, you need to configure:

- Network regions
- Network sites
- Network subnets

Define Network Regions

Use the Lync Server Windows PowerShell command, New-CsNetworkRegion, or Lync Server Control Panel to define network regions.

```
New-CsNetworkRegion -NetworkRegionID <region ID> -CentralSite <site ID>
```

For more information, see New-CsNetworkRegion.

For this example, the following Windows PowerShell command illustrates the network region, region 1 (India), defined in this scenario.

```
New-CsNetworkRegion -NetworkRegionID "India" -CentralSite "India Central Site"
```

Define Network Sites

Use the Lync Server Windows PowerShell command, New-CsNetworkSite, or the Lync Server Control Panel to define network sites.

```
New-CsNetworkSite -NetworkSiteID <site ID> -NetworkRegionID <region ID>
```

For more information, see New-CsNetworkSite.

For this example, the following table and Lync Server Windows PowerShell command illustrate the network sites defined in this scenario. Only settings that are specific to Location-Based Routing are included in the table for illustration purposes.

```
New-CsNetworkSite -NetworkSiteID "Delhi" -NetworkRegionID "India"
```

```
New-CsNetworkSite -NetworkSiteID "Hyderabad" -NetworkRegionID "India"
```

	Site 1 (Delhi)	Site 2 (Hyderabad)
Site ID	Site 1 (Delhi)	Site 2 (Hyderabad)
Region ID	Region 1 (India)	Region 1 (India)

Define Network Subnets

Use the Lync Server Windows PowerShell command, New-CsNetworkSubnet, or the Lync Server Control Panel to define network subnets and assign them to network sites.

```
New-CsNetworkSubnet -SubnetID <Subnet IP address> -MaskBits <Subnet bitmask> -Net
```

For more information, see New-CsNetworkSubnet.

For this example, the following table and Windows PowerShell commands illustrate the assignment of network subnets to the network sites, Delhi and Hyderabad, defined in this scenario. Only settings that are specific to Location-Based Routing are included in the table for illustration purposes.

```
New-CsNetworkSubnet -SubnetID "192.168.0.0" -MaskBits "24" -NetworkSiteID "Delhi"
New-CsNetworkSubnet -SubnetID "192.168.1.0" -MaskBits "24" -NetworkSiteID "Hydera
```

	Site 1 (Delhi)	Site 2 (Hyderabad)
Subnet ID	192.168.0.0	192.168.1.0
Mask	24	24
Site ID	Site 1 (Delhi)	Site 2 (Hyderabad)

Configuring Location-Based Routing

1.4.3.12.8.3 Enabling Location-Based Routing

Enabling Location-Based Routing

See Also

Deploying Enterprise Voice > Deploying Advanced Enterprise Voice Features > Configuring Location-Based Routing >

Topic Last Modified: *2013-03-12*

Once Enterprise Voice is deployed and network regions, sites and subnets are defined, you can enable Location-Based Routing. Location-Based Routing must be enabled for the following Enterprise Voice elements:

- Network sites
- Trunk configurations
- Voice policies
- Routing configuration

Enable Location-Based Routing to Network Sites

After you have deployed Enterprise Voice, and configured network sites, you are ready to configure Location-Based Routing. First, you create a voice routing policy to associate the network site with the appropriate PSTN usages. When assigning PSTN usages to a voice routing policy, make sure to only use PSTN usages that are associated to voice routes that use a PSTN gateway local to the site or a PSTN gateway that is located in a region where Location-Based Routing restrictions are not needed.Use the Lync Server Windows PowerShell command, New-CsVoiceRoutingPolicy, or Lync Server Control Panel to create voice routing policies.

```
New-CsVoiceRoutingPolicy -Identity <voice routing policy ID> -Name <voice routing
```

For more information, see New-CsVoiceRoutingPolicy.

For this example, the following table and Windows PowerShell commands illustrate two voice routing policies and their associated PSTN usages defined in this scenario. Only settings that are specific to Location-Based Routing are included in the table for illustration purposes.

```
New-CsVoiceRoutingPolicy -Identity "DelhiVoiceRoutingPolicy" -Name "Delhi voice r
New-CsVoiceRoutingPolicy -Identity "HyderabadVoiceRoutingPolicy" -Name " Hyderaba
```

	Voice routing policy 1	**Voice routing policy 2**
Voice policy ID	Delhi voice routing policy	Hyderabad voice routing policy
PSTN usages	Delhi usage, PBX Del usage, PBX Hyd usage	Hyderabad usage, PBX Hyd usage, PBX Del usage

Next, configure Location-Based Routing for the applicable network sites and associate your voice routing policies to them. Use the Lync Server Windows PowerShell command, New-CsNetworkSite, to enable Location-Based Routing and associate voice routing policies to your network sites that must enforce routing restrictions.

```
Set-CsNetworkSite -Identity <site ID> -EnableLocationBasedRouting <$true|$false>
```

In this example, the following table illustrates Location-Based Routing for two different network sites, Delhi and Hyderabad, defined in this scenario using the Lync Server Windows PowerShell. Only settings that are specific to Location-Based Routing are included in the table for illustration purposes.

```
Set-CsNetworkSite -Identity "Delhi" -EnableLocationBasedRouting $true -VoiceRouti
Set-CsNetworkSite -Identity "Hyderabad" -EnableLocationBasedRouting $true -VoiceR
```

	Site 1 (Delhi)	**Site 2 (Hyderabad)**
Site Name	Site 1 (Delhi)	Site 2 (Hyderabad)
EnableLocationBasedRouting	True	True
Voice routing policy	Delhi voice routing policy	Hyderabad voice routing policy
Subnets	Subnet 1 (Delhi)	Subnet 2 (Hyderabad)

⊟

Enable Location-Based Routing to Trunks

Before a trunk configuration can be enabled for Location-Based Routing, you need to create a trunk configuration for each trunk or each network site. Use the Lync Server Windows PowerShell command, New-CsTrunkConfiguration, to create a trunk configuration. If multiple trunks are associated with a given system (i.e. Gateway or PBX), each trunk configuration must be modified to enable Location-Based Routing restrictions.

```
New-CsTrunkConfiguration -Identity < trunk configuration ID>
```

For more information, see New-CsTrunkConfiguration.

For this example, the following Windows PowerShell commands illustrate creating one trunk configuration for each trunk in the deployment defined in this scenario.

```
New-CsTrunkConfiguration -Identity Service:PstnGateway:"<Trunk 1 DEL-GW>"
New-CsTrunkConfiguration -Identity Service:PstnGateway:"<Trunk 2 HYD-GW>"
New-CsTrunkConfiguration -Identity Service:PstnGateway:"<Trunk 3 DEL-PBX>"
New-CsTrunkConfiguration -Identity Service:PstnGateway:"<Trunk 4 HYD-PBX>"
```

Once a trunk configuration is configured per trunk, you can use the the Lync Server Windows PowerShell command, Set-CsTrunkConfiguration, to enable Location-Based Routing to your trunks that must enforce routing restrictions. Enable Location-Based Routing to trunks that route calls to PSTN gateways that route calls to the PSTN, and associate the network site where the gateway is located.

```
Set-CsTrunkConfiguration -Identity <trunk configuration ID> -EnableLocationRestri
```

For more information, see New-CsTrunkConfiguration.

In this example, Location-Based Routing is enabled for each trunk that is associated to PSTN gateways in Delhi and Hyderabad:

```
Set-CsTrunkConfiguration -Identity Service:PstnGateway:Trunk 1 DEL-GW -EnableLoca
Set-CsTrunkConfiguration -Identity Service:PstnGateway:Trunk 2 HYD-GW -EnableLoca
```

Do not enable Location-Based Routing for trunks that do not route calls to the PSTN; however, you must still associate the trunk to the network site where the system is located as Location-Based Routing restrictions need to be enforced for PSTN calls reaching endpoints connected via this trunk. For this example, Location-Based Routing is not enabled for each trunk that is associated to PBX systems in Delhi and Hyderabad:

```
Set-CsTrunkConfiguration -Identity Service:PstnGateway:Trunk 3 DEL-PBX -EnableLoc
Set-CsTrunkConfiguration -Identity Service:PstnGateway:Trunk 4 HYD-PBX -EnableLoc
```

Endpoints that are connected to systems that do not route calls to the PSTN (i.e. a PBX) will have similar restrictions as Lync endpoints of users enabled for Location-Based Routing. This means that these users will be able to place and receive calls to and from Lync user regardless of the user's location. They will also be able to place an receive calls to and from other systems that do not route calls to the PSTN network (i.e. an endpoint connected to a different PBX) regardless of the network site to which the system is associated. All inbound calls, outbound calls, call transfers and call forwarding involving PSTN endpoints will be subject to Location-Based Routing enforcements. Such calls must use only PSTN gateways that are defined as local to such systems.

Name	EnableLocationRestriction	NetworkSiteID
PstnGateway:Trunk 1 DEL-	True	Site 1 (Delhi)

GW		
PstnGateway:Trunk 2 HYD-GW	True	Site 2 (Hyderabad)
PstnGateway:Trunk 3 DEL-PBX	False	Site 1 (Delhi)
PstnGateway:Trunk 4 HYD-PBX	False	Site 2 (Hyderabad)

Enable Location-Based Routing to Voice Policies

To enforce Location-Based Routing to specific users, configure those users' voice policy to prevent PSTN toll bypass. Use the Lync Server Windows PowerShell command, New-CsVoicePolicy, to create a new voice policy or Set-CsVoicePolicy, if using an existing policy, to enable Location-Based Routing by preventing PSTN toll bypass.

```
Set-CsVoicePolicy -Identity <voice policy ID> -PreventPSTNTollBypass <$true|$fals
```

For more information, see New-CsVoicePolicy.

For this example, the following table and Windows PowerShell commands illustrate enabling the prevention of PSTN toll bypass to the Delhi and Hyderabad voice policies defined in this scenario. Only settings that are specific to Location-Based Routing are included in the table for illustration purposes.

```
Set-CsVoicePolicy -Identity "Delhi voice policy" -PreventPSTNTollBypass $true
Set-CsVoicePolicy -Identity "Hyderabad voice policy" -PreventPSTNTollBypass $true
```

	Voice policy 1	**Voice policy 2**
Voice policy ID	Delhi voice policy	Hyderabad voice policy
PSTN usages	Delhi usage, PBX Del usage, PBX Hyd usage	Hyderabad usage, PBX Hyd usage, PBX Del usage
PreventPSTNTollBypass	True	True

Enable Location-Based Routing in the routing configuration

Finally, globally enable Location-Based Routing to your routing configuration. Use the Lync Server Windows PowerShell command, New-CsRoutingConfiguration, to enable Location-Based Routing.

```
Set-CsRoutingConfiguration -EnableLocationBasedRouting $true
```

For more information, see Set-CsRoutingConfiguration.

Note:

while Location-Based Routing must be enabled via a global configuration, the set of rules to be applied will only be enforced for the sites, users and trunks for which it has been configured as specified in this documentation.

1.4.3.13 Deploying Call Management Features

Deploying Call Management Features

Microsoft Lync Server 2013 > Deployment > Deploying Enterprise Voice >

Topic Last Modified: *2012-12-18*

Enterprise Voice call management features control how incoming calls are routed and answered. Lync Server 2013 provides the following call management features:

- **Call Park:** Enables voice users to temporarily park a call and then pick it up from the same phone or another phone.
- **Group Pickup:** Enables users to answer calls made to another user who is assigned to a pickup group by dialing the call pickup group number.
- **Response Group:** Routes incoming calls to groups of agents by using hunt groups or interactive voice response (IVR) questions and answers.
- **Announcement:** Plays a message for calls made to an unassigned number, or routes the call elsewhere, or both.

This section describes how to configure these call management features during an Enterprise Voice deployment.

- Configuring Call Park
- Configuring Group Call Pickup
- Configuring Response Group
- Configuring Announcements for Unassigned Numbers

1.4.3.13.1 Configuring Call Park

Configuring Call Park

Deployment > Deploying Enterprise Voice > Deploying Call Management Features >

Topic Last Modified: *2012-10-30*

Call Park enables an Enterprise Voice user to put a call on hold from one telephone and then retrieve the call later by dialing an internal number (known as a Call Park *orbit*) from any telephone.

The components that Call Park uses are automatically installed and enabled on the Front End Server or Standard Edition server when you deploy Enterprise Voice. However, you must configure Call Park before it is available to users.

This section guides you through the configuration of Call Park.

- Call Park Configuration Prerequisites and User Rights
- Deployment Process for Call Park
- Configure the Call Park Orbit Table
- Configure Call Park Settings
- Customize Call Park Music on Hold
- Enable Call Park for Users
- Verify Normalization Rules for Call Park

- (Optional) Verify Call Park Deployment

1.4.3.13.1.1 Call Park Configuration Prerequisites and User Rights

Call Park Configuration Prerequisites and User Rights

See Also

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Call Park >

Topic Last Modified: *2012-09-10*

Call Park is a call management feature that is installed by default when you deploy Enterprise Voice. This topic describes what you need to have in place before you can configure Call Park and the user rights that you need to perform configuration tasks.

◆**Important:**
Customized music-on-hold files for the Call Park application are not backed up as part of the Lync Server 2013 disaster recovery process, and the files will be lost if the files uploaded to the pool are damaged, corrupted, or erased. Always keep a separate backup copy of the customized music-on-hold files that you have uploaded for Call Park.

This section assumes that you have read the planning documentation related to Call Park (see Planning for Call Management Features).

Call Park Configuration Prerequisites

Call Park requires the following components:

- Application service
- Call Park application

These components are installed automatically when you deploy Enterprise Voice.

If you want callers to hear music while the call is parked, a music-on-hold file is also required. A default music-on-hold file is installed automatically when you deploy Enterprise Voice. You can substitute the default file with your own music-on-hold file. Call Park uses File Store to hold the audio file.

Call Park Configuration User Rights

You can use the following administrative tools to configure Call Park:

- Lync Server Control Panel
- Lync Server Management Shell

You use these tools to set up the Call Park orbit table and to configure other settings used by Call Park.

Configuring Call Park requires any of the following administrative roles, depending on the task:

- **CsVoiceAdministrator:** This administrator role can create, configure, and manage all voice-related settings and policies.
- **CsUserAdministrator:** This administrator role can enable Call Park in voice policy. This administrator role also has read-only view access to all voice configurations.
- **CsServerAdministrator:** This administrator role can manage, monitor, and troubleshoot servers and services.
- **CsAdministrator:** This administrator role can perform all of the tasks of

CsVoiceAdministrator, CsServerAdministrator, and CsUserAdministrator.

Note:

For details about administrative rights, see Planning for Role-Based Access Control in the Planning documentation.

1.4.3.13.1.2 Deployment Process for Call Park

Deployment Process for Call Park

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Call Park >

Topic Last Modified: *2013-02-25*

This section provides an overview of the steps involved in deploying the Call Park application. You must deploy Enterprise Edition or Standard Edition with Enterprise Voice before you configure Call Park. The components required by Call Park are installed and enabled when you deploy Enterprise Voice.

Call Park Deployment Process

Phase	Steps	Required groups and roles	Deployment documentation
Configure the call park orbit ranges in the orbit table	Use Lync Server Control Panel or the **New-CSCallParkOrbit** cmdlet to create the orbit ranges in the call park orbit table and associate them with the Application service that hosts the Call Park application. **Note:** For seamless integration with existing dial plans, orbit ranges are typically configured as a block of virtual extensions. Assigning Direct Inward Dialing (DID) numbers as orbit numbers in the call park orbit table is not supported.	RTCUniversalServerAdmins CsVoiceAdministrator CsServerAdministrator CsAdministrator	Create or Modify a Call Park Orbit Range
Configure Call Park settings	Use the **Set-CsCpsConfiguration** cmdlet to configure Call Park settings. At a minimum, we recommend that you configure the **OnTimeoutURI** option to configure the fallback destination to use when a parked call times out. You can also configure the following settings: - (Optional)	RTCUniversalServerAdmins CsVoiceAdministrator CsServerAdministrator CsAdministrator	Configure Call Park Settings

	EnableMusicOnHold to enable or disable music on hold. • (Optional) **MaxCallPickupAttempts** to determine the number of times a parked call rings back to the answering phone before forwarding the call to the fallback Uniform Resource Identifier (URI). • (Optional) **CallPickupTimeoutThreshold** to determine the amount of time that elapses after a call has been parked before it rings back to the phone where the call was answered.		
Optionally, customize the music on hold	Use the **Set-CsCallParkServiceMusicOnHoldFile** cmdlet to customize and upload an audio file, if you don't want to use the default music on hold.	RTCUniversalServerAdmins CsVoiceAdministrator CsServerAdministrator CsAdministrator	Customize Call Park Music on Hold
Configure voice policy to enable Call Park for users	Use Lync Server Control Panel or the **Set-CSVoicePolicy** cmdlet with the **EnableCallPark** option to enable Call Park for users in voice policy. **Note:** By default, Call Park is disabled for all users. **Note:** If you have multiple voice policies, make sure the EnableCallPark property is set for each voice policy, not just for the default policy.	RTCUniversalServerAdmins CsVoiceAdministrator CsUserAdministrator CsAdministrator	Enable Call Park for Users
Verify normalization rules for Call Park	Call park orbits must not be normalized. Verify that your normalization rules do not include any of your orbit ranges. If necessary, create additional normalization rules to	RTCUniversalServerAdmins CsVoiceAdministrator	Verify Normalization Rules for Call Park

	prevent orbits being normalized.	CsServerAdministrator CsAdministrator	
Verify your Call Park deployment	Test parking and retrieving calls to make sure that your configuration works as expected.	-	(Optional) Verify Call Park Deployment

1.4.3.13.1.3 Configure the Call Park Orbit Table

Configure the Call Park Orbit Table

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Call Park >

Topic Last Modified: *2012-09-10*

Call Park uses orbits for parking calls. Before users can park and retrieve calls, you must configure the Call Park orbit table. You need to specify the ranges of extension numbers (orbits) that your organization will reserve for parking calls and define the routing for those ranges by specifying which Call Park pool handles each range. When you define orbit ranges, the goal is to have enough orbits so that any one orbit is not reused too quickly, but not so many orbits that you limit the number of extensions available for users or other services. You can create multiple Call Park orbit ranges for each Lync Server pool where the Call Park application is deployed. Each Call Park orbit range must have a globally unique name and a unique set of extensions.

Important:

An orbit range typically encompasses 100 or fewer orbits. Each range can be much larger, as long as it is smaller than the maximum of 10,000 orbits per range and you have fewer than 50,000 orbits per pool. If a range is too small, the orbits are reused more quickly.

Use blocks of virtual extensions (extensions that have no user or phone assigned to them) for your orbit ranges.

Note:

Assigning Direct Inward Dialing (DID) numbers as orbit numbers in the Call Park orbit table is not supported.

Create or Modify a Call Park Orbit Range

Create or Modify a Call Park Orbit Range

See Also

Deploying Call Management Features > Configuring Call Park > Configure the Call Park Orbit Table >

Topic Last Modified: *2012-11-01*

Use one of the following procedures to create or modify a call park orbit range.

⊟To use Lync Server Control Panel to create or modify a range of numbers for parking calls

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Features** and then click **Call Park**.
4. On the **Call Park** page, do one of the following:
   - To create a new orbit range, click **New**. In **Name**, type an identifying name for this range of numbers.

     > **Note:**
     > After you commit the orbit range to the database, you cannot change this name.

   - To modify an existing orbit range, type all or part of the name of the orbit range in the search field. In the resulting list of orbits, click the orbit you want, click **Edit**, and then click **Show details**.
5. In the first **Number range** field, type the beginning number of the range of extensions for this call park orbit, and in the second **Number range** field, type the ending number of the range.

   > **Note:**
   > - The beginning number of the range must be less than or equal to the ending number of the range.
   > - The value of the beginning number of the range must be the same length as the ending number of the range.
   > - The orbit range must be unique. This range cannot overlap with any other range.
   > - If the orbit range begins with the character * or #, the range must be greater than 100.
   > - Valid values: Must match the regular expression string ([*|#]?[1-9]\d{0,7})|([1-9]\d{0,8}). This means the value must be a string beginning with either the character * or # or a number 1 through 9 (the first character cannot be a zero). If the first character is * or #, the following character must be a number 1 through 9 (it cannot be a zero). Subsequent characters can be any number 0 through 9 up to seven additional characters (for example, "#6000", "*92000", "*95551212", and "915551212"). If the first character is not * or #, the first character must be a number 1 through 9 (it cannot be zero), followed by up to eight characters, each a number 0 through 9 (for example, "915551212", "41212", "300").
   > - You should not have more than a total of 50,000 orbits per pool. Each orbit range typically encompasses 100 or fewer orbits, but it can be much larger as long as it includes fewer than 10,000 orbits. For example, instead of specifying a starting number of "7000000" and an ending number of "8000000," consider specifying a starting number of "7000000" and an ending number of "7000100."

1. In **FQDN of destination server**, click the fully qualified domain name (FQDN) or service ID of the Application service that hosts the Call Park application. All calls parked to numbers within the range specified by the start number and end number in the orbit range will be routed to this server or pool.
2. Click **Commit**.

To use Windows PowerShell to create or modify a range of numbers for parking calls

1. Log on to the computer where Lync Server Management Shell is installed as a member of the RTCUniversalServerAdmins group or with the necessary user

rights as described in Delegate Setup Permissions.

2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Use **New-CsCallParkOrbit** to create a new range of orbit numbers. Use **Set-CsCallParkOrbit** to modify an existing range of orbit numbers.

   At the command line, run:

   ```
   New-CsCallParkOrbit -Identity <name of orbit range> -NumberRangeStart
   ```

   For example:

   ```
   New-CsCallParkOrbit -Identity "Redmond orbit 1" -NumberRangeStart 100
   ```

   The following example shows how to modify the numbers in an existing orbit range,

   ```
   Set-CsCallParkOrbit -Identity "Redmond orbit 1" -NumberRangeStart 500
   ```

Tasks

Delete a Call Park Orbit Range

New-CsCallParkOrbit
Set-CsCallParkOrbit

1.4.3.13.1.4 Configure Call Park Settings

Configure Call Park Settings

See Also

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Call Park >

Topic Last Modified: *2012-11-01*

If you don't want to use default Call Park settings, you can customize them. When you install the Call Park application, global settings are configured by default. You can modify the global settings, and you can also specify site-specific settings. Use the **New-CsCpsConfiguration** cmdlet to create new site-specific settings. Use the **Set-CsCpsConfiguration** cmdlet to modify existing settings.

Note:

At a minimum, we recommend that you configure the **OnTimeoutURI** option for the fallback destination to use when a parked call times out and ringback fails.

Use **New-CsCpsConfiguration** cmdlet or the **Set-CsCpsConfiguration** cmdlet to configure any of the following settings:

This option:	Specifies this:
CallPickupTimeoutThreshold	The amount of time that elapses after a call has been parked before it rings back to the phone where the call was answered. The value must be entered in the format hh:mm:ss to specify the hours, minutes, and seconds. The minimum value is 10 seconds, and the maximum value is 10 minutes. The default is 00:01:30.
EnableMusicOnHold	Whether music plays for a caller while a call is parked. Values are True or False. The default is True.

MaxCallPickupAttempts	The number of times a parked call rings back to the answering phone before it is forwarded to the fallback Uniform Resource Identifier (URI) that is specified for **OnTimeoutURI**. The default is 1.
OnTimeoutURI	The SIP address of the user or response group to which an unanswered parked call is routed when **MaxCallPickupAttempts** is exceeded. Value must be a SIP URI beginning with the string sip:. For example, sip:bob@contoso.com. The default is no forwarding address.

⊟To configure Call Park settings

1. Log on to the computer where Lync Server Management Shell is installed as a member of the RTCUniversalServerAdmins group or with the necessary user rights as described in Delegate Setup Permissions.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run:

```
New-CsCpsConfiguration -Identity site:<sitename to apply settings> [-C
```

Tip:

Use the **Get-CsSite** cmdlet to identify the site. For details, see Lync Server Management Shell documentation.

For example:

```
New-CsCpsConfiguration -Identity site:Redmond1 -CallPickupTimeoutThres
```

Tasks

Customize Call Park Music on Hold

1.4.3.13.1.5 Customize Call Park Music on Hold

Customize Call Park Music on Hold

See Also

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Call Park >

Topic Last Modified: *2012-09-10*

You can specify your own music file to use for music on hold, instead of the default music file that ships with Lync Server 2013. To customize music on hold, use the **Set-CsCallParkServiceMusicOnHoldFile** cmdlet.

Note:

If you customize music on hold and want the same music for multiple sites, you must configure the music file for each site that runs the Call Park application.

To customize the music file

1. Log on to the computer where Lync Server Management Shell is installed as a member of the RTCUniversalServerAdmins group or with the necessary user rights as described in Delegate Setup Permissions.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run:

```
Set-CsCallParkServiceMusicOnHoldFile -Service <ServiceID where the Cal
```

Tip:

Use the **Get-CsService** cmdlet to identify the service. For details, see Get-CsService.

The following example shows how to obtain the contents of a file, soothingmusic.wma, as a byte array and assign it to a variable. Then the audio file is assigned as the music-on-hold file for Call Park. For details, see Set-CsCallParkServiceMusicOnHoldFile.

```
$a = Get-Content -ReadCount 0 -Encoding byte "C:\MoHFiles\soothingmusi
Set-CsCallParkServiceMusicOnHoldFile -Service Redmond1-applicationserv
```

1.4.3.13.1.6 Enable Call Park for Users

Enable Call Park for Users

See Also

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Call Park >

Topic Last Modified: *2012-09-11*

Users cannot park calls or retrieve parked calls until they are enabled for Call Park in voice policy.

Note:

By default, Call Park is disabled for all users.

You can enable Call Park at the global scope, or at the site scope or user scope. User scope takes precedence over site scope, and site scope takes precedence over global scope. If you have multiple voice policies, review all the policies to enable Call Park, not just the global policy.

To Use Lync Server Control Panel to Enable Call Park for Users

1. Log on to the computer as a member of the **RTCUniversalServerAdmins** group, or as a member of the **CsVoiceAdministrator**, **CsServerAdministrator**, or **CsAdministrator** administrative role.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing**.
4. Click the **Voice Policy** tab.
5. Double-click an existing voice policy to open the **Edit Voice Policy** dialog box.
6. Under **Calling features**, select **Enable call park**.
7. Click **OK** to save the voice policy

To Use Cmdlets to Enable Call Park for Users

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator administrative role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run:

   ```
   Set-CsVoicePolicy -Identity <VoicePolicy> -EnableCallPark $true
   ```

   For example, to enable Call Park for the default global voice policy:

   ```
   Set-CsVoicePolicy -EnableCallPark $true
   ```

Tasks

Create a Voice Policy and Configure PSTN Usage Records

1.4.3.13.1.7 Verify Normalization Rules for Call Park

Verify Normalization Rules for Call Park

See Also

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Call Park >

Topic Last Modified: *2012-09-11*

Call Park orbits must not be normalized. Check your dial plans to be sure that your orbit numbers are not normalized. If you must create an additional normalization rule to prevent your orbits from being normalized, follow the procedure in Create a Dial Plan to define a new normalization rule, so that **Pattern to match** identifies the orbit range and **Translation pattern** is **$1**. For example, if your Call Park orbit range is 7000 – 7999, the **Pattern to match** is **^(7\d{3})$** and **Translation pattern** is **$1**.

Important:
Be sure that the default normalization rule in your dial plans does not contain **^(\d*)**. Otherwise, your Call Park normalization rule will never run.

Tasks

Create a Dial Plan

1.4.3.13.1.8 (Optional) Verify Call Park Deployment

(Optional) Verify Call Park Deployment

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Call Park >

Topic Last Modified: *2012-09-11*

After you install and configure Call Park, you need to verify the configuration to make sure that parking and retrieving calls works as expected. At minimum, verify the following:

- Call a user who has Call Park enabled and have the user park the call.

  Note:
  If you enabled Call Park in voice policy just before performing this test, the user who is parking the call needs to sign out of Lync Server, and then sign back in, to be able to see the Call Park option in the transfer call list.

- Dial the orbit number to retrieve the call.

- Park another call, let the parked call time out, and do not pick up the ringback. Verify that the timed-out call is correctly routed to the fallback destination that is specified for **OnTimeoutURI**.

1.4.3.13.2 Configuring Group Call Pickup

Configuring Group Call Pickup

Deployment > Deploying Enterprise Voice > Deploying Call Management Features >

Topic Last Modified: *2013-02-01*

Cumulative update for Lync Server 2013: February 2013 introduces Group Call Pickup as a new Enterprise Voice feature. Group Call Pickup lets users pick up calls that are ringing for another user by dialing a call pickup group number.

The components that Group Call Pickup uses are automatically installed and enabled on the Front End Server or Standard Edition server when you deploy Enterprise Voice. However, you must configure Group Call Pickup before it is available to users.

This section guides you through the configuration of Group Call Pickup.
Group Call Pickup Configuration Prerequisites and User Rights

Deployment Process for Group Call Pickup

Deploy the SEFAUtil tool

Configure Call Pickup Group Numbers

Enable Group Call Pickup for Users and Assign a Group Number

Communicate Group Call Pickup Assignment to Users

(Optional) Verify the Group Call Pickup Deployment

Group Call Pickup Configuration Prerequisites and User Rights

See Also

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Group Call Pickup >

Topic Last Modified: *2013-01-30*

Group Call Pickup is a call management feature that is installed by default when you deploy Enterprise Voice. This topic describes what you need to have in place before you can configure Group Call Pickup and the user rights that you need to perform configuration tasks.

This section assumes that you have read the planning documentation related to Group Call Pickup (see Planning for Group Call Pickup).

Group Call Pickup Configuration Prerequisites

Group Call Pickup requires the following components:

- Application service
- Call Park application

These components are installed automatically when you deploy Enterprise Voice.

Group Call Pickup Configuration User Rights

You use the following administrative tools to configure Group Call Pickup:

- Lync Server Management Shell
- SEFAUtil resource kit tool

Use Lync Server Management Shell to create and manage call pickup groups in the Call Park orbit table. Use the SEFAUtil resource kit tool to assign a call pickup group and enable Group Call Pickup for users or to disable Group Call Pickup for users.

Configuring Group Call Pickup requires any of the following administrative roles, depending on the task:

- **CsVoiceAdministrator:** This administrator role can create, configure, and manage all voice-related settings and policies.
- **CsUserAdministrator:** This administrator role can enable Group Call Pickup for users. This administrator role also has read-only view access to all voice configurations.
- **CsServerAdministrator:** This administrator role can manage, monitor, and troubleshoot servers and services.
- **CsAdministrator:** This administrator role can perform all of the tasks of CsVoiceAdministrator, CsServerAdministrator, and CsUserAdministrator.

Note:

For details about administrative rights, see Planning for Role-Based Access Control in the Planning documentation.

Deployment Process for Group Call Pickup

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Group Call Pickup >

Topic Last Modified: *2013-02-25*

This section provides an overview of the steps involved in deploying Group Call Pickup. You must deploy Enterprise Edition or Standard Edition with Enterprise Voice before you configure Group Call Pickup. The components required by Group Call Pickup are installed and enabled when you deploy Enterprise Voice.

Group Call Pickup Deployment Process

Phase	Steps	Required groups and roles	Deployment documentation
Enable the SEFAUtil resource kit tool in the topology	1. Use the **New-CsTrustedApplicationPool** cmdlet to create a new trusted application pool. 2. Use the **New-CsTrustedApplication** cmdlet to specify the SEFAUtil tool as trusted application. 3. Run the **Enable-CsTopology** cmdlet to enable the topology. 4. Install the resource kit tools on a Front End Server that is in the trusted application pool created in step 1. 5. Verify that SEFAUtil is running correctly by running it to display the call forwarding settings of a user in the deployment.	RTCUniversalServerAdmins	Deploy the SEFAUtil tool
Configure call pickup number ranges in the call park orbit table	Use the **New-CSCallParkOrbit** cmdlet to create call pickup number ranges in the call park orbit table and assign the call pickup ranges the type GroupPickup. **Note:** You must use Lync Server Management Shell to create, modify, remove, and view Group Call Pickup number ranges in the call park orbit table. Group Call Pickup number ranges are not available in Lync Server Control Panel. **Note:** For seamless integration with existing dial plans, number ranges are typically configured as a block of virtual extensions. Assigning Direct Inward Dialing (DID) numbers as range numbers in the call park orbit table is not supported. Assign a call pickup number to users, and enable	Use the /enablegrouppickup parameter in the SEFAUtil resource kit tool to enable Group	-	Enable Group Call Pickup for Users and Assign a

Group Call Pickup for the users	Call Pickup and assign a call pickup number for users.		Group Number
Notify users of their assigned call pickup number and any other number of interest	Because any user can retrieve a call made to a Group Call Pickup user, users may want to monitor more than one group.	-	Communicate Group Call Pickup Assignment to Users
Verify your Group Call Pickup deployment	Test placing and retrieving calls to make sure that your configuration works as expected.	-	(Optional) Verify the Group Call Pickup Deployment

1.4.3.13.2.3 Deploy the SEFAUtil tool

Deploy the SEFAUtil tool

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Group Call Pickup >

Topic Last Modified: *2013-01-30*

To deploy and manage Group Call Pickup, you need to use the SEFAUtil resource kit tool. The tool is part of the Lync Server 2013 resource kit tools. Before you can install SEFAUtil, you must have a trusted application pool in your topology, specify SEFAUtil as a trusted application, and enable the topology.

Important:

Microsoft Unified Communications Managed API (UCMA) 3.0 Core SDK must be installed on any computer where you plan to run the SEFAUtil tool.

You can run the SEFAUtil in any Front End pool in your deployment.

Note:

For more details about running SEFAUtil, see the Technet blog article, "How to get SEFAutil running?" at http://go.microsoft.com/fwlink/?LinkId=278940.

To deploy SEFAUtil

1. Log on to the computer where Lync Server Management Shell is installed as a member of the RTCUniversalServerAdmins group or with the necessary user rights as described in Delegate Setup Permissions.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. The SEFAUtil tool can be run only on a computer that is part of a trusted application pool. If needed, define a trusted application pool for the Front End pool where you plan to run SEFAUtil. At the command line, run:

   ```
   New-CsTrustedApplicationPool -id <Pool FQDN> -Registrar <Pool Registra
   ```

4. Define the SEFAUtil tool as a trusted application. At the command line, run:

   ```
   New-CsTrustedApplication -ApplicationId sefautil -TrustedApplicationPo
   ```

   Note:

   You can use a different port if needed.

5. Enable the topology with your changes. At the command line, run:

```
Enable-CsTopology
```

6. Install the Lync Server 2013 resource kit tools on a Front End Server that is in the trusted application pool that you created in step 3.
7. Verify that the SEFAUtil tool is running correctly, as follows:
   7.a. Run the tool from the Windows command prompt with administrator privileges to display the call forwarding settings of a user in your deployment.

   > **Note:**
   > The tool is located at \Program Files\Microsoft Lync Server 2013 \Reskit.

   7.b. Display the call forwarding settings of a user. At the command line, run:

   ```
   SEFAUtil.exe <user SIP address> /server:<Lync Server/Pool F
   ```

   The call forwarding settings for the user will be displayed.

1.4.3.13.2.4 Configure Call Pickup Group Numbers

Configure Call Pickup Group Numbers

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Group Call Pickup >

Topic Last Modified: *2013-01-30*

Group Call Pickup is based on the Call Park application. When you deploy Group Call Pickup, you configure the call park orbit table with ranges of phone numbers that are designated as call pickup group numbers. These group numbers are the numbers that users dial to pick up calls that are ringing for another user.

Like call park orbit numbers, call pickup group numbers need to be virtual extensions that have no user or phone assigned to them. Each Front End pool where you deploy Group Call Pickup can have one or more ranges of call pickup group numbers. The group number ranges must be globally unique across the Lync Server deployment.
Create or Modify a Group Call Pickup Number Range

Create or Modify a Group Call Pickup Number Range

See Also

Deploying Call Management Features > Configuring Group Call Pickup > Configure Call Pickup Group Numbers >

Topic Last Modified: *2013-01-30*

Use the following procedure to create or modify a call pickup group number range in the call park orbit table.

> **Note:**
> You must use Lync Server Management Shell to create, modify, remove, and view Group Call Pickup number ranges in the call park orbit table. Group Call Pickup number ranges are not available in Lync Server Control Panel.

> **Important:**
> The call pickup group number range must be assigned a type of GroupPickup. Users are enabled for Group Call Pickup only if the group number that they are assigned is type GroupPickup.

The call pickup group number ranges must comply with the following rules:

- The beginning number of the range must be less than or equal to the ending number of the range.
- The value of the beginning number of the range must be the same length as the ending number of the range.
- The number range must be unique. This range cannot overlap with any other range.
- If the number range begins with the character * or #, the range must be greater than 100.
- Valid values: Must match the regular expression string ([*|#]?[1-9]\d{0,7})|([1-9]\d{0,8}). This means the value must be a string beginning with either the character * or # or a number 1 through 9 (the first character cannot be a zero). If the first character is * or #, the following character must be a number 1 through 9 (it cannot be a zero). Subsequent characters can be any number 0 through 9 up to seven additional characters (for example, "#6000", "*92000", "*95551212", and "915551212"). If the first character is not * or #, the first character must be a number 1 through 9 (it cannot be zero), followed by up to eight characters, each a number 0 through 9 (for example, "915551212", "41212", "300").

To create or modify a call pickup group range

1. Log on to the computer where Lync Server Management Shell is installed as a member of the RTCUniversalServerAdmins group or with the necessary user rights as described in Delegate Setup Permissions.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Use **New-CsCallParkOrbit** to create a new range of call pickup group numbers. Use **Set-CsCallParkOrbit** to modify an existing range of call pickup numbers.

   At the command line, run:

   ```
   New-CsCallParkOrbit -Identity <name of call pickup group range> -Numbe
   ```

   For example:

   ```
   New-CsCallParkOrbit -Identity "Redmond call pickup" -NumberRangeStart
   ```

   The following example shows how to change a range of numbers from call park orbits to call pickup groups.

   ```
   Set-CsCallParkOrbit -Identity "Redmond call pickup" -Type GroupPickup
   ```

   Important:

   Use this cmdlet to change the type assigned to number ranges only if you initially specified the incorrect type and the group range is not yet in use. If you change the number range from CallPark to GroupPickup or vice versa and the number range is already in use, either Call Park or Group Call Pickup will stop working for that number range. For example, if you change a number range from CallPark to GroupPick, the Call Park application can no longer use that range of orbits to park calls.

Tasks

Delete a Call Park Orbit Range

Other Resources

New-CsCallParkOrbit
Set-CsCallParkOrbit

1.4.3.13.2.5 Enable Group Call Pickup for Users and Assign a Group Number

Enable Group Call Pickup for Users and Assign a Group Number

See Also

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Group Call Pickup >

Topic Last Modified: *2013-01-30*

After you add call pickup group numbers to the call park orbit table, you assign the group numbers to users and enable Group Call Pickup for them. Use the secondary extension feature activation (SEFAUtil) resource kit tool to assign group numbers and enable Group Call Pickup.

Note:

In a hybrid deployment, do not assign a Group Call Pickup group to users who are homed online. Users who are homed online cannot participate in Group Call Pickup. That is, their calls cannot be answered by other users, and they cannot answer calls to other users.

To assign a group number and enable Group Call Pickup for a user

1. Log on to the computer where you installed the SEFAUtil tool with administrator rights.
2. At the command line, run:

```
SEFAUtil.exe sip:<sip address of user> /server:<pool FQDN> /enablegrou
```

For example, to assign group number 199 to a user:

```
SEFAUtil.exe katarina@contoso.com /server:pool01.contoso.com /enablegr
```

Tasks

Disable Group Call Pickup for Users

1.4.3.13.2.6 Communicate Group Call Pickup Assignment to Users

Communicate Group Call Pickup Assignment to Users

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Group Call Pickup >

Topic Last Modified: *2013-01-30*

After you enable Group Call Pickup for users, use email or some other mechanism to notify users of their call pickup group number. Notify users of the call pickup group number for any group that they might want to monitor. Because users can retrieve calls for other users even if they are not in the same group, users might need the call pickup group number for multiple groups.

1.4.3.13.2.7 (Optional) Verify the Group Call Pickup Deployment

(Optional) Verify the Group Call Pickup Deployment

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Group Call Pickup >

Topic Last Modified: *2013-01-30*

After you enable Group Call Pickup for users, verify that the configuration works as expected. At a minimum, verify the following:

- Call a user who is enabled for Group Call Pickup and have another user retrieve the call. The other user can be in the same group, in a different group, or not have Group Call Pickup enabled.
- Call a user who is enabled for Group Call Pickup and do not answer the call.

1.4.3.13.3 Configuring Response Group

Configuring Response Group

See Also

Deployment > Deploying Enterprise Voice > Deploying Call Management Features >

Topic Last Modified: *2012-10-30*

Response Group is an Enterprise Voice feature that routes and queues incoming calls to groups of people, called *agents*, such as a help desk or a customer service desk.

The components that Response Group requires are installed and enabled automatically on the Front End Server or Standard Edition server when you deploy Enterprise Voice. To make Response Group available to users, you must configure agent groups, then queues, and then workflows. Additionally, a Response Group Administrator can delegate configuration of an existing workflow to a Response Group Manager, who can then modify and reconfigure the workflow and its associated agent groups and queues.

This section guides you through the configuration of Lync Server 2013 Response Group. It assumes that you have already read the planning sections related to Response Group and have deployed an Enterprise Edition server or a Standard Edition server with Enterprise Voice.

Tip:

For details about creating a Response Group by using Lync Server Management Shell, including a sample script, see "Creating Your First Response Group Using Lync Server Management Shell" at http://go.microsoft.com/fwlink/p/?linkId=204108.

- Response Group Configuration Permissions and Prerequisites
- Deployment Process for Response Group
- Overview of Workflow Creation Scenarios
- Create Response Group Agent Groups
- Create Response Group Queues
- (Optional) Define Response Group Business Hours
- (Optional) Define Response Group Holiday Sets
- Create Response Group Workflows

Planning for Call Management Features

1.4.3.13.3.1 Response Group Configuration Permissions and Prerequisites

Response Group Configuration Permissions and Prerequisites

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Response

Group >

Topic Last Modified: *2012-10-05*

Response Group is an Enterprise Voice call management feature. This topic describes what you need to have in place before you can configure Response Group and the administrative credentials and permissions you need to perform configuration tasks.

This section assumes that you have read the planning documentation related to Response Group. For details, see Planning for Call Management Features in the Planning documentation.

Configuration Tools and Administrative Roles

You can use the following administrative tools to configure Response Group:

- Lync Server Control Panel
- Response Group Configuration Tool
- Lync Server Management Shell

To configure response groups, you must be a member of at least one of the following administrative roles:

Active Directory Security Group (1)	Create Workflow	Assign Manager	Create / assign agents, queues	Create / manage holiday and business hours	Activate / deactivate workflow	Configure workflow (IVR or Hunt Group)
CsResponseGroupAdministrator	√	√	√	√	√	√
CsResponseGroupManager		√(2)	√(3)	√(3)	√(3)	√(3)
CsVoiceAdministrator	√	√	√	√	√	√
CsServerAdministrator	√	√	√	√	√	√
CsAdministrator	√	√	√	√	√	√
CsViewOnlyAdministrator	√(4)	√(4)	√(4)	√(4)	√(4)	√(4)

Note:

(1) An Active Directory Domain Services (AD DS) user object must be a member of the specified Active Directory security group listed. An administrator or other delegated Active Directory group member with appropriate permissions to add users to a security group (For example, Administrator, Account Operators) must add a user object to the listed security group or group for the user to be able to perform the functions listed. **(2)** Only for workflows that the CsResponseGroupAdministrator has assigned to the CsResponseGroupManager. **(3)** A Response Group Manager can assign another member of CsResponseGroupManager to a workflow that the current manager already manages.

(4) CsViewOnlyAdministrator can only run verb "Get" Lync Server Management Shell cmdlets.

Response Group Configuration Prerequisites

Response Group requires the following components:

- Application service
- Response Group application
- Language packs
- File store (to hold audio files)
- Web Services (includes the Response Group Configuration Tool and the agents' sign-in and sign-out console)

All of these components are installed by default when you deploy Enterprise Voice.

You might need to perform the following tasks before configuring Response Group:

- Enable users for Lync Server 2013 and Enterprise Voice.
- Modify a configuration file to be compliant with Federal Information Processing Standards (FIPS).
- Modify the database collation to support Yi, Meng, and Zang characters for queue names and agent group names.

Enabling Users

The first step in configuring Response Group is to create agent groups. Before you can create an agent group, you must enable the users who will be agents for Response Group for Lync Server 2013 and Enterprise Voice. Enabling users for Lync Server 2013 is typically a step in the Enterprise Edition server or Standard Edition server deployment. For details about enabling users for Lync Server 2013, see Disable or Re-Enable User Account for Lync Server. Enabling users for Enterprise Voice is typically a step in the Enterprise Voice deployment. For details, see Enable Users for Enterprise Voice.

Complying with FIPS requirements

This section applies to you only if your organization needs to comply with Federal Information Processing Standards (FIPS).

To be compliant with FIPS, you need to modify the application-level Web.config file to use a different cryptography algorithm after you install Web Services. You need to specify that ASP.NET use the Triple Data Encryption Standard (3DES) algorithm to process view state data. For the Response Group application, this requirement applies to the Response Group Configuration Tool and the agent sign-in and sign-out console. For details about this requirement, see Microsoft Knowledge Base article 911722, "You may receive an error message when you access ASP.NET webpages that have ViewState enabled after you upgrade from ASP.NET 1.1 to ASP.NET 2.0," at http://go.microsoft.com/fwlink/p/?linkId=196183.

To modify the Web.config file, do the following:

1. In a text editor such as Notepad, open the application-level Web.config file.
2. In the Web.config file, locate the **<system.web>** section.
3. Add the following **<machineKey>** section to in the **<system.web>** section:

   ```
   <machineKey validationKey="AutoGenerate,IsolateApps" decryptionKey="Au
   ```

4. Save the Web.config file.
5. Restart the Internet Information Services (IIS) service by running the following command at a command prompt:

   ```
   iisreset
   ```

Supporting Yi, Meng, and Zang Characters

This section applies to you only if your organization needs to support Yi, Meng, or Zang characters.

Note:

For information on what the Yi, Meng, and Zang characters are and why they may be important to your deployment, see the information on the GB18030 character sets http://go.microsoft.com/fwlink/p/?linkId=240223.

To support Yi, Meng, or Zang characters, you need to modify the collation for the Rgsconfig database. Change the collation of the **Name** column in the following tables in each Rgsconfig database:

- dbo.AgentGroups
- dbo.BusinessHours
- dbo.HolidaySets
- dbo.Queues
- dbo.Workflows

For SQL Server 2008 R2 and SQL Server 2012, use the Latin_General_100 (Accent Sensitive) collation. If you use this collation, all object names are not case-sensitive.

You can change the collation by using Microsoft SQL Server Management Studio. For details about using this tool, see "Using SQL Server Management Studio" at http://go.microsoft.com/fwlink/p/?linkId=196184. Follow these steps to change the collation:

1. Be sure that SQL Server Management Studio is configured to allow changes that require tables to be recreated. For details, see "Save (Not Permitted) Dialog Box" at http://go.microsoft.com/fwlink/p/?linkId=196186. For details about setting a column collation, see "How to: Set Column Collation (Visual Database Tools)" at http://go.microsoft.com/fwlink/p/?linkId=196185.
2. Using Microsoft SQL Server Management Studio, connect to the Rgsconfig database.
3. Find the table you want to change in the Rgsconfig database, right-click the table, and click **Design**.
4. Change the collation of the **Name** column and save the table.

1.4.3.13.3.2 Deployment Process for Response Group

Deployment Process for Response Group

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Response Groups >

Topic Last Modified: *2012-09-27*

This section provides an overview of the phases and steps involved in deploying the Response Group application.

Response Group Deployment Process

Phase	Steps	Permissions	Deployment documentation
Install the Response Group application	The Response Group application is installed and activated by default when you deploy Enterprise Voice.	RTCUniversalServerAdmins	Deploying Enterprise Voice

Install components for Response Group	Lync Server cmdlets, the Lync Server Control Panel, Response Group Configuration Tool, agents' sign-in and sign-out console, and Response Group Client Web service are installed as part of Web Services. Web Services is installed when you deploy an Enterprise Edition pool or a Standard Edition server.	RTCUniversalServerAdmins	Deploying Lync Server 2013
Enable users for Lync 2013 and for Enterprise Voice	Enable users who will be agents for Lync Server and Enterprise Voice. Users must be enabled before you can add them to agent groups. Typically, users are enabled for Lync Server during the Enterprise Edition or Standard Edition server deployment. Users are enabled for Enterprise Voice during the Enterprise Voice deployment.	RTCUniversalUserAdmins CsUserAdministrator CsAdministrator	Disable or Re-Enable User Account for Lync Server Enable Users for Enterprise Voice
Create and configure response groups, which consist of agent groups, queues, and workflows	1. Use the Lync Server Control Panel or Lync Server Management Shell to do the following: 1.a. Create and configure agent groups. 1.b. Create and configure queues. 2. Optionally, use Lync Server Management Shell to create predefined response group business hours and holidays. 3. Use the Response Group Configuration Tool or Lync Server Management Shell to create workflows (hunt groups or interactive voice response (IVR) call flows), including custom response group business hours and holidays. **Note:** You can access the Response Group Configuration Tool through Lync Server Control Panel.	RTCUniversalServerAdmins CsResponseGroupAdministrator CsVoiceAdministrator CsServerAdministrator CsAdministrator CsResponseGroupManager	Create Response Group Agent Groups Create Response Group Queues (Optional) Define Response Group Business Hours (Optional) Define Response Group Holiday Sets Create or Modify a Workflow
(Optional) Customize application-level	Use Lync Server Management Shell to customize the default music-on-hold configuration, the default	RTCUniversalServerAdmins CsResponseGrou	Managing Application-Level Response Group

settings	music-on-hold audio file, the agent ringback grace period, and the call context configuration.	pAdministrator CsVoiceAdministrator CsServerAdministrator CsAdministrator	Settings

Verify your Response Group deployment	Test answering calls to your hunt group and interactive voice response workflows to ensure that your configuration works as expected.	-	-

1.4.3.13.3.3 Overview of Workflow Creation Scenarios

Overview of Workflow Creation Scenarios

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Response Group >

Topic Last Modified: *2012-10-17*

When you create workflows, there are two possible scenarios:

- **The Administrator creates and configures the workflow** — The CsResponseGroupAdministrator role member (or equivalent) creates and activates the workflow and all elements in the workflow, such as the agent groups, queues, holiday and business hours, music on hold, and so on.
- **The Administrator creates the workflow and the Manager configures options** — The CsResponseGroupAdministrator role member (or equivalent) defines the primary SIP URI, Display Name, assigns a member or members of the CsResponseGroupManager role, and selects a queue and activates the workflow. The CsResponseGroupManager can then log on and edit the configuration of the workflow by creating agent groups and also assigns the group to the queue, configuring the telephone number, holiday and business hours, music on hold, and so on.

Note:

When you want to create a managed workflow, you need to create the workflow as active. After you save an active, managed workflow, you can then modify and deactivate the workflow.

1.4.3.13.3.4 Create Response Group Agent Groups

Create Response Group Agent Groups

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Response Group >

Topic Last Modified: *2012-09-12*

When you create an agent group, you select the agents that are assigned to the group and specify additional group settings, such as the routing method and whether an agent can sign in to and out of the group.

An agent who must sign in and out of the group, which is different from signing in or out of Lync Server, is called a *formal agent*. Formal agents must be signed in to the group before they can receive calls routed to the group. This can be useful for agents who answer calls from the group on a part-time basis. Formal agents sign in and out of their groups by clicking a menu item in Lync 2013 to open the Windows Internet Explorer Internet browser and display a webpage console.

An agent who does not sign in or out of the group is called an *informal agent*. Informal agents are automatically signed in to the group when they sign in to Lync Server, and they cannot sign out of the group.

Note:

Only on-premises users can be agents. If an agent is moved from on-premises to online, Response Group calls will not be routed to that agent.

Create or Modify an Agent Group

Create or Modify an Agent Group

See Also

Deploying Call Management Features > Configuring Response Group > Create Response Group Agent Groups >

Topic Last Modified: *2012-11-01*

Use one of the following procedures to create or modify an agent group.

Note:

An Administrator—for example, CsVoiceAdministrator—must enable users for Enterprise Voice and Lync Server before the users can be assigned to agent groups. If you are one of the delegated Response Group Managers for a managed workflow, you can create agent groups and use the agent groups in the workflows that you manage.

Important:

When you assign users as response group agents, inform them that, if they have Privacy mode enabled, they need to search for "RGS Presence Watcher" contacts and add them to their Contacts list. Agents who have Privacy mode enabled, but who do not have "RGS Presence Watcher" in their Contacts list, cannot receive calls to the response group. Agents who do not have Privacy mode enabled are not affected.

⊟To use Lync Server Control Panel to create or modify an agent group

1. Log on as a member of the RTCUniversalServerAdmins group, or as a member of one of the predefined administrative roles that support Response Group.

   Note:
   If you are one of the delegated Response Group Managers for a managed workflow, you can create groups and use them in the workflows that you manage.

2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Response Groups**, and then click **Group**.
4. On the **Group** page, do one of the following:
   - To create a new agent group, click **New**. In the **Select a Service** search field, type all or part of the name of the **ApplicationServer** service where you want to add the group. In the resulting list of services, click the service that you want, and then click **OK**.
   - To modify an existing agent group, type all or part of the name of the agent group in the search field. In the resulting list, click the group that you want, click **Edit**, and then click **Show details**.
5. In **Name**, type an identifying name for the agent group.
6. In **Description**, type a description for the group.
7. In the **Participation policy**, select one of the following to set up the sign-in behavior for the group:
   - Select **Informal** to specify that agents in the group do not need to sign in and out of the group. Agents are automatically signed in to the group when they sign in to Lync Server 2013.
   - Select **Formal** to specify that agents in the group must sign in and out of the group. When you select this option, agents click a menu item in Lync to open Internet Explorer and display a webpage console for signing in and out of the group.
8. In **Alert time (seconds)**, specify the number of seconds to ring an agent before offering the call to the next available agent (the default is 20 seconds).

   Important:
   The agent alert time setting cannot exceed 180 seconds. If the agent alert time exceeds 180 seconds, the client application rejects the call because the SIP transaction timer reaches its maximum wait time.

9. In **Routing method**, select the method for routing calls to agents in the group as follows:
   - To offer a new call first to the agent who has been idle the longest (has had a presence of **Available** or **Inactive** in Lync Server the longest), click **Longest idle**.
   - To offer a new call to all available agents at the same time, click **Parallel**. The call is sent to the first agent who accepts it.
   - To offer a new call to each agent in turn, click **Round robin**.
   - To always offer a new call to the agents in the order in which they are listed in the **Agent** list, click **Serial**.
   - To offer a new call to all agents who are signed into Lync Server 2013 and the Response Group application at the same time, regardless of their current presence, click **Attendant**. Lync 2010 Attendant users who are configured as agents can see all the calls that are waiting and answer waiting calls in any order. The call is sent to the first agent who accepts it, after which the other Lync 2010 Attendant users no longer see the call.
10. In **Agents**, specify how you want to create your agents list:
    - To use a custom list of agents, click **Define a custom group of agents**, and do one of the following:

    - To add a user to the agent group, click **Select**, and then in the **Select Agents** search field, type all or part of the name of the user that you want to add to this group, and then click **Find**. In the resulting list of agents, click the user, and then click **OK**.
    - To remove a user from the agent group, in the list of agents, click the user you want to remove, and then click **Remove**.
    - To change the order in which agents are offered calls in groups that use either round robin routing or serial routing, in the list of agents, click a user, and then click the up arrow or down arrow.
- To use a Microsoft Exchange Server distribution list as your agent group, click **Use an existing email distribution list**, and then in **Distribution list address**, type the email address of the distribution list (for example, NetworkSupport@contoso.com).

  If you use an email distribution list, you are subject to the following constraints:

    - You cannot select multiple distribution lists for the agent group. Each group supports only a single distribution list.
    - If the distribution list contains one or more distribution lists, members of the nested distribution lists are not added to the agent list.
    - If serial or round robin routing is selected, the server offers an incoming call to the appropriate agent according to the routing method and according to the order in which agents are listed in the distribution list.

> **Important:**
> If you use an email distribution list, hidden memberships or hidden lists might become visible to the Response Group administrator or users.

  Hidden memberships or hidden lists can become visible as follows:

    - If a distribution list was configured so that the membership is hidden and the Response Group administrator assigns the distribution list to the agent list, users can call the group to find out who the members are.
    - If a distribution list was configured so that it is hidden in the Exchange Global Address List, the Response Group administrator might be able to see the distribution list and assign it to the agent list if the Response Group process has the appropriate user rights and permissions, even if the administrator does not have the appropriate user rights and permissions.

11. Click **Commit**.

To use Windows PowerShell to create or modify an agent group

1. Log on as a member of the RTCUniversalServerAdmins group, or as a member of one of the predefined administrative roles that support Response Group.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Retrieve the service name for the Response Group service and assign it to a variable. At the command line, run:

```
$serviceId="service:"+(Get-CsService | ?{$_.Applications -Like "*RGS*"
```

> **Note:**
> If you run **Get-CsService** in a topology that has multiple pools, the variable $serviceId returns an array of all the service elements found in the topology.

4. Use **New-CsRgsAgentGroup** to create a new agent group. Use **Set-CsRgsAgentGroup** to modify an existing agent group. At the command line, run:

```
$ag = New-CsRgsAgentGroup -Name "<agent group name>" -Parent $serviceI
```

For example:

```
$ag = New-CsRgsAgentGroup -Name "Help Desk" -Parent $serviceId -Descri
```

> **Important:**
> The agent alert time setting cannot exceed 180 seconds. If the agent alert time is greater than 180 seconds, the client application rejects the call because the SIP transaction timer reaches its maximum wait time.

5. Confirm that the agent group is created. Run:

```
Get-CsRgsAgentGroup -Name "Help Desk"
```

1.4.3.13.3.5 Create Response Group Queues

Create Response Group Queues

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Response Group >

Topic Last Modified: *2012-01-18*

Queues hold callers until an agent answers the call. When the Response Group application searches for an available agent, it searches agent groups in the order that you list them. You can select the agent groups that are assigned to the queue and specify queue behavior, such as limiting the number of calls that the queue can hold and the period of time that a call waits until an agent answers the call.
Create or Modify a Queue

Create or Modify a Queue

Deploying Call Management Features > Configuring Response Group > Create Response Group Queues >

Topic Last Modified: *2013-02-23*

Use one of the following procedures to create or modify a queue.

⊟To use Lync Server Control Panel to create or modify a queue

1. Log on as a member of the RTCUniversalServerAdmins group, or as a member of one of the predefined administrative roles that support Response Group.

> **Note:**
> If you are one of the delegated Response Group Managers for a managed workflow, you can create or modify response group queues and assign them to the workflows that you manage.

2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Response Groups**, and then click **Queue**.
4. On the **Queue** page, do one of the following:

- To create a new queue, click **New**. In **Select a Service**, type part or all of the name of the **ApplicationServer** service where you want to add the queue in the search field. In the resulting list of services, click the service that you want, and then click **OK**.
- To modify an existing queue, type all or part of the queue name in the search field. In the resulting list of queues, click the queue that you want, click **Edit**, and then click **Show details**.

5. In **Name**, type an identifying name for the queue.
6. In **Description**, type a description for the queue.
7. In **Groups**, specify the groups you want to assign to the queue. Do one of the following:
   - To add a group to the queue, click **Select**. In the **Select Groups** search field, type all or part of the name of the agent group that you want to assign to the queue, click the agent group that you want, and then click **OK**.
   - To remove a group from the queue, in the list of agent groups, click the group that you want to remove, and then click **Remove**.
   - To change the order in which agents are searched, in the list of agent groups, click a group, and then click the up arrow or down arrow.

   > **Note:**
   > When the server searches for an available agent for the queue, it uses group order. That is, the first group in the list is searched first, followed by the second group in the list, and so on.

8. To specify a maximum period of time for a caller to wait on hold before an agent answers the call, select the **Enable queue time-out** check box, and then do the following:
   - In **Time-out period (seconds)**, specify the maximum number of seconds a caller waits for an agent to answer the call.
   - In **Call Action**, select the action that occurs when a call times out as follows:
   - To disconnect the call after the timeout, click **Disconnect**.
   - To forward the call to voice mail, click **Forward to voice mail**, and then in the **SIP address** field, type a voice mail address in the format sip:<*username*>@<*domainname*> (for example, sip:bob@contoso.com).
   - To forward the call to another telephone number, click **Forward to telephone number**, and then in the **SIP address** field, type the telephone number in the format sip:<*number*>@<*domainname*> (for example, sip:+14255550121@contoso.com).
   - To forward the call to another user, click **Forward to SIP address**, and then in the **SIP address** field, type the URI for the user in the format sip:<*username*>@<*domainname*>.
   - To forward the call to another queue, click **Forward to another queue**, and then browse to the queue that you want to use.
9. To specify a maximum number of calls that the queue can hold, select the **Enable queue overflow** check box, and then do the following:
   - In **Maximum number of calls**, select the maximum number of calls that you want the queue to hold.
   - In **Forward the call**, select which call is to be forwarded when the queue is full: **Newest Call** or **Oldest Call**.
   - In **Call action**, select the action that occurs when the overflow threshold is met as follows:
   - To disconnect the call after the timeout, click **Disconnect**.
   - To forward the call to voice mail, click **Forward to voice mail**, and then in the **SIP address** field, type a voice mail address in the format sip:<*username*>@<*domainname*> (for example, sip:bob@contoso.com).
   - To forward the call to another telephone number, click **Forward to telephone number**, and then in the **SIP address** field, type the telephone number in the format sip:<*number*>@<*domainname*> (for example,

sip:+14255550121@contoso.com).

- To forward the call to another user, click **Forward to SIP address**, and then in the **SIP address** field, type the URI for the user in the format sip:<*username*>@<*domainname*>.
- To forward the call to another queue, click **Forward to another queue**, and then browse to the queue that you want to use.

10.Click **Commit**.

To use Windows PowerShell to create or modify a queue

1.Log on as a member of the RTCUniversalServerAdmins group, or as a member of one of the predefined administrative roles that support Response Group.

> **Note:**
> If you are one of the delegated Response Group Managers for a managed workflow, you will be able to create agent groups and queues, and assign agent groups to queues.

2.Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.

3.Create the prompt to be played when the queue timeout threshold is met, and save it in a variable. At the command line, run:

```
$promptTO = New-CsRgsPrompt -TextToSpeechPrompt "<text for TTS prompt>
```

For example:

```
"All agents are currently busy. Please call back later."
```

> **Note:**
> To use an audio file for the prompt, use the **Import-CsRgsAudioFile** cmdlet. For details, see Import-CsRgsAudioFile.

4.Define the action to be taken when the queue timeout threshold is met, and save it in a variable. At the command line, run:

```
$actionTO = New-CsRgsCallAction -Prompt <saved prompt from previous st
```

> **Note:**
> For details about possible actions and their syntax, see New-CsRgsCallAction.

For example:

```
$action = New-CsRgsCallAction -Prompt $promptTO -Action Terminate
```

5.Create the prompt to be played when the queue overflow threshold is met, and save it in a variable. At the command line, run:

```
$promptOV = New-CsRgsPrompt -TextToSpeechPrompt "<text for TTS prompt>
```

For example:

```
$promptOV = New-CsRgsPrompt -TextToSpeechPrompt "Too many calls are wa
```

> **Note:**
> To use an audio file for the prompt, use the **Import-CsRgsAudioFile** cmdlet. For details, see Import-CsRgsAudioFile.

6.Define the action to be taken when the queue overflow threshold is met, and save it in a variable. At the command line, run:

```
$actionOV = New-CsRgsCallAction -Prompt <saved prompt from previous st
```

> **Note:**
> For details about possible actions and their syntax, see New-CsRgsCallAction.

For example:

```
$action = New-CsRgsCallAction -Prompt $promptOV -Action Terminate
```

7. Retrieve the service name for the Response Group service and assign it to a variable. At the command line, run:

```
$serviceId="service:"+(Get-CSService | ?{$_.Applications -Like "*RGS*"
```

8. Get the identity of the agent group to be assigned to the queue. At the command line, run:

```
$agid = (Get-CsRgsAgentGroup -Name "Help Desk").Identity;
```

Note:
For details about creating the agent group, see New-CsRgsAgentGroup

9. Create the queue. At the command line, run:

```
$q = New-CsRgsQueue -Parent <saved service ID from previous step> -Nam
```

For example:

```
$q = New-CsRgsQueue -Parent $serviceId -Name "Help Desk" -Description
```

10. Confirm that the queue is created. Run:

```
Get-CsRgsQueue -Name "Help Desk"
```

1.4.3.13.3.6 (Optional) Define Response Group Business Hours

(Optional) Define Response Group Business Hours

See Also

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Response Group >

Topic Last Modified: *2012-11-01*

Defining Business Hours

Business hour settings define when the workflow is available to answer calls and specify the actions to take for calls outside of business hours. Response Group administrators can use the **New-CsRgsHoursOfBusiness** cmdlet to create predefined schedules that you can use for any number of response groups.

Tip:
When you create or modify a workflow, you can specify a custom schedule that applies only to that workflow. For details, see Create or Modify a Hunt Group Workflow or Create or Modify an Interactive Workflow.

Note:
If a workflow is defined as a Managed workflow, then any user who is assigned the CsResponseGroupManager role can set and modify custom business hours for workflows that they manage.

Important:

Use 24-hour notation for the parameters in the following cmdlets (for example, 20:00=8:00 P.M.).

To create a predefined business hours collection

1. Log on as a member of the RTCUniversalServerAdmins group, or as a member of one of the predefined administrative roles that support Response Group.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. For each unique range of hours you want to define, run:

   ```
   $x = New-CsRgsTimeRange [-Name <name of time range>] -OpenTime <time w
   ```

   To create the business hours collection that uses the ranges you defined, run:

   ```
   New-CsRgsHoursOfBusiness -Parent <service where the workflow is hosted
   ```

   The following example specifies business hours of 9:00 A.M. to 5:00 P.M. for weekdays, 8:00 A.M. to 10:00 A.M. and again from 2:00 P.M. to 6:00 P.M. for Saturdays, and no business hours for Sundays:

   ```
   $a = NewRgsTimeRange -Name "Weekday Hours" -OpenTime "9:00" -CloseTime
   $b = NewRgsTimeRange -Name "Saturday Morning Hours" -OpenTime "8:00" -
   $c = NewRgsTimeRange -Name "Saturday Afternoon Hours" -OpenTime "14:00
   New-CsRgsHoursOfBusiness -Parent "ApplicationServer:Redmond.contoso.co
   ```

1.4.3.13.3.7 (Optional) Define Response Group Holiday Sets

(Optional) Define Response Group Holiday Sets

See Also

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Response Group >

Topic Last Modified: *2012-11-01*

Holiday settings define the days that a response group is closed for business and specify the action to take on those days. A holiday set is the collection of holidays that apply to a response group.

Note:

If a workflow is defined as a Managed workflow, then any user is assigned the CsResponseGroupManager role can set and modify holidays for workflows that they manage.

To create a holiday set

1. Log on as a member of the RTCUniversalServerAdmins group, or as a member of one of the predefined administrative roles that support Response Group.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.

3. For each holiday you want to define, run:

```
$x = New-CsRgsHoliday [-Name <holiday name>] -StartDate <starting date
```

To create the holiday set that contains the holidays you defined, run:

```
New-CsRgsHolidaySet -Parent <service where the workflow is hosted> -Na
```

The following example shows a holiday set that includes two holidays:

```
$a = New-CsRgsHoliday -Name "New Year's Day" -StartDate "1/1/2013" -En
$b = New-CsRgsHoliday -Name "Independence Day" -StartDate "7/4/2013" -
New-CsRgsHolidaySet -Parent "ApplicationServer:Redmond.contoso.com -Na
```

1.4.3.13.3.8 Create Response Group Workflows

Create Response Group Workflows

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Response Group >

Topic Last Modified: *2012-09-12*

A workflow defines the behavior of a call from the time that the phone rings to the time that someone answers the call. The workflow specifies the queue to use for holding the call, and specifies the routing method to use for hunt groups or the questions and answers to use for interactive response groups. A workflow also defines settings such as a welcome message, music on hold, business hours, and holidays.

You use the Response Group Configuration Tool to create workflows. You can access the Response Group Configuration Tool from the Response Group page of Lync Server Control Panel.

> **Note:**
> You must create agent groups and queues before you create a workflow that uses them.

Deploying Call Management Features > Configuring Response Group > Create Response Group Workflows >

Topic Last Modified: *2012-11-27*

Use one of the following procedures to create or modify a hunt group workflow.

Note:

You can use Lync Server Management Shell or the Response Group Configuration Tool to create and modify hunt group workflows. You can access the Response Group Configuration Tool from Lync Server Control Panel, or by opening the webpage directly from a web browser by typing the following URL: **https://***<webPoolFqdn>***/RgsConfig**.

To use Response Group Configuration Tool to create or modify a hunt group workflow

1. Log on as a member of the RTCUniversalServerAdmins group, or as a member of one of the predefined administrative roles that support Response Group.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Response Groups**, and then click **Workflow**.
4. On the **Workflow** page, click **Create or edit a workflow**.
5. In the **Select a Service** search field, type all or part of the name of the **ApplicationServer** service that hosts the workflow that you want to create or change. In the resulting list of services, click the service that you want, and then click **OK**.

   Note:

   The Response Group Configuration Tool opens. You can also open the Response Group Configuration Tool directly from a web browser by typing the following URL: **https://***<webPoolFqdn>***/RgsConfig**.
6. Do one of the following:
   - Under **Create a New Workflow**, next to **Hunt Group, click Create**.
   - Under **Manage an Existing Workflow**, locate the workflow you want to change, and then under **Action**, click **Edit**.
7. If you are ready for users to start calling the workflow, select **Activate the workflow**.

   Note:

   If you are to creating a managed workflow, you need to select **Activate the workflow**. After you save the active, managed workflow, you can then modify and deactivate it.
8. To allow federated users to call the group, select the **Enable for federation** check box. You must also have an external access policy that applies to the Response Group application configured for federation.

   Note:

   The global external access policy applies to the Response Group application. You can configure the global policy for response group federation by using Lync Server Control Panel or by using the **Set-CsExternalAccessPolicy** cmdlet to set the EnableOutsideAccess parameter to True. Keep in mind that global policy settings apply to all users unless they are assigned a site or user policy. Therefore, before changing this setting for response groups, make sure that the federation setting meets the requirements of your organization. For details about how policies apply to users, see Manage External Access Policy for Your Organization. For details about the federation setting, see Set-CsExternalAccessPolicy.
9. To hide the identity of agents during calls, select the **Enable agent anonymity** check box.

   Note:

   Anonymous calls cannot start with instant messaging (IM) or video, although

> the agent or the caller can add IM and video after the call is established. An anonymous agent can also put calls on hold, transfer calls (both blind and consultative transfers), and park and retrieve calls. Anonymous calls do not support conferencing, application sharing and desktop sharing, file transfer, whiteboarding and data collaboration, and call recording. Agents using the Lync VDI Plugin can receive incoming calls anonymously, but they cannot make outgoing calls anonymously.

10.Under **Enter the address of the group that will receive the calls**, type the primary SIP uniform resource identifier (URI) address of the group that will answer calls to the workflow.

> **Note:**
>
> The primary URI for a workflow is how the workflow is identified and referenced. The SIP URI that you enter is created as a contact object in Active Directory Domain Services (AD DS). To create the URI, the object must be unique in Active Directory.

11.In **Display name**, type the name that you want to display for the workflow (for example, Sales Response Group).

> **Note:**
>
> Do not include the "<" or ">" characters in the display name. Do not use the following display names because they are reserved: **RGS Presence Watcher** or **Announcement Service**.

12.Under **Telephone number**, type the line URI for the response group (for example, +14255550165).

13.In **Display number**, type the number as you want it to appear for the response group (for example, +1 (425) 555-0165).

14.(Optional) In **Description**, type a description for the workflow as you want it to appear on the contact card in Lync client.

15.In **Workflow Type**, select **Managed** if this workflow will be managed by a Response Group Manager. Do the following to assign Response Group Managers to the workflow:

- Type the SIP URI of a manager for this workflow, and click **Add**.
- Type the SIP URI of additional managers to add to the workflow, and click **Add**.

> **Important:**
>
> Every user who is designated as a manager of a response group must be assigned the CsResponseGroupManager role. If users are not assigned this role, they cannot manage response groups.

16.Under **Step 2 Select a Language**, click the language that you want to use for speech recognition and text-to-speech.

17.If you want to configure a welcome message, under **Step 3 Configure a Welcome Message**, select the **Play a welcome message** check box, and then do one of the following:

- To enter the welcome message as text that is converted to speech for callers, click **Use text-to-speech**, and then type the welcome message in the text box.

  > **Note:**
  >
  > Do not include HTML tags in the text you enter. If you include HTML tags, you will receive an error message.

- To use a wave (.wav) or Windows Media audio (.wma) file recording for the welcome message, click **Select a recording**. If you want to upload a new audio file, click the **a recording** link. In the new browser window, click **Browse**, select the audio file that you want to use, and then click **Open**. Click **Upload** to load the audio file.

  > **Note:**

> All user-provided audio files must meet certain requirements. For details about supported file formats, see Technical Requirements for Response Groups.

18. Under **Step 4 Specify Your Business Hours**, in **Your time zone**, click the time zone for the workflow.

> **Note:**
> The time zone is the time zone where the callers and agents of the workflow reside. It is used to calculate the open and close hours. For example, if the workflow is configured to use the North American Eastern Time zone and the workflow is scheduled to open at 7:00 A.M. and close at 11:00 P.M., the open and close times are assumed to be 7:00 Eastern Time and 23:00 Eastern Time respectively. (You must enter the times in 24-hour time notation.)

19. Select the type of business hours schedule you want to use by doing one of the following:
    - To use a predefined schedule of business hours, click **Use a preset schedule**, and then select the schedule you want to use from the drop-down list.

      > **Note:**
      > You must have defined at least one preset schedule previously to be able to select this option. You define preset schedules by using the **New-CSRgsHoursOfBusiness** cmdlet. For details, see (Optional) Define Response Group Business Hours.

      > **Note:**
      > When you select a preset schedule, **Day**, **Open**, and **Close** are automatically filled with the days and hours that the response group is available.

    - To use a custom schedule that applies only to this workflow, click **Use a custom schedule**.
20. If you are creating a custom schedule for this workflow, click the check boxes for the days of the week that the response group is available.
21. If you are creating a custom schedule, type the **Open** and **Close** hours for each day of the week that the response group available.

> **Note:**
> The **Open** and **Close** hours must be in 24-hour time notation. For example, if your office works a 9-to-5 work day and closes at noon for lunch, the business hours are specified as **Open** 9:00, **Close** 12:00, **Open** 13:00, and **Close** 17:00.

22. If you want to play a message when the office is not open, select the **Play a message when the response group is outside of business hours** check box, and then specify the message to play by doing one of the following:
    - To enter the message as text that is converted to speech for the caller, click **Use text-to-speech**, and then type the message in the text box.

      > **Note:**
      > Do not include HTML tags in the text you enter. If you include HTML tags, you will receive an error message.

    - To use an audio file recording for the message, click **Select a recording**. If you want to upload a new audio file, click the **a recording** link. In the new browser window, click **Browse**, select the file that you want to use, and then click **Open**. Click **Upload** to load the audio file.

      > **Note:**
      > All user-provided audio files must meet certain requirements. For details about supported audio file formats, see Technical

> Requirements for Response Groups.

23.Specify how to handle calls after the message is played (if a message is configured):

- To disconnect the call, click **Disconnect Call**.
- To forward the call to voice mail, click **Forward to voice mail**, and then type the voice mail address. The format for the voice mail address is *<username>*@*<domainName>* (for example, bob@contoso.com).
- To forward the call to another user, click **Forward to SIP URI**, and then type a user address. The format for the user address is *<username>*@*<domainName>*.
- To forward the call to another telephone number, click **Forward to telephone number**, and then type the telephone number. The format for the telephone number is *<number>*@*<domainName>* (for example, +14255550121@contoso.com). The domain name is used to route the caller to the correct destination.

24.Under **Step 5 Specify Your Holidays**, click the check boxes for one or more sets of holidays that define the days when the response group is closed for business.

> **Note:**
> You need to define holidays and holiday sets before you configure the workflow. Use the **New-CsRgsHoliday** and **New-CsRgsHolidaySet** cmdlets to define holidays and holiday sets. For details, see (Optional) Define Response Group Holiday Sets.

25.If you want to play a message on holidays, select the **Play a message during holidays** check box, and then specify the message to play by doing one of the following:

- To enter the message as text that is converted to speech for the caller, click **Use text-to-speech**, and then type the message in the text box.

> **Note:**
> Do not include HTML tags in the text you enter. If you include HTML tags, you will receive an error message.

- To use an audio file recording for the message, click **Select a recording**. If you want to upload a new audio file, click the **a recording** link. In the new browser window, click **Browse**, select the file that you want to use, and then click **Open**. Click **Upload** to load the audio file.

> **Note:**
> All user-provided audio files must meet certain requirements. For details about supported audio file formats, see Technical Requirements for Response Groups.

26.Specify how to handle calls after the message is played (if a message is configured):

- To disconnect the call, click **Disconnect Call**.
- To forward the call to voice mail, click **Forward to voice mail**, and then type the voice mail address. The format for the voice mail address is *<username>*@*<domainName>* (for example, bob@contoso.com).
- To forward the call to another user, click **Forward to SIP URI**, and then type a user address. The format for the user address is *<username>*@*<domainName>*.
- To forward the call to another telephone number, click **Forward to telephone number**, and then type the telephone number. The format for the telephone number is *<number>*@*<domainName>* (for example, +14255550121@contoso.com). The domain name is used to route the caller to the correct destination.

27.Under **Step 6 Configure a Queue**, in **Select the queue that will receive the calls**, select the queue that you want to hold callers until an agent becomes available.

28. Under **Step 7 Configure Music on Hold**, choose the music you want callers to listen to while waiting for an agent by doing one of the following:
    - To use the default music-on-hold recording, click **Use default**.
    - To use an audio file recording for the music on hold, click **Select a music file**. If you want to upload a new audio file, click the **a music file** link. In the new browser window, click **Browse**, select the file that you want to use, and then click **Open**. Click **Upload** to load the audio file.

> **Note:**
> All user provided audio files must meet certain requirements. For details about supported audio file formats, see Technical Requirements for Response Groups.

29. Click **Deploy**.

To use Windows PowerShell to create or modify a hunt group workflow

1. Log on as a member of the RTCUniversalServerAdmins group, or as a member of one of the predefined administrative roles that support Response Group.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Create the prompt to be played for the welcome message, and save it in a variable. At the command line, run:

```
$promptWM = New-CsRgsPrompt -TextToSpeechPrompt "<text for TTS prompt>
```

For example:

```
$promptWM = New-CsRgsPrompt -TextToSpeechPrompt "Welcome to Contoso. P
```

> **Note:**
> To use an audio file for the prompt, use the **Import-CsRgsAudioFile** cmdlet. For details, see Import-CsRgsAudioFile.

4. Get the identity of the queue or question where the calls will be directed. At the command line, run:

```
$qid = (Get-CsRgsQueue -Name "Help Desk").Identity
```

For details about creating the queue, see New-CsRgsQueue.

5. Define the default action to be taken when a workflow is opened during business hours, and save it in a variable. At the command line, run:

```
$actionWM = New-CsRgsCallAction -Prompt <saved prompt from previous st
```

> **Note:**
> For hunt group workflows, the default action must direct the call to a queue. This is parameter is required for active workflows. It is not required for inactive workflows.

For example:

```
$actionWM = New-CsRgsCallAction -Prompt $promptWM -Action TransferToQu
```

6. If you want to define business hours and holidays, you need to create them before you create or modify the workflow. For details, see (Optional) Define Response Group Business Hours and (Optional) Define Response Group Holiday Sets.
7. If you want to have prompts for calls that are received out of business hours or on holidays, use the **New-CsRgsPrompt** cmdlet to define the prompt, and use the **New-CsRgsCallAction** to define the action to be taken after the prompt. For details, see New-CsRgsPrompt and New-CsRgsCallAction.
8. Retrieve the service name for the Lync Server Response Group service and assign it to a variable. At the command, run:

```
$serviceId="service:"+(Get-CSService | ?{$_.Applications -like "*RGS*"
```

9. Create or modify the workflow. To create a workflow, use **New-CsRgsWorkflow**. To modify a workflow, use **Set-CsRgsWorkflow**. At the command line, type:

   ```
   $workflowHG = New-CsRgsWorkflow -Parent <service ID for the Response G
   ```

   For example:

   ```
   $workflowHG = New-CsRgsWorkflow -Parent $serviceID -Name "Human Resour
   ```

   > **Important:**
   > All users who are designated managers for workflows must be assigned the CsResponseGroupManager role.

   > **Note:**
   > For details about additional optional parameters, see New-CsRgsWorkflow or Set-CsRgsWorkflow

Design Interactive Voice Response Call Flows

Deploying Call Management Features > Configuring Response Group > Create Response Group Workflows >

Topic Last Modified: *2013-02-25*

You can use interactive voice response (IVR) to obtain information from callers and direct the call to the appropriate queue. Question-and-answer pairs determine which queue to use. Depending on the caller's response, the caller either hears a follow-up question, or is routed to the appropriate queue. The IVR questions and the caller's responses are provided to the responding agent who accepts the call, providing valuable information to the agent.

Overview of IVR Features

The Response Group application offers speech recognition and text-to-speech capabilities in 26 languages. You can enter IVR questions using text-to-speech or a wave (.wav) or Windows Media audio (.wma) file. Callers can respond by using voice or dual-tone multifrequency (DTMF) responses.

Interactive workflows support up to two levels of questions, with each question having up to four possible answers. The IVR asks the caller a question, and depending on the caller's response, routes the caller to a queue or asks a second question. The second question can also have four possible answers. Depending on the answer to the second-level question, the caller is routed to the appropriate queue.

> **Note:**

When you design call flows by using Lync Server Management Shell, you can define any number levels of IVR questions and any number of answers. However, for caller usability, we recommend that you not use more than three levels of questions, with not more than five answers each. In addition, if you design a call flow that has more than two levels of questions with more than four answers each, you cannot edit the call flow by using Lync Server 2013 Control Panel.

The IVR questions and the caller's responses are provided to the responding agent who accepts the call.

Working with Speech Technologies

Speech technologies, such as speech recognition and text-to-speech, can enhance customer experience and let people access information more naturally and effectively. However, there can be cases where the specified text or the user voice response is not recognized correctly by the speech engine. For example, the "#" symbol is translated by the text-to-speech engine as the word "number." This issue can be mitigated by the following:

- The speech engine gives the caller five attempts to answer the question. If the caller answers the question incorrectly (that is, the answer is not one of the specified responses) or does not provide an answer at all, the caller gets another chance to answer the question. The caller has five attempts to answer the question before being disconnected. You can configure the IVR to play a customized message after each caller error. The question is repeated each time.
- To minimize the potential for ambient noise to be interpreted by the speech engine as a response, use longer responses. For example, responses should have more than one syllable and should sound significantly different from each other.
- If your questions have both speech and DTMF responses, configure the speech responses with words that represent the concept rather than the DTMF response. For example, instead of using "Press or say one" use "Press 1 or say billing."
- After you design your IVR, call the workflow, listen to the prompts, respond to each of the prompts using voice, and verify that the IVR sounds and behaves as expected. You can then modify the IVR to fix any interpretation issues. Following the previous example, if you need to refer to the # key, you can rewrite your IVR prompt to use the key name, rather than the # symbol. For example, "To talk to sales, press the pound key."

IVR Design Examples

The following sections contain examples of different IVR scenarios and question-and-answer pairs.

IVR with One Level of Questions

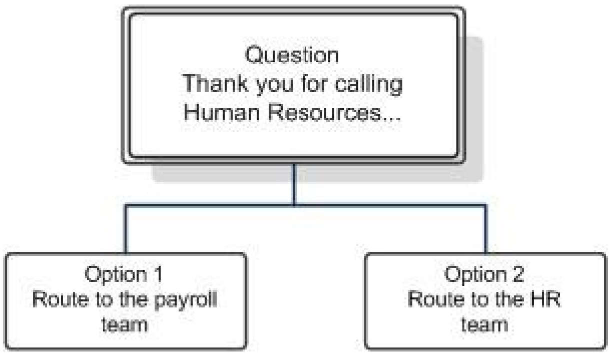
The following example shows an IVR that uses one level of questions. It uses speech recognition to detect the caller's response.

Question: "Thank you for calling Human Resources. If you would like to speak to payroll, say payroll. Otherwise, say HR."

- **Option 1 is selected:** The caller is routed to the payroll team.
- **Option 2 is selected:** The caller is routed to the human resources team.

The following figure shows the call flow.

One-level interactive call flow



IVR with Two Levels of Questions

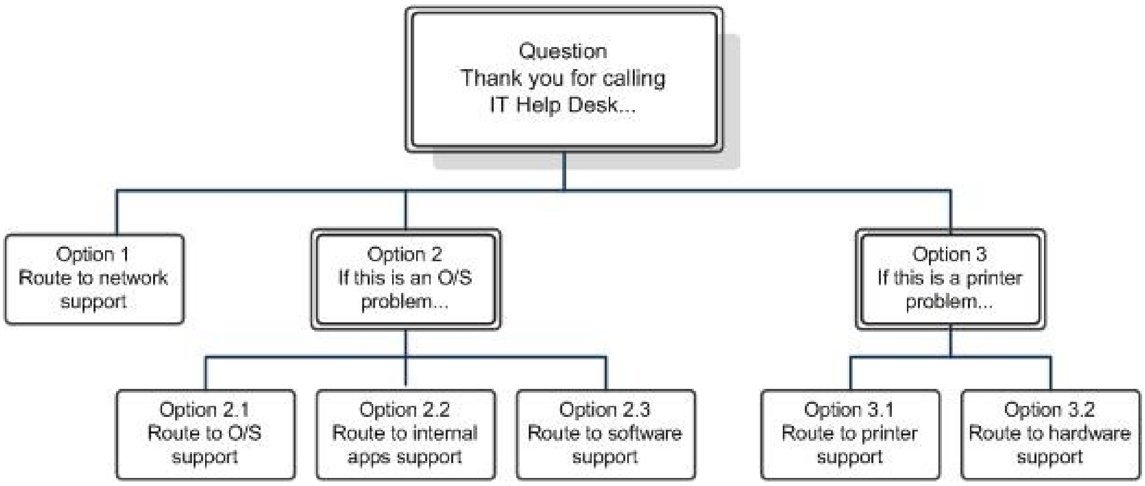
The following example shows an IVR that uses two levels of questions. It allows callers to respond using either speech or DTMF keypad input.

Question: "Thank you for calling the IT Help Desk. If you have a network access problem, press 1 or say network. If you have a software problem, press 2 or say software. If you have a hardware problem, press 3 or say hardware."

- **Option 1 is selected:** The caller is routed to the network support team.
- **Option 2 is selected:** The caller is asked a follow-up question:
  Question: "If this is an operating system problem, press 1 or say operating system. If this is a problem with an internal application, press 2 or say internal application. Otherwise, press 3 or say other."
  - **Option 1 is selected:** The caller is routed to the operating systems support team.
  - **Option 2 is selected:** The caller is routed to the internal applications support team.
  - **Option 3 is selected:** The caller is routed to the software support team.
- **Option 3 is selected:** The caller is asked a follow-up question:
  Question: "If this is a printer problem press 1. Otherwise, press 2."
  - **Option 1 is selected:** The caller is routed to the printer support team.
  - **Option 2 is selected:** The caller is routed to the hardware support team.

The following figure shows the call flow.

Two-level interactive call flow



Best Practices

The following list describes some best practices for designing your IVR:

- Let the caller get to the task quickly. Avoid providing too much information or lengthy marketing messages in your IVR.
- If you want to include a lengthy message, consider appending it to the first question instead of to the welcome message. Callers can bypass the message if it is part of the first question by answering the question, but they cannot bypass the welcome message.
- Speak in the caller’s language. Avoid stilted language. Speak naturally.
- Write efficient and effective prompts. Remove any unnecessary options. Structure the information so that the caller’s expected response is at the end of the sentence. For example, “To speak to the sales team, press 1."
- Make voice responses user friendly. For example, if you specify both DTMF and voice responses, use something like: "To speak to the sales team, press 1 or say sales."
- Test the IVR on a group of users before you deploy it across your organization.

Create or Modify an Interactive Workflow

Deploying Call Management Features > Configuring Response Group > Create Response Group Workflows >

Topic Last Modified: *2012-11-27*

Use one of the following procedures to create or modify an interactive workflow.

Note:
You can use Lync Server Management Shell or the Response Group Configuration Tool to create and modify interactive workflows. You can access the Response Group Configuration Tool from Lync Server Control Panel, or by opening the webpage directly from a web browser by typing the following URL: **https://***<webPoolFqdn>***/RgsConfig**.

To use Response Group Configuration Tool to create or modify an Interactive workflow

1. Log on as a member of the RTCUniversalServerAdmins group, or as a member of one of the predefined administrative roles that support Response Group.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Response Groups**, and then click **Workflow**.
4. On the **Workflow** page, click **Create or edit a workflow**.
5. In the **Select a Service** search field, type all or part of the name of the **ApplicationServer** service that hosts the workflow that you want to create or modify. In the resulting list of services, click the service that you want, and then click **OK**.

   Note:
   The Response Group Configuration Tool opens. You can also open the Response Group Configuration Tool directly from a web browser by typing the following URL: **https://***<webPoolFqdn>***/RgsConfig**.

6. Do one of the following:
   - Under **Create a New Workflow**, next to **Interactive**, click **Create**.
   - Under **Manage an Existing Workflow**, locate the workflow you want to change, and then under **Action**, click **Edit**.
7. If you are not ready for users to start calling the workflow, clear the **Activate**

the workflow check box.

> **Note:**
> If you are to creating a managed workflow, you need to select **Activate the workflow**. After you save the active, managed workflow, you can then modify and deactivate it.

8. To allow federated users to call the group, select the **Enable for federation** check box. You must also have an external access policy that applies to the Response Group application configured for federation.

> **Note:**
> The global external access policy applies to the Response Group application. You can configure the global policy for response group federation by using Lync Server Control Panel or by using the **Set-CsExternalAccessPolicy** cmdlet to set the EnableOutsideAccess parameter to True. Keep in mind that global policy settings apply to all users unless they are assigned a site or user policy. Therefore, before changing this setting for response groups, make sure that the federation setting meets the requirements of your organization. For details about how policies apply to users, see Manage External Access Policy for Your Organization. For details about the federation setting, see **Set-CsExternalAccessPolicy** in Lync Server Management Shell documentation.

9. To hide the identity of agents during calls, select the **Enable agent anonymity** check box.

> **Note:**
> Anonymous calls cannot start with instant messaging (IM) or video, although the agent or the caller can add IM and video after the call is established. An anonymous agent can also put calls on hold, transfer calls (both blind and consultative transfers), and park and retrieve calls. Anonymous calls do not support conferencing, application sharing and desktop sharing, file transfer, whiteboarding and data collaboration, and call recording. Agents using the Lync VDI Plugin can receive incoming calls anonymously, but they cannot make outgoing calls anonymously.

10. Under **Enter the address of the group that will receive the calls**, type the primary SIP uniform resource identifier (URI) address of the group that will answer calls to the workflow.
11. In **Display name**, type the name that you want to display for the workflow (for example, Sales IVR Response Group).

> **Note:**
> Do not include the "<" or ">" characters in the display name. Do not use the following display names because they are reserved: RGS Presence Watcher or Announcement Service.

12. In **Telephone number**, type the line URI for the response group (for example, +14255550165).
13. In **Display number**, type the number as you want it to appear for the response group (for example, +1 (425) 555-0165).
14. (Optional) In **Description**, type a description for the workflow that you want to appear on the contact card in the Lync client.
15. In **Workflow Type**, select **Managed** if this workflow will be managed by a Response Group Manager. Do the following to assign Response Group Managers to the workflow:
    - Type the SIP URI of a manager for this workflow, and click **Add**..
    - Type the SIP URI of additional managers to add to the workflow, and click **Add**..

> **Important:**
> Every user who is designated as a manager of a response group must be assigned the CsResponseGroupManager role. If users are not assigned this

role, they cannot manage response groups.

16. Under **Step 2 Select a Language**, click the language to use for speech recognition and text-to-speech.
17. If you want to configure a welcome message, under **Step 3 Configure a Welcome Message**, select the **Play a welcome message** check box, and then do one of the following:
    - To enter the welcome message as text that is converted to speech for callers, click **Use text-to-speech**, and then type the welcome message in the text box.

      Note:
      Do not include HTML tags in the text you enter. If you include HTML tags, you will receive an error message.

    - To use a Wave or Windows Media Audio file recording for the welcome message, click **Select a recording**. If you want to upload a new audio file, click the **a recording** link. In the new browser window, click **Browse**, select the audio file that you want to use, and then click **Open**. Click **Upload** to load the audio file.

      Note:
      All user-provided audio files must meet certain requirements. For details about supported file formats, see Technical Requirements for Response Groups.

18. Under **Step 4 Specify Your Business Hours**, in the **Your time zone** box, click the time zone of the workflow.

    Note:
    The time zone is the time zone where the callers and agents of the workflow reside. It is used to calculate the open and close hours. For example, if the workflow is configured to use the North American Eastern Time zone and the workflow is scheduled to open at 7:00 A.M. and close at 11:00 P.M., the open and close times are assumed to be 7:00 Eastern Time and 11:00 Eastern Time respectively. (You must enter the times in 24-hour time notation.)

19. Select the type of business hours schedule you want to use by doing one of the following:
    - To use a predefined schedule of business hours, click **Use a preset schedule**, and then select the schedule you want to use from the drop-down list.

      Note:
      You must have defined at least one preset schedule previously to be able to select this option. You define preset schedules by using the **New-CSRgsHoursOfBusiness** cmdlet. For details, see (Optional) Define Response Group Business Hours. When you select a preset schedule, **Day**, **Open**, and **Close** are automatically filled with the days and hours that the response group is available.

    - To use a custom schedule that applies only to this workflow, click **Use a custom schedule**.
20. If you are creating a custom schedule for this workflow, click the check boxes for the days of the week that the response group is available.
21. If you are creating a custom schedule, type the **Open** and **Close** hours when the response group available.

    Note:
    The **Open** and **Close** hours must be in 24-hour time notation. For example, if your office works a 9-to-5 work day and closes at noon for lunch, the business hours are specified as **Open** 9:00, **Close** 12:00, **Open** 13:00, and

Close 17:00.

22.If you want to play a message when the office is not open, select the **Play a message when the response group is outside of business hours** check box, and then specify the message to play by doing one of the following:

- To enter the message as text that is converted to speech for the caller, click **Use text-to-speech**, and then type the message in the text box.

  Note:
  Do not include HTML tags in the text you enter. If you include HTML tags, you will receive an error message.

- To use an audio file recording for the message, click **Select a recording**. If you want to upload a new audio file, click the **a recording** link. In the new browser window, click **Browse**, select the file that you want to use, and then click **Open**. Click **Upload** to load the audio file.

  Note:
  All user-provided audio files must meet certain requirements. For details about supported file formats, see Technical Requirements for Response Groups.

23.Specify how to handle calls after the message is played (if a message is configured):

- To disconnect the call, click **Disconnect Call**.
- To forward the call to voice mail, click **Forward to voice mail**, and then type the voice mail address. The format for the voice mail address is <*username*>@<*domainname*> (for example, bob@contoso.com).
- To forward the call to another user, click **Forward to SIP URI**, and then type a user address. The format for the user address is <*username*>@<*domainname*>.
- To forward the call to another telephone number, click **Forward to telephone number**, and then type the telephone number. The format for the telephone number is <*number*>@<*domainname*> (for example, +14255550121@contoso.com). The domain name is used to route the caller to the correct destination.

24.Under **Step 5 Specify Your Holidays**, click the check boxes for one or more sets of holidays that define the days when the response group is closed for business.

Note:
You need to define holidays and holiday sets before you configure the workflow. Use the **New-CsRgsHoliday** and **New-CsRgsHolidaySet** cmdlets to define holidays and holiday sets. For details, see (Optional) Define Response Group Holiday Sets.

25.If you want to play a message on holidays, select the **Play a message during holidays** check box, and then specify the message to play by doing one of the following:

- To enter the message as text that is converted to speech for the caller, click **Use text-to-speech**, and then type the message in the text box.

  Note:
  Do not include HTML tags in the text you enter. If you include HTML tags, you will receive an error message.

- To use an audio file recording for the message, click **Select a recording**. If you want to upload a new audio file, click the **a recording** link. In the new browser window, click **Browse**, select the file that you want to use, and then click **Open**. Click **Upload** to load the audio file.

  Note:
  All user-provided audio files must meet certain requirements. For details about supported audio file formats, see Technical

> Requirements for Response Groups.

26. Specify how to handle calls after the message is played (if a message is configured):
    - To disconnect the call, click **Disconnect Call**.
    - To forward the call to voice mail, click **Forward to voice mail**, and then type the voice mail address. The format for the voice mail address is *<username>*@*<domainname>* (for example, bob@contoso.com).
    - To forward the call to another user, click **Forward to SIP URI**, and then type a user address. The format for the user address is *<username>*@*<domainname>*.
    - To forward the call to another telephone number, click **Forward to telephone number**, and then type the telephone number. The format for the telephone number is *<number>*@*<domainname>* (for example, +14255550121@contoso.com). The domain name is used to route the caller to the correct destination.
27. Under **Step 6 Configure Music on Hold**, choose what you want callers to listen to while waiting for an agent by doing one of the following:
    - To use the default music on-hold recording, click **Use default**.
    - To use an audio file recording for the on-hold music, click **Select a music file**. If you want to upload a new audio file, click the **a music file** link. In the new browser window, click **Browse**, select the file that you want to use, and then click **Open**. Click **Upload** to load the audio file.

> **Note:**
>
> All user-provided audio files must meet certain requirements. For details about supported file formats, see Technical Requirements for Response Groups.

28. Under **Step 7 Configure Interactive Voice Response**, under the **The user will hear the following text or recorded message** heading, specify the question to ask callers as follows:
    - To enter the question in text format, click **Use text-to-speech**, and type the question in the text box.

> **Note:**
>
> Do not include HTML tags in the text you enter. If you include HTML tags, you will receive an error message.

> **Note:**
>
> The "#" symbol is translated by the text-to-speech engine as the word "number". If you need to refer to the # key, you should use the key name, rather than the symbol, in your prompt. For example, "To talk to sales, press the pound key."

- To use a prerecorded audio file that contains the question, click **Select a recording**, and then click the **a recording** link to upload the file. In the new browser window, click **Browse**, select the audio file, and then click **Open**. Click **Upload** to load the file, and then optionally you can type the question in the text box (this enables the question, and the caller's response, to be forwarded to the responding agent).

> **Note:**
>
> All user-provided audio files must meet certain requirements. For details about supported file formats, see Technical Requirements for Response Groups.

29. Under **Response 1**, specify the first possible answer to the question by doing the following:

> **Important:**
>
> Do not use quotation marks (") in any voice responses. Quotation marks cause the IVR to fail.

Note:
You can choose to allow callers to answer using speech, alphanumeric keypad input, or both.

- If you want to allow the caller to respond using speech, enter the answer in **Enter a voice response**.
- If you want to allow the caller to respond by pressing a key on the keypad, in **Digit**, click the keypad digit.

30. Specify whether to route the caller to a queue, or to ask another question as follows:
    - To route the caller to a queue, click **Send to a queue**, and in **Select a queue**, click the queue that you want to use.
    - To ask another question, click **Ask another question**, and then click **Use text-to-speech** and type the question, or click **Select a recording**. Use the response groupings in this section to specify up to four possible responses to the additional question and the queue to use for each response. To specify a third or fourth possible response, click the **Response 3** check box or the **Response 4** check box.
31. Specify up to three more possible answers to the original question by repeating steps 28 and 29 to specify the possible responses and the action to take for each response. To specify a third or fourth possible answer, click the **Response 3** check box or the **Response 4** check box.
32. Click **Deploy**.

To use Windows PowerShell to create or modify an Interactive workflow

1. Log on as a member of the RTCUniversalServerAdmins group, or as a member of one of the predefined administrative roles that support Response Group.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Retrieve the service name for the Response Group service and assign it to a variable. At the command line, run:

```
$serviceId="service:"+(Get-CSService | ?{$_.Applications -like "*RGS*"
```

4. An interactive workflow requires two or more queues and two or more agent groups. First, create the agent groups. Run:

```
$AGSupport = New-CsRgsAgentGroup -Parent $serviceId -Name "Technical S
$AGSales = New-CsRgsAgentGroup -Parent $serviceId -Name "Sales Team" [
```

5. Create the queues. Run:

```
$QSupport = New-CsRgsQueue -Parent $ServiceId -Name "Contoso Support"
$QSales = New-CsRgsQueue -Parent $ServiceId -Name "Contoso Sales" -Age
```

6. Create the first response group prompt. Run:

```
$SupportPrompt = New-CsRgsPrompt -TextToSpeechPrompt "Please be patien
```

7. Then create the action to be performed after the prompt. Run:

```
$SupportAction = New-CsRgsCallAction -Prompt $SupportPrompt -Action Tr
```

8. Create the first response group answer. Run:

```
$SupportAnswer = New-CsRgsAnswer -Action $SupportAction [-DtmfResponse
```

9. Now create the second prompt, call action, and answer. First create the prompt. Run:

```
$SalesPrompt = New-CsRgsPrompt -TextToSpeechPrompt "Please hold while
```

10. Create the second call action. Run:

```
$SalesAction = New-CsRgsCallAction -Prompt $SalesPrompt -Action Transf
```

11. Create the second response group answer. Run:

```
$SalesAnswer = New-CsRgsAnswer -Action $SalesAction [-DtmfResponse 2]
```

12. Create the top-level prompt. Run:

```
$TopLevelPrompt = New-CsRgsPrompt -TextToSpeechPrompt "Thank you for c
```

13. Create the top-level question. Run:

```
$TopLevelQuestion = New-CsRgsQuestion -Prompt $TopLevelPrompt [-Answer
```

14. Now create the workflow. Run:

```
$IVRAction = New-CsRgsCallAction -Action TransferToQuestion [-Question
$IVRWorkflow = New-CsRgsWorkflow -Parent $ServiceId -Name "Contoso Hel
```

Note:
All users who have been designated as manager of a response group must be assigned th CsResponseGroupManager role. If users are not assigned this role, they cannot manage response groups.

1.4.3.13.3.9 Managing Application-Level Response Group Settings

Managing Application-Level Response Group Settings

See Also

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Response Group >

Topic Last Modified: *2012-11-01*

Application-level settings for Response Group application include the default music-on-hold configuration, the default music-on-hold audio file, the agent ringback grace period, and the call context configuration. You can define only one set of application-level settings per pool. To view application-level settings, use the **Get-CsRgsConfiguration** cmdlet. To modify the application-level settings, use the **Set-CsRgsConfiguration** cmdlet.

The default music on hold is played when a call is placed on hold only if no custom music on hold is defined. Call context is available only for queues assigned to interactive workflows. If call context is enabled, an agent can see information such as caller wait time or workflow questions and answers when the call is received.

⊟To modify Response Group application-level settings

1. Log on as a member of the RTCUniversalServerAdmins group, or as a member of one of the predefined administrative roles that support Response Group.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. At the command line, run:

```
Set-CsRgsConfiguration -Identity <name of service hosting Response Gro
```

For example:

```
Set-CsRgsConfiguration -Identity "service:ApplicationServer:redmond.co
```

To specify an audio file to use as the default music on hold, you need to import the audio file first. For example:

```
$x = Import-CsRgsAudioFile -Identity "service:ApplicationServer:redmon
Set-CsRgsConfiguration -Identity "service:ApplicationServer:redmond.co
```

Other Resources

Get-CsRgsConfiguration
Set-CsRgsConfiguration

1.4.3.13.3.10 (Optional) Verify Response Group Deployment

(Optional) Verify Response Group Deployment

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Response Group >

Topic Last Modified: *2012-09-11*

After you configure Response Group, you need to verify the configuration to make sure your response groups work as expected. At minimum, verify the following scenarios by using the following types of users:

Users

- A user who is homed on Lync Server 2013
- An external user who uses the public switched telephone network (PSTN)
- An agent who is homed on Lync Server 2013

Scenarios

- The Lync Server 2013 user calls the response group.
- The external user calls the response group.
- A user calls the response group while the agent is on another call and goes to the queue.

1.4.3.13.4 Configuring Announcements for Unassigned Numbers

Configuring Announcements for Unassigned Numbers

See Also

Deployment > Deploying Enterprise Voice > Deploying Call Management Features >

Topic Last Modified: *2012-09-11*

The Announcement application is an Enterprise Voice feature that enables you to configure what happens to calls to unassigned extensions (extensions that are valid for your organization, but are not assigned to a person or a phone). For example, you can configure calls to unassigned numbers to play a message, or to be transferred to a different destination, or both.

The Announcement application is installed as a feature of Response Group application on the Front End Server or Standard Edition server when you deploy Enterprise Voice. You need to configure Announcements by uploading your audio files or by configuring text-to-speech (TTS) and configuring the unassigned number table.

This section guides you through the configuration of Lync Server Announcements. It assumes that you have already read the planning sections related to Announcements and deployed an Enterprise Edition server or a Standard Edition server with Enterprise Voice.

- Announcement Configuration Prerequisites and Roles
- Deployment Process for Announcements
- Create an Announcement
- Configure the Unassigned Number Table
- (Optional) Verify Announcement Deployment

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Announcements for Unassigned Numbers >

Topic Last Modified: *2013-02-25*

Announcement is an Enterprise Voice call management feature. This topic describes what you need to have in place before you can configure Announcement and the role assignments that you need to perform configuration tasks.

This section assumes that you have read the planning documentation related to Announcement (see Planning for Call Management Features).

Announcement Configuration Prerequisites

The Announcement application requires the following components:

- Application service
- Response Group application
- File Store, to hold audio files

All of these components are installed by default when you deploy Enterprise Voice.

Announcement Configuration Roles

You can use the following administrative tools to configure announcements:

- Lync Server Control Panel
- Lync Server Management Shell

Configuring Announcement application requires one of the following administrative roles:

- **CsVoiceAdministrator** This administrator role can create, configure, and manage all voice-related settings and policies, including Announcement settings.
- **CsServerAdministrator** This administrator role can manage, monitor, and troubleshoot servers and services, and configure all Announcement settings.
- **CsAdministrator** This administrator role can perform all administrative tasks and modify all settings.
- **CsViewOnlyAdministrator** This administrator role can view the deployment to monitor deployment health.

Note:

For details about administrative user rights, see Planning for Role-Based Access Control in the Planning documentation.

1.4.3.13.4.2 Deployment Process for Announcements

Deployment Process for Announcements

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Announcements >

Topic Last Modified: *2012-09-12*

This section provides an overview of the steps involved in deploying the Announcement application. You must deploy Enterprise Voice before you configure announcements. The components required by the Announcement application are installed and enabled when you deploy Enterprise Voice.

Announcement Deployment Process

Phase	Steps	Roles	Deployment documentation
Configure Announcement settings	• Create the announcement by recording and uploading audio files or by using text-to-speech (TTS). • Configure the unassigned number ranges in the unassigned number table and associate them with the appropriate announcement.	RTCUniversalServerAdmins CsVoiceAdministrator CsServerAdministrator CsAdministrator CsViewOnlyAdministrator	Create an Announcement Configure the Unassigned Number Table
Verify your Announcement deployment	Test by listening to announcements to verify that your configuration works as expected.	-	(Optional) Verify Announcement Deployment

1.4.3.13.4.3 Create an Announcement

Create an Announcement

See Also

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Announcements for Unassigned Numbers >

Topic Last Modified: *2012-11-01*

To create a new announcement, you need to perform the following steps:

1. For audio prompts, record the audio file by using your favorite audio recording application.
2. For audio prompts, run the **Import-CsAnnouncementFile** cmdlet to import the contents of the audio file to File Store.
3. Run the **New-CsAnnouncement** cmdlet to create and name the announcement. Perform this step to create announcements with an audio

prompt, a text-to-speech (TTS) prompt, or no prompt.

Tip:

You might want to create an announcement with no prompt (for example, if you want to transfer calls to a specific destination without playing a message).

4. Assign the new announcement to a number range in the unassigned number table.

This topic describes how to import and create announcements. For details about assigning announcements in the unassigned number table, see Configure the Unassigned Number Table.

⊟To create a new announcement

1. For audio prompts, create the audio file.
2. Log on to the computer where Lync Server Management Shell is installed as a member of the RTCUniversalServerAdmins group or with the necessary user rights as described in Delegate Setup Permissions.
3. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
4. For audio prompts, run:

```
Import-CsAnnouncementFile -Parent <service of the Application Server r
```

5. Run:

```
New-CsAnnouncement -Parent <service of Application Server running the
```

For transferring calls to voice mail, type SIPAddress in the format sip:username@domainname;opaque=app:voicemail (for example, sip:bob@contoso.com;opaque=app:voicemail). For transferring calls to a phone number, type SIPAddress in the format sip:number@domainname;user=phone (for example, sip:+14255550121@contoso.com;user=phone).

For example, to specify an audio prompt:

```
$a = Get-Content ".\PromptFile.wav" -ReadCount 0 -Encoding Byte
Import-CsAnnouncementFile -Parent service:ApplicationServer:pool0@cont
New-CsAnnouncement -Parent service:ApplicationServer:pool0.contoso.com
```

For example, to specify a TTS prompt:

```
New-CsAnnouncement -Parent service:ApplicationServer:pool0.contoso.com
```

For more detail about these cmdlets, and to see a list of the language codes to use in the **TextToSpeechPrompt** parameter, see New-CsAnnouncement.

New-CsAnnouncement
Configure the Unassigned Number Table

1.4.3.13.4.4 Configure the Unassigned Number Table

Configure the Unassigned Number Table

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Announcements for Unassigned Numbers >

Topic Last Modified: *2012-10-30*

In Lync Server 2013, you can specify what happens to incoming calls to phone numbers that are valid for your organization, but are not assigned to a user or phone. Callers can hear a message, or can be routed to another destination, or both.

How you configure the unassigned number table depends on how you want to use it. You can configure the table with all the valid extensions for your organization, with only unassigned extensions, or with a combination of both types of numbers. The unassigned number table can include both assigned and unassigned numbers, but it is invoked only when a caller dials a number that is not currently assigned. If you include all the valid extensions in the unassigned number table, you can specify the action that occurs whenever someone leaves your organization, without needing to reconfigure the table. If you include unassigned extensions in the table, you can modify the action that occurs for specific numbers. For example, if you change the extension for your customer service desk, you can include the old customer service number in the table and then assign it to an announcement that provides the new number.

Important:
Before you configure the unassigned number table, your system must already either have Announcements defined or an Exchange Unified Messaging (UM) Auto Attendant set up.

Tip:
When someone calls an unassigned number, Lync Server searches the unassigned number table from top to bottom and uses the first matching range. Therefore, an action that you want to be performed as a last resort should be specified for the last range in the table.

Create or Modify an Unassigned Number Range Create an Announcement

Create or Modify an Unassigned Number Range

See Also

Deploying Call Management Features > Configuring Announcements for Unassigned Numbers > Configure the Unassigned Number Table >

Topic Last Modified: *2012-11-01*

Use one of the following procedures to configure unassigned number ranges for the Announcement application.

Important:
Before you configure the unassigned number table, you must have already defined one or more announcements or set up an Exchange Unified Messaging (UM) Auto Attendant.

To use Lync Server Control Panel to configure unassigned phone numbers

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Features**, and then click **Unassigned Number**.
4. On the **Unassigned Number** page, do one of the following:
   - To create a new number range, click **New**. In **Name**, type an identifying name for this range of numbers.

     Note:
     After you commit the new unassigned number range to the database, you cannot change this name.

- To modify an existing number range, type all or part of the name of the number range in the search field. In the resulting list of number ranges, click the name you want, click **Edit**, and then click **Show details**.

5. In the first **Number range** field, type the beginning number of the range, and in the second **Number range** field, type the ending number of the range.

Note:

- The beginning number of the range must be less than or equal to the ending number of the range.
- If the beginning number of the range or the ending number of the range includes an extension number, both the beginning number and the ending number of the range must include an extension, and the extension number must be the same for both the beginning number and the ending number.
- The number must match the regular expression (tel:)?(\+)?[1-9]\d{0,17}(;ext=[1-9]\d{0,9})?. This means the number may begin with the string tel: (if you don't specify that string, it will be automatically added for you), a plus sign (+), and a digit 1 through 9. The phone number can be up to 17 digits and may be followed by an extension in the format ;ext= followed by the extension number.

1. In **Announcement service**, do one of the following:
   - Click **Announcement**.
   - Click **Exchange UM**.
2. If, in the previous step, you clicked **Announcement**, do the following:
   - Under **FQDN of destination server**, click **Select**, click the service ID of the Application service that runs the Announcement application that will handle incoming calls to this range of unassigned numbers, and then click **OK**.
   - In **Announcement**, click the announcement to be played for this range of unassigned numbers.
3. If, in the previous step, you clicked **Exchange UM**, under **Auto Attendant phone number**, click **Select**, click the phone number to be used for this range of unassigned numbers, and then click **OK**.
4. Click **OK**.
5. On the **Unassigned Number** page, be sure that the unassigned number ranges are arranged in the order that you want. To change a range's position in the table, click one or more consecutive names in the list of ranges, and then click the up arrow or the down arrow.

Tip:

Lync Server searches the unassigned number table from top to bottom and uses the first range that matches the unassigned number. If you have overlapping ranges and one range specifies a last resort action, make sure that range is at the bottom of the list.

6. When you have the unassigned number ranges in the order that you want, click **Commit all**.

To use Windows PowerShell to configure unassigned phone numbers

1. Log on to the computer where Lync Server Management Shell is installed as a member of the RTCUniversalServerAdmins group or with the necessary user rights as described in Delegate Setup Permissions.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Use **New-CsUnassignedNumber** to create a new unassigned number range. Use **Set-CsUnassignedNumber** to modify an existing unassigned number range.

Tip:

If you have overlapping ranges and want the ranges to be applied in a specific order, include the Priority parameter. The range with the highest priority will be applied to the call.

At the command line, do one of the following:

- To create a number range for an Announcement service, run:

```
New-CsUnassignedNumber -Identity <unique identifier for unas
```

- Or, to create a number range for Exchange UM Auto Attendant, run:

```
New-CsUnassignedNumber -ExUmAutoAttendantPhoneNumber <phone
```

For example:

```
New-CsUnassignedNumber -Identity "Unassigned range 1" -NumberRangeStar
```

Or

```
New-CsUnassignedNumber -ExUmAutoAttendantPhoneNumber "+12065551234" -I
```

The following example shows how to modify the numbers in an existing unassigned number range:

```
Set-CsUnassignedNumber -Identity "Unassigned range 1" -NumberRangeStar
```

1.4.3.13.4.5 (Optional) Verify Announcement Deployment

(Optional) Verify Announcement Deployment

Deploying Enterprise Voice > Deploying Call Management Features > Configuring Announcements for Unassigned Numbers >

Topic Last Modified: *2013-02-25*

After you install and configure Announcement, you need to verify the configuration to make sure that calls to unassigned numbers work as expected. At minimum, verify the following:

- Call a number that is valid for your organization but is an unassigned number.
- Call the unassigned number and verify that the correct announcement plays.

1.4.3.14 Enable Users for Enterprise Voice

Enable Users for Enterprise Voice

See Also

Microsoft Lync Server 2013 > Deployment > Deploying Enterprise Voice >

Topic Last Modified: *2012-11-01*

After you install files for one or more Mediation Servers, configure outbound call routing, and optionally deploy one or more advanced Enterprise Voice features, you can use the following procedures to enable a user to make calls by using Enterprise Voice:

Note:

Of the following procedures, only the first can be performed by using Lync Server Control Panel. For the remaining procedures, you can use only Lync Server Management Shell.

- Enable the user account for Enterprise Voice.
- (Optional) Assign the user account a user-specific voice policy.
- (Optional) Assign the user account a user-specific dial plan.

To enable a user account for Enterprise Voice

1. From a user account that is assigned to the CsUserAdministrator role or the CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Users**.
4. In the **Search users** box, type all or the first portion of the display name, first name, last name, Security Accounts Manager (SAM) account name, SIP address, or line Uniform Resource Identifier (URI) of the user account that you want to enable, and then click **Find**.
5. In the table, click the user account that you want to enable for Enterprise Voice.
6. On the **Edit** menu, click **Show details**.
7. On the **Edit Lync Server User** page, under **Telephony**, click **Enterprise Voice**.
8. Click **Line URI**, and then type a unique, normalized phone number (for example, tel:+14255550200).
9. Click **Commit**.

To finish enabling a user for Enterprise Voice, be sure that the user is assigned a voice policy and a dial plan, whether global (assigned by default) or user-specific.

By default, all users are assigned a global voice policy and dial plan. If a voice policy or dial plan exists at the site level for the site on which the user account is homed, those site policies will automatically apply to the user. To apply a per-user voice policy or dial plan to a user, you must run the **Grant-CsVoicePolicy** and **Grant-CsDialPlan** cmdlets. For details, see the Lync Server Management Shell documentation.

Voice Policy Assignment

Global and site-level voice policies are automatically assigned to all user accounts that are enabled for Enterprise Voice. You can also create voice policies that apply to specific users or groups. These per-user policies must be explicitly assigned to the users or groups. If you want to use the global or site voice policy for all users who are enabled for Enterprise Voice, you can skip this section and continue to Dial Plan Assignment section later in this topic.

To assign a user-specific voice policy

1. From a user account that is assigned to the CsUserAdministrator role or the CsAdministrator role, log on to any computer in your internal deployment.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. To assign an existing user voice policy to a user, run the following at the command prompt:

```
Grant-CsVoicePolicy -Identity <UserIdParameter> -PolicyName <String>
```

For example:

```
Grant-CsVoicePolicy -Identity "Bob Kelly" -PolicyName VoicePolicyJapan
```

In this example, the user with the display name Bob Kelly is assigned the voice policy with the name **VoicePolicyJapan**.

For details about assigning a user-specific voice policy or about running the **Grant-CsVoicePolicy** cmdlet, see the Lync Server Management Shell documentation.

Dial Plan Assignment

To complete user account configuration for either users of Enterprise Voice or users of dial-in conferencing, the user must be assigned a dial plan. User accounts will automatically use the global dial plan or, if one exists, the site-level dial plan, when you do not explicitly assign an existing per-user dial plan. If you want to use the global or site dial plan for all users who are enabled for Enterprise Voice, you can skip this section.

To assign a dial plan

1. From a user account that is assigned to the CsUserAdministrator role or the CsAdministrator role, log on to any computer in your internal deployment.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. To assign a user-specific dial plan, run the following at the command prompt:

   ```
   Grant-CsDialPlan -Identity <UserIdParameter> -PolicyName <String>
   ```

   For example:

   ```
   Grant-CsDialPlan -Identity "Bob Kelly" -PolicyName DialPlanJapan
   ```

   In this example, the user with the display name Bob Kelly is assigned the user dial plan with the name **DialPlanJapan**.

For details about assigning a user dial plan or about running the **Grant-CsDialPlan** cmdlet, see the Lync Server Management Shell documentation.

Deployment > Deploying Conferencing > Configuring Dial-in Conferencing >

Topic Last Modified: *2012-06-20*

Dial-in conferencing is an optional component of the Lync Server 2013 Conferencing workload. The components you need to install before you can configure dial-in conferencing are deployed when you use the Topology Builder to design your topology and then set up your Front End pool or Standard Edition server. This topic describes what you need to have accomplished before you can configure dial-in conferencing.

This section assumes that you have read the planning sections related to the Conferencing workload and dial-in conferencing in particular.

Dial-in Conferencing Configuration Prerequisites

Dial-in conferencing requires the following Lync Server 2013 components:

- Unified Communications Application Service (UCAS) (called the *Application service*)
- Conferencing Attendant application
- Conferencing Announcement application
- Dial-in Conferencing Settings webpage
- At least one Lync Server 2013 Mediation Server and at least one PSTN gateway

You deploy these components when you use the Topology Builder to define and publish your topology and then deploy a Front End pool or a Standard Edition server. If you are deploying Enterprise Voice, you should deploy it before you configure dial-in conferencing. If you are not deploying Enterprise Voice, you can deploy a Mediation Server and a public switched telephone network (PSTN) gateway when you deploy your Front End pool or Standard Edition server.

Note:

If you are upgrading from Office Communications Server 2007 R2 to Lync Server 2013, deploy dial-in conferencing in every pool that you plan to use to host Lync Server 2013 conferences. For details about migrating dial-in conferencing, see Migration from Office Communications Server 2007 R2 to Lync Server 2013.

This section assumes that you have done the following:

- Applied the latest updates to your Office Communications Server 2007 R2 environment, if you are migrating to Lync Server 2013.
- Used Topology Builder to design and configure your topology. While specifying the Conferencing workload, you selected the dial-in conferencing option. For details about defining your topology, see Defining and Configuring the Topology in the Deployment documentation.
- Published your topology, and set up the Front End pool or Standard Edition server. For details about publishing the topology and installing Lync Server 2013, see Deploying Lync Server 2013 in the Deployment documentation.

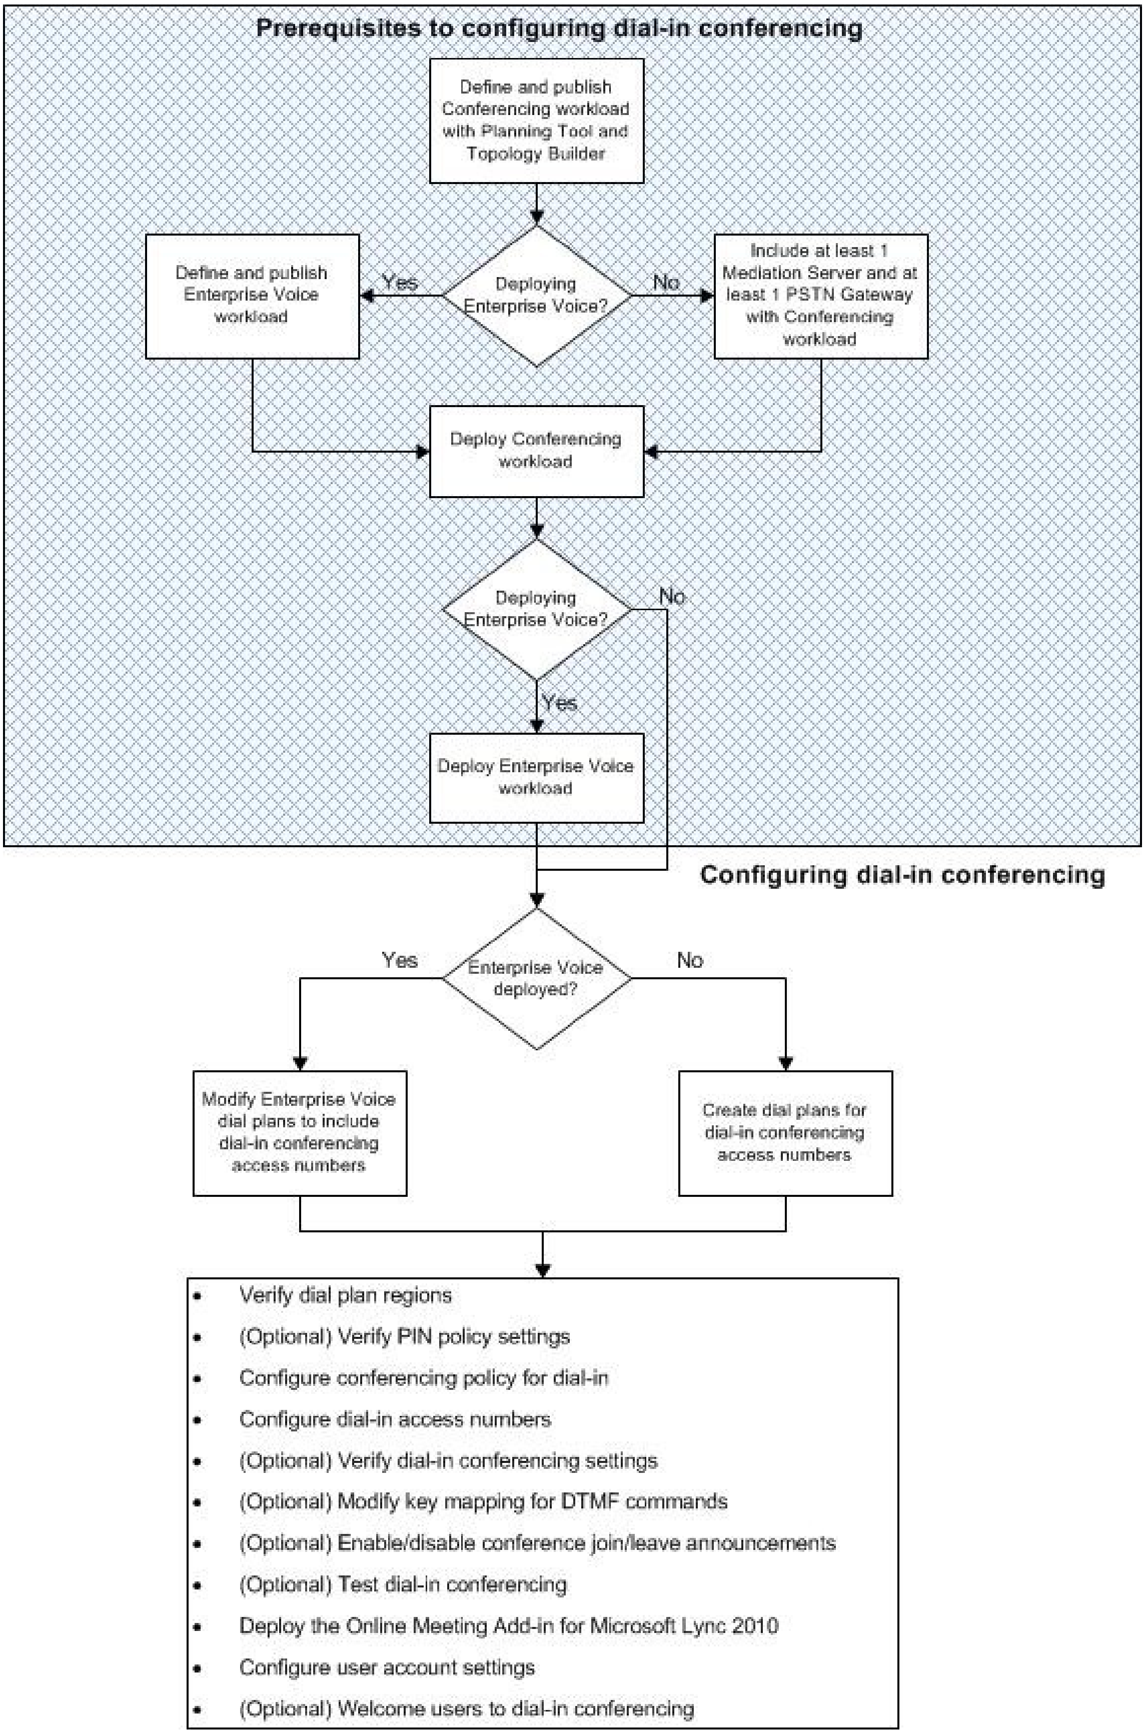
  Note:

  When you install your published topology, the Dial-in Conferencing Settings webpage is installed on the Front End Server or Standard Edition server as part of Web Services.

  Important:

  If you change the path for the File Store in Topology Builder after you deploy Lync Server 2013, you need to restart the Conferencing Attendant and Conferencing Announcement applications to use the new path.
- Deployed Enterprise Voice. If you are not deploying Enterprise Voice, you either collocated a Mediation Server on the Enterprise Edition Front End Server or the Standard Edition server, or you deployed a stand-alone Mediation Server, and you deployed a PSTN gateway. For details about deploying Enterprise Voice, see Deploying Enterprise Voice in the Deployment documentation. For details about installing a stand-alone Mediation Server and PSTN gateway, see Deploying Mediation Servers and Defining Peers in the Deployment documentation.

The following flowchart shows the steps that you must perform before you can configure dial-in conferencing and the steps that you perform to configure dial-in conferencing.



Prerequisites to configuring dial-in conferencing
Define and publish Conferencing workload with Planning Tool and Topology Builder
Deploying Enterprise Voice?
Yes
No
Define and publish Enterprise Voice workload
Include at least 1 Mediation Server and at least 1 PSTN Gateway with Conferencing workload
Deploy Conferencing workload
Deploying Enterprise Voice?
No
Yes
Deploy Enterprise Voice workload
Configuring dial-in conferencing
Enterprise Voice deployed?
Yes
No
Modify Enterprise Voice dial plans to include dial-in conferencing access numbers
Create dial plans for dial-in conferencing access numbers
• Verify dial plan regions
• (Optional) Verify PIN policy settings
• Configure conferencing policy for dial-in
• Configure dial-in access numbers
• (Optional) Verify dial-in conferencing settings
• (Optional) Modify key mapping for DTMF commands
• (Optional) Enable/disable conference join/leave announcements
• (Optional) Test dial-in conferencing
• Deploy the Online Meeting Add-in for Microsoft Lync 2010
• Configure user account settings
• (Optional) Welcome users to dial-in conferencing

Dial-in Conferencing Permissions

To configure dial-in conferencing, you need to use the following administrative tools:

- Lync Server 2013 Control Panel
- Lync Server Management Shell

You use these administrative tools to configure dial-in conferencing settings, and the dial plans, policies, and other settings that dial-in conferencing requires.

Configuring dial-in conferencing requires any of the following administrative roles, depending on the task:

- **CsVoiceAdministrator** This administrator role can create, configure, and manage voice-related settings and policies.
- **CsUserAdministrator** This administrator role can enable and disable users for Lync Server and assign existing policies, such as conferencing policies and PIN policies, to users.
- **CsAdministrator** This administrator role can perform all of the tasks of CsVoiceAdministrator and CsUserAdministrator.

1.4.4.1.2 Deployment Checklist for Dial-In Conferencing

Deployment Checklist for Dial-In Conferencing

Planning > Planning for Conferencing > Deployment Checklist for Conferencing >

Topic Last Modified: *2013-02-25*

The components required for dial-in conferencing are deployed when you deploy the conferencing workload. Before you can configure dial-in conferencing, you need to deploy either Enterprise Voice or a Mediation Server and a public switched telephone network (PSTN) gateway.

All the steps in the following table must be performed before users can dial in from the PSTN to join an audio/video conference.

Note:

If you are migrating from Office Communications Server 2007 R2, you must apply the latest updates to your Office Communications Server 2007 R2 environment before deploying dial-in conferencing.

Dial-in Conferencing Deployment Process

Phase	Steps	Permissions	Deployment documentation
Create a topology that includes the Conferencing workload, including a Mediation Server and PSTN gateway, and	1. Run Topology Builder to configure your topology. While configuring the topology, select the dial-in conferencing option. 2. Publish the	Domain Admins RTCUniversalServerAdmins Administrator	• Deploying Lync Server 2013 • To create a stand-alone Mediation Server pool: Deploying Mediation Servers and Defining Peers

deploy the Front End pool or Standard Edition server	topology and deploy the Front End pool or Standard Edition server. 3. If necessary, create a stand-alone Mediation Server and associate it with a PSTN gateway. **Note:** This step is required only if you do not deploy Enterprise Voice and do not collocate the Mediation Server with the Enterprise Edition Front End Server or Standard Edition server. If you deploy Enterprise Voice, you install and configure Mediation Servers and PSTN gateways as part of the Enterprise Voice deployment. If you collocate the Mediation Server, you install and configure the Mediation Server as part of the Front End pool or Standard Edition server deployment.		
Configure dial plans	A dial plan is a set of phone number normalization rules that translate phone numbers dialed from a specific location to a single standard (E.164) format for purposes of phone authorization and call routing. The same phone number dialed from different	RTCUniversalServerAdmins CsVoiceAdministrator CsServerAdministrator CsAdministrato	Configure Dial Plans for Dial-in Conferencing

	locations can, based on the respective dial plans, resolve to different E.164 numbers, as appropriate to each location. If you deploy Enterprise Voice, you set up dial plans as part of that deployment, and you need to make sure that the dial plans also accommodate dial-in conferencing. If you do not deploy Enterprise Voice, you need to set up dial plans for dial-in conferencing. Use the Lync Server 2013 Control Panel or Lync Server Management Shell to set up dial plans as follows: 1. Create one or more dial plans for routing dial-in access phone numbers. 2. Assign a default dial plan to each pool. Set the **Dial-in conferencing region** to the geographic location to which the dial plan applies. The region associates the dial plan with dial-in access numbers.	r	
Make sure that dial plans are assigned regions	Run the **Get-CsDialPlan** and **Set-CsDialPlan** cmdlets to make sure that all dial plans have a region assigned.	RTCUniversalServerAdmins CsVoiceAdministrator CsServerAdministrator CsAdministrator	Make Sure Dial Plans Have Assigned Regions
(Optional) Verify or modify user personal identification number (PIN) requirements	Use Lync Server 2013 Control Panel or Lync Server Management Shell to view or modify the Conferencing **PIN Policy**. You can specify minimum PIN length, maximum number of logon attempts, PIN expiration, and	RTCUniversalServerAdmins CsServerAdministrator CsAdministrator	(Optional) Verify PIN Policy Settings

	whether common patterns are allowable.		
Configure conferencing policy to support dial-in conferencing	Use Lync Server 2013 Control Panel or Lync Server Management Shell to configure **Conferencing Policy** settings. Specify whether: • PSTN conference dial-in is enabled. • Users can invite anonymous participants. • Unauthenticated users can join a conference by using dial-out phoning. With dial-out phoning, the conference server calls the user, and the user answers the phone to join the conference.	RTCUniversalServerAdmins CsServerAdministrator CsAdministrator	Configure Conferencing Policy for Dial-in
Configure dial-in access numbers	Use Lync Server 2013 Control Panel or Lync Server Management Shell to set up dial-in access numbers that users call to dial in to a conference, and specify the regions that associate the access number with the appropriate dial plans. The first three access numbers for the region specified by the organizer's dial plan are included in the conference invitation. All access numbers are available on the Dial-in Conferencing Settings page. **Note:** After you create dial-in access numbers, you can use the **Set-CsDialInConferencingAccessNumber** cmdlet to modify the display name of the Active Directory contact objects so that users can more easily identify the correct access number.	RTCUniversalServerAdmins CsServerAdministrator CsAdministrator	Configure Dial-in Conferencing Access Numbers

in conferencing and set the initial PIN	and send a welcome email that contains the initial PIN and a link to the Dial-in Conferencing Settings page.		

1.4.4.1.3 Configure Dial Plans for Dial-in Conferencing

Configure Dial Plans for Dial-in Conferencing

Deployment > Deploying Conferencing > Configuring Dial-in Conferencing >

Topic Last Modified: *2013-02-25*

When you deploy dial-in conferencing, you need to create or modify one or more dial plans for routing dial-in access phone numbers. Make sure that at least one normalization rule in each dial plan converts telephone extensions into complete phone numbers in E.164 format. Users of dial-in conferencing join conferences as authenticated enterprise users by entering their personal identification number (PIN) and their phone number. You need a normalization rule to convert extensions into complete phone numbers so that users can be authenticated when they enter just a telephone extension.

To set up dial plans for dial-in conferencing, do the following:

- Whether or not you deploy Enterprise Voice, modify the global dial plan to add a dial-in conferencing region and to make sure that a normalization rule accurately converts your dial-in access numbers. For detailed instructions, see Modify a Dial Plan.
- If you did not deploy Enterprise Voice, create dial plans for your dial-in conferencing access numbers. Be sure to include a dial-in conferencing region. For detailed instructions, see Create a Dial Plan.
- If you deployed Enterprise Voice, modify Enterprise Voice dial plans as necessary to include regions and use appropriate normalization rules for dial-in access numbers. For detailed instructions, see Modify a Dial Plan. You can also create dedicated dial plans that are used only for dial-in access numbers. For detailed instructions, see Create a Dial Plan.

For details about planning regions, see Dial-In Conferencing Requirements in the Planning documentation.

- Create a Dial Plan
- Modify a Dial Plan
- Defining Normalization Rules

1.4.4.1.3.1 View Dial Plan Information

View Dial Plan Information

See Also

Deployment > Deploying Enterprise Voice > Configuring Dial Plans >

Topic Last Modified: *2012-11-01*

To view information for an existing dial plan, perform the steps in the following procedure. If you want to create a new dial plan, see Create a Dial Plan.

⊟To view information about a dial plan from Lync Server Control Panel

1. Log on to the computer as a member of the RTCUniversalServerAdmins

group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.

2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing** and then click **Dial Plan**.
4. On the **Dial Plan** page, double-click a dial plan name.

> **Note:**
>
> You can view information for only one dial plan at a time.

⊟To view dial plans by using Windows PowerShell cmdlets

- Dial plans can be viewed by using the Windows PowerShell command-line interface and the **Get-CsDialPlan** cmdlet. This cmdlet can be run either from the Lync Server 2013 Management Shell or from a remote session of Windows PowerShell. For details about using remote Windows PowerShell to connect to Lync Server, see the Lync Server Windows PowerShell blog article "Quick Start: Managing Microsoft Lync Server 2010 Using Remote PowerShell" at http://go.microsoft.com/fwlink/p/?linkId=255876.

  To view information about all your dial plans, type the following command in the Lync Server Management Shell, and then press ENTER:

```
Get-CsDialPlan
```

  That command will return information similar to this:

```
Identity                   : Global
Description                :
DialinConferencingRegion   :
NormalizationRules         : {Description=;
                             Pattern=^(\d+)$;Translation=$1;Name=
                             KeepAll;IsInternalExtension=False}

1.4.4.1.3.2 Create a Dial Plan

Create a Dial Plan

See Also

Deployment > Deploying Enterprise Voice > Configuring Dial Plans >

Topic Last Modified: *2012-10-06*

To create a new dial plan, perform the steps in the following procedure. If you want to edit a dial plan, see Modify a Dial Plan.

⊟To create a dial plan

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.

3. In the left navigation bar, click **Voice Routing** and then click **Dial Plan**.
4. On the **Dial Plan** page, click **New** and select a scope for the dial plan:
   - **Site dial plan** applies to an entire site, except any users or groups that are assigned to a user dial plan. If you select **Site** for a dial plan's scope, you must choose the site from the **Select a Site** dialog box. If a dial plan has already been created for a site, the site does not appear in the **Select a Site** dialog box.
   - **Pool dial plan** can apply to a public switched telephone network (PSTN) gateway or a Registrar. If you select **Pool** for a dial plan's scope, choose the PSTN gateway or Registrar from the **Select a Service** dialog box. If a dial plan has already been created for a service (PSTN gateway or Registrar), the service does not appear in the list.
   - **User dial plan** can be applied to specified users or groups.

Note:

After you select the dial plan scope, it cannot be changed.

5. If you are creating a user dial plan, enter a descriptive name in the **Name** field on the **New Dial Plan** dialog box. After this name is saved, it cannot be changed.

Note:

For site dial plans, the **Name** field is prepopulated with the site name and cannot be changed.
For pool dial plans, the **Name** field is prepopulated with the PSTN gateway or Registrar name and cannot be changed.

6. The **Simple name** field is prepopulated with the same name that appears in the **Name** field. You can optionally edit this field to specify a more descriptive name that reflects the site, service, or user to which the dial plan applies.

Important:

The **Simple name** must be unique among all dial plans within the Lync Server deployment. It cannot exceed 256 Unicode characters, each of which can be an alphabetic or numeric character, a hyphen (-), a period (.), a plus sign (+), or an underscore (_).
Spaces are not allowed in the **Simple name**.

7. (Optional) In the **Description** field, you can type additional descriptive information about the dial plan.
8. (Optional) If you want to use this dial plan as a region for dial-in access numbers, specify a **Dial-in conferencing region**. If you do not want to use this dial plan for dial-in access numbers, leave this field empty.

Note:

Dial-in conferencing regions are required to associate dial-in conferencing access numbers with one or more dial plans.

9. (Optional) In the **External access prefix** field, specify a value only if users need to dial one or more additional leading digits (for example, 9) to get an external line. You can type in a prefix value of up to four characters (#, *, and 0-9).

Note:

If you specify an external access prefix, you do not need to create a new normalization rule to accommodate the prefix.

10. Associate and configure normalization rules for the dial plan as follows:
    - To choose one or more rules from a list of all normalization rules available in your Enterprise Voice deployment, click **Select**. In **Select Normalization Rules**, highlight the rules you want to associate with the dial plan and then click **OK**.
    - To define a new normalization rule and associate it with the dial plan, click **New**. For details about defining a new rule, see Defining Normalization Rules.

- To edit a normalization rule that is already associated with the dial plan, highlight the rule name and click **Show details**. For details about editing the rule, see Defining Normalization Rules.
- To copy an existing normalization rule to use as a starting point for defining a new rule, highlight the rule name and click **Copy**, and then click **Paste**. For details about editing the copy, see Defining Normalization Rules.
- To remove a normalization rule from the dial plan, highlight the rule name and click **Remove**.

> **Note:**
> Each dial plan must have at least one associated normalization rule. For information about how to determine all of the normalization rules a dial plan requires, see Dial Plans and Normalization Rules in the Planning documentation.

11. Verify that the dial plan's normalization rules are arranged in the correct order. To change a rule's position in the list, highlight the rule name and then click the up or down arrow.

> **Important:**
> Lync Server traverses the normalization rule list from the top down and uses the first rule that matches the dialed number. If you configure a dial plan so that a dialed number can match more than one normalization rule, make sure the more restrictive rules are sorted above the less restrictive ones.
> The default **Keep All** normalization rule **^(\d{11})$** matches any 11-digit number. For example, if you add a normalization rule that matches 11-digit numbers that start with 1425, make sure that **Keep All** is sorted below the more restrictive **^(1425\d{7})$** rule.

12. (Optional) Enter a number to test the dial plan and then click **Go**. The test results are displayed under **Enter a number to test**.

> **Note:**
> You can save a dial plan that does not yet pass the test and then reconfigure it later. For details, see Test Voice Routing.

13. Click **OK**.
14. On the **Dial Plan** page, click **Commit**, and then click **Commit all**.

> **Note:**
> Any time you create a dial plan, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

To modify an existing dial plan, perform the steps in the following procedure. If you want to create a new dial plan, see Create a Dial Plan.

To modify a dial plan

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing** and then click **Dial Plan**.
4. On the **Dial Plan** page, double-click a dial plan name.

   Note:

   The dial plan scope and name were set when the dial plan was created. They cannot be changed.

5. (Optional) In **Edit Dial Plan**, edit the **Simple name** field, which is prepopulated with the same name that appears in the **Name** field to specify a more descriptive name that reflects the site, service, or user to which the dial plan applies.

   Important:

   The **Simple name** must be unique among all dial plans within the Lync Server 2013 deployment. It cannot exceed 256 Unicode characters, each of which can be an alphabetic or numeric character, a hyphen (-), a period (.), a plus sign (+), or an underscore (_).

   Spaces are not allowed in the **Simple name** field.

6. (Optional) In the **Description** field, type descriptive information about the dial plan.
7. (Optional) If you want to use this dial plan as a region for dial-in access numbers, specify a **Dial-in conferencing region**. If you do not want to use this dial plan for dial-in access numbers, leave this field empty.

   Note:

   Dial-in conferencing regions are required to associate dial-in conferencing access numbers with one or more dial plans.

8. (Optional) In the **External access prefix** field, specify a value only if users need to dial one or more additional leading digits to get an external line (for example, 9). You can type in a prefix value of up to four characters (that is, #, *, and 0-9).

   Note:

   If you specify an external access prefix, you do not need to create a new normalization rule to accommodate the prefix.

9. Associate and configure normalization rules for the dial plan:
   - To choose one or more rules from a list of all normalization rules available in your Enterprise Voice deployment, click **Select**. In the **Select Normalization Rules** dialog box, highlight the rules that you want to associate with the dial plan and then click **OK**.
   - To define a new normalization rule and associate it with the dial plan, click **New**. For details about defining a new rule, see Defining Normalization Rules.
   - To edit a normalization rule that is already associated with the dial plan, highlight the rule name and click **Show details**. For details about editing the rule, see Defining Normalization Rules.
   - To copy an existing normalization rule to use as a starting point for defining a new rule, highlight the rule name and click **Copy**, and then click **Paste**. For details about editing the copy, see Defining Normalization Rules.
   - To remove a normalization rule from the dial plan, highlight the rule name and click **Remove**.

   Note:

Each dial plan must have at least one associated normalization rule. For details about how to determine all of the normalization rules a dial plan requires, see Dial Plans and Normalization Rules in the Planning documentation.

10. Verify that the dial plan’s normalization rules are arranged in the correct order. To change a rule’s position in the list, highlight the rule name and then click the up or down arrow.

> **Important:**
>
> Lync Server traverses the normalization rule list from the top down and uses the first rule that matches the dialed number. If you configure a dial plan so that a dialed number can match more than one normalization rule, make sure the more restrictive rules are sorted above the less restrictive ones.
> The default **Keep All** normalization rule **^(\d{11})$** matches any 11-digit number. If, for example, you add a normalization rule that matches 11-digit numbers that start with 1425, make sure that **Keep All** is sorted below the more restrictive **^(1425\d{7})$** rule.

11. (Optional) Enter a number to test the dial plan and then click **Go**. The test results are displayed under **Enter a number to test**.

> **Note:**
>
> You can save a dial plan that does not yet pass the test and then reconfigure it later. For details, see Test Voice Routing.

12. Click **OK**.
13. On the **Dial Plan** page, click **Commit**, and then click **Commit all**.

> **Note:**

1.4.4.1.3.4 Defining Normalization Rules

Defining Normalization Rules

See Also

Deployment > Deploying Enterprise Voice > Configuring Dial Plans >

Topic Last Modified: *2012-09-23*

Lync Server 2013 normalization rules use .NET Framework regular expressions to translate dialed phone numbers to E.164 format. Each dial plan must be assigned one or more normalization rules.

For details about normalization rules, see Dial Plans and Normalization Rules in the Planning documentation.

For details about how to write regular expressions, see ".NET Framework Regular Expressions" at http://go.microsoft.com/fwlink/p/?linkId=140927.

You can use either of the following methods to define or edit a normalization rule:

- Use the **Build a Normalization Rule** tool to specify values for the starting digits, length, digits to remove and digits to add, and then let Lync Server Control Panel generate the corresponding matching pattern and translation rule for you.

- Write regular expressions manually to define the matching pattern and translation rule.
- Create or Modify a Normalization Rule by Using Build a Normalization Rule
- Create or Modify a Normalization Rule Manually

Topic Last Modified: *2012-11-01*

Complete the following steps if you want to create or modify a normalization rule in Lync Server Control Panel. Alternatively, if you want to create or modify a normalization rule manually, see Create or Modify a Normalization Rule Manually.

⊟To define a rule by using Build a Normalization Rule

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. (Optional) Follow the steps in Create a Dial Plan through step 11 or Modify a Dial Plan through step 10.
4. In **New Normalization Rule** or **Edit Normalization Rule**, type a name that describes the number pattern being normalized in **Name** (for example, **5DigitExtension**).
5. (Optional) In **Description**, type a description of the normalization rule (for example, "Translates 5-digit extensions").
6. In **Build a Normalization Rule**, enter values in the following fields:
   - **Starting digits** (Optional) Specify the leading digits of dialed numbers you want the pattern to match. For example, type **425** if you want the pattern to match dialed numbers beginning with 425.
   - **Length** Specify the number of digits in the matching pattern and select whether you want the pattern to match this length exactly, match dialed numbers that are at least this length, or match dialed numbers of any length.
   - **Digits to remove** (Optional) Specify the number of starting digits to be removed from dialed numbers you want the pattern to match.
   - **Digits to add** (Optional) Specify digits to be added to dialed numbers you want the pattern to match.

   The values you enter in these fields are reflected in **Pattern to match** and **Translation rule**. For example, if you leave **Starting digits** empty, type **7** into the **Length** field and select **Exactly**, and specify **0** in **Digits to remove**, the resulting regular expression in the **Pattern to match** is:

   ^(\d{7})$

7. In **Translation rule**, specify a pattern for the format of translated E.164 phone numbers as follows:
   - A value that represents the number of digits specified in the matching pattern. For example, if the matching pattern is **^(\d{7})$** then **$1** in the translation rule represents 7-digit dialed numbers.
   - (Optional) Type a value into the **Digits to add** field to specify digits to be prepended to the translated number (for example, **+1425**).

   For example, if **Pattern to match** contains **^(\d{7})$** as the pattern for dialed numbers and **Translation rule** contains **+1425$1** as the pattern for E.164 phone numbers, the rule normalizes 5550100 to +14255550100.
8. (Optional) If the normalization rule results in a phone number that is internal to your organization, select **Internal extension**.
9. (Optional) Enter a number to test the normalization rule, and then click **Go**. The test results are displayed under **Enter a number to test**.

   > **Note:**
   > You can save a normalization rule that does not yet pass the test and then reconfigure it later. For details, see Test Voice Routing.

10. Click **OK** to save the normalization rule.
11. Click **OK** to save the dial plan.
12. On the **Dial Plan** page, click **Commit**, and then click **Commit all**.

   > **Note:**
   > Whenever you create or change a normalization rule, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

Topic Last Modified: *2012-09-22*

Complete the following steps if you want to create or modify a normalization rule manually. If you want to create or modify a normalization rule by using Build a Normalization Rule in Lync Server Control Panel, see Create or Modify a Normalization Rule by Using Build a Normalization Rule.

⊟To define a normalization rule manually

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. (Optional) Follow the steps in Create a Dial Plan or Modify a Dial Plan.
4. In **New Normalization Rule** or **Edit Normalization Rule**, type a name that describes the number pattern being normalized in **Name** (for example, name

the normalization rule **5DigitExtension**).

5. (Optional) In **Description** field, type a description of the normalization rule (for example, "Translates 5-digit extensions").
6. In **Build a Normalization Rule**, click **Edit**.
7. Enter the following in **Type a Regular Expression**:
   - In **Match this pattern**, specify the pattern that you want to use to match the dialed phone number.
   - In **Translation rule**, specify a pattern for the format of translated E.164 phone numbers.

   For example, if you enter **^(\d{7})$** in **Match this pattern** and **+1425$1** in **Translation rule**, the rule normalizes 5550100 to +14255550100.
8. (Optional) If the normalization rule results in a phone number that is internal to your organization, select **Internal extension**.
9. (Optional) Enter a number to test the normalization rule and then click **Go**. The test results are displayed under **Enter a number to test**.

   Note:
   You can save a normalization rule that does not yet pass the test and then reconfigure it later. For details, see Test Voice Routing.
10. Click **OK** to save the normalization rule.
11. Click **OK** to save the dial plan.
12. On the **Dial Plan** page, click **Commit**, and then click **Commit all**.

    Note:
    Whenever you create or change a normalization rule, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

1.4.4.1.4 Make Sure Dial Plans Have Assigned Regions

Make Sure Dial Plans Have Assigned Regions

Deployment > Deploying Conferencing > Configuring Dial-in Conferencing >

Topic Last Modified: *2010-11-02*

Dial plans that are used for dial-in conferencing need to have a **Dial-in conferencing region** specified to associate dial-in conferencing access numbers with the appropriate dial plan. When you set up a dial plan, you specify the dial-in conferencing region that applies to that dial plan. Then, when you create the dial-in access number, you select the regions that associate the access number with the appropriate dial plans.

Because it important to specify a region for all dial plans, we recommend that you use this procedure to verify that all dial plans have regions. This step is optional.

Use the **Get-CsDialPlan** cmdlet to verify whether the region is set for all dial-in conferencing dial plans. If the region is missing from dial plans, you can use the **Set-CsDialPlan** cmdlet to set the region. You can also use Lync Server Control Panel to update the region in existing dial plans. For details about using Lync Server Control Panel, see Modify a Dial Plan.

To verify whether dial plans have the region property set

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the **Cs-VoiceAdministrator**, **Cs-ServerAdministrator**, or **CsAdministrator** role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run the following at the command prompt:

   ```
   Get-CsDialPlan [-Identity <Identifier of the dial plans to be retrieve
   ```

   For example:

   ```
   Get-CsDialPlan
   ```

   In this example, all the dial plans configured for your organization are returned.
4. Review the returned dial plans to identify any that are missing the dial-in conferencing region. For details, see the Lync Server Management Shell documentation.

To set the region property for a dial plan

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the **Cs-VoiceAdministrator**, **Cs-ServerAdministrator**, or **CsAdministrator** role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. For any dial plans that are missing the dial-in conferencing region, run:

   ```
   Set-CsDialPlan [-Identity <Identity of the dial plan to be modified>]
   ```

   For example:

   ```
   Set-CsDialPlan -Identity Redmond -DialinConferencingRegion "US West Co
   ```

   In this example, the dial plan with the Identity of Redmond is modified to set the DialinConferencingRegion property to "US West Coast". For details, see the Lync Server Management Shell documentation.

1.4.4.1.5 (Optional) Verify PIN Policy Settings

(Optional) Verify PIN Policy Settings

Deployment > Deploying Conferencing > Configuring Dial-in Conferencing >

Topic Last Modified: *2012-06-20*

Lync Server 2013 users who have Active Directory Domain Services (AD DS) credentials can enter a personal identification number (PIN) to join dial-in conferences as authenticated users. A PIN policy defines the rules for how dial-in conferencing PINs work.

When you deploy dial-in conferencing, you should verify that the default global PIN policy meets your requirements. If you need to make changes, you can modify the default global policy or you can create a new PIN policy. You can create PIN policies that apply to a specific site, a specific user, or a specific group of users.

- Modify the Default Dial-in Conferencing PIN Settings
- Create or Modify Dial-in Conferencing PIN Settings for a Site or Group of Users

1.4.4.1.5.1 Modify the Default Dial-in Conferencing PIN Settings

Modify the Default Dial-in Conferencing PIN Settings

Deploying Conferencing > Configuring Dial-in Conferencing > (Optional) Verify PIN Policy Settings >

Topic Last Modified: *2012-10-18*

The global PIN policy defines the rules for dial-in conferencing PINs at the forest level. Follow these steps to modify the global dial-in conferencing PIN policy. For details about creating or modifying a dial-in conferencing PIN policy at the site or user level, see Create or Modify Dial-in Conferencing PIN Settings for a Site or Group of Users.

⊟To modify the global PIN policy

1. From a user account that is a member of the RTCUniversalServerAdmins group (or has equivalent user rights), or assigned to the CsServerAdministrator or CsAdministrator role, log on to any computer that is in the network in which you deployed Lync Server 2013.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Conferencing**, and then click **PIN Policy**.
4. On the **PIN Policy** page, click the **Global** policy, click **Edit**, and then click **Show details**.
5. In **Edit PIN Policy**, in **Minimum PIN length**, type or select the minimum PIN length that you want to allow. The default minimum length is five digits.
6. To be able to specify the maximum number of logon attempts before a user is locked out, select the **Specify maximum logon attempts** check box. If you do not select this option, the maximum number of allowed attempts is automatically determined based on the PIN length. By default, the maximum number of attempts is automatically determined.
7. If you selected the **Specify maximum logon attempts** check box, in **Maximum logon attempts**, type or select the maximum number of logon attempts that you want to allow.
8. To have PINs expire, select the **Enable PIN expiration** check box. If you do not select this option, PINs will never expire. By default, PINs never expire.
9. If you selected the **Enable PIN expiration** check box, in **PIN expires after (days)**, type or select the number of days after which PINs expire.
10. In **PIN history count**, type the number of PINs that a user must create before the user can reuse a PIN. By default, users can reuse their PINs.
11. To allow common patterns of digits in PINs, such as sequential numbers and repetitive sets of numbers, select the **Allow common patterns** check box. If you do not select this option, only complex patterns of digits are allowed. By default, only complex patterns of digits are allowed.

◆**Important:**
We recommend that you do not allow common patterns.

12. Click **Commit**.

1.4.4.1.5.2 Create or Modify Dial-in Conferencing PIN Settings for a Site or Group of Users

Create or Modify Dial-in Conferencing PIN Settings for a Site or Group of Users

Deploying Conferencing > Configuring Dial-in Conferencing > (Optional) Verify PIN Policy Settings >

Topic Last Modified: *2012-10-18*

Follow these steps to create or modify a user-level or a site-level dial-in conferencing personal identification number (PIN) policy. For details about how to change the global PIN policy, see Modify the Default Dial-in Conferencing PIN Settings.

⊟To create a user or site PIN policy

1. From a user account that is a member of the RTCUniversalServerAdmins group (or has equivalent user rights), or assigned to the CsServerAdministrator or CsAdministrator role, log on to any computer that is in the network in which you deployed Lync Server 2013.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Conferencing**, and then click **PIN Policy**.
4. On the **PIN Policy** page, click **New**, and then do one of the following:
   - To create a user-level policy, click **User policy**. In **New PIN Policy**, in **Name**, type a name that describes the policy.
   - To create a site-level policy, click **Site policy**. In the **Select a Site** search field, type all or part of the name of the site for which you want to create a policy. In the list of sites, click the site you want, and then click **OK**.
5. In the **Description** field, type a description of the PIN policy.
6. In the **Minimum PIN length** field, type or select the minimum PIN length that you want to allow. The default minimum length is five digits.
7. To be able to specify the maximum number of logon attempts before a user is locked out, select the **Specify maximum logon attempts** check box. If you do not select this option, the maximum number of allowed attempts is automatically determined based on the PIN length. By default, the maximum number of attempts is automatically determined.
8. If you selected the **Specify maximum logon attempts** check box, in **Maximum logon attempts**, type or select the maximum number of logon attempts that you want to allow.
9. To have PINs expire, select the **Enable PIN expiration** check box. If you do not select this option, PINs will never expire. By default, PINs never expire.
10. If you selected the **Enable PIN expiration** check box, in **PIN expires after (days)**, type or select the number of days after which PINs expire.
11. In **PIN history count**, type the number of PINs that a user must create before the user can reuse a PIN. By default, users can reuse their PINs.
12. To allow common patterns of digits in PINs, such as sequential numbers and repetitive sets of numbers, select the **Allow common patterns** check box. If you do not select this option, only complex patterns of digits are allowed. By default, only complex patterns of digits are allowed.

◆**Important:**
We recommend that you do not allow common patterns.

13. Click **Commit**.

⊟To change a user or site PIN policy

1. From a user account that is a member of the RTCUniversalServerAdmins group (or has equivalent user rights), or assigned to the CsServerAdministrator or CsAdministrator role, log on to any computer that is in the network in which you deployed Lync Server 2013.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Conferencing**, and then click **PIN Policy**.

4. On the **PIN Policy** page, click the PIN policy that you want to change, click **Edit**, and then click **Show details**.
5. In **Edit PIN Policy**, modify any of the policy settings (except for the policy name, which cannot be modified).

6. Click **Commit**.

1.4.4.1.6 Configure Conferencing Policy for Dial-in

Configure Conferencing Policy for Dial-in

Deployment > Deploying Conferencing > Configuring Dial-in Conferencing >

Topic Last Modified: *2012-10-07*

Conferencing policy is a user account setting that specifies the conferencing experience for participants. You can create conferencing policies with a site scope or a user scope. Conferencing policy settings encompass many aspects of conference scheduling and participation. Several conferencing policy settings support dial-in conferencing for participants. When you configure dial-in conferencing, you should verify that these fields are set appropriately for your organization, and modify them as necessary.

Verify the following fields in your conferencing policy:

- **Allow participants to invite anonymous users** This setting allows meeting organizers to invite anonymous (that is, unauthenticated) participants to meetings. This setting is optional for dial-in conferencing. This setting is selected by default in the default global conferencing policy.
- **Enable PSTN dial-in conferencing** This setting allows users to join the audio portion of a conference by dialing in from the PSTN. This setting is required for dial-in conferencing. This setting is selected by default in the default global conferencing policy.
- **Allow anonymous participants to dial out** This setting allows anonymous users who are already joined to the meeting to dial out to a phone number to join the audio portion of the conference. This setting is optional for dial-in conferencing. This setting is not selected by default in the default global conferencing policy.
- **Allow participants not enabled for Enterprise Voice to dial out** This setting allows meeting participants and organizers that are not enabled for Enterprise Voice to dial out to a phone number to join the audio portion of the conference. The dial-out call is authorized based on the organizer’s assigned voice policy. This setting is not selected by default in the default global conferencing policy. The setting default value is disabled.

Note:
To enable this capability, a meeting organizer that is not enabled for Enterprise Voice should have an appropriate voice policy assigned to them to authorize any dial-out from a conference organized by that user. A voice policy can be assigned to a user that is not enabled for Enterprise Voice from the Lync Server Management Shell. If the user does not have a voice policy explicitly assigned to him, the global voice policy will be used to authorize the dial-out request.

The procedure in this section explains how to modify conferencing policy. For details about how to configure all of the settings that define the participant experience in the default conferencing policy, see Create or Modify a Collection of Meeting Configuration Settings. For details about how to create a conferencing policy for a specific user or group of users, see Create or Modify a Conferencing Policy. For a list of all available conferencing policy settings, see Conferencing Policy Settings Reference.

⊟To modify the conferencing policy for dial-in

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the **Cs-ServerAdministrator** or **CsAdministrator** role.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Conferencing**.
4. On the **Conferencing Policy** tab, double-click a conferencing policy name to open the **Edit Conferencing Policy** dialog box.
5. Verify that the fields for dial-in conferencing are appropriate for your organization, and modify the settings if necessary.
6. Click **Commit**.

1.4.4.1.7 Configure Dial-in Conferencing Access Numbers

Configure Dial-in Conferencing Access Numbers

See Also

Deployment > Deploying Conferencing > Configuring Dial-in Conferencing >

Topic Last Modified: *2011-07-17*

When you deploy dial-in conferencing, you need to set up phone numbers that users can dial from the public switched telephone network (PSTN) to join the audio portion of conferences. These dial-in access numbers appear in meeting invitations and on the Dial-in Conferencing Settings webpage.

Before you can create dial-in access numbers, you must first plan your dial-in conferencing regions and then configure dial plans with the regions. For details about regions, see Dial-In Conferencing Requirements in the Planning documentation. For details about configuring dial plans for dial-in conferencing, see Configure Dial Plans for Dial-in Conferencing.

Note:
You cannot use a new dial-in access number until Active Directory Domain Services (AD DS) replication of that access number is complete. Replication can take several hours to complete.

Note:
After you create dial-in access numbers, you can modify the display name for the Active Directory contact objects so that users can more easily identify the correct access number. Use the **Set-CsDialInConferencingAccessNumber** cmdlet to modify the display name. You should not modify Active Directory objects manually. For details about modifying an access number, see Lync Server Management Shell documentation for the **Set-CsDialInConferencingAccessNumber** cmdlet.

Create or Modify a Dial-in Conferencing Access Number

⊟See Also

Configure Dial Plans for Dial-in Conferencing

1.4.4.1.7.1 Create or Modify a Dial-in Conferencing Access Number

Create or Modify a Dial-in Conferencing Access Number

Deploying Conferencing > Configuring Dial-in Conferencing > Configure Dial-in Conferencing Access Numbers >

Topic Last Modified: *2012-09-17*

Follow these steps if you want to create or modify a dial-in conferencing access number.

Important:
Before you create a new dial-in access number, you must set a dial-in conferencing region in the dial plan that is associated with the new dial-in access number. Multiple dial plans can use the same region.

⊟To create or modify a dial-in access number

1. From a user account that is assigned to the CsUserAdministrator role or the CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Conferencing** and then click **Dial-in Access Number**.
4. On the **Dial-in Access Number** page, do one of the following:
   - Click **New** to open **New Dial-in Access Number**.
   - Click one of the dial-in access numbers in the list, click **Edit**, and then click **Show details**.

Note:
Using the search field to search for the contents of a column in the list of dial-in access numbers may not yield the results you expect. Instead, sort the list by the column of interest to identify the dial-in access number you want to view or change.

5. In **Display number**, type the phone number that public switched telephone network (PSTN) phone users dial to join a conference.

Note:
This number is displayed in meeting invitations and on the Dial-in Conferencing Settings webpage.

6. In **Display name**, type a description for the dial-in access number. This is the name that is associated with the dial-in access number in Lync search results.

Note:
This name is displayed in the client when a user calls the access number.

7. In **Line URI**, type the E.164 number of the dial-in access number in TEL URI format, including the + symbol before the number and excluding spaces. For example, tel:+14255550200.

Note:
The same Line URI cannot be reused by another dial-in conferencing access number.

8. In **SIP URI**, do the following:
   - In the text box, type a unique SIP URI for this dial-in conferencing access number. This SIP URI is displayed in various locations including, but not limited to, call notification messages and previous versions of Communicator clients.

Note:

> The same SIP URI cannot be reused by another dial-in conferencing access number. The SIP URI cannot be modified after the access number is created. The only way to change the SIP URI is to delete and recreate the access number.

- In the drop-down list box, click the domain of the Conferencing Attendant application that supports this dial-in access number.

9. In **Pool**, click the pool that is running the instance of Conferencing Attendant that supports this dial-in access number.

> **Note:**
> If you need to change the pool after you create the access number, you must use the **Move-CsApplicationEndpoint** cmdlet or delete and recreate the access number.

10. In **Primary language**, click the language in which prompts are played for this dial-in access number.

> **Note:**
> The primary language is the language that the Conferencing Attendant uses to answer the call. Supported languages are displayed alongside each access phone number on the Dial-in Conferencing Settings webpage.

11. (Optional) In **Secondary languages (maximum of four)**, click **Add**, select one or more additional languages that you want to support for callers to this dial-in access number, and then click **OK**.

> **Note:**
> You can choose up to four secondary languages for each dial-in access number. Users can select a secondary language before entering the conference ID when they dial in to a conference.

12. To add a region for the dial-in access number, under **Associated regions**, click **Add**, click one or more regions that are associated with the dial plans for this dial-in access number, and then click **OK**.
13. To delete a region from the dial-in access number, under **Associated regions**, click the region you want to delete, and then click **Remove**.

14. Click **Commit**.

1.4.4.1.8 (Optional) Verify Dial-in Conferencing Settings

(Optional) Verify Dial-in Conferencing Settings

Deployment > Deploying Conferencing > Configuring Dial-in Conferencing >

Topic Last Modified: *2010-11-02*

As final verification of your dial-in conferencing configuration, you can search for dial plans that have a dial-in conferencing region that is not used by any access number and for access numbers that have not specified a dial-in conferencing region. This step is optional.

⊟To find dial plans with a dial-in conferencing region that is not used by an access number

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the **Cs-ServerAdministrator** or **CsAdministrator** role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.

3. Run the following at the command prompt:

```
Get-CsDialinConferencingAccessNumber -EmptyRegion
```

This cmdlet returns all of the dial plans that have a dial-in conferencing region that is not used by an access number.

⊟To find access numbers without assigned regions

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the **Cs-ServerAdministrator** or **CsAdministrator** role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run the following at the command prompt:

```
Get-CsDialinConferencingAccessNumber -Region NULL
```

This cmdlet returns all the dial-in conferencing access numbers that are not associated with a region.

1.4.4.1.9 (Optional) Modify Key Mapping for DTMF Commands

(Optional) Modify Key Mapping for DTMF Commands

Deployment > Deploying Conferencing > Configuring Dial-in Conferencing >

Topic Last Modified: *2012-09-30*

Dial-in conferencing users can press keys on the telephone keypad to perform dual-tone multi-frequency (DTMF) commands. DTMF commands enable users who dial in to a conference to control conference settings (such as muting and unmuting themselves or locking and unlocking the conference) by using the keypad on their telephone. You can use cmdlets to modify the keys used for the DTMF commands. This step is optional.

Note:

For details about these cmdlets and the possible DTMF options, see Lync Server Management Shell documentation or Lync Server Management Shell command-line Help.

⊟To modify the key mapping of DTMF commands

1. Log on to the computer as a member of the **RTCUniversalServerAdmins** group, or as a member of the **Cs-ServerAdministrator** or **CsAdministrator** role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run the following at the command prompt:

```
Get-CsDialinConferencingDtmfConfiguration
```

This cmdlet returns the DTMF settings used for dial-in conferencing.

4. Run the following cmdlet and specify the key to be pressed for each option that you want to change:

```
Set-CsDialinConferencingDtmfConfiguration [-Identity <global or site c
[-AdmitAll <default key is 8>] [-AudienceMuteCommand <default key is 4
[-CommandCharacter <* (default) | #>] [-EnableDisableAnnouncementsComm
[-HelpCommand <default key is 1>] [-LockUnlockConferenceCommand <defau
[-MuteUnmuteCommand <default key is 6>] [-PrivateRollCallCommand <defa
```

This cmdlet modifies the DTMF settings used for dial-in conferencing.

For example:

```
Set-CsDialinConferencingDtmfConfiguration -EnableDisableAnnouncementsC
```

This example swaps the key that is pressed to enable or disable announcements and the key that is pressed to mute and unmute all participants. Because no Identity is specified, these changes apply to the global DTMF settings.

5. (Optional) To create additional sets of DTMF commands for specific sites, use the **New-CsDialinConferencingDtmfConfiguration** cmdlet with a site identity. When you create new DTMF settings for sites, the site settings take precedence over the global settings. For details, see Lync Server Management Shell documentation or Lync Server Management Shell command-line Help.

1.4.4.1.10 (Optional) Enable and Disable Conference Join and Leave Announcements

(Optional) Enable and Disable Conference Join and Leave Announcements

Deployment > Deploying Conferencing > Configuring Dial-in Conferencing >

Topic Last Modified: *2012-09-30*

When dial-in users join or leave a conference, the Conferencing Announcement application can announce their entrance or exit by playing a tone or saying their names. You can change how announcements work by running cmdlets. This step is optional.

To modify the conference join and leave announcement behavior

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the **Cs-ServerAdministrator** or **CsAdministrator** role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run the following at the command prompt:

```
Get-CsDialinConferencingConfiguration
```

This cmdlet retrieves information about whether participants are required to record their name when joining a conference and how Lync Server responds when participants join or leave a dial-in conference.

4. Run the following at the command prompt:

```
Set-CsDialinConferencingConfiguration -Identity <identity of dial-in c
[-EnableNameRecording <$true | $false>]
[-EntryExitAnnouncementsEnabledByDefault <$true | $false>]
[-EntryExitAnnouncementsType <UseNames | ToneOnly]
```

EnableNameRecording Determines whether anonymous participants are asked to record their name before entering the conference. The default value is "$true," which means that anonymous participants are prompted to state their name when joining a conference. (Authenticated participants do not record their name because their display name is used instead.)

EntryExitAnnouncementsEnabledByDefault Indicates whether announcements are turned on or off by default. The default value is "$false," which means that by default there are no announcements when participants join or leave a conference. The meeting organizer can override this setting when scheduling a meeting.

EntryExitAnnouncementsType Indicates the action taken whenever a participant joins or leaves a conference for which announcements are enabled. The default value is "UseNames," which means there is an announcement similar to the following: "Ken Myer has joined the conference" when announcements are turned on.

You can configure these settings at the global scope or at the site scope. Settings configured at the site scope take precedence over settings configured at the global scope.

For example:

```
Set-CsDialinConferencingConfiguration -Identity site:Redmond
-EnableNameRecording $false
-EntryExitAnnouncementsEnabledByDefault $true
-EntryExitAnnouncementsType ToneOnly
```

In this example, settings are configured at the site scope for Redmond. Announcements are turned on, but participants are not prompted to say their name when they join a conference. A tone is played when participants enter or leave a conference.

1.4.4.1.11 (Optional) Verify Dial-in Conferencing

(Optional) Verify Dial-in Conferencing

Deployment > Deploying Conferencing > Configuring Dial-in Conferencing >

Topic Last Modified: *2011-01-21*

To verify that the Dial-in Conferencing Settings webpage and the dial-in access numbers work correctly, you need to do the following:

- Test the Dial-in Conferencing Settings webpage by signing in to the simple URL.
- Test that access numbers work correctly for a specific pool by running the script later in this topic. This script simulates calls to access numbers. You need the SIP address and credentials of one unified communications (UC) client that is hosted on the specific pool to use this script.

This step is optional.

To test access numbers for a specific pool

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the **Cs-ServerAdministrator** or **CsAdministrator** role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run the following at the command prompt:

```
$credentials = Get-Credential
   User name:  testuser1@contoso.com
   Password:   ********
Test-CsDialInConferencing -UserSipAddress sip:testuser1@contoso.com -U
```

The resulting report shows either Success or Failure, along with specific diagnostic information. The –Verbose flag provides more detailed information about how many access numbers were found and details about them.

1.4.4.1.12 Deploy the Online Meeting Add-in for Lync 2013

Deploy the Online Meeting Add-in for Lync 2013

Deployment > Deploying Conferencing > Configuring Dial-in Conferencing >

Topic Last Modified: *2012-09-30*

Deploy the Online Meeting Add-in for Lync 2013 so that users can schedule conferences that support dial-in conferencing.

The Online Meeting Add-in for Lync 2013 is installed automatically when you install Lync 2013. For details about customizing Online Meeting Add-in for Lync 2013 for Lync, see Configuring the Meeting Invitation.

1.4.4.1.13 Configure User Account Settings

Configure User Account Settings

Deployment > Deploying Conferencing > Configuring Dial-in Conferencing >

Topic Last Modified: *2012-10-05*

Dial-in users enter their phone number or extension and a PIN to join conferences as authenticated users. The telephony **Line URI** specified on Lync Server user accounts is required for authentication.

The procedure in this topic describes how to assign a **Line URI** for a single user account. If you need to assign a **Line URI** for multiple user accounts, you can create a script that uses the **Set-CsUser** cmdlet. For details about using a sample script to assign **Line URI** to multiple user accounts, see "Assign Line URIs to Multiple Users" at http://go.microsoft.com/fwlink/p/?linkId=196945.

⊟To configure user account settings

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the **Cs-UserAdministrator** or **CsAdministrator** role.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Users**.
4. In the search field, type the name of the user you want to configure for dial-in conferencing or click **Add filter** to specify search fields, and then click **Find**.
5. Double-click the user name to open the **Edit Lync Server User** dialog box.
6. Under **Telephony**, in the **Line URI** field, type a unique, normalized phone number (for example, tel:+14255550200).

   > **Note:**
   >
   > You can specify **Line URI** only if **Telephony** is set to **PC-to-PC only**, **Enterprise Voice**, **Remote call control** or **Remote call control only**.

7. Click **Commit**.

1.4.4.1.14 (Optional) Welcome Users to Dial-in Conferencing

(Optional) Welcome Users to Dial-in Conferencing

Deployment > Deploying Conferencing > Configuring Dial-in Conferencing >

Topic Last Modified: *2012-09-30*

After you configure dial-in conferencing and test to verify that it is functioning properly, you should set initial personal identification numbers (PINs) for users and notify users about the availability of the feature, including introductory instructions such as the initial PIN and the link to the Dial-in Conferencing Settings webpage. This step is optional. Typically, you use the **Set-CsClientPin** cmdlet to reset PINs, but you can use the procedure in this topic the first time if you want to send a welcome email with the information. If you do not want to send the email, you can use **Set-CsClientPin** instead.

You can use the **Set-CsPinSendCAWelcomeMail** script to set the PIN and send a welcome email to a single user. By default, the script does not reset a PIN if it is already set, but you can use the **Force** parameter to force reset a PIN. The email message is sent using Simple Mail Transfer Protocol (SMTP).

You can create a script that runs the **Set-CsPinSendCAWelcomeMail** script iteratively to set PINs and send email to a group of users. You can modify the email template (that is, the **CAWelcomeEmailTemplate.html** file) to add more links to intranet pages or modify the email text.

To set an initial PIN and send welcome email

1. Log on as a member of the RTCUniversalServerAdmins group.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Run the following at the command prompt:

```
Set-CsPinSendCAWelcomeMail -UserUri <user identifier>
-From <email address of sender> [-Subject <subject for email message>]
[-UserEmailAddress <destination email address>]
[-Cc <email address of recipients who receive copy of email>]
[-Bcc <email address of recipients who receive blind copies>]
[-TemplatePath <path for email template>]
[-SmtpServer] <SMTP server name>]
[-BodyAsPlainText] [-UseSsl]
[-Pin <new numeric PIN>] [-Force] `
[-Credential <SMTP server credentials used to send email with the spec
```

SmtpServer By default, the script uses the value of the reserved environment variable **$PSEmailServer** for this parameter. If the **$PSEmailServer** variable is not set, you must specify this parameter.

Credential By default, the script uses the credentials of the current user. If the current user does not have permission to send email on behalf of the specified From address, you must specify this parameter. As a general rule, specify this parameter if you do not specify your email address as the From address.

For example:

```
Set-CsPinSendCAWelcomeMail -UserUri "bob@contoso.com"
-From "marco@contoso.com"
```

This example creates a new PIN and then sends a welcome email from Marco to Bob. It uses the email text from the default template and creates the email message in HTML format. The default Subject is "Welcome to Dial In Conferencing".

Another example:

```
Set-CsPinSendCAWelcomeMail -UserUri "bob@contoso.com"
-From "marco@contoso.com" -Subject "Your new dial-in conferencing PIN"
-Pin "383042650" -Force
-Credential Admin@contoso.com -UseSsl
```

This example forces a new PIN with a value of "383042650" for Bob, even though Bob had an existing PIN, and then sends a welcome email from Marco to Bob. Because the Credential parameter is specified, the person running the command is prompted to enter a password. The email is sent by using the Secure Sockets Layer (SSL).

1.4.4.2 Enabling Office Web Apps Server and Lync Server 2013

Configuring Integration with Office Web Apps Server and Lync Server 2013

Microsoft Lync Server 2013 > Deployment > Deploying Conferencing >

Topic Last Modified: *2013-01-22*

Lync Server 2013 employs Office Web Apps Server to handle PowerPoint presentations. For information about the advantages to this approach, see Web Conferencing Overview.

In order to use these new capabilities administrators must install Office Web Apps Server and they must configure Lync Server 2013 to communicate with Office Web Apps Server. This documentation provides information on how to configure Lync Server 2013 to work with Office Web Apps Server. What this documentation does not provide is information on how to install Office Web Apps Server itself; for that information, see the Microsoft Office Web Apps Deployment website at http://go.microsoft.com/fwlink/p/?linkid=257525. That guide includes complete prerequisite information for Office Web Apps Server; note that Office Web Apps Server should be installed on a stand-alone computer that is not running Lync Server, Microsoft SQL Server, or any other server application. (You must not have any version of Microsoft office installed on that computer.) Any computer used to run Office Web Apps Server must also have a specific set of software installed (including .NET Framework 4.5 and Windows PowerShell 3.0); these requirements, along with information on configuring certificates and Internet Information Services (IIS), are discussed in detail in the Microsoft Office Web Apps Deployment website at http://go.microsoft.com/fwlink/p/?linkid=257525.

This document covers the following topic areas:

- Configuring Lync Server 2013 to Work with Office Web Apps Server
- Publishing Office Web Apps Server Using a Reverse Proxy Server
- Validating the Configuration of Office Web Apps Server
- Configuring Clients for Use With Office Web Apps Server

1.4.4.2.1 Configuring Lync Server 2013 to Work with Office Web Apps Server

Configuring Lync Server 2013 to Work with Office Web Apps Server

Deployment > Deploying Conferencing > Configuring Integration with Office Web Apps Server and Lync Server 2013 >

Topic Last Modified: *2013-02-25*

Before you can configure Lync Server 2013 to use Office Web Apps Server, Office Web Apps Server must be deployed and configured. See the document **Guide to Deploying Office Web Apps Server and Office Web Apps** for detail information on how to install and configure a single Office Web Apps Server, or for information on how to install and configure an Office Web Apps Server Farm for high availability.

After Office Web Apps Server has been successfully installed and your Web farm correctly configured, you must then configure Lync Server to communicate with the new server; this is done by adding the Office Web Apps Server discovery URL to your Lync Server topology. To add Office Web Apps Server to your topology, complete the following steps:

1. Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013 (Preview)**, and then click **Lync Server Topology Builder**.
2. In the **Topology Builder** dialog box, select **Download Topology from existing deployment** and then click **OK**.
3. In the **Save Topology As** dialog box, type a name for your topology document (for example, **PreWebAppsServerTopology**) in the **File name** box and then click **Save**. This topology can later be retrieved and republished if you encounter problems with your new topology.
4. In Topology Builder, expand **Lync Server 2013 (Preview)**, expand the name of your site, expand **Enterprise Edition Front End pools**, right-click the name of one of your pools, and then click **Edit Properties**.
5. In the **Edit Properties** dialog box, on the **General** tab, find the heading **Associate Office Web Apps Server** and then click **New** (or select an existing Office Web Apps Server from the drop-down list).
6. In the **Define New Office Web Apps Server** dialog box, type the fully qualified domain name (FQDN) of your Office Web Apps Server computer in the **Office Web Apps Server FQDN** box; when you do this, your Office Web Apps Server discovery URL should automatically be entered into the **Office Web Apps Server discovery URL** box.
   If the Office Web Apps Server is installed on-premises and in the same network zone as Lync Server 2013 then the option **Office Web Apps Server is deployed in an external network (that is, perimeter/Internet)** should not be selected.
   If the Office Web Apps Server is deployed outside your internal firewall, then select the option **Office Web Apps Server is deployed in an external network (that is, perimeter/Internet)**.
7. In the **Define New Office Web Apps Server** dialog box, click **OK**, and then click **OK** in the **Edit Properties** dialog box. The Office Web Apps discovery URL will then be listed as one of the pool's Associations.

You will have to repeat this process for each pool that needs to be associated with your Office Web Apps Server.

After you have added the discovery URL to the topology you must then publish this updated topology. To do that in Topology Builder:

1. Click **Action** and then click **Publish Topology**.
2. In the Publish Topology wizard, on the **Publish the Topology** page, click **Next**.
3. On the **Publishing wizard complete** page, click **Finish**.

4. Close Topology Builder.

1.4.4.2.2 Publishing Office Web Apps Server Using a Reverse Proxy Server

Publishing Office Web Apps Server Using a Reverse Proxy Server

Microsoft Lync Server 2013 > Deployment > Deploying External User Access >

Topic Last Modified: *2013-02-25*

If you want external users (that is, users logging on from outside your organization’s firewall) to have access to Office Web Apps Server PowerPoint presentations then you will need to use Office Web Apps Server and a reverse proxy server such as Microsoft Forefront Threat Management Gateway. That also means that you will need to create and configure a website publishing rule; that rule will help ensure that users are able to connect to the server. If you do not need to provide access to external users then you do not need to configure a website publishing rule.

To configure a website publishing rule in Forefront Threat Management Gateway complete the following procedure:

1. Click **Start**, click **All Programs**, click **Microsoft Forefront TMG**, and then click **Forefront TMG Management**.
2. In Forefront TMG, right-click **Firewall Policy**, point to **New**, and then click **Web Site Publishing Rule**.
3. In the New Web Publishing Rule Wizard, on the **Welcome to the New Web Publishing Rule Wizard** page, type a name for your new rule in the **Web publishing rule name** box (for example, **Office Web Apps Server Rule**) and then click **Next**.
4. On the **Specify Rule Action** page, select **Allow** and then click **Next**.
5. On the **Publishing Type** page, select **Publish a single Web site or load balancer** and then click **Next**.
6. On the **Server Connection Security** page, select **Use SSL to connect to the published Web server or server farm** and then click **Next**.
7. On the **Internal Publishing Details** page, type the FQDN of your Office Web Apps server (for example, **officewebapps01.contoso.com**) in the **Internal site name** box and then click **Next**. The name entered in the **Internal site name** box must appear in the Subject field or the Subject Alternative Name field of the certificate you have assigned to Office Web Apps Server.
8. On the **Internal Publishing Details** page, type **/*** in the **Path (optional)** box and then click **Next**. The /* syntax will help ensure that all the folders and subfolders for the site are published.
9. On the **Public Name Details** page, select **This domain name (type below)** from the **Accept requests for** drop-down list and then type the fully qualified for your Office Web Apps Server in the Public name box. This name should be the name used to access your website. For example, if your site is accessed using the URL http://officewebapps01.contoso.com then you should enter **officewebapps01.contoso.com** in the **Public name** box.
10. Click **Next**.
11. On the **Select Web Listener** page, click **New**.
12. In the New Web Listener Definition Wizard, type a name for the new Web listener (for example, **SSL**) in the **Web listener name** box and then click **Next**.
13. On the **Client Connection Security** page, select **Require SSL secured connections with clients** and then click **Next**.
14. On the **Web Listener IP Addresses** page, select **External**, select **Internal**, and then click **Next**.
15. On the **Listener SSL Certificates** page, select **Use a single certificate for this Web Listener** and then click **Select Certificate**.
16. In the **Select Certificate** dialog box, select the certificate to be used for this Web Listener and then click **Select**.
17. On the **Listener SSL Certificates** page, click **Next**.
18. On the **Authentication Settings** page, select **No Authentication** from the **Select how clients will provide credentials to Forefront TMG** drop-down list, and then click **Next**.
19. On the **Single Sign On Settings** page, click **Next**.
20. On the **Completing the New Web Listener Wizard** page, review the summary of the configuration choices you have made. When ready, click **Finish**.
21. On the **Select Web Listener** page, click **Next**.
22. On the **Authentication Delegation** page, select **No delegation, but client may authenticate directly** from the **Select the method used by Forefront TMG to authenticate to the published Web server** drop-down list and then click **Next**.
23. On the **User Sets** page, confirm that the appropriate user sets are listed. By default, this is the **All Users** user set. Click **Add** to add other user sets you may have defined. When complete, click **Next**.
24. On the **Completing the New Web Publishing Rule Wizard** page, click

Finish.

Note that clicking **Finish** does not mean that you completed the process; that is, this does not automatically apply and enable the new rule. Instead, you will need to click the **Apply** button that will appear in the Forefront TMG user interface. When you click **Apply** the **Configuration Change Description** dialog box will appear. Click **Apply** in that dialog box to enable the new publishing rule.

After your new rule has been applied, you will then need to make some minor modifications to the rule to make sure that users can use the new PowerPoint presentation capabilities. To do that, complete the following procedure:

1. In Forefront TMG, right-click the name of the new publishing rule and then click **Properties**.
2. In the **Properties** dialog box, on the **To** tab, select the option **Forward the original host header instead of the actual one**.
3. On the **Traffic** tab, click **Filtering** and then click **Configure HTTP**.
4. In the **Configuring HTTP policy for rule** dialog box, clear the **Verify normalization** check box and then click **OK**.
5. In the **Properties** dialog box, click **OK**.
6. In Forefront TMG, click **Apply** to enable the changes. When the **Configuration Change Description** dialog box appears, click **Apply**.

After completing the installation you can test your Office Web Apps Server using the procedures in the topic Validating the Configuration of Office Web Apps Server.

1.4.4.2.3 Validating the Configuration of Office Web Apps Server

Validating the Configuration of Office Web Apps Server

Deployment > Deploying Conferencing > Configuring Integration with Office Web Apps Server and Lync Server 2013 >

Topic Last Modified: *2012-08-29*

After Office Web Apps Server has been added to the topology, and after that topology has been published, you should see two new event log events in the Lync Server event log. First, an LS Data MCU event (event ID 41032) should be added; this event will report that the Office Web Apps Server has been discovered:

Web Conferencing Server WAC is discovered, PowerPoint content is enabled.

In addition to that you should see another LS Data MCU event (event ID 41032) that reports back Office Web Apps Server URLs. For example, you should see something similar to this:

Web Conferencing Server WAS discovery has succeeded.

WAC internal presenter page: https://atl-officewebapps-001.litwareinc.com/m/Presenter.aspx?a=0&embed=

WAC internal attendee page: https://atl-officewebapps-001.litwareinc.com/m/ParticipantFrame.aspx?a=0&embed=true&=

WAC external presenter page: https://atl-officewebapps-001.litwareinc.com/m/Presenter.aspx?a=0&embed

WAC internal attendee page: https://atl-officewebapps-001.litwareinc.com/m/ParticipantFrame.aspx?a=0&embed=true&

If you see an LS Data MCU event with the event ID of 41033 that means that Office Web Apps Server discovery has failed. In that case, Microsoft Lync Server 2013 will try as many times as needed to discover the newly-configured Office Web Apps Server. If the discovery process fails repeatedly you should remove Office Web Apps Server from your topology document, publish the updated topology, and then try adding Office Web Apps Server back to the topology after the connectivity issues have been resolved.

If Office Web Apps Server appears to be configured correctly and has been recognized by the discovery process you can verify that Office Web Apps Server is working as expected by sharing a PowerPoint presentation between a pair of Microsoft Lync 2013 clients. If User A can load and display the PowerPoint presentation and if User B can then join the meeting and see that presentation then Office Web Apps Server is working.

Even if Office Web Apps Server appears to be configured correctly, you could potentially receive the error message “Some sharing features are unavailable due to server connectivity issues” when you try sharing a PowerPoint presentation. If you receive that error message you should restart the Front End server (or servers) associated with the new Office Web Apps Server.

1.4.4.2.4 Configuring Clients for Use With Office Web Apps Server

Configuring Clients for Use With Office Web Apps Server

Deployment > Deploying Conferencing > Configuring Integration with Office Web Apps Server and Lync Server 2013 >

Topic Last Modified: *2013-02-25*

If you want users to experience the full capabilities of Office Web App Server then you should upgrade those users to Microsoft Lync 2013; only users of Lync 2013 will be able to do such things as scroll through PowerPoint slides independent of the actual PowerPoint presentation. (That is, these users can look at any slide in the presentation at any time, without interfering in any way with the actual presentation.) Users who are not using Lync 2013 will still be able to join online conferences and view the PowerPoint presentation; however, they will not be able to independently scroll through the slides, nor will they be able to see slide transitions or view embedded videos.

Note that these capabilities will always be available to users of Lync 2013; this is true even if the PowerPoint presenter is running Microsoft Lync 2010. If a PowerPoint presentation is being hosted by a user running Lync 2010, Lync Server 2013 will coordinate with Office Web Apps Server to make sure that Lync 2013 users will view the Office Web Apps Server version of that presentation. Office Web Apps Server does not provide PowerPoint services for users running clients other than Lync 2013. Instead, those users connect to the Conferencing server service and view PowerPoint presentations the same way they did in Microsoft Lync Server 2010. This also means that these users will only have access to the more-limited capabilities offered by Lync Server 2010.

Although no client configuration is required for Office Web Apps Server (other than upgrading users to Lync 2013), it is recommended that conference attendees be upgrade to Internet Explorer 9. Although conferences can be accessed using Internet Explorer 8, there are some limitations to using that Web browser. For example, users of Internet Explorer 8 will not be able to resize the PowerPoint stage to a custom size; instead, they will be limited to using one of three predefined stage sizes. Likewise, Internet Explorer 8 users will not be able to play media files.

1.4.4.3 Configuring the Meeting Join Page

Configuring the Meeting Join Page

See Also

Microsoft Lync Server 2013 > Deployment > Deploying Conferencing >

Topic Last Modified: *2012-12-14*

When a user clicks a meeting link in a meeting request, the meeting join page detects whether a Lync 2013 client is already installed on the user's computer. If a client is already installed, the client opens and joins the meeting. If a client is not installed, by default the 2013 version of Lync Web App opens.

You can modify the behavior of the meeting join page if you want to allow users to join meetings with Office Communicator 2007 R2 or Lync 2010 Attendant. These configuration options have been removed from the Lync Server 2013 Control Panel, but you configure them by using the Set-CsWebServiceConfiguration cmdlet.

Meeting Join Page Set-CsWebServiceConfiguration Parameters

Set-CsWebServiceConfiguration Parameter	Description
ShowJoinUsingLegacyClientLink	If set to True, users joining a meeting by using a client application other than Lync will be given the opportunity to join the meeting by using Office Communicator 2007 R2. The default value is False.
ShowAlternateJoinOptionsExpanded	When set to True then alternate options for joining an online conference (such as Office Communicator 2007 R2) will automatically be expanded and shown to users. When set to False (the default value) these options will be available, but the user will have to display the list of options for themselves.

To configure the meeting join page by using Lync Server 2013 Management Shell

1. Start the Lync Server 2013 Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. To view the web service configuration settings, run the following cmdlet:

   ```
   Get-CsWebServiceConfiguration
   ```

3. Run the following command, with the parameters set to True or False, depending on your preference (for details about the parameters for this cmdlet, see Set-CsWebServiceConfiguration in the Lync Server 2013 Management Shell documentation):

   ```
   Set-CsWebServiceConfiguration -Identity global -ShowJoinUsingLegacyCli
   ```

Set-CsWebServiceConfiguration

1.4.5 Deploying Monitoring

Deploying Monitoring

Microsoft Lync Server 2013 > Deployment >

Topic Last Modified: *2012-08-21*

Major changes have been made to the Microsoft Lync Server 2013 monitoring infrastructure, beginning with the fact that the Monitoring Server role has been deprecated. Instead of separate Monitoring Server roles (which typically required organizations to set up dedicated computers to act as Monitoring servers) monitoring services are now collocated on each Front End server. Among other things, this change helps to:

- Decrease the number of server roles required when implementing Lync Server 2013. In this case, decrementing the Monitoring Server server role also helps to reduce costs by eliminating the need to maintain dedicated servers for monitoring.
- Reduce the complexity of Lync Server setup and administration. By automatically collocating the monitoring services on each Front End server you no longer have to install, configure, and manage the Monitoring Server role.

Note:

The Archiving Server role has also been deprecated in Lync Server 2013. Like the monitoring services, Lync Server 2013 archiving services are now collocated on each Front End server. This is important to note simply because monitoring and archiving often share the same SQL Server database instance.

As you might expect, these changes have a major impact on how monitoring services are installed and managed. For example, because the Monitoring Server role no longer exists, the Monitoring Server node has been removed from the Lync Server Topology Builder; in turn, that means you no longer use Topology Builder's New Monitoring Server Wizard in order to add a new Monitoring Server to your topology. (That wizard no longer exists.) Instead, you will typically implement monitoring services within your topology by completing the following two steps:

1. Enabling monitoring at the same time you set up a new Lync Server pool. (In Lync Server 2013, monitoring is enabled or disabled on a pool-by-pool basis.) Note that you can enable monitoring for a pool without actually collecting monitoring data, a process explained in the Configuring Call Detail Recording and Quality of Experience Settings section of this documentation.
2. Associating a monitoring store (that is, a monitoring database) with the new pool. Note that a single monitoring store can be associated with multiple pools. Depending on the number of users homed on your Registrar pools, that means that you do not have to set up a separate monitoring database for each of your pools. Instead, single monitoring store can be used by multiple pools.

Although it's often easier to enable monitoring at the same time that you create a new pool, it's also possible to create a new pool with monitoring disabled. If you do that, you can later use Topology Builder to enable the service: Topology Builder provides a way to enable or disable monitoring for a pool, or to associate a pool with a different monitoring store. Keep in mind that even though there is no longer a Monitoring Server role you will still need to create one or more monitoring stores: backend databases used to store the data gathered by the monitoring service. These backend databases can be created using either Microsoft SQL Server 2008 R2 or Microsoft SQL Server 2012.

Note:

If monitoring has been enabled for a pool you can disable the process of collecting monitoring data without having to change your topology: Lync Server Management Shell provides a way for you to disable (and then later re-enable) call detail recording (CDR) or Quality of Experience (QoE) data collection. For more information, see the Configuring Call Detail Recording and Quality of Experience Settings section of this document.

One other important enhancement to monitoring in Lync Server 2013 is the fact that Lync Server Monitoring Reports now support IPv6: reports that use the IP Address field will display either IPv4 or IPv6 addresses depending on : 1) the SQL query being used; and, 2) where or not the IPv6 address is stored in the monitoring database.

This documentation walks you through the process of installing and configuring monitoring and Monitoring Reports for Lync Server 2013. The documentation provides step-by-step instructions that will help you to:

- Enable monitoring in your topology and associate a monitoring store with a Front End pool.
- Install SQL Server Reporting Services and the Lync Server Monitoring Reports. Monitoring Reports are preconfigured reports that provide different views into the information stored in a monitoring database.
- Configure call detail recording (CDR) and Quality of Experience (QoE) data collection. Call detail recording provides a way for you to track usage of Lync Server capabilities such as Voice over IP (VoIP) phone calls; instant messaging (IM); file transfers; audio/video (A/V) conferencing; and application sharing sessions. QoE metrics track the quality of audio and video calls made in your organization, including such things as the number of network packets lost, background noise, and the amount of "jitter" (differences in packet delay).
- Manually purge CDR and/or QoE records from the monitoring database.

1.4.5.1 Associating a Monitoring Store with a Front End Pool

Associating a Monitoring Store with a Front End Pool

Microsoft Lync Server 2013 > Deployment > Deploying Monitoring >

Topic Last Modified: *2012-06-19*

In Microsoft Lync Server 2013 monitoring data can only be collected on Front End pools that have been associated with a monitoring store, a task typically carried out you define a Front End pool in Topology Builder. To associate a monitoring store with a new Front End pool, make sure that you select the option **Monitoring (call detail recording and logging of quality of experience metrics)** on the **Select Features** page of the Define New Front End Pool wizard. Note that, if you select this option, you must also specify a SQL store in order to complete the wizard; however, this store does not have to exist at the time you run the wizard. That means that you can first associate a pool with a monitoring store, then later setup and configure that store.

Alternatively, you can associate an existing Front End pool with a new or different monitoring store by completing the following procedure:

1. Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013 (Preview)**, and then click **Lync Server Topology Builder**.
2. In the **Topology Builder** dialog box, select **Download Topology from existing deployment** and then click **OK**.
3. In the **Save As** dialog box, enter a file name for your current topology and then click **Save**. The saved topology can later be retrieved and re-published in case there are problems with the new topology.
4. In Topology Builder, expand **Lync Server 2013 (Preview)**, expand the name of the site containing the Front End pool, then click expand **Enterprise Edition Front End pools**.
5. Right-click the name of the pool to be associated with the monitoring store

and then click **Edit Properties**.

6. In the **Edit Properties** dialog box, on the **General** tab, select the option **Monitoring (CDR and QoE metrics)** and then select an existing SQL Server database from the **Monitoring SQL Server store** dropdown list. (Or, click **New** to associate the pool with a new database store.) If you choose to use a new database store then, in the **Define New SQL Store** dialog box, enter the fully qualified domain name of the SQL Server computer in the **Sql Server FQDN** box. If you want to use the default SQL Server instance for that store select **Default Instance**; otherwise select **Named Instance** and enter the instance name in the **Named Instance** box.
   The **Edit Properties** dialog box also gives you the option of creating a SQL mirror for your monitoring database (a SQL mirror enables you to maintain two copies of your monitoring database, one copy stored on the monitoring store computer and the other on the SQL mirror computer). To enable mirroring, select T**his SQL instance is in mirroring relation** and enter the port number for the mirror server in the **Mirroring port number** box.
7. In the **Edit Properties** dialog box, click **OK**.

After associating the monitoring store with a Front End pool you must publish the new topology before the changes take effect. To publish your new topology, complete the following steps in Topology Builder:

1. Click **Action**, point to **Topology**, and then click **Publish**.
2. In the Publish Topology wizard, on the **Publish the topology** page, click **Next**.
3. On the **Publishing wizard complete** page, click **Finish**.

After the topology has been published you can then install the monitoring database on the computer that will host the monitoring store. The monitoring database can be installed by using the Lync Server Management Shell and Windows PowerShell. To install the database locally (that is, to install the database on the same computer where you are running the Lync Server Management Shell), start the Management Shell on the appropriate computer, then type in the following command and press ENTER:

```
Install-CsDatabase -LocalDatabases
```

When you run the preceding command, Install-CsDatabase will read the current Lync Server topology, determine which databases need to be installed on the local computer, and then automatically install and configure each of those databases.

To install the database on a remote computer (that is, a computer other than the computer where the Management Shell is running) you must include at least two parameters: the ConfiguredDatabases parameter and the SqlServerFqdn parameter. These parameters tell the Install-CsDatabase cmdlet to retrieve the Lync Server topology and then install and configure the required databases on the computer specified by the SqlServerFqdn parameter. The SqlServerFqdn parameter must use a parameter value representing the fully qualified domain name of the computer where the databases are to be installed.

For example, this command installs the monitoring database on the computer atl-sql-001.litwareinc.com:

```
Install-CsDatabase -ConfiguredDatabases -SqlServerFqdn atl-sql-001.litwareinc.com
```

Alternatively, you can install the monitoring database by running the Lync Server Deployment Wizard on the computer that will host the monitoring store. To do this, log on to the appropriate computer and complete the following procedure:

1. Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013 (Preview)**, and then click **Lync Server Deployment Wizard**.
2. In the Deployment Wizard, click **Install or Update Lync Server System**.
3. On the **Deploy** page, under **Step 2: Setup or Remove Lync Server Components**, click **Run Again**.
4. In the Setup Lync Server components wizard, on the **Setup Lync Server**

components page, click **Next**.

5. On the **Specify path to MSIs** page, type the path to the file Ocscore.msi (a file included with your Lync Server installation media) and then click **Next**.
6. On the **Executing Commands** page, click **Finish**.

To ensure that all the required Lync Server services have started, click **Run** under the heading **Step 4: Start Services** on the **Deploy** page

1.4.5.2 Installing SQL Server Reporting Services

Installing SQL Server Reporting Services

Microsoft Lync Server 2013 > Deployment > Deploying Monitoring >

Topic Last Modified: *2012-06-20*

If you intend to use Microsoft Lync Server 2013 Monitoring Reports (see the next section of this documentation for more information) you must first install SQL Server Reporting Services; Reporting Services can be installed at the same time you install Microsoft SQL Server or any time after SQL Server has been installed. If you have not installed SQL Server, then follow the instructions provided earlier in this documentation. When installing SQL Server, make sure that, on the Feature Selection page, you select Reporting Services. That will install SQL Server Reporting Services.

If you have already installed SQL Server but did not install SQL Server Reporting Services you can add that feature by following the appropriate set of instructions for SQL Server 2008 R2 or SQL Server 2012, as appropriate.

To verify that the reporting Services have been successfully installed, complete the following steps:

1. If you are running Microsoft SQL Server 2008 R2, then click **Start**, click **All Programs**, click **Microsoft SQL Server 2008 R2**, click **Configuration Tools**, and then click **Reporting Services Configuration Manager**.
   If you are running Microsoft SQL Server 2012, then click **Start**, click **All Programs**, click **Microsoft SQL Server 2012**, click **Configuration Tools**, and then click **Reporting Services Configuration Manager**.
2. In the **Reporting Services Configuration Connection** dialog box, verify that the name of your server appears in the **Server Name** box and that the name of the SQL Server instance that stores your monitoring data appears in the **Report Server Instance** box. Click **Connect**.

In the Reporting Service Configuration Manager, the Report Server Status pane should show that SQL Server Reporting Services has been installed and that the Reporting Services are currently running: the Report Server Status should be shown as **Started** and the **Start** button should be grayed-out and unavailable. If the Reporting Service is not running, click **Start** in order to start the service.

If no database is listed next to the Report Server Database Name label then do the following:

1. In the Reporting Services Configuration Manager click **Database**.
2. In the Report Server Database pane click **Change Database**.
3. In the Report Server Database Configuration wizard, in the Action pane, select **Create a new report server database** and then click **Next**.
4. In the Report Server Database Configuration wizard, in the Database Server pane, verify that the information listed in the **Server Name**, **Authentication Type**, and **Username** boxes is correct. Click **Test Connection** to verify that a connection can be made to the database server and then click **Next**.
5. In the Report Server Database Configuration wizard, in the Database pane,

accept the default values for **Database Name**, **Language**, and **Report Server Mode** and then click **Next**.

6. In the Report Server Database Configuration wizard, in the Credentials pane, verify that the correct information is listed in the **Authentication Type** dropdown list and the **User name** and **Password** boxes, and then click **Next**.
7. In the Report Server Database Configuration wizard, in the Summary pane, click **Next**.
8. In the Report Server Database Configuration wizard, in the Progress and Finish pane, click **Finish**.

To verify that the Reporting Service URLs have been configured, click **Web Service URL**. You should see one or more URLs listed under the heading **Report Server Web Service URLs**. Click each of these URLs to verify that you can reach the home page for the local installation of SQL Server Reporting Services.

1.4.5.3 Associating Monitoring Reports with a Mirror Database

Associating Monitoring Reports with a Mirror Database

See Also

Microsoft Lync Server 2013 > Deployment > Deploying Monitoring >

Topic Last Modified: *2013-02-19*

If you configure a mirror for your monitoring database, that mirror database will take over as the primary database if a failover occurs. However, if you use Lync Server Monitoring Reports and a failover occurs, you might find that your Monitoring Reports are not connecting to the mirror database. This is because, when you install Monitoring Reports, you specify only the location of the primary database; you do not specify the location of the mirror database.

To get Monitoring Reports to automatically failover to the mirror database, you must add the mirror database as a "failover partner" to the two databases that are used by Monitoring Reports (one database for Call Detail Record data, and the other for Quality of Experience (QoE) data). You can add the failover partner information by manually editing the connection string values used by these two databases. To do that, complete the following procedure:

1. Use Internet Explorer to open the **SQL Server Reporting Services** home page. The Reporting Services home page URL includes:
   - The **http:** prefix.
   - The fully qualified domain name (FQDN) of the computer where the Reporting Services are installed (for example, **atl-sql-001.litwareinc.com**).
   - The character string **/Reports_**.
   - The name of the database instance where the Monitoring Reports are installed (for example, **archinst**).

   For example, if SQL Server Reporting Services was installed on the computer atl-sql-001.litwareinc.com and the Monitoring Reports use the database instance archinst, the home page URL would look like this:
   http://atl-sql-001.litwareinc.com/Reports_archinst
2. After you have accessed the Reporting Services home page, click **LyncServerReports**, and then click **Reports_Content**. That will take you to the **Reports_Content** page for the Lync Server Monitoring Reports.
3. On the **Reports_Content** page, click the **CDRDB** data source.
4. On the **CDRDB** page, on the **Properties** tab, look for the text box labeled **Connection string**. The current connection string will look similar to this:
   Data source=(local)\archinst;initial catalog=LcsCDR
5. Edit the connection string to include the server name and database instance for the mirror database. For example, if the server is named atl-mirror-001

and the mirror database is in the archinst instance, you will need to add to specify the mirror database using this syntax:
FailoverPartner=atl-mirror-001\archinst
Your edited connection string will look like this:
Data source=(local)\archinst;FailoverPartner=atl-mirror-001\archinst;initial catalog=LcsCDR

6. After updating the connection string, click **Apply**.
7. On the **CDRDB** page, click the **Reports_Content** link. Click the **QMSDB** data source, and then edit the connection string for the QoE database. For example:
Data source=(local)\archinst;FailoverPartner=atl-mirror-001\archinst;initial catalog=QoEMetrics
8. Click **Apply**.

Concepts

Installing Lync Server 2013 Monitoring Reports
Using Monitoring Reports

1.4.5.4 Installing Lync Server 2013 Monitoring Reports

Installing Lync Server 2013 Monitoring Reports

Microsoft Lync Server 2013 > Deployment > Deploying Monitoring >

Topic Last Modified: *2013-02-18*

Microsoft Lync Server 2013 Monitoring Reports provide you with a wealth of information about the quality and quantity of the communication sessions that take place in your organization. However, Monitoring Reports are not automatically installed when you install Lync Server 2013; instead, you must install Monitoring Reports separately, and only after Lync Server has been installed on the computer.

Note:

It is recommended that you install Monitoring Reports on the same computer where the monitoring database is installed. This simplifies the process of assigning permissions for accessing the reports: installing Monitoring Reports on the computer that hosts the monitoring store means that you will not have to configure permissions that allow a database on one computer to interact with Reporting Services running on a second computer.

Lync Server Monitoring Reports include over 30 reports designed to provide detailed information about conferences, peer-to-peer IM sessions, user registrations, the Response Group application, and much more. For the 2013 version, Lync Server Monitoring Reports include a number of enhancements:

- **New voice quality reports**. These new reports include the Media Quality Comparison Report, which compares quality between different types of calls (for example, between wired calls and wireless calls); and the Conference Join Time Report, which provides information regarding the amount of time requires for users to join a conference.
- **Improved reports for analyzing and troubleshooting both video and application sharing sessions.** The Media Quality Summary Report provides a way to analyze video and application sharing calls, while the Server Performance Report details the performance of servers generating these calls. Video and application sharing metrics are also now reported by the Peer-to-Peer Session Detail Report and the Conference Detail Report.
- **Improved report performance**. This includes faster response and data retrieval time, as well as faster and easier navigation through the reports.

More information on the individual reports can be found in the Monitoring Reports documentation.

Note:
There is another new report – QoE Call Detail Subreport – included in Lync Server 2013. However, this report is primarily for internal use, and is not intended to be directly accessed.

There are two ways to install Lync Server Monitoring Reports: you can use the Lync Server Deployment Wizard or you can use a Windows PowerShell script included with the Lync Server 2013 installation files. Regardless of the method you use to install the reports you must first make sure that you:

- Have the right to add a database role to a user account in the monitoring database.
- Hold the Content Manager role in SQL Server Reporting Services. This role gives you the right to deploy reports to SQL Server Reporting Services.

To install the Monitoring Reports by using the Deployment Wizard, complete the following steps:

1. Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013 (Preview)**, and then click **Lync Server Deployment Wizard**.
2. In the Deployment Wizard, click **Deploy Monitoring Reports** in order to start the Deploy Monitoring Reports wizard.
3. In the Deploy Monitoring Reports wizard, on the **Specify Monitoring Database** page, make sure that the fully qualified domain name of the computer hosting your monitoring store appears in the **Monitoring database** dropdown list. (If you have multiple monitoring stores you will need to select the appropriate server from the dropdown list.) Verify that the correct SQL Server instance appears in the **SQL Server Reporting Services (SSRS) instance** box (for example, **atl-sql-001.litwareinc.com/archinst**) and then click **Next**.
4. On the **Specify Credentials** page, in the **User name** box, type the domain name and user name of the account to be used when accessing the Monitoring Reports (for example, **litwareinc\kenmyer**). If you do not use this format (domain\user name) an error will occur.
   Type the user account password in the **Password** box, and then click **Next**. Note that no special rights are required for this account. The account will automatically be granted the required logon and database permissions when setup completes.
5. On the **Specify Read-Only Group** page enter the name of a security group that will be granted read-only access to the SQL Server Reporting Services in the User group box. For example, to give read-only administrators access to the reports enter **RTCUniversalReadOnlyAdmins**. Click **Next**.
6. On the **Executing Commands** page, click **Finish**.

Monitoring Reports can also be installed from the Lync Server Management Shell by running the script DeployReports.ps1; this Windows PowerShell script can be found in the Lync Server installation folder ..\Setup\ReportingSetup. To install Monitoring Reports using DeployReports.ps1, type a command similar to the following at the Management Shell prompt:

```
C:\Scripts\DeployReports.ps1 -storedUserName "litwareinc\kenmyer" -storedPassword
```

The parameters used in the preceding command are described in the following table:

Parameter Name	Required	Description
storedUserName	Yes	User account (in the format domain\username) used to access the monitoring store; for example: `-storedUserName "litwareinc\kenmyer"`

		This account must have the previously-specified SQL Server and SQL Server Reporting Services permissions or the script will fail.
storedPassword	Yes	Password for the user account used to access the monitoring store.
readOnlyGroupName	No	Domain or local security group whose members will be granted read-only access to the Monitoring Reports. Note that the script will fail if the specified group does not exist. If you later decide to revoke these permissions, or if you decide to grant other users or other groups access permissions, you can do so using the SQL Service Reporting Services Report Manager.
reportSqlServerInstance	No	SQL Server instance that hosts the Reporting Service. The Reporting instance must be specified using the fully qualified domain name of the Report Server; for example: `-reportServerSqlInstance atl-sql-001.litwareinc.com` If this parameter is not included the script will assume that the reporting services are hosted by the same SQL Server instance that hosts the monitoring database.
monitoringDatabaseId	No	Service Identity for the monitoring database. You can return the Identities for your monitoring databases by running this command: `Get-CsService -MonitoringDatabase`

After the Monitoring Reports have been installed you must then use the Set-CsReportingConfiguration cmdlet to configure the URL used to access these reports. This task can be carried out from the Lync Server Management Shell by running the following Windows PowerShell command. Note that it is recommended, but not required, that you use the HTTPS protocol when configuring the reporting URL:

```
Set-CsReportingConfiguration -Identity "MonitoringDatabase:atl-sql-001.litwareinc
```

In the preceding command, the ReportingUrl property should be set to the Report Manager URL used by SQL Server 2008 R2 Reporting Services. You can determine the Report Manager URL by completing the following steps on the computer where SQL Server Reporting Services has been installed:

1. Click Start, click All Programs, click Microsoft SQL Server 2008 R2, click Configuration Tools, and then click Reporting Services Configuration Manager.
2. In the Reporting Services Configuration Connection dialog box, make sure that the name of the Reporting Services computer appears in the Server Name box. Select the SQL Server instance from the Report Server Instance dropdown list and then click Connect.
3. In Reporting Services Configuration Manager, click Report Manager URL. One or more URLs should appear in the Report Manager URL pane. Any of these URLs can be used as the Reporting URL although, again, it is recommended that the ReportingUrl use the HTTPS protocol.

If you have set up a mirror database for your monitoring database then you must also associate the Monitoring Reports with the mirror database. See the article Associating Monitoring Reports with a Mirror Database for details.

1.4.5.5 Configuring Call Detail Recording and Quality of Experience Settings

Configuring Call Detail Recording and Quality of Experience Settings

Microsoft Lync Server 2013 > Deployment > Deploying Monitoring >

Topic Last Modified: *2012-10-17*

After you have associated a monitoring store with a Front End pool, set up the monitoring store, and then installed and configured SQL Server Reporting Services and Monitoring Reports you can manage Call Detail Recording (CDR) and Quality of Experience (QoE) monitoring by using Lync Server Management Shell. Lync Server Management Shell cmdlets allow you to enable and disable CDR and/or QoE monitoring for a particular site or for your entire Lync Server deployment; that can be done with a command as simple as this:

```
Set-CsQoEConfiguration -Identity "global" -EnableQoE $False
```

When you install Microsoft Lync Server 2013, you will also install a predefined collection of global configuration settings for both CDR and QoE. Default values for some of the more commonly-used settings used by Call Detail Recording are shown in the following table:

Property	Description	Default Value
EnableCDR	Indicates whether or not CDR is enabled. If True, all CDR records will be collected and written to the monitoring database.	True
EnablePurging	Indicates whether or not CDR records will periodically be deleted from the database. If True, records will be deleted after the time period specified by the properties KeepCallDetailForDays (for CDR records) and KeepErrorReportForDays (for CDR errors). If False, CDR records will be maintained indefinitely.	True
KeepCallDetailForDays	Indicates the number of days that CDR records will be kept in the database; any records older than the specified number of days will automatically be deleted. However, this will occur only if purging has been enabled. KeepCallDetailForDays can be set to any integer value between 1 and 2562 days (approximately 7 years).	60 days
KeepErrorReportForDays	Indicates the number of days that CDR error reports are kept; any reports older than	60 days

	the specified number of days will automatically be deleted. CDR error reports are diagnostic reports uploaded by client applications such as Microsoft Lync 2013. You can set this property to any integer value between 1 and 2562 days.	

Similarly, default values for selected QoE settings are shown in this table:

Property	**Description**	**Default Value**
EnableQoE	Indicates whether or not QoE monitoring is enabled. If True, all QoE records will be collected and written to the monitoring database.	True
EnablePurging	Indicates whether or not QoE records will periodically be deleted from the database. If True, records will be deleted after the time period specified by the KeepQoEDataForDays property. If False, QoE records will be maintained indefinitely.	True
KeepQoEDataForDays	Indicates the number of days that QoE records will be kept in the database; any records older than the specified number of days will automatically be deleted. However, this will occur only if purging has been enabled. KeepCallDetailForDays can be set to any integer value between 1 and 2562 days.	60 days

If you need to modify these global settings you can do so by using the Set-CsCdrConfiguration and the Set-CsQoEConfiguration cmdlets. For example, this command (run from within the Lync Server Management Shell) disables CDR monitoring at the global scope; that's done by setting the EnableCDR property to False ($False):

```
Set-CsCdrConfiguration -Identity "global" -EnableCDR $False
```

Note that disabling monitoring does not dissociate the monitoring store from the Front End pool, nor does it uninstall or otherwise affect the backend monitoring database. When you use Lync Server Management Shell to disable either CDR or QoE monitoring all you really do is temporarily stop Lync Server from collecting and archiving monitoring data. If you want to resume, in this case, the collection and archiving of CDR data, all you need to do is set the EnableCDR property back to True ($True):

```
Set-CsCdrConfiguration -Identity "global" -EnableCDR $True
```

Similarly, this command disables the purging of QoE records at the global scope:

```
Set-CsQoEConfiguration -Identity "global" -EnablePurging $False
```

In addition to the global settings, CDR and QoE configurations settings can be assigned to the site scope. This provides additional management flexibility when it comes to monitoring; for example, an administrator can enable CDR monitoring for the Redmond site but disable CDR monitoring for the Dublin site. To create new CDR configuration settings at the site scope, use a command similar to this:

```
New-CsCdrConfiguration -Identity "site:Redmond" -EnableCDR $False
```

Keep in mind that settings configured at the site scope take precedence over settings configured at the global scope. For example, suppose CDR monitoring is enabled at the global scope, but disabled at the site scope (for the Redmond site). That means that call detail recording information will not be archived for users in the Redmond site. However, users in other sites (that is, users managed by the global settings instead of the Redmond site settings) will have their call detail recording information archived.

New QoE configuration settings can be created at the site scope by using a command like this one:

```
New-CsQoEConfiguration -Identity "site:Redmond" -KeepQoEDataForDays 15
```

For more information, type the following commands from within the Lync Server Management Shell:

```
Get-Help New-CsCdrConfiguration | more
Get-Help Set-CsCdrConfiguration | more
Get-Help New-CsQoEConfiguration | more

Get-Help Set-CsQoEConfiguration | more
```

1.4.5.6 Manually Purging the Call Detail Recording and Quality of Experience Databases

Manually Purging the Call Detail Recording and Quality of Experience Databases

Microsoft Lync Server 2013 > Deployment > Deploying Monitoring >

Topic Last Modified: *2012-11-01*

Administrators can configure the Call Detail Recording (CDR) and/or the Quality of Experience (QoE) databases to automatically purge old records from the database; this occurs if purging has been enabled for the specified database (CDR or QoE) and if there are any records that have been in the database longer than the specified amount of time. For example, every day at 1:00 AM administrators might configure the system so that QoE records more than 60 days old will be deleted from the QoE database.

In addition to that automatic purging, two new cmdlets -- Invoke-CsCdrDatabasePurge and Invoke-CsQoEDatbasePurge -- have been added to Microsoft Lync Server 2013; these cmdlets allow administrators to manually purge records from the CDR and the QoE databases at any time. For example, to manually purge all the records more than 10 days old from the CDR database you can use a command similar to this:

```
Invoke-CsCdrDatabasePurge -Identity MonitoringDatabase:atl-sql-001.litwareinc.com
```

In the preceding command both call detail records and diagnostic data records older than 10 days are deleted from the monitoring database on atl-sql-001.litwareinc.com. (Call detail records are user/session reports. Diagnostic data records are diagnostic logs uploaded by client applications such as Lync 2013.)

As shown above, when you run the Invoke-CsCdrDatabasePurge cmdlet you must include both the PurgeCallDetaiDataOlderThanDays and the PurgeDiagnosticDataOlderThanDays parameters. However, these parameters do not have to be set to the same value. For example, it's possible to purge call detail records more than 10 days old and yet, at the same time, leave all the diagnostic data records in the database. To do that, set PurgeCallDetailDataOlderThanDays to 10 and PurgeDiagnosticDataOlderThanDays to 0. For example:

```
Invoke-CsCdrDatabasePurge -Identity MonitoringDatabase:atl-sql-001.litwareinc.com
```

By default, any time you run Invoke-CsCdrDatabasePurge you will see a prompt similar to this one for each database table that must be purged:

```
Confirm
Are you sure you want to perform this action?
Performing operation "Stored procedure: RtcCleanupDiag" on Target "Target SQL Ser
[Y] Yes  [A] Yes to All  [N] No  [L] No to All [S] Suspend  [?] Help (default is
```

You must type either Y (for Yes) or A (for Yes to All) before the database purging will actually take place. If you would prefer to suppress these confirmation prompts, add the following parameter to the end of your call to Invoke-CsCdrDatabasePurge:

```
-Confirm:$False
```

For example:

```
Invoke-CsCdrDatabasePurge -Identity MonitoringDatabase:atl-sql-001.litwareinc.com
```

If you do that, confirmation prompts will not be displayed, and database purging will immediately be performed.

To purge the QoE database, use the Invoke-CsQoEDatabasePurge cmdlet and specify the age (in days) of the records to be deleted:

```
Invoke-CsQoEDatabasePurge -Identity MonitoringDatabase:atl-sql-001.litwareinc.com
```

1.4.6 Deploying Archiving

Deploying Archiving

Microsoft Lync Server 2013 > Deployment >

Topic Last Modified: *2012-09-28*

Lync Server 2013 provides a solution for archiving instant messaging (IM) content and conferencing communications in Lync Server. You can implement archiving support by integrating archiving storage with Exchange 2013 storage, by using SQL Server databases for storage of Lync Server 2013 archiving data, or by using both Lync Server 2013 and Exchange 2013 storage. You control how data is archived using policies and archiving configurations. For details, see Planning for Archiving in the Planning documentation and How Archiving Works in the Planning documentation, Deployment documentation, or Operations documentation.

You can use the information in this section to set up and configure Archiving initially. After deployment, you can change Archiving settings. For details about how you implement archiving support for day-to-day management or to meet new requirements in your organization, see Managing Lync Server 2013 Archiving in the Operations documentation.

- How Archiving Works

- Deployment Checklist for Archiving
- Setting Up Systems and the Infrastructure for Archiving
- Adding Archiving Databases to an Existing Lync Server 2013 Deployment
- Configuring Support for Archiving

1.4.6.1 How Archiving Works

How Archiving Works

Microsoft Lync Server 2013 > Planning > Planning for Archiving >

Topic Last Modified: *2013-01-22*

Lync Server 2013 Archiving provides options to help you meet your compliance needs. To implement and maintain it in a way that most effectively meets your organization's requirements, you should understand:

- What information can be archived.
- How to enable and disable Archiving in your deployment.
- The archiving options that you can configure to control how Archiving is implemented.

What Information Can Be Archived?

The following types of content can be archived:

- Peer-to-peer instant messages
- Conferences (meetings), which are multiparty instant messages
- Conference content, including uploaded content (for example, handouts) and event-related content (for example, joining, leaving, uploading sharing, and changes in visibility)
- Whiteboards and polls shared during a conference

The following types of content are not archived:

- Peer-to-peer file transfers
- Audio/video for peer-to-peer instant messages and conferences
- Desktop and application sharing for peer-to-peer instant messages and conferences

Lync Server also does not archive Persistent Chat conversations. To archive Persistent Chat conversations, you must enable and configure the compliance service, which is a component that can be deployed with Microsoft Lync Server 2013, Persistent Chat Server. For details, see Planning for Persistent Chat Server in the Planning documentation.

How Do I Start Using Archiving?

Archiving is automatically installed on each Front End Server when you deploy the server, but Archiving is not enabled until you configure it. How you configure it is determined by how you deploy Archiving:

- **Archiving using Microsoft Exchange integration.** If you have users who are homed on Exchange 2013 and their mailboxes have been put on In-Place Hold, you can select the option to integrate Lync Server 2013 storage with Exchange storage. If you choose the Microsoft Exchange integration option, you use Exchange 2013 policies and configurations to control the archiving of Lync Server 2013 data for those users.
- **Archiving using Lync Server Archiving databases.** If you have users who are not homed on Exchange 2013 or who have not had their mailboxes put on In-Place Hold, or if you don't want to use Microsoft Exchange integration for any or all users in your deployment, you can deploy Lync Server Archiving

databases using SQL Server to store Archiving data for those users. In this case, Lync Server 2013 Archiving policies and configurations determine whether Archiving is enabled and how it is implemented. To use Lync Server 2013, you must add the appropriate SQL Server databases to your topology and publish the topology.

Archiving Setup When Using Microsoft Exchange Integration

If your users are homed on Exchange 2013 and their mailboxes have been put on In-Place Hold, you can choose the **Microsoft Exchange integration** option (as described later in this section) to archive Lync Server 2013 for those users, and then you control archiving for those users by specifying Exchange In-Place Hold policies and settings, as well as Lync Server configurations to control the following:

- Whether to archive IM, conferencing, or both.
- Whether to implement critical mode for your Lync Server deployment.
- Selection of the Microsoft Exchange integration option to use Exchange 2013 for storage of archived data.

These Lync Server 2013 Archiving configuration options are described later in this section. For information about how to configure Exchange In-Place Hold policies and settings to support archiving, see the Exchange 2013 product documentation.

Archiving Setup When Using Lync Server Archiving Database Storage

If you want to use Lync Server Archiving databases (using SQL Server databases) to archive data for any users in your deployment, you can configure Lync Server Archiving policies to control whether Archiving is enabled for those users. In each Archiving policy, you can enable or disable Archiving for either or both of the following:

- Internal communications
- External communications

By default, archiving is not enabled for internal communications or external communications in any Lync Server Archiving policy. You enable and disable communications using Lync Server 2013 Control Panel or using cmdlets in the Lync Server 2013 Management Shell.

Lync Server 2013 Archiving policies include the following:

- **Global Archiving policy**. This is the default Archiving policy and applies to your entire deployment. It is created when you deploy Lync Server 2013 and, by default, disables Archiving for both internal and external communications. You cannot delete this policy. If you choose the delete option, the global policy is reset to the default settings.
- **Site Archiving policy**. Optionally, you can enable or disable Archiving for one or more specific sites by creating and configuring a site-level Archiving policy for the site. When you create a site-level Archiving policy, by default, archiving is not enabled. You can delete any site-level Archiving policy that you create. A site-level Archiving policy overrides the global policy, but only for the site specified in the policy. For example, if you enable Archiving for internal and external communications in your global policy and create a site policy in which you disable Archiving for external communications, only internal communications would be archived for that site.
- **User Archiving policy**. Optionally, you can enable or disable Archiving for one or more specific users and group of users by creating, configuring, and applying a user-level Archiving policy for the specified users and user groups. When you create a user-level Archiving policy, by default, archiving is not enabled. You can delete any user-level Archiving policy that you create, and you can change which users and group of users the Archiving policy applies to. A user-level Archiving policy overrides the global policy and any site policies, but only for the users and user groups to whom the policy is applied. For example, if you disable Archiving for internal and external communications in

your global policy, create a site-level policy in which you enable Archiving for internal and external communications, and then create a user-level policy in which you disable Archiving for external communications, the communications would be archived for both external and internal communications for all site users except that, for the users to whom you apply the user-level policy, only internal communications would be archived.

For details about how to set up initial Archiving policies when you deploy Archiving, see Configuring and Assigning Archiving Policies in the Deployment documentation. For details about using Archiving policies to enable and disable communications after deployment, see Managing the Archiving of Internal and External Communications in the Operations documentation.

Note:

If you implement both Lync Server 2013 Archiving databases and enable Microsoft Exchange integration, Exchange 2013 policies override Lync Server Archiving policies, but only for users who are homed on Exchange 2013 and have had had their mailboxes put on In-Place Hold. Lync Archiving depends on Microsoft Exchange In-Place Hold policy only.

What Options Do I Have for Configuring Archiving?

In addition to using policies and to enable and disable Archiving, you have other Archiving options that can be configure for your entire deployment and, optionally, for specific sites and pools. You control most Archiving options by using one or more Archiving configurations, which are available in Lync Server 2013 Control Panel, but also have another option that is only available for configuration using Lync Server 2013 Management Shell.

Archiving Configuration Options Available in Lync Server 2013 Control Panel

Each archiving configuration provides the following options:

The global-level configuration is created automatically when you deploy archiving and can be configured, but not deleted. If you select the option to delete the global configuration, the settings are reset to the default values. You can create multiple site and pool configurations that, together with the global configuration, control archiving settings. For the global configuration and each site and pool configuration, you have the following options:

- Disable archiving, enable archiving only for instant messaging (IM), or enable archiving of both IM and conferencing.
- Configure critical mode to block IM and conferencing sessions in the event of a Lync Server failure. Failures include the following:
  - **IM**. A problem with the Lync Server storage service. In this case, IM is blocked for users who are enabled for Archiving.
  - **Conferencing**. A failure could be an unavailable file share or a problem with the storage service. In this case, all active conferences hosted in the pool at the time of failure are switched to restricted mode and new conferences cannot be activated.

  Both IM and conferencing automatically recover after the failures are corrected.
- Specify the use of Microsoft Exchange Server 2013 integration to use Exchange 2013 for storage of archived data, instead of setting up separate SQL Server databases for storage of Lync Server 2013 archiving data.
- Configure purging options for archived data. This includes specifying when to purge archived data, which can be either of the following:
  - After a specific number of days that you specify
  - After the archiving data has been exported (which includes data that has been uploaded to Exchange, if you enable Microsoft Exchange integration).

  Note:

  If you enable Microsoft Exchange integration, purging for users homed on Exchange 2013 and with their mailboxes put on In-Place Hold is controlled by Exchange. The only qualification is for conferencing files, which are stored on

> the Lync Server file share. These files are purged from the file share only after the files have been exported (uploaded to Exchange), if you select the option to purge data after the archiving data has been exported, or after the specified maximum number of days, if you specify a maximum number of days for retention.

By default, no archiving options are enabled. You can manage Archiving configurations using Lync Server 2013 Control Panel.

You can specify the following Archiving configurations:

- **Global Archiving configuration**. This is the default Archiving configuration and applies to your entire deployment. It is created when you deploy Lync Server 2013 and, by default, does not enable archiving functionality. You can modify the global configuration, but you cannot delete it. If you choose the delete option for the configuration, the global configuration is reset to the default settings.
- **Site Archiving configuration**. Optionally, you can configure Archiving for one or more specific sites by creating and configuring a site-level Archiving configuration for an individual site. A site-level Archiving configuration exists only if you create it. You can modify or delete any site-level Archiving configuration. A site-level Archiving configuration overrides the global configuration, but only for the site specified in the site-level configuration. For example, if you enable Archiving for only IM in your global configuration and create a site configuration in which you enable Archiving for both IM and conferencing, conferencing would only be archived for the site, not for the remainder of your organization.
- **Pool Archiving configuration**. Optionally, you can specify Archiving settings for one or more specific pools by creating and configuring a pool-level configuration for the individual pool. A pool-level Archiving configuration exists only if you create it. You can modify and delete any pool-level Archiving configuration. A pool-level Archiving configuration overrides the global configuration and any site archiving configuration you may have created. For example, if you enable Archiving for only IM in your global configuration, create a site-level configuration in which you enable Archiving for both IM and conferencing for the site, and then create a pool-level configuration in which you enable Archiving only for IM, the communications would be archived for both IM and conferencing for all users of the site except the users homed in the pool specified in the pool-level configuration. For all other users in your organization, Archiving would be enabled only for IM.

For details about how to set up initial Archiving configurations when you deploy Archiving, see Configuring Archiving Options in the Deployment documentation. For details about using Archiving policies to enable and disable communications after deployment, see Managing Archiving Configuration Options for Your Organization, Sites, and Pools in the Operations documentation.

Archiving Options Available Only in Windows PowerShell

Using Lync Server 2013 Management Shell, you can use cmdlets to implement options that are not available in Lync Server 2013 Control Panel. These options include the following:

- **Archive duplicate messages**. For details, see New-CsArchivingConfiguration and Set-CsArchivingConfiguration in the Operations documentation.
- **Export archived data**. For details, see Export-CsArchivingData

How Do I Access Archived Data?

Access to archived data is dependent on where the data is stored:

- **Microsoft Exchange storage**. If you choose the SharePoint integration option, Lync Server deposits the archiving content in the Exchange 2013 store for all users who are homed on Exchange 2013, and who have had their mailboxes put on In-Place Hold. Archived data is stored in user mailboxes Recoverable items folder, which is generally invisible to users, and can only be searched by users with an Exchange **Discovery Management** role. Exchange enables federated search and discovery, along with SharePoint, if it is deployed. For more details about storage, retention, and discovery of data stored in Exchange, see the Exchange 2013 and SharePoint documentation.

- **Lync Server storage**. If you set up Lync Server 2013 Archiving databases for storage of Lync Server data, Lync Server deposits archiving content in the Lync Server Archiving databases (SQL Server databases) for any users not homed on Exchange 2013, and who have not had their mailboxes put on In-Place Hold. This data is not searchable, but it can be exported to formats that are searchable using other tools. For details about exporting data stored in Archiving databases, see Exporting Archived Data in the Operations documentation.

For more details about how Lync Server 2013 and Exchange 2013 work together, see Exchange Server and SharePoint Integration Support in the Supportability documentation.

1.4.6.2 Deployment Checklist for Archiving

Deployment Checklist for Archiving

Microsoft Lync Server 2013 > Planning > Planning for Archiving >

Topic Last Modified: *2012-10-18*

Archiving is automatically installed on each Front End Server in your Lync Server 2013 deployment, but you still need to set it up before you can use it. The steps required to set it up, as summarized in this section, constitute the deployment of Archiving.

Deployment Sequence

How you set up Archiving depends on which storage option you choose:

- If you use Microsoft Exchange integration for all users in your deployment, you don’t need to configure Lync Server 2013 Archiving policies for your users. Instead, configure your Exchange In-Place Hold policies to support archiving for users homed on Exchange 2013, with their mailboxes put on In-Place Hold. For details about configuring these policies, see the Exchange 2013 product documentation.
- If you do not use Microsoft Exchange integration for all users in your deployment, you need to add Lync Server Archiving databases (SQL Server databases) to your topology and then publish it, as well as configure policies and settings for your users, before you can archive data for those users. You can deploy Archiving databases at the same time that you deploy your initial topology or after you have deployed at least one Front End pool or Standard Edition server. This document describes how to deploy Archiving databases by adding them to an existing deployment.

If you enable archiving in one Front End pool or Standard Edition server, you should enable it for all other Front End pools and Standard Edition servers in your deployment. This is because users whose communications are required to be archived can be invited to a group IM conversation or meetings hosted on a different pool. If archiving is not enabled on the pool where the conversation or meeting is hosted, the complete session may not be archived. In these cases, IMs with archiving-enabled users still can be archived, but not for conferencing content files, and conference join or leave events.

Important:

If archiving is critical in your organization for compliance reasons, be sure to deploy Archiving, configure policies and other options at the appropriate level, and enable it for all appropriate users, before you enable those users for Lync Server 2013.

Archiving Deployment Process

The following table provides an overview of the steps required to deploy archiving in an existing topology.

Phase	Steps	Roles and group memberships	Documentation
Install prerequisite hardware and software	• To use Microsoft Exchange integration (using Exchange 2013 for archiving storage for some or all users), you need an existing Exchange 2013 deployment. • To use separate Archiving databases (using SQL Server databases) for archiving storage for some or all users, SQL Server on the server that will store archiving data. **Note:** Archiving runs on Front End Servers of an Enterprise pool and Standard Edition servers. It has no additional hardware or software requirements beyond what is required to install those servers.	Domain user who is a member of the local administrators group.	Supported Hardware in the Supportability documentation. Server Software and Infrastructure Support in the Supportability documentation. Technical Requirements for Archiving in the Planning documentation. Setting Up Systems and the Infrastructure for Archiving in the Deployment documentation. Exchange Server and SharePoint Integration Support in the Supportability documentation.
Create the appropriate internal topology to support archiving (only if not using Microsoft Exchange integration for all users in your deployment)	Run Topology Builder to add Lync Server 2013 Archiving databases (SQL Server databases) to the topology, and then publish the topology.	To define a topology to incorporate Archiving databases, an account that is a member of the local users group. To publish the topology, an account that is a member of the domain admins group and RTCUniversalServerAdmins group,	Adding Archiving Databases to an Existing Lync Server 2013 Deployment in the Deployment documentation.

		and that has full control permissions (read/write/modify) on the file share to be used for the Lync Server 2013 file store (so that Topology Builder can configure the required DACLs).	
Configure server-to-server authentication (only if using Microsoft Exchange integration)	Configure servers to enable authentication between Lync Server 2013 and Exchange 2013. We recommend running **Test-CsExchangeStorageConnectivity testuser_sipUri –Folder Dumpster** to validate Exchange Archiving storage connectivity before enabling archiving.	An account with the appropriate permissions for managing certificates on the servers.	Managing Server-to-Server Authentication (Oauth) and Partner Applications in the Deployment documentation or the Operations documentation.
Configure archiving policies and configurations	Configure archiving, including whether to use Microsoft Exchange integration, the global policy and any site and user policies (when not using Microsoft Exchange integration for all data storage), and specific archiving options, such as critical mode and data export and purging. If using Microsoft Exchange integration, configure Exchange In-Place Hold policies as appropriate.	RTCUniversalServerAdmins group (Windows PowerShell only) or assign users to the CSArchivingAdministrator or CSAdministrator role.	Configuring Support for Archiving in the Deployment documentation. Exchange product documentation (if using Microsoft Exchange integration).

Deploying Lync Server and Microsoft Exchange in Different Forests

If Microsoft Exchange Server is not deployed in the same forest as Lync Server, you must make sure that the following Exchange Active Directory attributes are synchronized to the forest where Lync Server is deployed:

1. msExchUserHoldPolicies
2. proxyAddresses

This is a multi-value attribute. When synchronizing this attribute, you need to merge the values, not replace them to ensure the existing values are not lost.

1.4.6.3 Setting Up Systems and the Infrastructure for Archiving

Setting Up Systems and the Infrastructure for Archiving

Microsoft Lync Server 2013 > Deployment > Deploying Archiving >

Topic Last Modified: *2012-06-23*

Before you deploy archiving, you need to deploy the appropriate hardware and software to support archiving and verify that your infrastructure supports your Archiving deployment.

- Setting Up System Platforms for Archiving
- Setting Up the Infrastructure for Archiving
- Setting Up Storage for Archiving
- Setting Up Permissions for Archiving

1.4.6.3.1 Setting Up System Platforms for Archiving

Setting Up System Platforms for Archiving

Deployment > Deploying Archiving > Setting Up Systems and the Infrastructure for Archiving >

Topic Last Modified: *2012-10-09*

Before starting the deployment of Archiving, you must install the required operating system and any other prerequisite software on hardware that meets system requirements:

- **Lync Server 2013 platform** Lync Server 2013 deployments do not have Archiving Servers. Instead, Unified Data Collection Agents run on Front End Servers and Standard Edition servers to capture data for archiving, so no separate system platform is required to host Archiving.
- **Data storage platform** In Lync Server 2013, you can store data by using either of the following:
  - **Microsoft Exchange integration** If you want to store Lync Server 2013 Archiving data by using your Exchange 2013 deployment, instead of or in addition to setting up a separate database for storage of Archiving data, your Exchange deployment must be running Exchange 2013. For details about setting up system platforms for Exchange 2013, see the Exchange product documentation.
  - **SQL Server** If you want to use a separate SQL Server database for storage of archiving data, instead of or in addition to using Microsoft Exchange integration, you must set up the system platform for the database prior to deployment of Archiving. The specific system platform requirements depend on whether you use Microsoft SQL Server 2008 R2 or Microsoft SQL Server 2012 for the Archiving database. For details about setting up system platforms for these databases, see the Microsoft SQL Server 2008 R2 and Microsoft SQL Server 2012 product documentation.
- **File server platform** Lync Server 2013 stores Lync Server archiving files in the same location that you specify for file storage when you set up your Front End Servers or Standard Edition servers. You cannot specify a separate location for archiving file storage, so no separate system platform is required for Archiving file storage. If you use Microsoft Exchange integration, Exchange 2013 the files for archived Lync communications are stored on Exchange 2013 servers for users homed on those Exchange servers.

1.4.6.3.2 Setting Up the Infrastructure for Archiving

Setting Up the Infrastructure for Archiving

Deployment > Deploying Archiving > Setting Up Systems and the Infrastructure for Archiving >

Topic Last Modified: *2012-10-01*

The infrastructure requirements for Archiving are the same as for your Lync Server deployment, except for storage. No additional infrastructure setup is required, except for setting up storage using Exchange 2013 storage, Archiving databases, or both. For details about infrastructure requirements for Lync Server 2013, see Determining Your Infrastructure Requirements in the Planning documentation and Preparing the Infrastructure and Systems in the Deployment documentation. For details about storage requirements for Archiving, see Technical Requirements for Archiving in the Planning documentation, Setting Up System Platforms for Archiving in the Deployment documentation, and Setting Up Storage for Archiving in the Deployment documentation.

1.4.6.3.3 Setting Up Storage for Archiving

Setting Up Storage for Archiving

Deployment > Deploying Archiving > Setting Up Systems and the Infrastructure for Archiving >

Topic Last Modified: *2012-10-01*

Archiving storage for Lync Server 2013 includes the following:

- **Data storage** Data storage is required to store IM content.
- **File storage** File storage is required to store conferencing (meeting) content data storage and file storage.

Setting Up Data Storage

Requirements for setting up data storage for Archiving in Lync Server 2013 depend on how you want to store archiving data:

- Integrate Lync Server 2013 Archiving with your Exchange deployment to store Archiving data using Exchange storage.
- Set up separate SQL Server database servers to store Archiving data.

Setting Up Exchange Storage for Archiving Data

Setting up Exchange for storage of Archiving data requires that your Exchange deployment is running Exchange 2013. Additionally, user mailboxes must be homed on the Exchange 2013 server and their mailboxes must be put on In-Place Hold. For details about configuring Exchange 2013, see the Exchange product documentation.

Setting Up SQL Server Database Servers for Storage of Archiving Data

Archiving in Lync Server 2013 requires the SQL Server database software to store the archived data, unless you integrate your deployment with Exchange.

For SQL Server archiving databases, you must install SQL Server on the computer that will host the Archiving database. You can use the same SQL instance that you use for the back-end database of a Front End pool. For best performance, you should deploy the Archiving database on a computer that is separate from the Central Management store. For details about collocating Lync Server 2013 components, see Supported Server Collocation in the Supportability documentation.

Each database server must be running a supported version of SQL Server. For details about the supported versions, see Technical Requirements for Archiving in the Planning documentation.

You must set up the SQL Server platforms prior to deploying and enabling Archiving. If the account to be used to publish the topology has the appropriate administrator rights and permissions, you can create the Archiving database (LcsLog) when you publish your topology. You can also create the database later, including as part of the installation procedure. For details about SQL Server, see the SQL Server TechCenter at http://go.microsoft.com/fwlink/p/?linkID=129045.

Setting Up File Storage

Archiving uses the Lync Server 2013 file share that you specified when you set up your Front End pool or Standard Edition server. You cannot change the file share used for Archiving. For details about supported file storage systems, see File Storage Support in the Supportability documentation.

1.4.6.3.4 Setting Up Permissions for Archiving

Setting Up Permissions for Archiving

Deployment > Deploying Archiving > Setting Up Systems and the Infrastructure for Archiving >

Topic Last Modified: *2012-10-01*

In Lync Server 2013, specific tasks still require that users who perform those tasks be members of one or more specific groups. However, you can also use role-based access control (RBAC) to grant privileges by assigning users to predefined Lync Server administrative roles.Before you deploy Archiving, be sure that the appropriate user rights and permissions are in place, and that any users who you want to assign to a specific RBAC role have been assigned to that role. For details about the user rights, permissions, and roles for deploying support for Archiving, see Deployment Checklist for Archiving, which is available in the Planning documentation and the Deployment documentation. For details about RBAC, see Planning for Role-Based Access Control in the Planning documentation.

1.4.6.4 Adding Archiving Databases to an Existing Lync Server 2013 Deployment

Adding Archiving Databases to an Existing Lync Server 2013 Deployment

Microsoft Lync Server 2013 > Deployment > Deploying Archiving >

Topic Last Modified: *2012-06-23*

After you set up the system platforms and infrastructure for Archiving, you must use Topology Builder to add Archiving to your topology, and then publish the topology.

- Adding Archiving Databases to the Lync Server 2013 Topology
- Publishing the Updated Topology to Add Archiving Databases

1.4.6.4.1 Adding Archiving Databases to the Lync Server 2013 Topology

Adding Archiving Databases to the Lync Server 2013 Topology

Deployment > Deploying Archiving > Adding Archiving Databases to an Existing Lync Server 2013 Deployment >

Topic Last Modified: *2012-10-10*

You must incorporate archiving into your topology before you can configure your deployment to support archiving. The information in this topic explains how to use Topology Builder to add archiving to your existing topology.

Note:

If you want to use Microsoft Exchange integration to store archiving data and files on Exchange 2013 servers for all your users in your deployment, do not specify **Archiving SQL Server store** or **Use SQL Server Store mirroring** information.

⊟To add Archiving database support to your topology

1. On a computer that is running Lync Server 2013, or on which the Lync Server administrative tools are installed, log on by using an account that is a member of the local Users group (or an account with equivalent user rights).

   Note:

   You can define a topology by using an account that is a member of the local Users group, but to publish a topology, which is required to add a server to the topology, you must use an account that is a member of the **Domain Admins** group and the **RTCUniversalServerAdmins** group, and that has full control permissions (that is, read, write, and modify) on the file share that you are using for the Lync Server 2013 file store (that is, so that Topology Builder can configure the required discretionary access control list (DACLs), or an account with equivalent rights.
2. Start Topology Builder.
3. In the console tree, navigate to the Front End pool in which you want to deploy Archiving, and then click the name of the Front End pool where you want to deploy Archiving.
4. In the **Action** menu, click **Edit Properties**.
5. In the **Edit Properties** dialog box, click **General**.
6. Scroll down to **Archiving**.
7. Select the **Archiving** check box.
8. Under **Archiving SQL Server store,** do one of the following:
   - To use an existing SQL Server store, in the drop-down list box, click the name of the SQL Server store that you want to use. If all of your users are homed on Microsoft Exchange Server 2013 or above, you can archive Lync communications for all your users in Exchange. In this case, you don’t need to configure SQL Server Archiving store.
   - To specify a new SQL Server store, click **New**, and then in the **Define New SQL Server Store** dialog box, do the following:
     - In **SQL Server FQDN**, specify the FQDN of the server on which you want to create the new SQL Server store.
     - Either click **Default Instance** to use the default instance, or, to specify a different instance, click **Named instance**, and then specify the instance you want to use.
     - If the specified SQL Server instance is in a mirroring relationship, select the **This SQL instance is in mirroring relation** check box, and then, in **Mirror port number**, specify the port number.
9. If you want to use SQL Server store mirroring, select **Enable SQL Server Store mirroring**, and then do the following:

- To use an existing SQL Server store for mirroring, in the **Archiving SQL Server store mirror** drop-down list box, click the name of the SQL Server store that you want to use for mirroring.
- To specify a new SQL Server store for mirroring, click **New**, and then in the **Define New SQL Server Store** dialog box, do one of the following:
  - In **SQL Server FQDN**, specify the FQDN of the SQL Server on which you want to create the new SQL Server store.
  - Either click **Default Instance** to use the default instance, or, to specify a different instance, click **Named Instance**, and then specify the instance you want to use.
  - If the specified SQL Server instance is in a mirroring relationship, select the **This SQL instance is in mirroring relation** check box, and then, in **Mirror port number**, specify the port number.
- If you enable SQL Server mirroring and want to include a SQL Server mirroring witness (a third, separate SQL Server instance that can detect the health of the primary SQL Server server and mirror instances), select the **Use SQL Server mirroring witness to enable automatic failover** check box, and then do one of the following:
  - In **SQL Server FQDN**, specify the FQDN of the server on which you want to create the new SQL Server mirroring witness.
  - Either click **Default Instance** to use the default instance, or, to specify a different instance, click **Named Instance**, and then specify the instance you want to use for the mirroring witness.
  - If the specified SQL Server instance is in a mirroring relationship, select the **This SQL instance is in mirroring relation** check box, and then, in **Mirror port number**, specify the port number.

10.To save the configuration, click **OK**.

1.4.6.4.2 Publishing the Updated Topology to Add Archiving Databases

Publishing the Updated Topology to Add Archiving Databases

Deployment > Deploying Archiving > Adding Archiving Databases to an Existing Lync Server 2013 Deployment >

Topic Last Modified: *2012-10-01*

After updating your topology in Topology Builder, you must publish the topology to the Central Management store before you can configure and use Archiving. Read-only copies of the data are replicated to all servers in the topology to keep all servers in sync with topology and other configuration changes.

⊟To publish your updated topology

1. On a computer that is running Lync Server 2013, or on which the Lync Server administrative tools are installed, log on using an account that is a member of the local Users group (or an account with equivalent user rights).

Note:

You can define a topology by using an account that is a member of the local Users group, but to publish a topology, which is required to add a server to the topology, you must use an account that is a member of the **Domain Admins** group and the **RTCUniversalServerAdmins** group, and that has full control permissions (that is, read, write, and modify) on the file share that you are using for the Lync Server 2013 file store (that is, so that Topology Builder can configure the required discretionary access control list (DACLs), or an account with equivalent rights.

2. Open the topology you created in the previous section using Topology Builder.
3. In the console tree, right-click **Lync Server 2013**, and then click **Publish Topology**.
4. On the **Publish the topology** page, click **Next**.
5. On the **Create databases** page, verify that the database is selected, and then click **Next**.

Note:

If you do not have the appropriate permissions to create databases, you can cancel the selection of the database and someone with appropriate permissions can create the database. For details about the required administrator rights and permissions, see Deployment Permissions for SQL Server in the Deployment documentation.

Only databases on dedicated SQL Server servers can be installed by using Topology Builder. Databases on SQL Server servers that are collocated with other server components must be installed by running local setup on that computer.

6. On the **Publishing wizard complete** page, verify that the topology was successfully published, and then click **Finish**.

Important:

After publishing the topology, you must configure options and policies for Archiving before any content can be archived. For details, see Configuring Support for Archiving in the Deployment documentation.

1.4.6.5 Configuring Support for Archiving

Configuring Support for Archiving

Microsoft Lync Server 2013 > Deployment > Deploying Archiving >

Topic Last Modified: *2012-10-01*

After adding Archiving to your topology and publishing the new topology, you need to configure options for how Archiving is initially implemented in your deployment, and then configure one or more Archiving policies to enable Archiving for your deployment and, optionally, for specific sites and users. You can use Lync Server 2013 Control Panel to do this.

Note:

After deployment, you can change Archiving settings to disable or enable Archiving. For details about how to implement archiving support for day-to-day management or to meet new requirements in your organization after deployment, see Managing Lync Server 2013 Archiving in the Operations documentation.

- Configuring Archiving Options
- Configuring and Assigning Archiving Policies
- Enable or Disable Sending an Archiving Disclaimer to Federated Partners

1.4.6.5.1 Configuring Archiving Options

Configuring Archiving Options

Deployment > Deploying Archiving > Configuring Support for Archiving >

Topic Last Modified: *2012-10-10*

In Lync Server 2013 Control Panel, you use Archiving configurations to specify how archiving is implemented. This includes the following Archiving configurations:

- A global configuration that is created by default when you deploy Lync Server 2013.
- Optional site-level and pool-level configurations that you can create and use to specify how archiving is implemented for specific sites or pools.

You initially set up Archiving configurations when you deploy Archiving, but you can change, add, and delete configurations after deployment. In Lync Server 2013 Control Panel, you can use the **Archiving Configuration** page of the **Archiving and Monitoring** group to manage configurations at the global level, site level, and pool level. For details about how Archiving configurations are implemented, including which options you can specify and the hierarchy of Archiving configurations, see How Archiving Works in the Planning documentation, Deployment documentation, or Operations documentation. For details about how to manage configurations after deployment, see Managing Archiving Configuration Options for Your Organization, Sites, and Pools in the Operations documentation.

Note:

To use archiving, you must configure Archiving policies to specify whether to enable archiving for internal communications, for external communications, or for both for users homed on Lync Server 2013. By default, archiving is not enabled for either internal or external communications. Before enabling Archiving in any policies, you should specify the appropriate Archiving configurations for your deployment and, optionally, for specific sites and pools, as described in this section. For details about enabling Archiving, see Configuring and Assigning Archiving Policies in the Deployment documentation.
If you do not use Microsoft Exchange integration for all users in your deployment, you must configure Archiving policies to specify whether to enable archiving for internal communications, for external communications, or for both. By default, archiving is not enabled for either internal or external communications for archiving of data when using Lync Server 2013 Archiving databases. Prior to enabling Archiving in any policies, you should specify the appropriate Archiving configurations for your deployment and, optionally, for specific sites and pools, as described in this section. For details about enabling Archiving for use with Lync Server 2013 Archiving databases, see Configuring and Assigning Archiving Policies in the Deployment documentation.

- Configuring Archiving Options at the Global Level
- Configuring Archiving Options for a Site
- Configuring Archiving Options for a Pool

1.4.6.5.1.1 Configuring Archiving Options at the Global Level

Configuring Archiving Options at the Global Level

Deploying Archiving > Configuring Support for Archiving > Configuring Archiving Options >

Topic Last Modified: *2012-10-10*

When you add Archiving to your topology and publish the topology, Lync Server creates a global configuration for Archiving. By default, no Archiving options are enabled in the global configuration. The global configuration controls which options are enabled for your entire deployment, unless you set up site or pool configurations, which override the global configuration.

For details about how Archiving configurations work, including the hierarchy for global, site, and pool configurations, see How Archiving Works in the Planning documentation, Deployment documentation, or Operations documentation.

Note:

You should specify all appropriate options in the Archiving configurations before enabling Archiving.

⊟To configure archiving options at the global level

1. From a user account that is assigned to the CsArchivingAdministrator or CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync Server 2013 Control Panel. For details about the different methods that you can use to start Lync Server 2013 Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Monitoring and Archiving**, and then click **Archiving Configuration**.
4. On the **Archiving Configuration** page, click **Global**, click **Edit**, and then click **Show details**.
5. In **Edit Archiving Setting - Global**, in the **Archiving setting** drop-down list, select one of the following archiving options:
   - **Disable archiving**
   - **Archive IM sessions**
   - **Archive IM and web conferencing sessions**
6. Also on the **Edit Archiving Setting – Global** page, do the following:
   - To block activity when archiving is not available, select the **Block instant messaging (IM) or web conferencing sessions if archiving fails** check box.
   - To use Microsoft Exchange Server to store archiving data, click the **Microsoft Exchange integration** check box.
   - To enable data purging, select the **Enable purging of archiving data** check box, and then do one of the following:
     - To specify purging after a specific number of days, click **Purge exported archiving data and stored archiving data after maximum duration (days)**, and then specify the number of days.
     - To limit purging to archiving data that has been exported, click **Purge exported archiving data only**.
7. Click **Commit**.

1.4.6.5.1.2 Configuring Archiving Options for a Site

Configuring Archiving Options for a Site

Deploying Archiving > Configuring Support for Archiving > Configuring Archiving Options >

***Topic Last Modified:** 2012-10-09*

You can specify Archiving options to be applied to specific sites by creating and configuring options in an Archiving configuration for each of those sites. A site configuration overrides the global configuration, but only for the site specified in the site configuration. Pool configurations override site configurations

For details about how Archiving configurations work, including the hierarchy for global, site, and pool configurations, see How Archiving Works in the Planning documentation, Deployment documentation, or Operations documentation.

Note:

You should specify all appropriate options in the Archiving configurations before enabling Archiving.

> **Important:**
>
> To enable archiving, you must specify archiving policies to control the archiving of internal and external communications at the global level and, if appropriate, at site and user levels. If you configure user-level policies, you must also assign the user policies to specific users. For details about creating and configuring archiving policies, see Managing the Archiving of Internal and External Communications in the Operations documentation.

To configure archiving options at the site level

1. From a user account that is assigned to the CsArchivingAdministrator or CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync Server 2013 Control Panel. For details about the different methods you can use to start Lync Server 2013 Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Monitoring and Archiving**, and then click **Archiving Configuration**.
4. On the **Archiving Configuration** page, click **New**, and then click **Site Configuration**.
5. In **Select a Site**, select the site to be configured for archiving.
6. In **New Archiving Setting**, in the **Archiving setting** drop-down list box, do one of the following:
    - To enable archiving only for instant messaging (IM) sessions, click **Archive IM sessions**.
    - To enable archiving for both IM sessions and conferences, click **Archive IM and web conferencing sessions**.
    - To disable archiving for the policy, click **Disable archiving**.
7. Also in **New Archiving Setting**, do the following:
    - To block activity when archiving is not available, select the **Block instant messaging (IM) or web conferencing sessions if archiving fails** check box.
    - To use Microsoft Exchange Server to store archiving data, click the **Microsoft Exchange integration** check box.
    - To enable data purging, select the **Enable purging of archiving data** check box, and then do one of the following:
        - To specify purging after a specific number of days, click **Purge exported archiving data and stored archiving data after maximum duration (days)**, and then specify the number of days.
        - To limit purging to archiving data that has been exported, click **Purge exported archiving data only**.
8. Click **Commit**.

1.4.6.5.1.3 Configuring Archiving Options for a Pool

Configuring Archiving Options for a Pool

Deploying Archiving > Configuring Support for Archiving > Configuring Archiving Options >

Topic Last Modified: *2012-10-10*

You can specify Archiving options to be applied to specific pools by creating and configuring options in an Archiving configuration for each of those pools. A pool configuration overrides the global configuration and site configuration, but only for the pool specified in the pool configuration.

For details about how Archiving configurations work, including the hierarchy for global, site, and pool configurations, see How Archiving Works in the Planning documentation, Deployment documentation, or Operations documentation.

> **Note:**
>
> You should specify all appropriate options in the Archiving configurations before enabling Archiving. For details, see Configuring Archiving Options in the Deployment documentation.

⊟To configure archiving options at the pool level

1. From a user account that is assigned to the CsArchivingAdministrator or CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync Server 2013 Control Panel. For details about the different methods that you can use to start Lync Server 2013 Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Monitoring and Archiving**, and then click **Archiving Configuration**.
4. On the **Archiving Configuration** page, click **New**, and then click **Pool Configuration**.
5. In **Select a Service**, select the pool to be configured for archiving.
6. In **New Archiving Setting**, in the **Archiving setting** drop-down list, select one of the following archiving options:
   - **Disable archiving**
   - **Archive IM sessions**
   - **Archive IM and web conferencing sessions**
7. Also in **New Archiving Setting** page, do the following:
   - To block activity when archiving is not available, select the **Block instant messaging (IM) or web conferencing sessions if archiving fails** check box.
   - To use Microsoft Exchange Server to store archiving data, click the **Microsoft Exchange integration** check box.
   - To enable data purging, select the **Enable purging of archiving data** check box, and then do one of the following:
     - To specify purging after a specific number of days, click **Purge exported archiving data and stored archiving data after maximum duration (days)**, and then specify the number of days.
     - To limit purging to archiving data that has been exported, click **Purge exported archiving data only**.
8. Click **Commit**.

1.4.6.5.2 Configuring and Assigning Archiving Policies

Configuring and Assigning Archiving Policies

Deployment > Deploying Archiving > Configuring Support for Archiving >

Topic Last Modified: *2012-10-01*

In Lync Server 2013, you use policies to enable and disable archiving for internal communications and external communications for users who are homed on Lync Server 2013. This includes the following Archiving policies:

- A global policy that is created by default when you deploy Lync Server 2013.
- Optional site-level and user-level policies that you can create and use to specify how archiving is implemented for specific sites or users.

You initially set up Archiving policies when you deploy Archiving, but you can change, add, and delete policies after deployment. In Lync Server 2013 Control Panel, you can use the **Archiving Policy** page of the **Archiving and Monitoring** group to manage policies at the global level, site level, and user level.

Note:

To control the implementation of Archiving, you must specify options in Archiving configurations, such as whether to archive IM or conferencing, the use of critical mode, and purging options. By default no options are enabled in the global Archiving configuration or any site or pool Archiving configuration. You should specify all appropriate options in the Archiving configurations before enabling Archiving for internal or external communications in the Archiving policies. For details, see Managing Archiving Configuration Options for Your Organization, Sites, and Pools in the Operations documentation.

If you integrate your Lync Server storage with Exchange 2013 storage, the Exchange user policies take precedence over the Lync Server 2013 archiving policies but only for those users who are homed on Exchange 2013 who have had their mailboxes put on In-Place Hold.

For details about how policies are implemented, including the hierarchy of policies, see How Archiving Works in the Planning documentation, Deployment documentation, or Operations documentation. For details about how to manage policies after deployment, see Managing the Archiving of Internal and External Communications in the Operations documentation.

- Configuring the Global Policy for Archiving
- Setting Up Site Policies for Archiving
- Setting Up Archiving Policies for Users

1.4.6.5.2.1 Configuring the Global Policy for Archiving

Configuring the Global Policy for Archiving

Deploying Archiving > Configuring Support for Archiving > Configuring and Assigning Archiving Policies >

Topic Last Modified: *2012-10-09*

When you deploy your Front End Servers, Lync Server creates a global policy for Archiving. By default, Archiving is disabled in the global policy. The global policy controls whether archiving is enabled for internal and external communications for your entire deployment, unless you set up site or user policies, which override the global policy, or if you use Microsoft Exchange integration for some or all of your users. If you use Microsoft Exchange integration, the global policy does not apply to any users who are homed on Exchange 2013 and have the mailboxes put on In-Place Hold.

For details about how Archiving policies work, including the hierarchy for global, site, and user policies, see How Archiving Works Planning documentation, Deployment documentation, or Operations documentation.

Note:

If you enable Microsoft Exchange integration for your deployment, Exchange In-Place Hold policies control whether archiving is enabled for the users who are homed on Exchange 2013 and have their mailboxes put on In-Place Hold. For details, see Setting Up Policies for Archiving When Using Exchange Server Integration in the Deployment documentation.

You should specify all appropriate options in the Archiving configurations before enabling Archiving. For details, see Configuring Archiving Options in the Deployment documentation.

⊟To configure the global policy for archiving when using Lync Server Archiving databases

1. From a user account that is assigned to the CsArchivingAdministrator or CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync Server 2013 Control Panel. For details about the different methods you can use to start Lync Server 2013 Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Monitoring and Archiving**, and then click **Archiving Policy**.
4. On the **Archiving Policy** page, click **Global**, click **Edit**, and then click **Show details**.
5. In **Edit Archiving Policy - Global**, do the following:
   - In **Name**, if you do not want to use the default name of Global, specify a new name for the global policy.
   - In **Description**, provide information about what the policy is (for example, Global policy for *divisionName*).
   - To control archiving of internal communications for all sites and users not specifically controlled through a site policy or user policy, select or clear the **Archive internal communications** check box.
   - To control archiving of external communications for all sites and users not specifically controlled through a site policy or user policy, select or clear the **Archive external communications** check box.
6. Click **Commit**.

1.4.6.5.2.2 Setting Up Site Policies for Archiving

Setting Up Site Policies for Archiving

Deploying Archiving > Configuring Support for Archiving > Configuring and Assigning Archiving Policies >

Topic Last Modified: *2012-10-09*

You can enable or disable Archiving for specific sites by creating and configuring an Archiving policy for each of those sites. A site policy overrides the global policy, but user policies override site policies. Archiving policies only apply if you do not use Microsoft Exchange integration or, if you do use Microsoft Exchange integration, but have some users who are not homed on Exchange 2013 and have their mailboxes put on In-Place Hold.

For details about how Archiving policies work, including the hierarchy for global, site, and user policies, see How Archiving Works Planning documentation, Deployment documentation, or Operations documentation.

Note:

If you enable Microsoft Exchange integration for your deployment, Exchange In-Place Hold policies control whether archiving is enabled for the users who are homed on Exchange 2013 and have their mailboxes put on In-Place Hold. For details, see Setting Up Policies for Archiving When Using Exchange Server Integration in the Deployment documentation.

You should specify all appropriate options in the Archiving configurations before enabling Archiving of internal or external communications in the Archiving policies. For details, see Configuring Archiving Options in the Deployment documentation.

⊟To create an archiving policy for a site

1. From a user account that is assigned to the CsArchivingAdministrator or CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync Server 2013 Control Panel.
3. In the left navigation bar, click **Monitoring and Archiving**, and then click **Archiving Policy**.

   For details about how Archiving policies work, including the hierarchy for global, site, and user policies, see How Archiving Works Planning documentation, Deployment documentation, or Operations documentation.
4. Click **New**, and then click **Site policy**.
5. In **Select a site**, click the site to which the policy is to be applied.
6. In **New Archiving Policy**, do the following:
   - In **Name**, specify the name for the site policy.
   - In **Description**, provide information about what the site policy is (for example, site policy for Redmond).
   - To control archiving of internal communications for the specified site, select or clear the **Archive internal communications** check box.
   - To control archiving of external communications for the specified site, select or clear the **Archive external communications** check box.
7. Click **Commit**.

1.4.6.5.2.3 Setting Up Archiving Policies for Users

Setting Up Archiving Policies for Users

Deploying Archiving > Configuring Support for Archiving > Configuring and Assigning Archiving Policies >

Topic Last Modified: *2012-10-09*

You can enable or disable Archiving for specific users by creating and configuring an Archiving policy for users, and then applying the policy to specific users or user groups. User policies override any global policy or site policies. Archiving policies only apply if you do not use Microsoft Exchange integration or, if you do use Microsoft Exchange integration, but have some users who are not homed on Exchange 2013 and have their mailboxes put on In-Place Hold.

For details about how Archiving policies work, including the hierarchy for global, site, and user policies, see How Archiving Works Planning documentation, Deployment documentation, or Operations documentation.

Note:

If you enable Microsoft Exchange integration for your deployment, Exchange In-Place Hold policies control whether archiving is enabled for the users who are homed on Exchange 2013 and have their mailboxes put on In-Place Hold. For details, see Setting Up Policies for Archiving When Using Exchange Server Integration in the Deployment documentation.
You should specify all appropriate options in the Archiving configurations before enabling Archiving of internal or external communications in the Archiving policies. For details, see Configuring Archiving Options in the Deployment documentation.

- Setting Up User Policies for Archiving in Lync Server
- Setting Up Policies for Archiving When Using Exchange Server Integration

Setting Up User Policies for Archiving in Lync Server

Configuring Support for Archiving > Configuring and Assigning Archiving Policies > Setting Up Archiving Policies for Users >

Topic Last Modified: *2012-10-10*

Enabling or disabling Archiving for specific users homed on Lync Server 2013 requires creating and configuring one or more user policies, and then applying the appropriate policy to specific users or user groups. User policies override site and global policies, but only for users homed on Lync Server 2013.

Users are always homed in Lync Server. If Microsoft Exchange integration is enabled, users whose mailboxes are in Microsoft Exchange Server 2013 don't need to have their Archiving policies in Lync Server managed. These users with Archiving will be managed by Exchange In-Place Hold.

For details about how Archiving policies work, including the hierarchy for global, site, and user policies, see How Archiving Works in the Planning documentation, Deployment documentation, or Operations documentation.

Note:

If you enabled Microsoft Exchange integration for your deployment, Exchange In-Place Hold policies control whether archiving is enabled for the users who are homed on Exchange 2013. Archiving for these users requires that they have their mailboxes put on In-Place Hold. For details, see Setting Up Policies for Archiving When Using Exchange Server Integration in the Deployment documentation.

You should specify all appropriate options in the Archiving configurations before enabling Archiving. For details, see Configuring Archiving Options in the Deployment documentation.

- Creating and Configuring User Policies for Archiving in Lync Server
- Applying a Lync Server Archiving Policy to a User

Creating and Configuring User Policies for Archiving in Lync Server

Configuring and Assigning Archiving Policies > Setting Up Archiving Policies for Users > Setting Up User Policies for Archiving in Lync Server >

Topic Last Modified: *2012-10-09*

To enable or disable Archiving for specific users homed on Lync Server, you must first create a user policy and then apply the policy to one or more users or user groups. For details about applying user policies to specific users and user groups, see Applying a Lync Server Archiving Policy to a User in the Deployment documentation.

For details about how Archiving policies work, including the hierarchy for global, site, and user policies, see How Archiving Works in the Planning documentation, in the Deployment documentation, or in the Operations documentation.

Note:

If you enabled Microsoft Exchange integration for your deployment, Exchange In-Place Hold policies control whether archiving is enabled for the users who are homed on Exchange 2013 and have their mailboxes put on In-Place Hold. For details, see Setting Up Policies for Archiving When Using Exchange Server Integration in the Deployment documentation.

You should specify all appropriate options in the Archiving configurations before enabling

Archiving. For details, see Configuring Archiving Options in the Deployment documentation.

⊟To configure an archiving policy for users homed on Lync Server

1. From a user account that is assigned to the CsArchivingAdministrator or CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync Server 2013 Control Panel. For details about the different methods that you can use to start Lync Server 2013 Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Monitoring and Archiving**, and then click **Archiving Policy**.
4. Click **New**, and then click **User policy**.
5. In **New Archiving Policy**, do the following:
   - In **Name**, specify the name for the user policy.
   - In **Description**, provide information about what the user policy is (for example, user policy for legal department).
   - To control archiving of internal communications for the user policy, select or clear the **Archive internal communications** check box.
   - To control archiving of external communications for the user policy, select or clear the **Archive external communications** check box.
6. Click **Commit**.

A user policy applies only to users to whom you assign the policy. For details about applying a user policy to specific users, see Applying a Lync Server Archiving Policy to a User in the Deployment documentation.

Applying a Lync Server Archiving Policy to a User

Configuring and Assigning Archiving Policies > Setting Up Archiving Policies for Users > Setting Up User Policies for Archiving in Lync Server >

Topic Last Modified: *2012-10-10*

After creating a Lync Server user policy, you must apply it to specific the users or user groups that are homed on Lync Server 2013 before it can take effect. For details about creating user policies for specific users, see Creating and Configuring User Policies for Archiving in Lync Server in the Deployment documentation.

For details about how Archiving policies work, including the hierarchy for global, site, and user policies, see How Archiving Works in the Planning documentation, Deployment documentation, or Operations documentation.

Note:

In order to configure and use archiving, you must first deploy archiving. For details, see Deploying Archiving in the Deployment documentation.

If you enabled Microsoft Exchange integration for your deployment, Exchange In-Place Hold policies control whether archiving is enabled for the users who are homed on Exchange 2013 and have their mailboxes put on In-Place Hold. For details, see Setting Up Policies for Archiving When Using Exchange Server Integration in the Deployment documentation.

You should specify all appropriate options in the Archiving configurations before enabling Archiving. For details, see Configuring Archiving Options in the Deployment documentation.

⊟To apply a Lync Server archiving policy to a user

1. From a user account that is assigned to the CsArchivingAdministrator or CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync Server 2013 Control Panel. For details about the different methods you can use to start Lync Server 2013 Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Users**, and then search for the user account that you want to configure.
4. In the table that lists the search results, click the user account, click **Edit**, and then click **Show details**.
5. In **Edit Lync Server user** under **Archiving policy**, select the archiving user policy that you want to apply.

   Note:
   The **<Automatic>** settings apply the default server installation settings. These settings are applied automatically by the server.

6. Click **Commit**.

Setting Up Policies for Archiving When Using Exchange Server Integration

Configuring Support for Archiving > Configuring and Assigning Archiving Policies > Setting Up Archiving Policies for Users >

Topic Last Modified: *2012-10-09*

If users homed on Exchange 2013 have their mailboxes put on In-Place Hold, Exchange In-Place Hold policies control archiving for those users. If you use Microsoft Exchange integration for your deployment, Exchange 2013 policies override Lync Server Archiving policies for users who are homed on Exchange 2013. For information about configuring Exchange Archiving policies, see the Exchange 2013 documentation. For details about setting up user policies for users homed on Lync Server 2013, see Setting Up User Policies for Archiving in Lync Server in the Deployment documentation. For details about how policies work, see How Archiving Works in the Planning documentation, Deployment documentation, or Operations documentation.

Note:
If you deploy Exchange 2013 and Lync Server 2013 in the same forest, your Exchange 2013 In-Place Hold policies control archiving. If you deploy Exchange 2013 and Lync Server 2013 in separate forests, see “Deploying Lync Server and Microsoft Exchange in Different Forests” in Deployment Checklist for Archiving.

1.4.6.5.3 Enable or Disable Sending an Archiving Disclaimer to Federated Partners

Enable or Disable Sending an Archiving Disclaimer to Federated Partners

Deployment > Deploying Archiving > Configuring Support for Archiving >

Topic Last Modified: *2013-02-23*

At the time you deployed your Edge Servers and enabled federation for your organization, you should have specified whether to automatically send the archiving disclaimer to federated partners. If you archive external communications, you should enable the sending of an archiving disclaimer. Use the procedure in this topic to change that configuration.

Note:

The following procedure assumes that you have already enabled federation for your organization. For details about enabling federation, see Enable or Disable Remote User Access in the Deployment documentation or the Operations documentation.

To enable or disable sending of an archiving disclaimer to federated partners

1. From a user account that is a member of the RTCUniversalServerAdmins group (or has equivalent user rights), or is assigned to the CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **External User Access**, click **Access Edge Configuration**.
4. On the **Access Edge Configuration** tab, click **Global**, click **Edit**, and then click **Show details**.
5. In **Edit Access Edge Configuration**, under **Enable communications with federated users**, select or clear the **Send archiving disclaimer to federated partners** check box to enable or disable automatically sending the archiving disclaimer.
6. Click **Commit**.

To enable federated users to collaborate with users in your Lync Server 2013 deployment, you must have also configured at least one external access policy to support federated user access. For details, see Manage XMPP Federated Partners for Your Organization in the Deployment documentation or the Operations documentation. For details about controlling access for specific federated domains, see Configure Support for Allowed External Domains in the Deployment documentation or Operations documentation.

Enabling or Disabling the Archiving Disclaimer by Using Windows PowerShell Cmdlets

The use of the archiving disclaimer can be managed by using Windows PowerShell and the Set-CsAccessEdgeConfiguration cmdlet. This cmdlet can be run either from the Lync Server 2013 Management Shell or from a remote session of Windows PowerShell. For details about using remote Windows PowerShell to connect to Lync Server, see the Lync Server Windows PowerShell blog article "Quick Start: Managing Microsoft Lync Server 2010 Using Remote PowerShell" at http://go.microsoft.com/fwlink/p/?linkId=255876.

To enable the archiving disclaimer

- To enable the archiving disclaimer, set the value of the **EnableArchivingDisclaimer** property to True ($True):

```
Set-CsAccessEdgeConfiguration -EnableArchivingDisclaimer $True
```

To disable the archiving disclaimer

- To disable the archiving disclaimer, set the value of the **EnableArchivingDisclaimer** property to False ($False):

```
Set-CsAccessEdgeConfiguration -EnableArchivingDisclaimer $False
```

1.4.7 Configuring Video

Configuring Video

Microsoft Lync Server 2013 > Deployment >

Topic Last Modified: *2012-10-02*

Lync Server 2013 introduces the following new video features:

- **HD video** Users can experience resolutions up to full high definition (HD) (that is, 1920 x 1080) in two-party calls and multiparty conferences.
- **Gallery View** In video conferences that have more than two people, users can see videos of participants in the conference. If the conference has more than five participants, video of only the most active participants appears in the top row, and a photo appears for the other participants.
- **H.264 video** The H.264 video codec is now the default for encoding video on Lync 2013 clients. H.264 video supports a greater range of resolutions and frame rates, and improves video scalability.

> **Note:**
> Lync Server 2013 still supports the VC1 codec for interoperability with previous versions of Lync. For details and background information about the new video codec, see Jeff Schertz's Blog article, "Video Interoperability in Lync 2013," at http://blog.schertz.name/2012/07/video-interoperability-in-lync-2013/.

This section describes how to manage bandwidth for video in Lync Server 2013 and how to configure video features.

- Configuring Video Bandwidth in Lync Server 2013
- Configuring Gallery View
- Configuring Video Example Scenarios
- Interoperability Considerations for Video Conferencing

1.4.7.1 Configuring Video Bandwidth in Lync Server 2013

Configuring Video Bandwidth in Lync Server 2013

Microsoft Lync Server 2013 > Deployment > Configuring Video >

Topic Last Modified: *2012-10-02*

Lync Server 2013 includes several settings for managing video for two-party calls and multiparty conferences. When you deploy Lync Server 2013, you should evaluate whether the default settings are appropriate for your organization, and modify them as necessary.

The parameters described in this section apply to both two-party calls and multiparty conferencing. View or modify these settings by using one of the following cmdlets:

- **Get-CsConferencingPolicy**
- **Set-CsConferencingPolicy**
- **New-CsConferencingPolicy**

Verify the following settings in your conferencing policy:

- **VideoBitRateKb** This setting specifies the maximum video bit rate in kilobits per second (kbps) used for video sent by a user. The default value is 50000 kbps. Valid values are 0 to 50000.
  This setting applies separately to main video and panoramic video.
  Example: if you specify 2000 kbps, then Lync Server can send 2000 kbps for the main video stream and 2000 kbps for the panoramic video stream.

Note:
The maximum video network bandwidth for a Lync 2013 endpoint is 8000 kbps for the main video and 2500 kbps for panoramic video. These maximum values are reached only if multiple videos are received or sent. For details, see the "Media Traffic Network Usage" section in Network Bandwidth Requirements for Media Traffic. This section lists the maximum and typical video stream bandwidth for all supported resolutions.

- **TotalReceiveVideoBitRateKb** This setting, which is new in Lync Server 2013, specifies the maximum allowed bitrate (in kilobits per second) for all the video streams received by a client. That is, it specifies the combined total for all the video streams, except for panoramic video streams, that a client can receive. For example, if you specify 1500 kbps, then a client can receive up to 1500 kbps of video, which may consist of multiple video streams or a single video stream. This setting applies only to Lync Server 2013 clients.
  The default value for **TotalReceiveVideoBitRateKb** is 50000 kbps. If the **EnableMultiviewJoin** setting for Gallery View is set to True, **TotalReceiveVideoBitRateKb** must not be set below 420 kbps. If the **EnableMultiviewJoin** setting for Gallery View is set to False, **TotalReceiveVideoBitRateKb** must not be set below 100 kbps. If **EnableMultiviewJoin** is set to True and you set the value below 420 kbps, the values will default to the threshold value. This threshold helps prevent accidental misconfiguration that might result in poor user experience.

  Note:
  For details about the **EnableMultiviewJoin** setting, see Configuring Gallery View.

- **MaxVideoConferencingResolution** This parameter is no longer used for Lync Server 2013 clients in Lync Server 2013 conferences. Lync Server 2013 conferences use the bit rate controls described earlier in this section. This setting is still used for legacy clients joining a Lync Server 2013 conference. This parameter determines the maximum resolution allowed for legacy clients in conferences organized by users who are homed on Lync Server 2013. That is, legacy clients are treated the same as they were in previous versions of Lync Server or Office Communications Server.

In addition to conferencing policy settings that apply to users, evaluate media configuration settings. View or modify these settings by using one of the following cmdlets:

- **Get-CsMediaConfiguration**
- **Set- CsMediaConfiguration**
- **New- CsMediaConfiguration**

Verify the following setting:

- **MaxVideoRateAllowed** This per-pool setting specifies the maximum rate at which video signals will be transferred at the client endpoints. It applies only to previous versions of Lync Server clients.

  Note:
  Lync Server 2013 clients ignore this setting and use the TotalReceiveVideoBitRateKb setting in conferencing policy instead.

  The default value is HD720P. Valid values are HD720p15M, VGA600K, and CIF250K.
  Example: If you specify 1500 kbps, then all the legacy clients in the pool can receive up to 1500 kbps of video in two-party or multiparty conferences.

The following procedures are examples of using Lync Server Management Shell to modify the settings described in this section.

⊟To modify conferencing policy for video settings

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. At the command line, run the following cmdlet to edit conferencing policy:

```
Set-CsConferencingPolicy -Identity Pool01ConferencingPolicy -VideoBitR
```

To modify media configuration for legacy clients

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. At the command line, run the following cmdlet to edit the media configuration:

```
Set-CsMediaConfiguration -Identity site:Redmond01 -MaxVideoRateAllowed
```

1.4.7.2 Configuring Gallery View

Configuring Gallery View

Microsoft Lync Server 2013 > Deployment > Configuring Video >

Topic Last Modified: *2012-10-30*

In Lync Server 2013, you configure Gallery View video conferencing in conferencing policy. Gallery View is turned on by default. If you do not want to allow Gallery View, or want to allow it for only some users, you need to turn off the feature in conferencing policy.

When a conference participant's video is not available, the users' Gallery View experience can be enhanced if you deploy high-resolution photos, a new feature in Lync Server 2013. High-resolution photos provide an alternative to the smaller, limited resolution contact photos stored in Active Directory Domain Services (AD DS). High-resolution photos are stored in a user's Exchange 2013 mailbox, and, therefore, require you to integrate Lync Server 2013 with Exchange 2013. For details, see the NextHop blog article, "Integrating Exchange 2013 and Lync Server 2013," at http://go.microsoft.com/fwlink/p/?LinkId=260987.

Note:

The content of each blog and its URL are subject to change without notice.

You can view or modify the Gallery View parameters by using Lync Server 2013 Control Panel or by using one of the following cmdlets:

- **Get-CsConferencingPolicy**
- **Set-CsConferencingPolicy**
- **New-CsConferencingPolicy**

Configure Gallery View with the following conferencing policy settings:

- **AllowMultiview** This parameter controls whether a user is allowed to organize Gallery View video conferences. This parameter applies to scheduled and ad-hoc meetings created by the user.
  Examples:
  - This parameter is set to True for User A, who is homed on a Lync Server 2013 pool. Meetings organized by User A enable users to join and receive multiple video streams.
  - This parameter is set to False for User B, who is homed on a Lync Server 2013 pool. Meetings organized by User B have a single video stream that is similar to the video conference experience provided by Lync Server 2010.

  This parameter determines who can organize meetings that allow multiple video streams. Participants in meetings that allow multiple video streams may or may not be allowed to receive multiple video streams, based on their individual permissions (see the description for the EnableMultiviewJoin parameter).

- **EnableMultiviewJoin** This parameter controls whether a participant in a meeting receives the Gallery View video experience in meetings that allow it. This parameter controls the user's experience in any meeting in which he or she participates.
  Examples:
  - This parameter is set to True for User C. User C can receive multiple video streams when participating in a meeting organized or started by User A. User C receives a single video stream that is similar to the video conference experience provided by Lync Server 2010 when participating in a meeting organized or started by User B.
  - This parameter is set to False for User D. User D receives single video stream that is similar to the video conference experience provided by Lync Server 2010 when participating in any meeting organized by User A or User B.

The following procedure is an example of using Lync Server Management Shell to enable Gallery View video conferencing.

⊟To modify conferencing policy for Gallery View video conferencing

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. At the command line, run the following cmdlet to edit conferencing policy:

```
Set-CsConferencingPolicy -Identity Pool01ConferencingPolicy -AllowMult
```

1.4.7.3 Configuring Video Example Scenarios

Configuring Video Example Scenarios

Microsoft Lync Server 2013 > Deployment > Configuring Video >

Topic Last Modified: *2012-10-02*

Lync 2013 adds new video features to support 1920 x 1080 full high definition (HD) video and Gallery View video. Measurements based on customer data show that the typical video bandwidth increased only slightly compared to Lync 2010, but the maximum video stream bandwidth has increased due to full HD support (for details, see the "Media Traffic Network Usage" section in Network Bandwidth Requirements for Media Traffic). Therefore, administrators may want to restrict video bandwidth for certain users (such as users in a branch office that has less network capacity) and help to ensure the best possible video quality for other users (such as executives).

The following table provides a list of recommended settings for configuring video for different network capacities. These settings will restrict some user scenarios from sending and receiving higher resolution videos (see rightmost column). The minimum setting will result in Gallery Video being unavailable, due to the low maximum receive network bandwidth.

Recommended Video Settings

-	AllowMultiView	EnableMultiViewJoin	VideoBitRate KB	TotalReceiveVideoBitRate KB	Expected video resolution for good quality video
Best	True	True	8000	8000	Peer-to-peer: Up to 1920 x

					1080 video resolution Gallery View: Up to two 1920 x 1080 videos or multiple smaller resolution videos
Good	True	True	2500	2500	Peer-to-peer: Up to 1280 x 720 video resolution Gallery View: Up to five 640 x 360 resolution videos
Medium	True	True	1000	1000	Peer-to-peer: Up to 960 x 540 video resolution Gallery View: Up to five 424 x 240 resolution videos
Minimum	True	False	350	350	Peer-to-peer: Up to 424 x 240 video resolution Gallery View: Unavailable

You can use the information in the preceding table to deploy the new HD video and Gallery View video conferencing features for some users in your organization, while allowing different video resolutions for others.

In the following example, the administrator rolls out the new video features with the highest video quality available only to executives. For employees in a remote branch office that has low network capacity, only the minimum setting from the preceding table is deployed. For all other employees, the "Good" setting from the preceding table is deployed.

To roll out the new features to the executives, the administrator creates a conferencing policy named ExecutiveVideo. This conferencing policy has the following settings:

- VideoBitRateKB is set to 8000 Kbps
- TotalReceiveVideoBitRateKB is set to 8000 Kbps
- AllowMultiview is set to True
- EnableMultiviewJoin is set to True

For employees in the branch office, the administrator creates a conferencing policy named

BranchOfficeVideo. This conferencing policy has the following settings:

- VideoBitRateKB is set to 350 Kbps
- TotalReceiveVideoBitRateKB is set to 350 Kbps
- AllowMultiview is set to True
- EnableMultiviewJoin is set to False

For all other employees, the administrator creates a conferencing policy named StandardVideo. This conferencing policy has the following settings:

- VideoBitRateKB is set to 2500 Kbps
- TotalReceiveVideoBitRateKB is set to 2500 Kbps
- AllowMultiview is set to True
- EnableMultiviewJoin is set to True

The administrator assigns conferencing policy to users as follows:

- The ExecutiveVideo conferencing policy is assigned to the executives.
- The BranchOfficeVideo conferencing policy is assigned to all employees in the branch office.
- The StandardVideo conferencing policy is assigned to all other employees.

These conferencing policy assignments result in the following user experience:

- All conferences organized by any user support Gallery View, but employees in the branch office cannot experience Gallery View.
- For any two-party or multiparty conferences, executives can send 1920 x 1080 full HD video, if their hardware and network link supports it, and can receive 1920 x 1080 full HD video where the other participant clients support it.
- Employees who are not executives experience lower resolutions than the executives in their two-party or multiparty conferences, but still get good resolution.
- Employees who are in the branch office will get good video quality in two-party calls when Lync displays the default video window size; however, if the Lync window is maximized to full screen, the video resolution will not increase. For multiparty conferences, the employees in the branch office will see only one active video.

1.4.7.4 Interoperability Considerations for Video Conferencing

Interoperability Considerations for Video Conferencing

Microsoft Lync Server 2013 > Deployment > Configuring Video >

Topic Last Modified: *2012-10-02*

This section describes the user experience during the coexistence phase of migration, when there is interoperability between legacy clients and a Lync Server 2013 pool or Lync Server 2013 clients and a legacy pool.

Lync Server 2013 Pools

Users will experience the following behavior when a legacy client is used in a Lync Server 2013 pool:

- For two-party calls, video resolution is the same as in the legacy pool.
- For multiparty conferences, video resolution and video conferencing features are the same as in the legacy pool. Gallery View and high resolution are not available.

Legacy Pools

Users will experience the following behavior when a Lync Server 2013 client is used in a legacy pool:

- For two-party calls, Lync Server 2013 clients can use new features as follows:
  - H.264 is available if both participants are using Lync Server 2013 clients.
  - The Lync Server 2013 client uses the default value for TotalReceiveVideoBitRateKb, since the legacy server doesn't send this information with in-band provisioning.
- For multiparty conferences, video resolution and video conferencing features are the same as experienced by a legacy client in the legacy pool.

Note:

When a legacy server hosts a Lync Server 2013 client, it's possible to configure video conferencing bandwidth so that all users on the pool receive only low-resolution video, but send high-resolution video. An example of this is when MaxVideoRateAllowed is set to CIF-250K in the media configuration and VideoBitRateKb is set to 2000 kbps in conferencing policy. The net effect in this situation is that high resolution is not possible for users on the pool.

Because MaxVideoRateAllowed is no longer used for Lync Server 2013 clients, it cannot prevent Lync Server 2013 clients from requesting high-resolution video. Instead, set VideoBitRateKb in conferencing policy for all users on the pool to the same value as MaxVideoRateAllowed (that is, CIF is set to 250 kbps, or VGA is set to 600 kbps, or HD is set to 1500 kbps).

1.4.8 Deploying Branch Sites

Deploying Branch Sites

Microsoft Lync Server 2013 > Deployment >

Topic Last Modified: *2012-09-21*

Branch site users get most of their Lync Server 2013 functionality from the server at the central site that the branch site is associated with. Each branch site is associated with exactly one central site. To provide calls to and from the public switched telephone network (PSTN), a branch site might contain any of the following:

- A PSTN gateway and possibly a Meditation Server
- A SIP trunk
- An existing voice infrastructure with a private branch exchange (PBX)
- A Survivable Branch Appliance
- A Survivable Branch Server

Branch sites with a Survivable Branch Appliance or a Survivable Branch Server are more resilient in times of wide-area network or central site failures than branch sites without one of these solutions. For example, in a site with a Survivable Branch Appliance or a Survivable Branch Server deployed, users can still make and receive PSTN calls if the network connecting the branch site to the central site is down. Another way to achieve branch-site resiliency is by using a PSTN gateway or a SIP trunk with a full-scale Lync Server deployment at the branch site.

For details about which branch site deployment is right for your organization, including prerequisites and other planning considerations, see Planning for PSTN Connectivity and Planning for Branch-Site Voice Resiliency in the Planning documentation.

- Providing PSTN Connectivity at a Branch Site
- Deploying a Survivable Branch Appliance or Server

1.4.8.1 Providing PSTN Connectivity at a Branch Site

Providing PSTN Connectivity at a Branch Site

See Also

Microsoft Lync Server 2013 > Deployment > Deploying Branch Sites >

Topic Last Modified: *2012-10-05*

We recommend using the Microsoft Lync Server 2013, Planning Tool to add branch sites to your topology and to set up your voice infrastructure in branch sites.

If you are not using the Planning Tool, use the procedures in the topics in this section—first, to add the branch sites, and then, to set up your voice infrastructure by defining the IP/public switched telephone network (PSTN) gateway and/or by configuring the SIP trunk (with or without media bypass). Connecting a private branch exchange (PBX) to the branch site is another option.

Note:
If you want to provide branch-site resiliency, you must deploy a Survivable Branch Appliance, a Survivable Branch Server, or Standard Edition server at the branch site. For details, see Deploying a Survivable Branch Appliance or Server or Deploying Lync Server 2013, as appropriate, in the Deployment documentation.

- Add Branch Sites to Your Topology
- Define a PSTN Gateway for a Branch Site
- Configure a Trunk with Media Bypass
- Configure a Trunk without Media Bypass

1.4.8.1.1 Add Branch Sites to Your Topology

Add Branch Sites to Your Topology

Deployment > Deploying Branch Sites > Providing PSTN Connectivity at a Branch Site >

Topic Last Modified: *2012-10-05*

Branch sites represent physical branch offices that are connected to your main offices over a WAN link. To add a branch site to your Lync topology, perform this procedure at the central site.

⊟To add branch sites to your topology

1. Click **Start**, click **All Programs**, click **Microsoft Lync Server**, and then click **Lync Server Topology Builder**.
2. In the console tree, expand the central site, right-click **Branch Sites**, and then click **New Branch Site**.
3. In the **Define New Branch Site** dialog box, click **Name**, and then type the name of the branch site.
4. (Optional) Click **Description**, and then type a meaningful description for the branch site.
5. Click **Next**.
6. (Optional) In the next **Define New Branch Site** dialog box, do any of the following:

- Click **City**, and then type the name of the city in which the branch site is located.
- Click **State/Region**, and then type the name of the state or region in which the branch site is located.
- Click **Country Code**, and then type the two-digit calling code for the country/region in which the branch site is located.

7. Click **Next**, and then do one of the following:
   - If you are using a Survivable Branch Appliance or Server at this site, be sure that the **Open the New Survivable Wizard when this wizard closes** check box is selected, click **Finish**, and then follow the directions in the wizard that opens. For information about wizard items, see Define a Survivable Branch Appliance or Server.
   - If you are not using a Survivable Branch Appliance or Server at this site, clear the **Open the New Survivable Wizard when this wizard closes** check box, and then click **Finish**.
8. Repeat the previous steps for each branch site that you want to add to the topology.

Next step:

For Survivable Branch Appliances or Servers: Define a Survivable Branch Appliance or Server

For non-resilient PSTN connectivity: Define a PSTN Gateway for a Branch Site, Configure a Trunk with Media Bypass, or Configure a Trunk without Media Bypass

1.4.8.1.2 Define a PSTN Gateway for a Branch Site

Define a PSTN Gateway for a Branch Site

See Also

Deployment > Deploying Branch Sites > Providing PSTN Connectivity at a Branch Site >

Topic Last Modified: *2012-09-21*

Perform this procedure at the central site, which contains at least one Front End pool or Standard Edition server.

◆**Important:**
Before you perform the procedure, the following conditions must be in place: • Lync Server 2013 communications software must be set up at the central site. • Mediation Server must be deployed at the central site.

⊟To define a PSTN gateway

1. Click **Start**, click **All Programs**, click **Microsoft Lync Server**, and then click **Lync Server Topology Builder**.
2. In the console tree, expand the central site, expand **Branch Office Sites**, expand name of the branch site that you want to define a public switched telephone network (PSTN) gateway for, and then expand **Shared Components**.
3. Right-click **PSTN gateways**, and then click **New IP/PSTN Gateway**.
4. In the **Define New IP/PSTN Gateway** dialog box, click **Gateway FQDN or IP Address**, and then type the fully qualified domain name (FQDN) or IP address of the gateway that you are deploying at the branch site.
5. Click **Listening Port for IP/PSTN Gateway**, and then accept the default values.
6. In the **SIP Transport Protocol** list, click the transport protocol the gateway

uses, and then click **OK**.

> **Note:**
> For security reasons, we strongly recommend that you use a PSTN gateway that supports Transport Layer Security (TLS).

> **Tip:**
> Use the cmdlet **Set-CsPstnGateway** to modify properties of a PSTN gateway. For details, see Set-CsPstnGateway, in the Lync Server Management Shell Help.

Next step for branch-site resiliency: Configuring Users for Branch Site Resiliency

Concepts

PSTN Gateway Deployment Options

1.4.8.1.3 Configure a Trunk with Media Bypass

Configure a Trunk with Media Bypass

See Also

Deployment > Deploying Enterprise Voice > Configuring Trunks >

Topic Last Modified: *2013-02-24*

Follow these steps to configure a trunk with media bypass enabled. To configure a trunk with media bypass disabled, see Configure a Trunk without Media Bypass.

We strongly recommend that you enable media bypass. However, before you enable media bypass on a SIP trunk, confirm that your qualified SIP trunk provider supports media bypass and is able to accommodate the requirements for successfully enabling the scenario. Specifically, the provider must have the IP addresses of servers in your organization’s internal network. If the provider cannot support this scenario, media bypass will not succeed. For details, see Planning for Media Bypass in the Planning documentation.

> **Note:**
> Media bypass will not interoperate with every public switched telephone network (PSTN) gateway, IP-PBX, and Session Border Controller (SBC). Microsoft has tested a set of PSTN gateways and SBCs with certified partners and has done some testing with Cisco IP-PBXs. Media bypass is supported only with products and versions that are listed on Unified Communications Open Interoperability Program – Lync Server at http://go.microsoft.com/fwlink/p/?linkId=214406.

A trunk configuration as described below groups a set of parameters that are applied to trunks assigned this trunk configuration. A particular trunk configuration can be scoped globally (to all trunks that do not have more specific site or pool configuration), or to a site, or to a pool. The pool-level trunk configuration is used to scope a specific trunk configuration to a single trunk.

⊟To configure a trunk with media bypass

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing**, and then click **Trunk**

Configuration.

4. On the **Trunk Configuration** page, use one of the following methods to configure a trunk:
   - Double-click an existing trunk (for example, the **Global** trunk) to display the **Edit Trunk Configuration** dialog box.
   - Click **New**, and then select a scope for the new trunk configuration:
     - **Site trunk:** Choose the site for this trunk configuration from **Select a Site**, and then click **OK**. Note that if a trunk configuration has already been created for a site, the site does not appear in **Select a Site**. This trunk configuration will be applied to all trunks in the site.
     - **Pool trunk:** Choose the name of the trunk that this trunk configuration applies to. This trunk can be the root trunk or any additional trunks defined in Topology Builder. From **Select a Service**, click **OK**. Note that if a trunk configuration has already been created for a specific trunk, the trunk does not appear in **Select a Service**.

   Note:

   After you select the scope of the trunk configuration, it cannot be changed. The **Name** field is prepopulated with the name of the trunk configuration's associated site or service and cannot be changed.

5. Specify a value in **Maximum early dialogs supported**. This is the maximum number of forked responses a public switched telephone network (PSTN) gateway, IP-PBX, or ITSP Session Border Controller (SBC) can receive to an INVITE that it sent to the Mediation Server. The default value is 20.

   Note:

   Before you change this value, consult your service provider or equipment manufacturer for details about the capabilities of your system.

6. Select one of the following **Encryption support level** options:
   - **Required:** Secure real-time transport protocol (SRTP) encryption must be used to help protect traffic between the Mediation Server and the gateway or private branch exchange (PBX).
   - **Optional:** SRTP encryption will be used if the service provider or equipment manufacturer supports it.
   - **Not Supported:** SRTP encryption is not supported by the service provider or equipment manufacturer and therefore will not be used.
7. Select the **Enable media bypass** check box if you want media to bypass the Mediation Server for processing by the trunk peer.

   Important:

   For media bypass to work successfully, the PSTN gateway, IP-PBX, or ITSP Session Border Controller must support certain capabilities. For details, see Planning for Media Bypass in the Planning documentation.

8. Select the **Centralized media processing** check box if there is a well-known media termination point (for example, a PSTN gateway where the media termination has the same IP as the signaling termination). Clear this check box if the trunk does not have a well-known media termination point.
9. If the trunk peer supports receiving SIP REFER requests from the Mediation Server, select the **Enable sending refer to the gateway** check box.

   Note:

   If you disable this option while the **Enable media bypass** option is selected, additional settings are required. If the trunk peer does not support receiving SIP REFER requests from the Mediation Server and media bypass is enabled, you must also run the **Set-CsTrunkConfiguration** cmdlet to disable RTCP for active and held calls in order to support proper conditions for media bypass. For details, see the Lync Server Management Shell documentation. Alternatively, you can select **Enable refer using third-party-call control** if you want transferred calls to be media bypassed, and the gateway does not support SIP REFER requests.

10.(Optional) To enable inter-trunk routing, associate and configure PSTN usage records to this trunk configuration. The PSTN usages associated to this trunk configuration will be applied for all incoming calls through the trunk that is not originating from a Lync endpoint. To manage PSTN usage records associated to a trunk configuration, use one of the following methods:

- To select one or more records from a list of all PSTN usage records available in your Enterprise Voice deployment, click **Select**. Highlight the records you want to associate with this trunk configuration and then click **OK**.
- To remove a PSTN usage record from this trunk configuration, select the record and click **Remove**.
- To define a new PSTN usage record and associate it with this trunk configuration, do the following:
  - Click **New**.
  - In the **Name** field, specify a descriptive name for the record that is unique.

    Note:
    The PSTN usage record name must be unique within the Enterprise Voice deployment. After the record is saved, the **Name** field cannot be edited.

  - Use one of the following methods to associate and configure routes for this PSTN usage record:
    - To select one or more routes from the list of all available routes in your Enterprise Voice deployment, click **Select**. Highlight the routes you want to associate with this PSTN usage record, and click **OK**.
    - To remove a route from the PSTN usage record, select the route, and click **Remove**.
    - To define a new route and associate it to this PSTN usage record, click **New**. For details, see Create a Voice Route.
    - To edit a route that is associated with this PSTN usage record, select the route, and click **Show details**. For details, see Modify a Voice Route.
  - Click **OK**.
- To edit a PSTN usage record that is already associated with this trunk configuration, do the following:
  - Select the PSTN usage record you want to edit, and click **Show details**.
  - Use one of the following methods to associate and configure routes for this PSTN usage record:
    - To select one or more routes from the list of all available routes in your Enterprise Voice deployment, click **Select**. Highlight the routes you want to associate with this PSTN usage record, and click **OK**.
    - To remove a route from the PSTN usage record, select the route, and click **Remove**.
    - To define a new route and associate it to this PSTN usage record, click **New**. For details, see Create a Voice Route.
    - To edit a route that is associated with this PSTN usage record, select the route, and click **Show details**. For details, see Modify a Voice Route.
  - Click **OK**.

Important:
It important to associate PSTN usage records according to the Mediation Server peer that is associated to the trunk being configured. If the Mediation Server peer is a PSTN gateway or a Session Border Controller (SBC), it is strongly recommended that the trunk configuration is not associated to a PSTN usage record that routes to a PSTN destination or any other downstream systems connected via Lync Server.

11.Arrange the PSTN usage records for optimum performance. To change a record’s position in the list, select the PSTN usage record, and click the up or down arrows.

Important:

The order in which PSTN usage records are listed in the trunk configuration is significant. Lync Server traverses the list from top to down.

12. **Enable RTP Latching** should be selected to enable bypass media for clients behind a network address translation (NAT) or firewall and an SBC that supports latching.
13. **Enable forward call history** should be selected to enable sending of call history information to the gateway peer of the Mediation Server.
14. **Enable forward P-Asserted-Identity data** should be selected to enable the P-Asserted-Identity (PAI) call originator information to be forwarded between the Mediation Server side and gateway side (and vice versa), when present.
15. **Enable outbound routing failover timer** should be selected to enable fast failover. The gateway associated with this trunk can give notification within 10 seconds that it is processing an outbound call. Rerouting to another trunk will occur if this notification is not received by the Mediation Server. On networks where latency may delay the response time or the gateway takes longer than 10 seconds to respond, the fast failover should be disabled.
16. (Optional) Associate and configure **calling number translation rules** for the trunk. These translation rules apply to the calling number for outbound calls
    - To choose one or more rules from a list of all translation rules that are available in your Enterprise Voice deployment, click **Select**. In **Select Translation Rules**, click the rules that you want to associate with the trunk, and then click **OK**.
    - To define a new translation rule and associate it with the trunk, click **New**. For details about defining a new rule, see Defining Translation Rules in the Deployment documentation.
    - To edit a translation rule that is already associated with the trunk, click the rule name, and then click **Show details**. For details, see Defining Translation Rules in the Deployment documentation.
    - To copy an existing translation rule to use as a starting point for defining a new rule, click the rule name and click **Copy**, and then click **Paste**. For details, see Defining Translation Rules.
    - To remove a translation rule from the trunk, highlight the rule name and click **Remove**.

Warning:

Do not associate translation rules with a trunk if you have configured translation rules on the associated trunk peer, because the two rules might conflict.

17. (Optional) Associate and configure **called number translation rules** for the trunk. The translation rules apply to the called number in an outbound call.
    - To choose one or more rules from a list of all translation rules that are available in your Enterprise Voice deployment, click **Select**. In **Select Translation Rules**, click the rules that you want to associate with the trunk, and then click **OK**.
    - To define a new translation rule and associate it with the trunk, click **New**. For details about defining a new rule, see Defining Translation Rules in the Deployment documentation.
    - To edit a translation rule that is already associated with the trunk, click the rule name, and then click **Show details**. For details, see Defining Translation Rules in the Deployment documentation.
    - To copy an existing translation rule to use as a starting point for defining a new rule, click the rule name and click **Copy**, and then click **Paste**. For details, see Defining Translation Rules.
    - To remove a translation rule from the trunk, highlight the rule name and click **Remove**.

Warning:

Do not associate translation rules with a trunk if you have configured translation rules on the associated trunk peer, because the two rules might conflict.

18. Make sure that the trunk's translation rules are arranged in the correct order. To change a rule's position in the list, highlight the rule name and then click the up or down arrow.

Important:

Lync Server 2013 traverses the translation rule list from the top down and uses the first rule that matches the dialed number. If you configure a trunk so that a dialed number can match more than one translation rule, be sure that the more restrictive rules are sorted above the less restrictive rules. For example, if you have included a translation rule that matches any 11-digit number and a translation rule that matches only 11-digit numbers that start with +1425, be sure that the rule that matches any 11-digit number is sorted *below* the more restrictive rule.

19. When you are finished configuring the trunk, click **OK**.
20. On the **Trunk Configuration** page, click **Commit**, and then click **Commit all**.

Note:

Whenever you create or modify a trunk configuration, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

After you have configured the trunk, continue configuring media bypass by choosing between global media bypass options, as described in Global Media Bypass Options in the Deployment documentation.

***Topic Last Modified:** 2013-02-24*

If you want to configure a trunk with media bypass disabled, follow these steps. If you want to configure a trunk with media bypass enabled, see Configure a Trunk with Media Bypass.

A trunk configuration, as described below, groups a set of parameters that are applied to trunks assigned this trunk configuration. A particular trunk configuration can be scoped globally (to all trunks that do not have more specific site or pool configuration), or to a site, or to a pool. The pool-level trunk configuration is used to scope a specific trunk configuration to a single trunk.

⊟To configure a trunk without media bypass

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Voice Routing**, and then click **Trunk Configuration**.
4. On the **Trunk Configuration** page, use one of the following methods to configure a trunk:
   - Double-click an existing trunk (for example, the **Global** trunk) to display the **Edit Trunk Configuration** dialog box.
   - Click **New**, and then select a scope for the new trunk configuration:
     - **Site trunk:** Choose the site for this trunk configuration in **Select a Site** , and then click **OK**. Note that if a trunk configuration has already been created for a site, the site does not appear in **Select a Site**. This trunk configuration will be applied to all trunks in the site.
     - **Pool trunk:** Choose the name of the trunk that this trunk configuration applies to in **Select a Service** and click **OK**. This trunk can be the root trunk, or any additional trunks defined in Topology Builder. Note that if a trunk configuration has already been created for a specific trunk, the trunk does not appear in **Select a Service**.

   Note:

   After you select the scope of the trunk configuration, it cannot be changed. The **Name** field is prepopulated with the name of the trunk configuration's associated site or service and cannot be changed.
5. Select one of the following **Encryption support level** options:
   - **Required:** Secure real-time transport protocol (SRTP) encryption must be used to help protect traffic between the Mediation Server and the gateway or private branch exchange (PBX).
   - **Optional:** SRTP encryption will be used if the service provider or equipment manufacturer supports it.
   - **Not Supported:** SRTP encryption is not supported by the service provider or equipment manufacturer and therefore will not be used.
6. Be sure that the **Enable media bypass** check box is cleared.
7. Select the **Centralized media processing** check box if there is a well-known media termination point (for example, a public switched telephone network (PSTN) gateway where the media termination has the same IP as the signaling termination). Clear this check box if the trunk does not have a well-known media termination point.
8. If the trunk peer supports receiving SIP REFER requests from the Mediation Server, select the **Enable sending refer to the gateway** check box.
9. (Optional) To enable inter-trunk routing, associate and configure PSTN usage records to this trunk configuration. The PSTN usages associated to this trunk configuration will be applied for all incoming calls through the trunk that is not originating from a Lync endpoint. To manage PSTN usage records associated to a trunk configuration, use one of the following methods:
   - To select one or more records from a list of all PSTN usage records available in your Enterprise Voice deployment, click **Select**. Highlight the records you want to associate with this trunk configuration and then click **OK**.
   - To remove a PSTN usage record from this trunk configuration, select the record and click **Remove**.
   - To define a new PSTN usage record and associate it with this trunk configuration, do the following:
     - Click **New**.
     - In the **Name** field, specify a descriptive name for the record that is

unique.

> **Note:**
> The PSTN usage record name must be unique within the Enterprise Voice deployment. After the record is saved, the **Name** field cannot be edited.

- Use one of the following methods to associate and configure routes for this PSTN usage record:
  - To select one or more routes from the list of all available routes in your Enterprise Voice deployment, click **Select**. Highlight the routes you want to associate with this PSTN usage record, and click **OK**.
  - To remove a route from the PSTN usage record, select the route, and click **Remove**.
  - To define a new route and associate it to this PSTN usage record, click **New**. For details, see Create a Voice Route.
  - To edit a route that is associated with this PSTN usage record, select the route, and click **Show details**. For details, see Modify a Voice Route.
- Click **OK**.

- To edit a PSTN usage record that is already associated with this trunk configuration, do the following:
  - Select the PSTN usage record you want to edit, and click **Show details**.
  - Use one of the following methods to associate and configure routes for this PSTN usage record:
    - To select one or more routes from the list of all available routes in your Enterprise Voice deployment, click **Select**. Highlight the routes you want to associate with this PSTN usage record, and click **OK**.
    - To remove a route from the PSTN usage record, select the route, and click **Remove**.
    - To define a new route and associate it to this PSTN usage record, click **New**. For details, see Create a Voice Route.
    - To edit a route that is associated with this PSTN usage record, select the route, and click **Show details**. For details, see Modify a Voice Route.
  - Click **OK**.

> **Important:**
> It important to associate PSTN usage records according to the Mediation Server peer that is associated to the trunk being configured. If the Mediation Server peer is a PSTN gateway or a Session Border Controller (SBC), it is strongly recommended that the trunk configuration is not associated to a PSTN usage record that routes to a PSTN destination or any other downstream systems connected via Lync Server.

10. Arrange the PSTN usage records for optimum performance. To change a record’s position in the list, select the PSTN usage record, and click the up or down arrows.

> **Important:**
> The order in which PSTN usage records are listed in the trunk configuration is significant. Lync Server traverses the list from top to down.

11. **Enable RTP Latching** should be selected to enable bypass media for clients behind a NAT or firewall and an SBC that supports latching.
12. **Enable forward call history** should be selected to enable sending of call history information to the gateway peer of the Mediation Server.
13. **Enable forward P-Asserted-Identity data** should be selected to enable PAI call originator information to be forwarded between the Mediation Server side and gateway side (and vice versa), when present.
14. **Enable outbound routing failover timer** should be selected to enable fast failover. The gateway associated with this trunk can give notification within 10 seconds that it is processing an outbound call. Rerouting to another trunk will occur if this notification is not received by the Mediation Server. On

networks where latency may delay the response time or the gateway takes longer than 10 seconds to respond, the fast failover should be disabled.

15.(Optional) Associate and configure **calling number translation rules** for the trunk. These translation rules apply to the calling number for outbound calls

- To choose one or more rules from a list of all translation rules that are available in your Enterprise Voice deployment, click **Select**. In **Select Translation Rules**, click the rules that you want to associate with the trunk, and then click **OK**.
- To define a new translation rule and associate it with the trunk, click **New**. For details about defining a new rule, see Defining Translation Rules in the Deployment documentation.
- To edit a translation rule that is already associated with the trunk, click the rule name, and then click **Show details**. For details, see Defining Translation Rules in the Deployment documentation.
- To copy an existing translation rule to use as a starting point for defining a new rule, click the rule name and click **Copy**, and then click **Paste**. For details, see Defining Translation Rules.
- To remove a translation rule from the trunk, highlight the rule name and click **Remove**.

Security Note:

Do not associate translation rules with a trunk if you have configured translation rules on the associated trunk peer, because the two rules might conflict.

16.(Optional) Associate and configure **called number translation rules** for the trunk. The translation rules apply to the called number in an outbound call.

- To choose one or more rules from a list of all translation rules that are available in your Enterprise Voice deployment, click **Select**. In **Select Translation Rules**, click the rules that you want to associate with the trunk, and then click **OK**.
- To define a new translation rule and associate it with the trunk, click **New**. For details about defining a new rule, see Defining Translation Rules in the Deployment documentation.
- To edit a translation rule that is already associated with the trunk, click the rule name, and then click **Show details**. For details, see Defining Translation Rules in the Deployment documentation.
- To copy an existing translation rule to use as a starting point for defining a new rule, click the rule name and click **Copy**, and then click **Paste**. For details, see Defining Translation Rules.
- To remove a translation rule from the trunk, highlight the rule name and click **Remove**.

Caution:

Do not associate translation rules with a trunk if you have configured translation rules on the associated trunk peer, because the two rules might conflict.

17.Make sure that the trunk's translation rules are arranged in the correct order. To change a rule's position in the list, highlight the rule name, and then click the up or down arrow.

Important:

Lync Server traverses the translation rule list from the top down and uses the first rule that matches the dialed number. If you configure a trunk so that a dialed number can match more than one translation rule, be sure that the more restrictive rules are sorted above the less restrictive rules. For example, if you have included a translation rule that matches any 11-digit number and a translation rule that matches only 11-digit numbers that start with +1425, be sure that the rule that matches any 11-digit number is sorted *below* the more restrictive rule.

18. When you are finished configuring the trunk, click **OK**.
19. On the **Trunk Configuration** page, click **Commit**, and then click **Commit all**.

> **Note:**
> Whenever you create or modify a trunk configuration, you must run the **Commit all** command to publish the configuration change. For details, see Publish Pending Changes to the Voice Routing Configuration in the Operations documentation.

Tasks

Configure a Trunk with Media Bypass

Defining Translation Rules

1.4.8.2 Deploying a Survivable Branch Appliance or Server

Deploying a Survivable Branch Appliance or Server

See Also

Microsoft Lync Server 2013 > Deployment > Deploying Branch Sites >

Topic Last Modified: *2012-10-10*

Resilient Enterprise Voice refers to branch-site resiliency, that is, the ability to provide continuous Enterprise Voice service to branch site users in the event that the link to the central site becomes unavailable.

For small and medium-sized branch sites (branch sites with 25 to 1,000 users), we recommend deploying a Survivable Branch Appliance, which will terminate public switched telephone network (PSTN) calls by using its built-in PSTN gateway or a SIP trunk to a telephone service provider. A Survivable Branch Appliance is a third-party device that includes a blade server running the Windows Server 2008 R2 operating system, Lync Server 2013 Registrar, Mediation Server software, and a PSTN gateway, all in a single appliance chassis.

For branch sites with 1,000 to 5,000 users and no resilient WAN, we recommend a Survivable Branch Server connected to either a PSTN gateway or a SIP trunk to a telephone service provider. A Survivable Branch Server is a Windows Server-based computer that has Registrar and Mediation Server software installed on it.

> **Note:**
> For branch sites with more than 5,000 users and dedicated Lync Server administrators, we recommend a full Lync Server 2013 deployment, separate from that of the central site. For details about choosing the best resiliency solution for the branch sites in your organization, including prerequisites and planning considerations, see Branch-Site Resiliency Requirements in the Planning documentation.

1.4.8.2.1 Deploying a Survivable Branch Appliance or Server - Central Site Tasks

Deploying a Survivable Branch Appliance or Server - Central Site Tasks

Deployment > Deploying Branch Sites > Deploying a Survivable Branch Appliance or Server >

Topic Last Modified: *2012-10-18*

Complete the tasks in this section at the central site. If you're deploying a Survivable Branch Server, skip the first task.

Important:

Before you perform the tasks in this section, the following conditions must be in place:

- Lync Server must be set up at the central site.
- An installation technician at the branch site must be added to the RTCUniversalSBATechnicians group.

In addition, we recommend that you do the following:

- Deploy a DHCP server at each branch site to enable clients to obtain IP addresses.
- As an alternative to deploying a DHCP server at each branch site, enable Lync Server DHCP on the Survivable Branch Appliance or Survivable Branch Server by using the Lync Server Management Shell cmdlet **Set-CsRegistrarConfiguration –EnableDHCPServer $true**. For details, see the "Hardware and Software Requirements" section of Branch-Site Resiliency Requirements in the Planning documentation.

- Add a Survivable Branch Appliance to Active Directory
- Add Branch Sites to Your Topology
- Define a Survivable Branch Appliance or Server

1.4.8.2.1.1 Add a Survivable Branch Appliance to Active Directory

Add a Survivable Branch Appliance to Active Directory

Deploying Branch Sites > Deploying a Survivable Branch Appliance or Server > Deploying a Survivable Branch Appliance or Server - Central Site Tasks >

Topic Last Modified: *2012-09-23*

If you plan to deploy a Survivable Branch Appliance, you must add the Survivable Branch Appliance to Active Directory Domain Services. Perform this procedure at the central site.

Important:

Perform this procedure only if you are deploying a Survivable Branch Appliance. Do not perform it if you are deploying a Survivable Branch Server.

To add an Survivable Branch Appliance to Active Directory Domain Services

1. Log on to a member server as a member of the Enterprise Admins group.
2. Click **Start**, click **Administrative Tools**, and then click **Active Directory Users and Computers**.
3. On the **Actions** menu, click **New** and then click **Computer**.
4. In the **New Object-Computer** dialog box, type in a name for the Survivable Branch Appliance computer object (for example, BranchOffice1), and then click **Change**.
5. In the **Select User or Group** dialog box, add the RTCUniversalSBATechnicians group and then click **OK**.

Note:
A member of the RTCUniversalSBATechnicians group at the branch site will add this device to the domain later.

6. Click **OK** to save the Survivable Branch Appliance computer object.
7. Click **Start**, click **Administrative Tools**, and then click **ADSI Edit**.
8. In **ADSI Edit**, right-click the computer object that you created in the previous steps, and then click **Properties**.
9. In the attribute list, click **servicePrincipalName**, and then click **Edit**.
10. In the **Value to add** field, type HOST/<SBA FQDN> where <SBA FQDN> is the fully qualified domain name (FQDN) of your Survivable Branch Appliance. For example, type **HOST/BranchOffice1.contoso.com**.
11. Click **OK** to save the **servicePrincipalName** attribute setting, and then click **OK** to save the computer object properties.
12. In **Active Directory Users and Computers**, right-click **Users**, click **New**, and then click **User**.
13. Enter information into the wizard to create a domain user account for a Survivable Branch Appliance technician.
14. In **Active Directory Users and Computers**, click **Users**, right-click the user object, and then click **Add to a group**.
15. In **Enter the object names to select**, type **RTCUniversalSBATechnicians**, and then click **OK**.
16. Repeat Steps 12-15 for each branch site technician.

Next step: Add Branch Sites to Your Topology

1.4.8.2.1.2 Add Branch Sites to Your Topology

Add Branch Sites to Your Topology

Deployment > Deploying Branch Sites > Providing PSTN Connectivity at a Branch Site >

Topic Last Modified: *2012-10-05*

Branch sites represent physical branch offices that are connected to your main offices over a WAN link. To add a branch site to your Lync topology, perform this procedure at the central site.

⊟To add branch sites to your topology

1. Click **Start**, click **All Programs**, click **Microsoft Lync Server**, and then click **Lync Server Topology Builder**.
2. In the console tree, expand the central site, right-click **Branch Sites**, and then click **New Branch Site**.
3. In the **Define New Branch Site** dialog box, click **Name**, and then type the name of the branch site.
4. (Optional) Click **Description**, and then type a meaningful description for the branch site.
5. Click **Next**.
6. (Optional) In the next **Define New Branch Site** dialog box, do any of the following:
   - Click **City**, and then type the name of the city in which the branch site is located.
   - Click **State/Region**, and then type the name of the state or region in which the branch site is located.
   - Click **Country Code**, and then type the two-digit calling code for the

country/region in which the branch site is located.

7. Click **Next**, and then do one of the following:
    - If you are using a Survivable Branch Appliance or Server at this site, be sure that the **Open the New Survivable Wizard when this wizard closes** check box is selected, click **Finish**, and then follow the directions in the wizard that opens. For information about wizard items, see Define a Survivable Branch Appliance or Server.
    - If you are not using a Survivable Branch Appliance or Server at this site, clear the **Open the New Survivable Wizard when this wizard closes** check box, and then click **Finish**.
8. Repeat the previous steps for each branch site that you want to add to the topology.

Next step:

For Survivable Branch Appliances or Servers: Define a Survivable Branch Appliance or Server

For non-resilient PSTN connectivity: Define a PSTN Gateway for a Branch Site, Configure a Trunk with Media Bypass, or Configure a Trunk without Media Bypass

1.4.8.2.1.3 Define a Survivable Branch Appliance or Server

Define a Survivable Branch Appliance or Server

Deploying Branch Sites > Deploying a Survivable Branch Appliance or Server > Deploying a Survivable Branch Appliance or Server - Central Site Tasks >

Topic Last Modified: *2012-10-07*

Perform this procedure at the central site if you did not define the Survivable Branch Appliance or Server when you added it to your topology.

⊟To define a Survivable Branch Appliance or Survivable Branch Server

1. Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
2. In the console tree, expand the central site, expand **Branch sites**, and then expand the name of the branch site where you plan to deploy the Survivable Branch Appliance or Survivable Branch Server.
3. Right-click **Survivable Branch Appliances**, and then click **New Survivable Branch Appliance**.

    Important:

    Survivable Branch Appliances is where you define Survivable Branch Servers and Survivable Branch Appliances.

4. In the **Define Survivable Branch Appliance** dialog box, click **FQDN**, type the fully qualified domain name (FQDN) of the Survivable Branch Appliance or Survivable Branch Server you will deploy at this branch site, and then click **Next**.

    Important:

    If you are defining a Survivable Branch Appliance, the name you enter in **FQDN** must be the same as the Survivable Branch Appliance FQDN you assigned to the **servicePrincipalName** attribute. For details, see Add a Survivable Branch Appliance to Active Directory.

5. Click **Front End pool**, click the Front End Server (User Services pool) at the central site that this Survivable Branch Appliance or Survivable Branch Server will connect to, and then click **Next**.

6. Click **Edge Server**, click the Edge pool that this Survivable Branch Appliance or Survivable Branch Server will connect to provide PSTN connectivity to remote users of the branch site, and then click **Next**.
7. Click **Gateway FQDN or IP Address**, and then type the FQDN or IP address of the gateway peer that the Survivable Branch Appliance or Survivable Branch Server is associated with for routing inbound or outbound PSTN calls.

   Important:

   If you are defining a Survivable Branch Appliance, this is the gateway to which the Mediation Server inside the Survivable Branch Appliance will connect for PSTN connectivity.

8. Click **Listening Port for IP/PSTN Gateway**, and then accept the default port.
9. In **Sip Transport Protocol**, click the transport protocol the Survivable Branch Appliance or Survivable Branch Server will use, and then click **Finish**.

   Note:

   For security reasons, we strongly recommend that you use Transport Layer Security (TLS). If you are defining a Survivable Branch Appliance, refer to your Survivable Branch Appliance vendor documentation to verify that your Survivable Branch Appliance supports the TLS protocol.

10. In the console tree, right-click the new Survivable Branch Appliance or Server, click **Topology**, and then click **Publish**.

Next step: Deploy a Survivable Branch Appliance or Server - Branch Site Task

1.4.8.2.2 Deploy a Survivable Branch Appliance or Server - Branch Site Task

Deploy a Survivable Branch Appliance or Server - Branch Site Task

See Also

Deployment > Deploying Branch Sites > Deploying a Survivable Branch Appliance or Server >

Topic Last Modified: *2012-09-22*

Perform one of the two procedures described in this topic at the branch site, after successfully completing the tasks in Deploying a Survivable Branch Appliance or Server - Central Site Tasks.

Important:

To perform this procedure, you must be a member of the RTCUniversalSBATechnicians group.

⊟To deploy the Survivable Branch Appliance

- Survivable Branch Appliance deployment is enabled by the Survivable Branch Appliance vendor through a web user interface (UI). For information about deploying the Survivable Branch Appliance, see your Survivable Branch Appliance vendor documentation.

⊟To deploy the Survivable Branch Server

- Install Microsoft Lync Server 2010 on a computer running Windows Server 2008 or Windows Server 2008 R2, just as you would install any other Lync Server 2013 server role.

  Note:

  For information about installing Lync Server, see Deploying Lync Server 2013 in the Deployment documentation.

Next step: Configuring Users for Branch Site Resiliency

Tasks

Appendix A: Using Cmdlets to Deploy a Survivable Branch Appliance

1.4.8.2.3 Configuring Users for Branch Site Resiliency

Configuring Users for Branch Site Resiliency

Deployment > Deploying Branch Sites > Deploying a Survivable Branch Appliance or Server >

Topic Last Modified: *2012-10-11*

After successfully completing the tasks in Deploy a Survivable Branch Appliance or Server - Branch Site Task, perform the following procedures to enable users for Enterprise Voice, assign them a voice policy and voice mail settings. Then in Home Users on a Survivable Branch Appliance or Server, you will home these users on the Survivable Branch Appliance or Server.

- Enable Users for Enterprise Voice
- Create the VoIP Routing Policy for Branch Users
- Configure Voice Mail Rerouting Settings

1.4.8.2.3.1 Enable Users for Enterprise Voice

Enable Users for Enterprise Voice

See Also

Microsoft Lync Server 2013 > Deployment > Deploying Enterprise Voice >

Topic Last Modified: *2012-11-01*

After you install files for one or more Mediation Servers, configure outbound call routing, and optionally deploy one or more advanced Enterprise Voice features, you can use the following procedures to enable a user to make calls by using Enterprise Voice:

Note:
Of the following procedures, only the first can be performed by using Lync Server Control Panel. For the remaining procedures, you can use only Lync Server Management Shell.

- Enable the user account for Enterprise Voice.
- (Optional) Assign the user account a user-specific voice policy.
- (Optional) Assign the user account a user-specific dial plan.

To enable a user account for Enterprise Voice

1. From a user account that is assigned to the CsUserAdministrator role or the CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Users**.
4. In the **Search users** box, type all or the first portion of the display name, first name, last name, Security Accounts Manager (SAM) account name, SIP address, or line Uniform Resource Identifier (URI) of the user account that you want to enable, and then click **Find**.
5. In the table, click the user account that you want to enable for Enterprise Voice.

6. On the **Edit** menu, click **Show details**.
7. On the **Edit Lync Server User** page, under **Telephony**, click **Enterprise Voice**.
8. Click **Line URI**, and then type a unique, normalized phone number (for example, tel:+14255550200).
9. Click **Commit**.

To finish enabling a user for Enterprise Voice, be sure that the user is assigned a voice policy and a dial plan, whether global (assigned by default) or user-specific.

By default, all users are assigned a global voice policy and dial plan. If a voice policy or dial plan exists at the site level for the site on which the user account is homed, those site policies will automatically apply to the user. To apply a per-user voice policy or dial plan to a user, you must run the **Grant-CsVoicePolicy** and **Grant-CsDialPlan** cmdlets. For details, see the Lync Server Management Shell documentation.

Voice Policy Assignment

Global and site-level voice policies are automatically assigned to all user accounts that are enabled for Enterprise Voice. You can also create voice policies that apply to specific users or groups. These per-user policies must be explicitly assigned to the users or groups. If you want to use the global or site voice policy for all users who are enabled for Enterprise Voice, you can skip this section and continue to Dial Plan Assignment section later in this topic.

To assign a user-specific voice policy

1. From a user account that is assigned to the CsUserAdministrator role or the CsAdministrator role, log on to any computer in your internal deployment.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. To assign an existing user voice policy to a user, run the following at the command prompt:

```
Grant-CsVoicePolicy -Identity <UserIdParameter> -PolicyName <String>
```

   For example:

```
Grant-CsVoicePolicy -Identity "Bob Kelly" -PolicyName VoicePolicyJapar
```

   In this example, the user with the display name Bob Kelly is assigned the voice policy with the name **VoicePolicyJapan**.

For details about assigning a user-specific voice policy or about running the **Grant-CsVoicePolicy** cmdlet, see the Lync Server Management Shell documentation.

Dial Plan Assignment

To complete user account configuration for either users of Enterprise Voice or users of dial-in conferencing, the user must be assigned a dial plan. User accounts will automatically use the global dial plan or, if one exists, the site-level dial plan, when you do not explicitly assign an existing per-user dial plan. If you want to use the global or site dial plan for all users who are enabled for Enterprise Voice, you can skip this section.

To assign a dial plan

1. From a user account that is assigned to the CsUserAdministrator role or the CsAdministrator role, log on to any computer in your internal deployment.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management**

Shell.

3. To assign a user-specific dial plan, run the following at the command prompt:

```
Grant-CsDialPlan -Identity <UserIdParameter> -PolicyName <String>
```

For example:

```
Grant-CsDialPlan -Identity "Bob Kelly" -PolicyName DialPlanJapan
```

In this example, the user with the display name Bob Kelly is assigned the user dial plan with the name **DialPlanJapan**.

For details about assigning a user dial plan or about running the **Grant-CsDialPlan** cmdlet, see the Lync Server Management Shell documentation.

Tasks

Disable a User for Enterprise Voice

1.4.8.2.3.2 Create the VoIP Routing Policy for Branch Users

Create the VoIP Routing Policy for Branch Users

Deploying Branch Sites > Deploying a Survivable Branch Appliance or Server > Configuring Users for Branch Site Resiliency >

Topic Last Modified: *2012-09-23*

We recommend creating a separate voice over IP (VoIP) policy for users at branch sites. This policy should contain routes to egress from the Survivable Branch Appliance gateway or the Survivable Branch Server external gateway and backup routes to egress from a gateway at the central site. Regardless of where the user is registered, either on the Registrar on the Survivable Branch Appliance or Survivable Branch Server or on the backup Registrar cluster at the central site, the user’s VoIP policy is always in effect.

⊟To configure the VoIP routing policy for branch users

1. Create a user-level dial plan and assign it to branch users. (See Create a Dial Plan in the Operations documentation.)
2. Assign normalization rules corresponding to the dialing habits of users at that site. If the Survivable Branch Appliance or Survivable Branch Server user fails over to the backup Registrar pool at the central site, the same dial plan will be in effect. (See Create a Dial Plan in the Operations documentation.)
3. Configure a voice route that egresses from the Survivable Branch Appliance gateway or the Survivable Branch Server external gateway. (See Create a Voice Route in the Operations documentation.)
4. Set a backup call route on the Survivable Branch Appliance or Survivable Branch Server gateway to point to the backup Registrar pool (collocated with Mediation Server) at the central site. (See your Survivable Branch Appliance or Survivable Branch Server vendor documentation.)

> **Note:**
>
> This backup call route setup helps ensure that inbound calls to the branch user will work when the Survivable Branch Appliance or Survivable Branch Server is not available (for example, if it is down for maintenance). If the Registrar and Mediation Server on the Survivable Branch Appliance or Survivable Branch Server are not available, and the user is registered with the backup Registrar pool at the central site, inbound calls can still be routed to the user.

Next step: Configure Voice Mail Rerouting Settings

1.4.8.2.3.3 Configure Voice Mail Rerouting Settings

Configure Voice Mail Rerouting Settings

Deploying Branch Sites > Deploying a Survivable Branch Appliance or Server > Configuring Users for Branch Site Resiliency >

Topic Last Modified: *2012-10-18*

Survivable Branch Appliances and Survivable Branch Servers can provide voice mail survivability for branch users during a WAN outage, if Exchange Unified Messaging (UM) is installed at the central site and an Exchange UM Message Auto Attendant (AA) is deployed. We recommend that your Exchange administrator configure the AA to accept messages only, which disables other generic functionality, such as transfer to a user or transfer to an operator. Alternatively, you might use a generic AA or an AA customized to route the call.

For details, see the “Preparing for Voice Mail Survivability” section of Branch-Site Resiliency Requirements in the Planning documentation.

⊟To configure voice mail survivability

1. Ask your Exchange administrator to configure the AA to accept messages only (in the Exchange Shell use the following cmdlet: **Set-UMAutoAttendant <AA name> -CallSomeoneEnabled $false**. The parameter that specifies to allow leaving messages (*SendVoiceMsgEnabled*) is true by default.
2. In the Lync Server Management Shell, use the **New-CSVoiceMailReroutingConfiguration** cmdlet to set the AA phone number as the Exchange UM Auto Attendant phone number in the voice mail rerouting configuration on the Survivable Branch Appliance or Survivable Branch Server.

   Note:
   If you need to modify the voice mail rerouting setting later, use the **Set-CsVoiceMailReRoutingConfiguration** cmdlet to do so. For details, about **New-** and **Set-CSVoiceMailReroutingConfiguration**, in the Shell Help topics.

3. Set the Exchange UM subscriber access number that corresponds to the branch user’s Exchange UM dial plan as the Exchange UM subscriber access number in the voice mail rerouting configuration on the Survivable Branch Appliance or Survivable Branch Server.

   Note:
   Configure the Exchange UM users’ dial plan so that there is only one dial plan associated with all branch users who need access to the Get Voice Mail functionality during a WAN outage.

Next step for Survivable Branch Appliances or Survivable Branch Servers: Home Users on a Survivable Branch Appliance or Server.

1.4.8.2.4 Home Users on a Survivable Branch Appliance or Server

Home Users on a Survivable Branch Appliance or Server

See Also

Deployment > Deploying Branch Sites > Deploying a Survivable Branch Appliance or Server >

***Topic Last Modified:** 2012-09-21*

The process of homing users on a Survivable Branch Appliance or a Survivable Branch Server is similar to the process of homing users on a Front End pool. Perform the Survivable Branch Appliance or Survivable Branch Server procedure at the central site.

⊟To home users on Survivable Branch Appliance or Survivable Branch Server

1. Before moving users to the Survivable Branch Server or Survivable Branch Server, open the Lync Server Management Shell, and then do all of the following:
   - Run the cmdlet **Test-CsPstnOutboundCall** to verify that the Survivable Branch Server is running and that the public switched telephone network (PSTN) connectivity is configured. If you need to modify PSTN gateway properties, use the cmdlet **Set-CsPstnGateway**.
   - Run the cmdlet **Get-CsVoicePolicy** to verify that the users who will be homed on the Survivable Branch Server have the appropriate VoIP routing policy. If you need to modify the VoIP policy, use the cmdlet **Set-CsVoicePolicy**.
   - Run the cmdlet **Get-CsVoicemailReroutingConfiguration** to verify that the voice mail rerouting settings are configured. If you need to modify the voice mail rerouting settings, use the cmdlet **Set-CsVoicemailReroutingConfiguration**.
2. In the Lync Server Management Shell, run the cmdlet **Move-CsUser** to move home users.

Note:
You can also use Lync Server Control Panel to verify prerequisites and home users.

1.4.8.2.5 Connecting Survivable Branch Appliance to Lync Server 2013 Front End pool

Connecting Survivable Branch Appliance to Lync Server 2013 Front End pool

Deployment > Deploying Branch Sites > Deploying a Survivable Branch Appliance or Server >

***Topic Last Modified:** 2012-10-05*

Every Survivable Branch Appliance (SBA) is associated with a Front End pool, which serves as a backup Registrar for the SBA. When the Front End pool is upgraded to Lync Server 2013, the SBA must be disassociated from the Front End pool while the Front End pool is upgraded. After the Front End pool is upgraded, the SBA can be reassociated with the Front End pool. This involves deleting the SBA from the topology in Topology Builder and then adding the SBA, again, to Topology Builder. Users homed on the SBA must be moved to another Front End pool before removing the SBA from the topology. After the SBA is added back to the topology, those users can be moved back to the SBA.

These steps are summarized below:

1. Move branch users homed on SBA to another Front End pool.
2. Remove SBA from your topology to disassociate the existing Front End pool as the backup Registrar.

3. Upgrade Front End pool to Microsoft Lync Server 2013.
4. Add SBA back into your topology.
5. Associate the new Front End pool to the SBA as a backup Registrar.
6. Move branch users back to the SBA.

- Add Lync Server 2013 Survivable Branch Appliance branch site to your Topology
- Add Lync Server 2010 Survivable Branch Appliance branch site to your Topology

1.4.8.2.5.1 Add Lync Server 2013 Survivable Branch Appliance branch site to your Topology

Add Lync Server 2013 Survivable Branch Appliance branch site to your Topology

See Also

Deploying Branch Sites > Deploying a Survivable Branch Appliance or Server > Connecting Survivable Branch Appliance to Lync Server 2013 Front End pool >

Topic Last Modified: *2012-10-07*

Microsoft Lync Server 2013 Survivable Branch Appliances (SBA) cannot be associated to a Microsoft Lync Server 2010 Front End pool as a backup Registrar. The SBA must be associated with a Microsoft Lync Server 2013 Front End pool. These steps assume a Microsoft Lync Server 2013 SBA. Perform this procedure at the central site.

⊟To add branch sites with Microsoft Lync Server 2013 SBA to your topology

1. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
2. In the console tree, expand the central site, expand **Branch Sites**, and then click **New Branch Site**.
3. In the **Define New Branch Site** dialog box, click **Name**, and then type a name for the new branch site.
4. (Optional) Click **Description**, and then type a meaningful description for the branch site.
5. Click **Next**.
6. (Optional) In the next **Define New Branch Site** dialog box, do any of the following:
   - Click **City**, and then type the name of the city in which the branch site is located.
   - Click **State/Region**, and then type the name of the state or region in which the branch site is located.
   - Click **Country Code**, and then type the two-digit calling code for the country/region in which the branch site is located.
7. Click **Next**, and then do one of the following:
   - If you are using a Survivable Branch Appliance or Survivable Branch Server at this site, be sure that the **Open the New Survivable Wizard when this wizard closes** check box is selected.
   - If you are not using a Survivable Branch Appliance or Survivable Branch Server at this site, clear the **Open the New Survivable Wizard when this wizard closes** check box.
   - Click **Finish**, and then follow the directions in the wizard that opens. For information about wizard items, see Define a Survivable Branch Appliance or Server.
8. Repeat the previous steps for each branch site that you want to add to the topology.

1.4.8.2.6.1 Appendix A: Using Cmdlets to Deploy a Survivable Branch Appliance

Appendix A: Using Cmdlets to Deploy a Survivable Branch Appliance

Deploying Branch Sites > Deploying a Survivable Branch Appliance or Server > Appendices: Survivable Branch Appliances and Servers >

Topic Last Modified: *2012-10-07*

This topic describes how to deploy a Survivable Branch Appliance using the Lync Server Management Shell. Perform this procedure at the central site.

To deploy a Survivable Branch Appliance remotely

1. Follow the procedure in Add Branch Sites to Your Topology to add a new branch site.
2. Join the branch site to the domain.
3. Add the RTCUniversalSBATechnicians group to the local Administrators group.
4. Restart the server, and log on to it as a member of the RTCUniversalSBATechnicians group.
5. In the Lync Server Management Shell, type the following commands, replacing the placeholders with the correct information for your organization:

```
Export-CsConfiguration -FileName C:\CSConfig.zip
Import-CsConfiguration -LocalStore -FileName C:\CSConfig.zip -Verbose
Enable-CSReplica -Verbose
Enable-CsComputer -Verbose
Request-CsCertificate -New -Type default -CA <YourCA> -Verbose
Set-CsCertificate -Type Default -Thumbprint <YourCertThumbprint>
Start-cswindowsservice -verbose
```

1.4.8.2.6.2 Appendix B: Managing a Survivable Branch Appliance

Appendix B: Managing a Survivable Branch Appliance

Deploying Branch Sites > Deploying a Survivable Branch Appliance or Server > Appendices: Survivable Branch Appliances and Servers >

Topic Last Modified: *2012-10-18*

This topic describes the procedures for managing a Survivable Branch Appliance. Specifically, how to replace and rename a Survivable Branch Appliance, and how to change the Lync Server 2013 Front End pool that the Survivable Branch Appliance is associated with.

To Replace a Survivable Branch Appliance

1. Stop all Lync Server 2013 services on the Survivable Branch Appliance. (See the Survivable Branch Appliance vendor documentation.)
2. (Recommended) Remove the Survivable Branch Appliance from the domain.
3. Delete the Survivable Branch Appliance computer object in Active Directory Domain Services (AD DS), by following these steps:
    - Log on to a member server as a member of the Enterprise Admins group.
    - Click **Start**, click **Administrative Tools**, and then click **Active Directory Users and Computers**.
    - Right-click the Survivable Branch Appliance object, and click **Delete**.
4. Add the Survivable Branch Appliance computer object again. (See Add a Survivable Branch Appliance to Active Directory.)
5. Wait for Active Directory replication to take place.
6. Open the Lync Server Management Shell, and type **Enable-CSTopology**.
7. Connect the new Survivable Branch Appliance to the network, and follow the steps in Deploying a Survivable Branch Appliance or Server - Central Site Tasks and Deploy a Survivable Branch Appliance or Server - Branch Site Task.

To Rename a Survivable Branch Appliance

1. Move users to the central site. For details, see Move Users to Another Pool.
2. Stop all Lync Server 2013 services on the Survivable Branch Appliance. (See the Survivable Branch Appliance vendor documentation.)
3. Remove the Survivable Branch Appliance from the topology, by following these steps:
    - Click **Start**, click **All Programs**, click **Microsoft Lync Server**, and then click

Lync Server Topology Builder.
- In the console tree, expand **Branch Sites**, click the Survivable Branch Appliance, and then click **Delete** on the Action pane.

4. Remove the Survivable Branch Appliance from the domain.
5. Delete the Survivable Branch Appliance computer object in Active Directory, by following these steps:
   - Log on to a domain controller as a member of the Enterprise Admins group.
   - Click **Start**, click **Administrative Tools**, and then click **Active Directory Users and Computers**.
   - Right-click the Survivable Branch Appliance object, and click **Delete**.
6. Restore the Survivable Branch Appliance to factory defaults. (See the Survivable Branch Appliance vendor documentation.)
7. Follow the steps in Deploying a Survivable Branch Appliance or Server - Central Site Tasks and Deploy a Survivable Branch Appliance or Server - Branch Site Task.
8. Move users to the renamed Survivable Branch Appliance. For details, see Move Users to Another Pool.

⊟To Change the Lync Server Front End Pool that the Survivable Branch Appliance Is Associated With

1. Move users from the Survivable Branch Appliance to the Lync Server Front End pool at the central site. For details, see Move Users to Another Pool.
2. Stop all Lync Server services on the Survivable Branch Appliance. (See the Survivable Branch Appliance vendor documentation).
3. Update the Lync Server Front End pool that the Survivable Branch Appliance is associated with, by following these steps:
   - Click **Start**, click **All Programs**, click **Microsoft Lync Server**, and then click **Lync Server Topology Builder**.
   - Expand **Branch Sites**.
   - Right-click the Survivable Branch Appliance object to modify, and click **Edit Properties**
   - Under Resiliency, select the new Front End pool the Survivable Branch Appliance is to be associated to, and then click **Next**.
   - In the console tree, right-click the new Survivable Branch Appliance, click **Topology**, and then click **Publish**.
4. Restart all Lync Server Services on the Survivable Branch Appliance.
5. Test the Survivable Branch Appliance. For details, see Home Users on a Survivable Branch Appliance or Server.
6. Move users from the Lync Server Front End pool at the central site to the Survivable Branch Appliance.

1.4.9 Deploying Persistent Chat Server

Deploying Persistent Chat Server

Microsoft Lync Server 2013 > Deployment >

Topic Last Modified: *2012-10-11*

Lync Server 2013, Persistent Chat Server is part of the Lync Server 2013 infrastructure.

Deploying Persistent Chat Server requires that you:
- Use Topology Builder to define, or import, and subsequently publish your topology and the components that you want to deploy.
- Prepare your environment for deploying Persistent Chat Server components.
- Install and configure Persistent Chat Server components for your deployment.

Persistent Chat Server is available with Lync Server 2013 Enterprise Edition as a separate pool (not collocated with the Enterprise Edition Front End Servers). Persistent Chat Server requires a SQL Server Back End Server in your Enterprise Edition pool to store the chat room content and other relevant metadata. We recommend that you install the **PersistentChatStore** on a dedicated SQL Server Back End Server, although collocating Lync Server 2013 Back End Server and **PersistentChatStore** on the same SQL Server instance is supported.

Persistent Chat Server can also be deployed with Lync Server 2013 Standard Edition. In this case, the **PersistentChatService** Front End Server is collocated on the Standard Edition computer, and the **PersistentChatStore** Back End Server can be deployed on the local SQL Server Express instance.

Important:
We do not support high availability for Persistent Chat Server Standard Edition. Performance and scale will be limited. Furthermore, we support only new Persistent Chat Server Standard Edition server. We do not support upgrading Lync Server 2010, Group Chat Server to a Lync Server 2013 Persistent Chat Server Standard Edition.

If your organization requires compliance support, you can install the Persistent Chat Server Compliance service on the Persistent Chat Server Front End Server. A separate database is required for compliance.

At a minimum, each topology requires a server with Lync Server 2013 installed and a server with SQL Server database software installed.

Use Topology Builder to add Persistent Chat Server to your Lync Server 2013 deployments. You can choose to add one or more Persistent Chat Server pools using Topology Builder. Follow the same deployment instructions for deploying multiple Persistent Chat Server pools as you would for any pool. For details, see Deploying Lync Server 2013 in the Deployment documentation.

For details about available topologies and the technical and software requirements for installing Persistent Chat Server, see Planning for Persistent Chat Server in the Planning documentation, How Persistent Chat Server Works in the Planning documentation, Deployment documentation, or Operations documentation, and Supported Hardware in the Supportability documentation.

For details about acquiring certificates, creating the SQL Server database, and creating file stores, see Deploying Lync Server 2013 in the Deployment documentation.

A single Persistent Chat Server Front End Server can support 20,000 active users. You can have a Persistent Chat Server pool with up to 4 active Front End Servers supporting a total of 80,000 concurrent users.

Persistent Chat Server is also supported on a virtual server. The virtual server can support up to 20,000 concurrent users if it matches the specifications of the physical server. We recommend four-core processors and 8 GB of memory.

Important:
Persistent Chat Server must be installed on an NTFS file system to help enforce file system security. FAT32 is not a supported file system for Persistent Chat Server.

In This Section

1.4.9.1 How Persistent Chat Server Works

How Persistent Chat Server Works

Microsoft Lync Server 2013 > Planning > Planning for Persistent Chat Server >

***Topic Last Modified:** 2012-11-21*

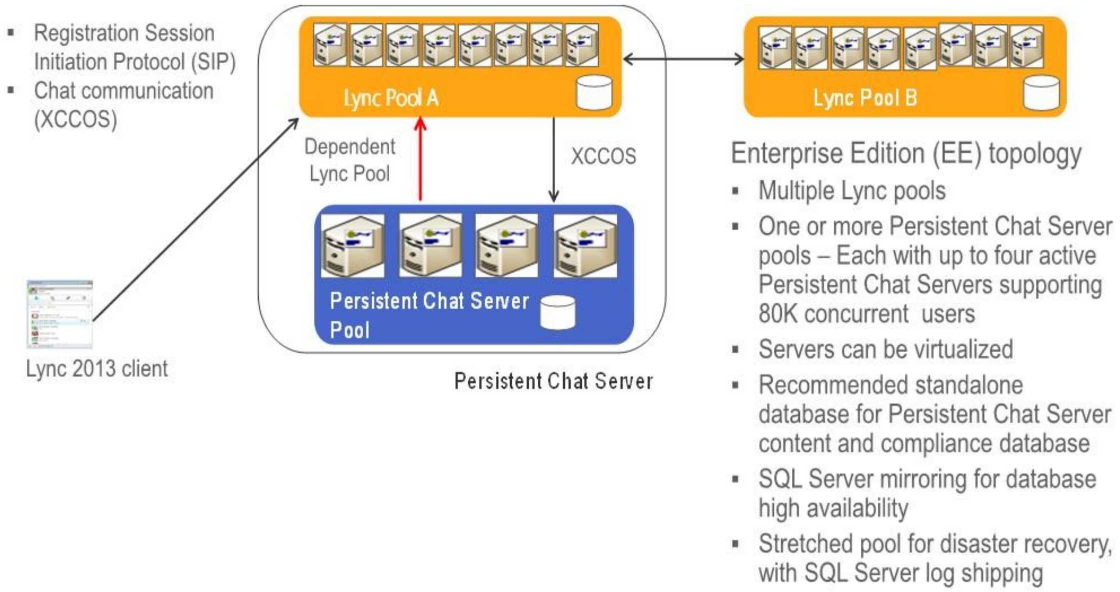
Lync Server 2013, Persistent Chat Server enables you to participate in multiparty, topic-based conversations that persist over time. Persistent Chat Server can help your organization do the following:

- Improve communication between geographically dispersed and cross-functional teams
- Broaden information awareness and participation
- Improve communication with your extended organization
- Reduce information overload
- Improve information awareness
- Increase dispersion of important knowledge and information

You can deploy Persistent Chat Server as an optional role with Lync Server 2013. Persistent Chat services run on a dedicated pool, and a Persistent Chat Server pool depends on a Lync Server pool to route messages to it. Clients use eXtensible Chat Communication Over SIP (XCCOS). The Lync Server Front End Servers are configured to route the traffic to a Persistent Chat Server pool.

High-Level Architecture

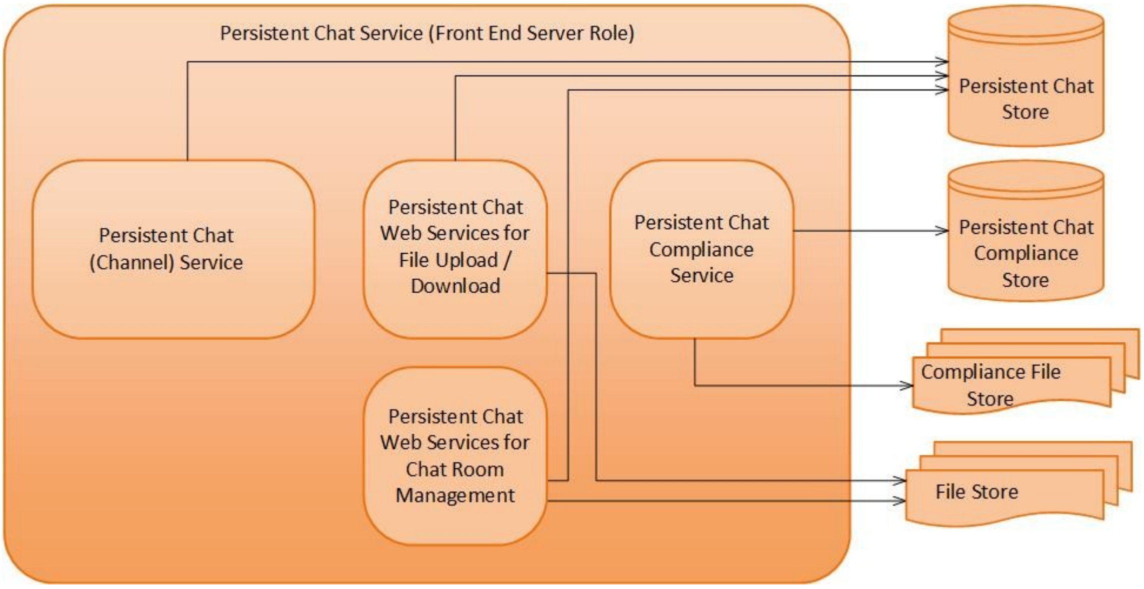
The following diagrams provide high-level perspectives of the Persistent Chat Server architecture and services.



- Registration Session Initiation Protocol (SIP)
- Chat communication (XCCOS)

Enterprise Edition (EE) topology

- Multiple Lync pools
- One or more Persistent Chat Server pools – Each with up to four active Persistent Chat Servers supporting 80K concurrent users
- Servers can be virtualized
- Recommended standalone database for Persistent Chat Server content and compliance database
- SQL Server mirroring for database high availability
- Stretched pool for disaster recovery, with SQL Server log shipping



Persistent Chat Service (Front End Server Role)
Persistent Chat (Channel) Service
Persistent Chat Web Services for File Upload / Download
Persistent Chat Compliance Service
Persistent Chat Web Services for Chat Room Management
Persistent Chat Store
Persistent Chat Compliance Store
Compliance File Store
File Store

Two services run on the Persistent Chat Server Front End Servers:

- Persistent Chat (Channel)
- Compliance

Persistent Chat (Channel) Service

The Persistent Chat (Channel) service is the core service responsible for Persistent Chat Server. This service provides the following functions:

- Accepts incoming messages
- Registers and lists online participants within a Persistent Chat room
- Retransmits messages to other channel subscribers
- Implements logic for channel management, chat room invitation, search, and new content notifications

The Persistent Chat (Channel) service stores and accesses chat room content and other system metadata (authorization rules, and so on) by using the Persistent Chat Store. This service stores files that are uploaded into chat rooms in the Persistent Chat File Store.

Compliance Service

The Compliance service is an optional component of Persistent Chat Server and is responsible for archiving chat content and events to the Persistent Chat Compliance Store. If your organization has regulations that require Persistent Chat activity to be archived, you can deploy the optional Persistent Chat Compliance service. The Compliance service is installed on each Persistent Chat Server in a Persistent Chat pool. When configured, Persistent Chat Server compliance records user activity such as joining and leaving rooms, and posting and reading of messages. The Compliance service stores files that need to be archived in the Persistent Chat Compliance File Store.

Persistent Chat Web Services

On the Lync Server Front End Servers, two services run that depend on Internet Information Services (IIS), and are implemented as web components:

- **Persistent Chat Web Services for File Upload/Download** Responsible for posting and retrieving files from chat rooms.
- **Persistent Chat Web Services for Chat Room Management** Responsible for providing users the ability to manage their chat rooms, and create new chat rooms.

How Do I Start Using Persistent Chat Server?

Persistent Chat Server is an optional server role within the Lync Server 2013 infrastructure. If you install the Persistent Chat Server role, any users who have been enabled through policy by an administrator can use Persistent Chat with the Lync 2013 client.

For details about how to deploy Persistent Chat Server and enable users to leverage the capabilities by policy, see Deploying Persistent Chat Server.

For details about how to configure settings on your Persistent Chat Server deployment, see Deploying Persistent Chat Server and Managing Lync Server 2013, Persistent Chat Server.

For details about how to enable users by policy such that they can leverage Persistent Chat functionality in Lync 2013 client, see Deploying Persistent Chat Server and Managing Lync Server 2013, Persistent Chat Server.

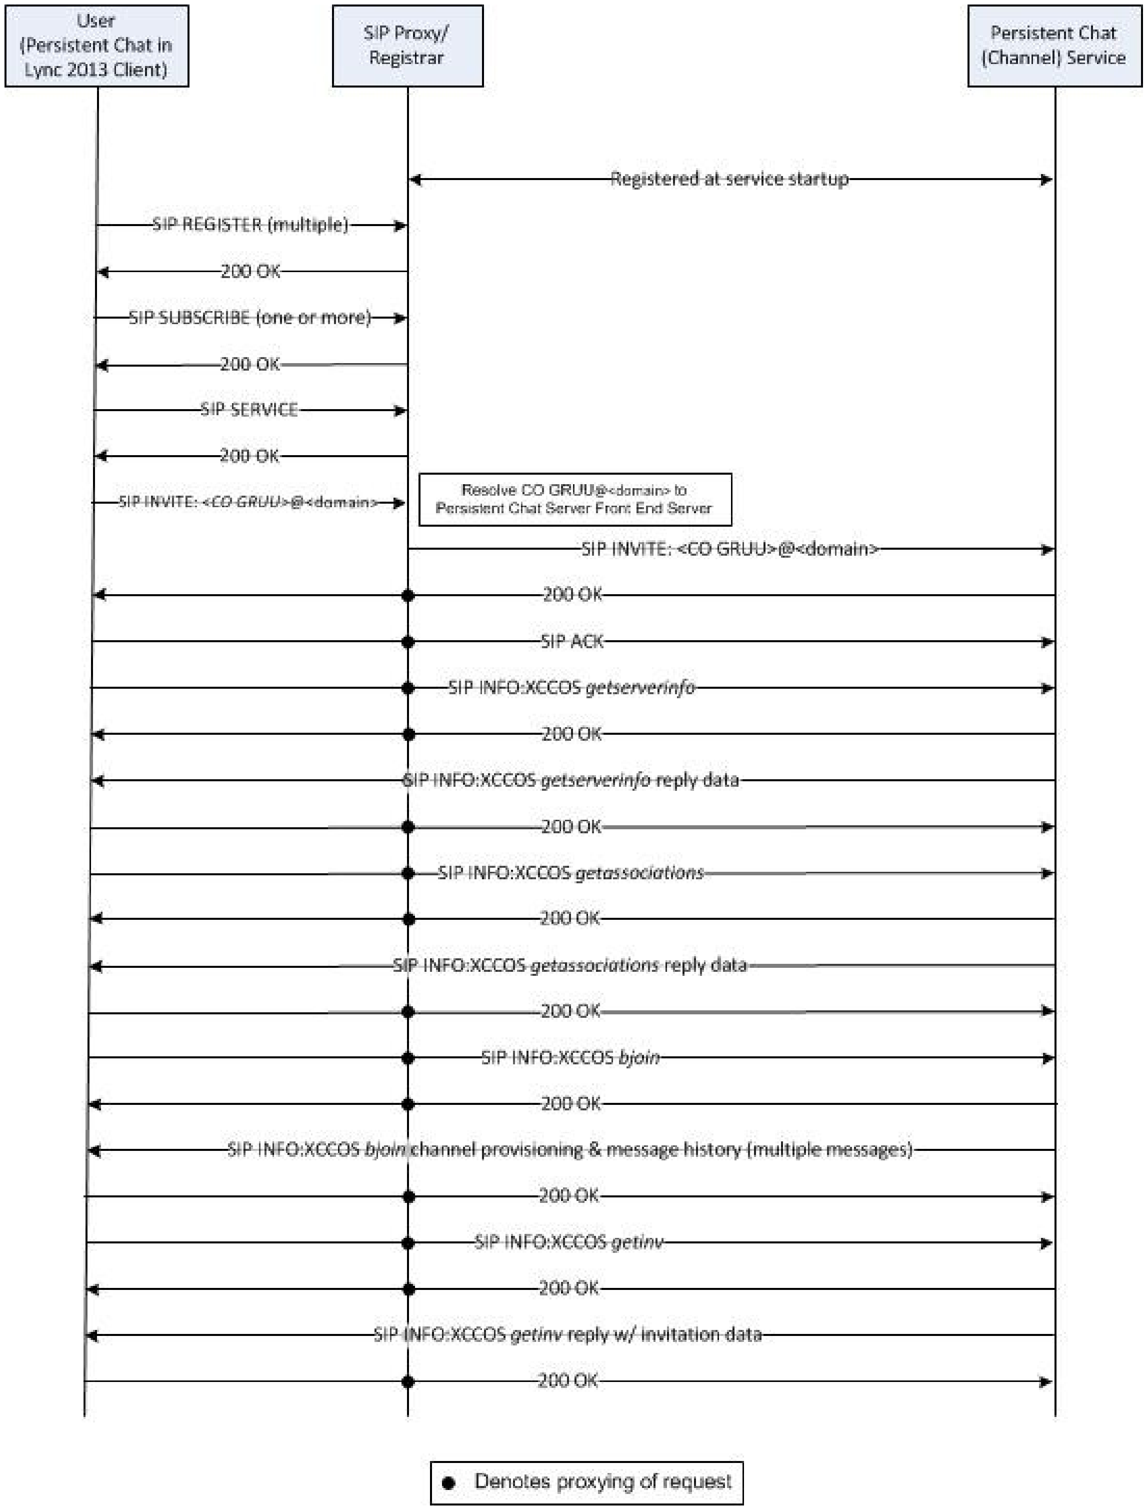
If you deployed Persistent Chat compliance, see Managing Lync Server 2013, Persistent Chat Server for details about how to configure settings for compliance.

Persistent Chat Call Flows

The Persistent Chat client communicates with the Persistent Chat service by using XCCOS. The following sequences describe the sign-in process and a typical room subscription and message post scenario.

Sign-in

The following call flow diagram and steps describe the sign-in process.



User (Persistent Chat in Lync 2013 Client)
SIP Proxy/ Registrar
Persistent Chat (Channel) Service
Registered at service startup
SIP REGISTER (multiple)
200 OK
SIP SUBSCRIBE (one or more)
200 OK
SIP SERVICE
200 OK
SIP INVITE: <CO GRUU>@<domain>
Resolve CO GRUU@<domain> to Persistent Chat Server Front End Server
SIP INVITE: <CO GRUU>@<domain>
200 OK
SIP ACK
SIP INFO:XCCOS getserverinfo
200 OK
SIP INFO:XCCOS getserverinfo reply data
200 OK
SIP INFO:XCCOS getassociations
200 OK
SIP INFO:XCCOS getassociations reply data
200 OK
SIP INFO:XCCOS bjoin
200 OK
SIP INFO:XCCOS bjoin channel provisioning & message history (multiple messages)
200 OK
SIP INFO:XCCOS getinv
200 OK
SIP INFO:XCCOS getinv reply w/ invitation data
200 OK
● Denotes proxying of request

1. The Persistent Chat client first sends a SIP SUBSCRIBE to retrieve the in-band provisioning document from the server. This document indicates if Persistent Chat is enabled or disabled for the user and the list of SIP URIs for the Persistent Chat Server pool.
2. The Persistent Chat client sends a SIP INVITE message to the SIP URI of the Persistent Chat Server that it obtained in the previous step. The INVITE sequence is followed by 200 OK and ACK, and the Persistent Chat client has

now opened a SIP session with a Persistent Chat Server endpoint. Consequently, the Persistent Chat client communicates with Persistent Chat Server by sending SIP INFO messages that contain either chat messages or commands requesting the server to take an action. All of these messages are acknowledged with either 200 OK or 503 Service Unavailable (that is, in the event of heavy server load). If the client receives a 503 response, it will retry the message. (This example does not include a 503 response.) If the server accepts the message or command and sends 200 OK, it provides a response to the client in the form of a separate SIP INFO message. This response includes a reference to the originating command.

3. The Persistent Chat client sends a SIP INFO message that contains the XCCOS **getserverinfo** command. Persistent Chat Server replies with a new SIP INFO message that contains information about the Persistent Chat service configuration.
4. The Persistent Chat client sends a SIP INFO message that contains the XCCOS **getassociations** command. Persistent Chat Server replies with a new SIP INFO message that contains the list of rooms of which the user is a member. The Persistent Chat client repeats the command to retrieve the list of rooms of which the user is a manager.
5. The Persistent Chat client gets the list of followed rooms from the "presence" document, where each followed room is represented by a "roomSetting" category. All followed rooms are joined by a single SIP INFO message that contains the XCCOS **bjoin** command that contains the list of room URIs. Because the list of followed rooms is kept on the server, any client on any computer has the same list of followed rooms for the specified user URI. The Persistent Chat client also keeps the list of opened rooms (if this option is enabled by the user) in the local computer registry, and joins each of these rooms at sign-in by sending a SIP INFO message that contains the XCCOS **join** command for each opened room. Because this list is kept in the registry, it can be different on two Persistent Chat clients running on different computers.
6. For each room joined, the Persistent Chat client sends a SIP INFO message that contains the XCCOS **bccontext** command. Persistent Chat Server replies with a new SIP INFO message that contains the most recent chat message in the room.
7. The Persistent Chat client sends a SIP INFO message that contains a XCCOS **getinv** (that is, get invitation) command to request any new room invitations that the client has not yet seen. In a separate SIP INFO message, Persistent Chat Server returns a list of those rooms.

Subscribe to a Room and Post a Message

The following call flow diagram and steps describe a typical room subscription and message post scenario.

1. From the Persistent Chat client, User1 clicks **Join a Chat Room**, clicks **Search**, and then enters some search criteria. The Persistent Chat client sends a SIP INFO message that contains the XCCOS **chansrch** (room search) command, along with the search criteria. Persistent Chat Server queries the back-end database and replies in a new SIP INFO message that contains a list of available rooms that meet the search criteria.
2. User1 selects the chat room that he or she wants to join, and then clicks **Follow this room**. The Persistent Chat client sends Persistent Chat Server a SIP INFO message that contains the XCCOS **join** command and the room ID of the chat room that the user selected. Persistent Chat Server replies with a SIP INFO message that contains the provisioning data.
3. The Persistent Chat client sends Persistent Chat Server a SIP INFO message that contains the XCCOS **bccontext** (backchat context) command. Persistent Chat Server retrieves the chat history, and returns it to the Persistent Chat client in a separate SIP INFO message. At this point, the user enters the chat

room and is ready to participate.

4. User1 enters a new message, and then clicks **Send**. The Persistent Chat client posts the message to the chat room in a SIP INFO XCCOS **grpchat** command. Persistent Chat Server stores a copy of this new message in the Persistent Chat back-end database.
5. Persistent Chat Server sends a separate copy of the SIP INFO XCCOS **grpchat** message to User2, who has already entered the chat room.

Persistent Chat Compliance Call Flows

Persistent Chat Server uses Message Queuing (also known as MSMQ) and an additional compliance database (mgccomp) to process compliance data. As an example of how compliance events are processed, the following sequence of events describes how a message post event is processed.

1. A user posts a message to a room.
2. Persistent Chat Server places information pertaining to the event in a private Message Queuing queue.
3. Persistent Chat Compliance server reads this event from the queue, and places it into the mgccomp database for processing later.
4. Periodically, the Persistent Chat Compliance server processes a set of events in the database, and sends them to the Persistent Chat Compliance adapter for processing.
5. If the adapter successfully processes the data, Persistent Chat Compliance server deletes the events from the mgccomp database.

1.4.9.2 Deployment Checklist for Persistent Chat Server

Deployment Checklist for Persistent Chat Server

Microsoft Lync Server 2013 > Planning > Planning for Persistent Chat Server >

Topic Last Modified: *2012-10-16*

Deployment of Lync Server 2013, Persistent Chat Server requires that you deploy it in the correct sequence and that you complete all required deployment steps.

Deployment Sequence

You can deploy Persistent Chat Server after you deploy your initial topology, including at least one Lync Server 2013, Front End pool or one Lync Server 2013, Standard Edition server. This topic describes how to deploy Persistent Chat Server by adding it to an existing deployment.

Deployment Process

The following table lists the basic steps to deploy Persistent Chat Server and provides links for more details.

Persistent Chat Server Deployment Process

Task	**Steps**	**Required roles and group memberships**	**Related topics**
Install prerequisite hardware and	On hardware that meets system requirements, install the following: • On the Persistent	Any user who is a member of the local	Supported Hardware in the Supportability documentation

software	Chat Server Front End Servers: • An operating system that meets system requirements • Software prerequisites for computers running Lync Server 2013 • SQL Server on the server that will host Persistent Chat Server database If Persistent Chat Server compliance is required: • SQL Server on the server that will host Persistent Chat Server compliance database	Administrators group.	Server Software and Infrastructure Support in the Supportability documentation Determining Your System Requirements Technical Requirements for Persistent Chat Server
Create the appropriate internal topology to support Persistent Chat Server (and optionally, Persistent Chat compliance)	Run Topology Builder to add a Persistent Chat Server pool to your topology: • Add Persistent Chat Server components to the topology • Create a SQL Server database for the Persistent Chat Server store (and a backup SQL Server for disaster recovery) • Define a new Lync File Store or use an existing Lync File Store for Persistent Chat Server files • Associate the Lync Server 2013 pool that can route requests to this Persistent Chat Server pool If Persistent Chat compliance is required: • Add Persistent Chat Compliance Store • Click the Persistent Chat Server pool definition check box for enabling compliance • Publish the topology If you install Persistent Chat	To define a topology, an account that is a member of the local Users group. To publish the topology, an account that is a member of the Domain Admins group and RTCUniversalServerAdmins group, and the user should also have full control permissions (read/write/modify) on the Lync File Store for Persistent Chat Server files (so that Topology Builder can configure the required DACLs).	Adding Persistent Chat Server to Your Deployment in the Deployment documentation

	Server on Standard Edition, the fully qualified domain name (FQDN) of the Persistent Chat Server pool must match the Standard Edition server, and the SQL Server databases are collocated on the SQL Server Express instance on the Standard Edition server		
Deploy Persistent Chat Server	Run the Lync Server setup on all the computers running Persistent Chat Server. The Persistent Chat Server setup is integrated into the Lync Server 2013 Deployment wizard that provides the following instructions: • Deploy local management store • Install Persistent Chat Server services • Request and assign certificates • Run and start the services	Any user who is a member of the local Administrators group.	Deploying Persistent Chat Server in the Deployment documentation
Create a Persistent Chat administrator	Add users to the CsPersistentChatAdministrator security group.	Any user who is a member of domain administrators.	Adding a Persistent Chat Administrator in the Deployment documentation
Configure Persistent Chat Server	Configure users: • User has to be enabled by policy to access Persistent Chat Server. By default, the policy is turned off for all users and can be defined at global/site/pool/user scopes. • Configure settings	User must be a member of CsPersistentChatAdministrator. To change policy, user must be in CsUserAdministrator, at a minimum.	Configuring Persistent Chat Server in the Deployment documentation

◆Important:

You can deploy one or more Persistent Chat Server pools. We support multiple Persistent Chat Server pools for regulatory reasons whereby data generated in a given region is required to stay in that region. For example, if you deploy a Persistent Chat Server pool in Chicago, and another in Zurich to comply with regulations for data in Switzerland, users can connect to rooms in both the Persistent Chat Server pools, provided they have access.

1.4.9.3 Technical Requirements for Persistent Chat Server

Technical Requirements for Persistent Chat Server

Microsoft Lync Server 2013 > Planning > Planning for Persistent Chat Server >

Topic Last Modified: *2013-01-06*

Each computer that hosts Persistent Chat Server must have access to an existing Lync Server 2013 topology with the following components:

- **Lync Server 2013, Front End Server.** The Front End Server is the foundation for Session Initiation Protocol (SIP) routing, which makes communication between computers running Persistent Chat Server and the Persistent Chat functionality possible. Before you begin to deploy Persistent Chat Server, verify the deployment of Lync Server 2013, Standard Edition, or a Lync Server Front End pool and any other internal computers running Lync Server, as appropriate to your organization.

The following sections describe the specific requirements for the Persistent Chat Server and the database that stores the Persistent Chat data.

Persistent Chat Server Requirements

For details about the recommended hardware for deploying Lync Server and the latest version of Persistent Chat Server, see Server Hardware Platforms in the Supportability documentation.

For details about the server and tools operating system support for Lync Server and Persistent Chat Server, see Server and Tools Operating System Support in the Supportability documentation.

For details about additional software required for deploying Persistent Chat Server, see the following table.

Persistent Chat Server Software Prerequisites

Software	Description
Message Queuing	Used by the Persistent Chat Server and Persistent Chat Compliance service, if deployed.

Persistent Chat Server Database Requirements

Persistent Chat Server uses the Persistent Chat database to store chat history, configuration, and user provisioning data. Optionally, it uses the Persistent Chat compliance database to store compliance data.

◆Important:

The Persistent Chat database (mgc) and the compliance database (mgccomp) can be located in the same instance of SQL Server or on different SQL Servers.

To prepare a database server platform, be sure that each computer meets the hardware requirements, and then install the prerequisite software.

The server platform for the Persistent Chat database servers requires the same hardware as the Lync Server back-end database server. For details, see Server Hardware Platforms in the Supportability documentation.

On the database server, be sure that one of the following software applications is installed:

- Microsoft SQL Server 2012. For details about how to install Microsoft SQL Server 2012, see "Install SQL Server 2012" at http://go.microsoft.com/fwlink/p/?LinkID=248559.
- Microsoft SQL Server 2008 R2. For details about how to install Microsoft SQL Server 2008 R2, see "SQL Server Installation (SQL Server 2008 R2)" at http://go.microsoft.com/fwlink/?LinkId=275702.

Persistent Chat Server Certificate Requirements

For details about acquiring certificates, creating the SQL Server database, and creating file stores, see Deploying Lync Server 2013 in the Deployment documentation.

1.4.9.4 Setting Up Systems and the Infrastructure for Persistent Chat Server

Setting Up Systems and the Infrastructure for Persistent Chat Server

Microsoft Lync Server 2013 > Planning > Planning for Persistent Chat Server >

Topic Last Modified: *2012-03-23*

Before deploying Lync Server 2013, Persistent Chat Server, you need to deploy the appropriate hardware and software for all Persistent Chat Server components.

In This Section

- Set Up System Platforms
- Install Lync Server 2013 Prerequisite Software

1.4.9.4.1 Set Up System Platforms

Set Up System Platforms

See Also

Deployment > Deploying Persistent Chat Server > Setting Up Systems and the Infrastructure for Persistent Chat Server >

Topic Last Modified: *2013-02-21*

Before starting the deployment of Persistent Chat Server, you must install the required operating system on hardware that meets system requirements on servers:

For details about supported hardware for servers running Lync Server 2013, database servers, and file servers, see Supported Hardware in the Supportability documentation. For details about supported operating systems and database software, see Server Software and Infrastructure Support in the Supportability documentation. For details about Windows update requirements, see Additional Server Support and Requirements in the Supportability documentation.

The Persistent Chat Server Front End Server, **PersistentChatService**, can be deployed on one or more stand-alone computers in a Lync Server 2013 Enterprise Edition pool. They cannot be collocated on the Lync Server Enterprise Edition Front End Servers. Persistent Chat Server can be deployed by the Bootstrapper, just like other Lync Server roles. The **Persistent Chat Web Services for File Upload/Download**, and **Persistent Chat Web Services for Chat Room Management** are web components deployed on the Lync Server 2013 Front End Servers.

A single Persistent Chat Server Front End Server can support 20,000 active users. You can have a Persistent Chat Server pool with up to 4 active front ends supporting a total of 80,000 concurrent users. The Persistent Chat Back End Server, **PersistentChatStore**, stores the chat rooms and categories. We recommend that you install the **PersistentChatStore** on a dedicated SQL Server Back End Server in your Enterprise Edition pool; although we support collocating Lync Server 2013 Back End Server and **PersistentChatStore** on the same SQL Server instance.

If your organization requires compliance support, you can install it by using Topology Builder. The Persistent Chat Server Compliance service is installed on the same computer as the Persistent Chat Server Front End Server. A separate database is required for compliance. For details about compliance requirements for Persistent Chat Server, see Planning for Persistent Chat Server in the Planning documentation.

At a minimum, each topology requires a server with Lync Server 2013 installed and a server with SQL Server database software installed. Topology Builder supports multiple Persistent Chat Server pools. Follow the same deployment instructions for deploying multiple Persistent Chat Server pools as you would for any pool from Deploying Lync Server 2013 in the Deployment documentation.

You can also deploy Persistent Chat Server with Lync Server 2013 Standard Edition. In this case, the **PersistentChatService** Front End Server is collocated on the Standard Edition server, and you can deploy the **PersistentChatStore** Back End Server on the local SQL Server Express instance.

Important:
We do not support Persistent Chat Server Standard Edition for high availability. Performance and scale will be limited. Furthermore, we support only new Persistent Chat Server Standard Edition server deployments. We do not support an upgrade of Lync Server 2010, Group Chat Server to a Lync Server 2013 Persistent Chat Server Standard Edition.

1.4.9.4.2 Install Lync Server 2013 Prerequisite Software

Install Lync Server 2013 Prerequisite Software

See Also

Deployment > Deploying Persistent Chat Server > Setting Up Systems and the Infrastructure for Persistent Chat Server >

Topic Last Modified: *2013-02-21*

The prerequisite software for Persistent Chat Server is the same as the prerequisite software for the Lync Server 2013 Front End Servers and the Lync Server 2013 Standard Edition server on which Persistent Chat Server features are installed.

The prerequisite software required for the Persistent Chat Server file store is the same as that for Lync Server 2013.

The prerequisite software for the SQL Server databases for Persistent Chat Server content and compliance is also the same as that for Lync Server 2013.

For details about all the software requirements for Lync Server 2013 servers, see Additional Server Support and Requirements in the Supportability documentation.

Additional Server Support and Requirements

1.4.9.5 Adding Persistent Chat Server to Your Deployment

Adding Persistent Chat Server to Your Deployment

Microsoft Lync Server 2013 > Deployment > Deploying Persistent Chat Server >

Topic Last Modified: *2012-09-12*

After you install the prerequisite software on each server on which you plan to deploy Lync Server 2013, Persistent Chat Server, you must use Topology Builder to add Persistent Chat Server support to your topology, and then publish the topology.

In This Section

- Add Persistent Chat Server to the Topology
- Publish the Updated Topology

1.4.9.5.1 Add Persistent Chat Server to the Topology

Add Persistent Chat Server to the Topology

Deployment > Deploying Persistent Chat Server > Adding Persistent Chat Server to Your Deployment >

Topic Last Modified: *2012-10-06*

You must incorporate Lync Server 2013, Persistent Chat Server support in your topology before you can configure your deployment to support Persistent Chat Server. The information in this topic describes how to use Topology Builder to add Persistent Chat Server support to your existing topology.

To add Persistent Chat Server to a topology

Perform the following steps for installing a single Persistent Chat Server pool without a disaster recovery configuration. For configuring a stretched Persistent Chat Server pool for high availability and disaster recovery, see Configuring Persistent Chat Server for High Availability and Disaster Recovery in the Deployment documentation.

To deploy multiple Persistent Chat Server pools, repeat the same process for each pool.

1. On a computer that is running Lync Server 2013 or on which the Lync Server administrative tools are installed, log on using an account that is a member of the local Users group (or an account with equivalent user rights).

   Note:
   You can define a topology by using an account that is a member of the local Users group, but to publish a topology, which is required to install a Lync Server 2013 server, you must use an account that is a member of the **Domain Admins** group and the **RTCUniversalServerAdmins** group, and that has full control permissions (that is, read, write, and modify) on the file store that you are going to use for the Persistent Chat Server file store (that is, so that Topology Builder can configure the required DACLs), or an account with equivalent rights.

2. Start Topology Builder.
3. In the console tree, navigate to the **Persistent Chat Pools** node and expand it to select a Persistent Chat Server pool, or right-click the node and select **New Persistent Chat Pool**. You must define the pool's fully qualified domain name (FQDN), and indicate whether the pool will be a single-server pool or multiple-server pool deployment.
   You can choose a **Multiple Computer Pool** or a **Single Computer Pool**. Choose the former if you are planning to have more than one Persistent Chat Server Front End Server in your Persistent Chat Server pool. Make this choice now, or at a later point, because after you create a single computer pool, you cannot add additional servers to it later. If you choose a multiple computer pool, enter the names of the individual Persistent Chat Server Front End Servers that comprise the pool.

   Important:
   If the Persistent Chat Server role is being installed on a Lync Server 2013 Standard Edition server, the FQDN needs to match the FQDN of the Standard Edition server.

4. Define a simple **Display Name** for the Persistent Chat Server pool. The display name can be used by custom clients, particularly when there are multiple Persistent Chat Server pools, to differentiate rooms.
5. Define the port used by the Persistent Chat Server to communicate with Lync Server Front End Servers. The default port is 5041.
6. If your organization requires compliance support, select the **Enable compliance** check box. If chosen, the Persistent Chat Server Compliance service is installed on the same computer as the Persistent Chat Server Front End Server. You are prompted to select a SQL Server Back End Server for Persistent Chat Server Compliance later.
7. Assign site affinity for the Persistent Chat Server pool. Select the **Use this pool as default for site <SiteName>** check box or **Use this pool as default for all sites** to designate this Persistent Chat Server pool as the default pool for the current site or all sites. When the Lync 2013 client is used to create and manage rooms, the default pool associated with the user's site is used by the room creation and management experience so that it can route room creation and management operations to that pool. This only applies when you have multiple Persistent Chat Server pools deployed, and want to use the room creation and management features of Persistent Chat Server.

   Important:
   You can customize the room creation and management features using the Persistent Chat Server Software Development Kit (SDK).
   For details about how to configure SQL Server backup databases for disaster recovery, see Configuring Persistent Chat Server for High Availability and Disaster Recovery in the Deployment documentation.

8. Define the **SQL store for the Persistent Chat Server Back End (where chat**

room content is stored) by doing one of the following:

- To use an existing SQL Server database, in the drop-down list, click the name of the SQL Server database that you want to use.
- To specify a new SQL Server database, click **New**, and in **Define New SQL Store**, perform the following:
- In **SQL Server FQDN**, specify the FQDN of the SQL Server on which you want to create the new SQL Server database.
- Either select **Default Instance** to use the default instance or, to specify a different instance, select **Named Instance**, and specify the instance that you want to use.

9. Define the SQL Server compliance database if you enabled Compliance.

> **Important:**
> For details about how to configure SQL Server mirrors for high availability for the Persistent Chat Server database and the Persistent Chat Server compliance database, see Configuring Persistent Chat Server for High Availability and Disaster Recovery in the Deployment documentation.

10. Define the file store. A file store is a folder where a copy of any file uploaded to the file repository is stored (for example, storing file attachments posted to a chat room). In the case of a multiple-server Persistent Chat Server topology, this must be a Universal Naming Convention (UNC) path; and for a single-server Persistent Chat Server topology, it can be a local file path.
    To use an existing file store, perform the following steps:
    - In **File Server FQDN**, specify the FQDN of the file store on which you want to create the new file store.
    - In **File Share**, specify the file store that you want to use.

> **Important:**
> You can define the file store in Topology Builder before you create the file store, but you must create the file store in the defined location you define before you publish the topology.

11. Select the Front End Server pool to be used as a next hop for this Persistent Chat Server pool. This is the Front End Server pool that will be able to route Persistent Chat Server requests to this pool.
12. To save the configuration, click **Finish**. The Persistent Chat Server pool appears in Topology Builder accompanied by your specific pool settings.
    To now publish your updated topology to which you've Persistent Chat Server, see Publish the Updated Topology in the Deployment documentation.

> **Note:**
> With Topology Builder already open, you can proceed to step 3 in Publish the Updated Topology to begin publishing your updated topology.

1.4.9.5.2 Publish the Updated Topology

Publish the Updated Topology

Deployment > Deploying Persistent Chat Server > Adding Persistent Chat Server to Your Deployment >

Topic Last Modified: *2012-10-01*

After updating your topology in Topology Builder, you must publish the topology to the Central Management store before you can configure and use Persistent Chat Server. Read-only copies of the data are replicated to all servers in the topology to keep all servers in sync with topology and other configuration changes.

To publish an updated topology

Before you publish your topology, install the databases for Persistent Chat Server. Use Topology Builder to install databases by selecting **Action** and **Install Database**.

1. On a computer that is running Lync Server 2013 or on which the Lync Server administrative tools are installed, log on using an account that is a member of both the **Domain Admins** group and the **RTCUniversalServerAdmins** group, and that has full control permissions (that is, read, write, and modify) on the file store to be used for the Persistent Chat Server file store (so that Topology Builder can configure the required discretionary access control lists (DACLs)), or an account with equivalent user rights.
2. Start Topology Builder. Select **Download Topology from existing deployment**, or **Open Topology from a local file** if you saved it locally.
3. In the console tree, right-click **Lync Server 2013**, and then click **Publish Topology**.
4. On the **Publish the topology** page, click **Next**.
5. On the **Publishing wizard complete** page, verify that the topology was successfully published, and then click **Finish**.

Important:

After publishing the topology, you must configure support for Persistent Chat Server before any content can be archived.

1.4.9.6 Installing Persistent Chat Server

Installing Persistent Chat Server

Microsoft Lync Server 2013 > Deployment > Deploying Persistent Chat Server >

Topic Last Modified: *2012-10-01*

Installing Persistent Chat Server is integrated into Lync Server 2013 setup and uses the same Bootstrapper that Lync Server 2013 uses for installation. For installation instructions, see Deploying Lync Server 2013 in the Deployment documentation.

1.4.9.7 Adding a Persistent Chat Administrator

Adding a Persistent Chat Administrator

Microsoft Lync Server 2013 > Deployment > Deploying Persistent Chat Server >

Topic Last Modified: *2012-10-06*

In Lync Server 2013, users who perform specific tasks must be assigned as members of one or more specific groups. Role-based access control (RBAC) can also be used to grant privileges by assigning users to predefined Lync Server 2013 administrative roles.

Before configuring and administering Persistent Chat Server, be sure that the appropriate user rights and permissions are in place, and that any users to be classified as Persistent Chat administrators are added to the CsPersistentChatAdministrator security group.

1.4.9.8 Configuring Persistent Chat Server

Configuring Persistent Chat Server

Microsoft Lync Server 2013 > Deployment > Deploying Persistent Chat Server >

Topic Last Modified: *2012-04-12*

After deploying support for Lync Server 2013, Persistent Chat Server in Topology Builder, you use the Lync Server 2013 Control Panel to configure how Persistent Chat Server is implemented in your deployment.

In This Section

- Enable Persistent Chat Server Policy
- Configure Persistent Chat Server Options Globally or for Persistent Chat Server Pool
- Configure Categories
- Configure Rooms
- Configure Add-ins for Rooms

1.4.9.8.1 Enable Persistent Chat Server Policy

Enable Persistent Chat Server Policy

Deployment > Deploying Persistent Chat Server > Configuring Persistent Chat Server >

Topic Last Modified: *2012-10-06*

In the Lync Server 2013 Control Panel, you can use the **Persistent Chat Policy** page of the **Persistent Chat** group to manage policies at a global, pool, site, or user level, including configuring the default global policy and creating one or more additional user and site policies for your deployment. If a user is enabled for Persistent Chat Server by policy, then the Persistent Chat Server environment appears in their Lync 2013 client.

Note:

In the topology, Persistent Chat Server site policies apply globally, per user’s pool, or per user’s site, or per user.

The global policy is created automatically when you deploy Persistent Chat Server, and it can be configured, but not deleted. Because the global policy applies to all users, it doesn’t have to be set per user.

You can create and configure multiple site and user policies which, together with the global policy, enable users for Persistent Chat Server. Pool and site Persistent Chat Server policies override the global Persistent Chat Server policy, but only for users of that site. User policies override both global, pool, and site policies for the users to whom the user policy is assigned.

Note:

To configure and use Persistent Chat Server, you must first use Topology Builder to add Persistent Chat Server support to the topology, and then publish the topology. For details, see Adding Persistent Chat Server to Your Deployment in the Deployment documentation.

In This Section

- Configure the Global Policy for Persistent Chat
- Create a Site Policy for Persistent Chat
- Create a User Policy for Persistent Chat
- Apply a Persistent Chat Policy to a User or User Group

1.4.9.8.1.1 Configure the Global Policy for Persistent Chat

Configure the Global Policy for Persistent Chat

Deploying Persistent Chat Server > Configuring Persistent Chat Server > Enable Persistent Chat Server Policy >

Topic Last Modified: *2012-10-06*

You can use the default global policy by itself to enable Persistent Chat settings for all users in your deployment. You can also specify additional policies for sites and users to control whether Persistent Chat is enabled or disabled for specific users and sites.

You cannot delete the global policy. If you attempt to delete it, the configuration resets to the default values.

Note:

To configure and use Persistent Chat Server, you must first use Topology Builder to add Persistent Chat Server support to the topology, and then publish the topology. For details, see Adding Persistent Chat Server to Your Deployment in the Deployment documentation.
To configure Persistent Chat Server configuration settings, see Configure Persistent Chat Server Options Globally or for Persistent Chat Server Pool in the Deployment documentation.

To configure the Global Policy for Persistent Chat

1. From a user account that is assigned to the CsPersistentChatAdministrator, CsAdministrator, or CsUserAdministrator role, log on to any computer in your internal deployment.
2. From the **Start** menu, select the Lync Server Control Panel or open a browser window, and then enter the Admin URL. For details about the different methods that you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools in the Operations documentation.

   Important:

   You can also use Windows PowerShell cmdlets. For details, see Configuring Persistent Chat Server by Using Windows PowerShell Cmdlets in Deployment documentation.

3. In Lync Server Control Panel, click **Persistent Chat**, and then click **Persistent Chat Policy**.
4. Click **Global** in the list of policies, click **Edit**, and then click **Show details**.
5. In **Edit Persistent Chat Policy - Global**, do the following:
   - In **Name**, specify a new name for the global policy, if you do not want to use the default of Global.
   - In **Description**, provide details about what the user policy is (for example, Global policy for *centralSiteName*).
   - To control Persistent Chat for all sites and users not specifically controlled through a site policy or user policy, select or clear the **Enable Persistent Chat** check box.

6. Click **Commit**.

Create a Site Policy for Persistent Chat

Deploying Persistent Chat Server > Configuring Persistent Chat Server > Enable Persistent Chat Server Policy >

Topic Last Modified: *2012-10-06*

For each site you have deployed, you can create a site-specific Persistent Chat policy.

The configuration in the site policy overrides the global policy, but only for the specific site covered by the site policy.

Note:

To configure and use Persistent Chat Server, you must first use Topology Builder to add Persistent Chat Server support to the topology, and then publish the topology. For details, see Adding Persistent Chat Server to Your Deployment in the Deployment documentation.
To configure Persistent Chat Server configuration settings, see Configure Persistent Chat Server Options Globally or for Persistent Chat Server Pool in the Deployment documentation.

To create a Persistent Chat policy for a site

1. From a user account that is assigned to the CsPersistentChatAdministrator, CsAdministrator, or CsUserAdministrator role, log on to any computer in your internal deployment.
2. From the **Start** menu, select the Lync Server Control Panel or open a browser window, and then enter the Admin URL. For details about the different methods that you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Persistent Chat**, and then click **Persistent Chat Policy**.

   Important:

   You can also use Windows PowerShell cmdlets. For details, see Configuring Persistent Chat Server by Using Windows PowerShell Cmdlets in the Deployment documentation.
4. Click **New**, and then click **Site policy**.
5. In **Select a Site**, click the site to which the policy is to be applied.
6. In **New Persistent Chat Policy**, do the following:
   - In **Name**, specify a name for the new site policy (for example, Redmond).
   - In **Description**, provide details about what the site policy is (for example, chat room policy for Redmond).
   - To control Persistent Chat for all sites not specifically controlled through a site policy, select or clear the **Enable Persistent Chat** check box.
7. Click **Commit**.

1.4.9.8.1.3 Create a User Policy for Persistent Chat

Create a User Policy for Persistent Chat

Deploying Persistent Chat Server > Configuring Persistent Chat Server > Enable Persistent Chat Server Policy >

Topic Last Modified: *2012-10-06*

In the Lync Server Control Panel, you define user policies that can be assigned to users in **Users**.

The user policy overrides the global policy and site policies, but only for the specific users who are assigned the user policy.

> **Note:**
>
> To configure and use Persistent Chat Server, you must first use Topology Builder to add Persistent Chat Server support to the topology, and then publish the topology. For details, see Adding Persistent Chat Server to Your Deployment in the Deployment documentation.
> To configure Persistent Chat Server configuration settings, see Configure Persistent Chat Server Options Globally or for Persistent Chat Server Pool in the Deployment documentation.

To create a user policy for Persistent Chat

1. From a user account that is assigned to the CsPersistentChatAdministrator, CsAdministrator, or CsUserAdministrator role, log on to any computer in your internal deployment.
2. From the **Start** menu, select the Lync Server Control Panel or open a browser window, and then enter the Admin URL. For details about the different methods that you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.

   > **Important:**
   >
   > You can also use Windows PowerShell cmdlets. See Configuring Persistent Chat Server by Using Windows PowerShell Cmdlets in the Deployment documentation.

3. In the left navigation bar, click **Persistent Chat**, and then click **Persistent Chat Policy**.
4. Click **New**, and then click **User policy**.
5. In **New Persistent Chat Policy**, do the following:
   - In **Name**, specify a name for the new user policy.
   - In **Description**, provide details about what the user policy is (for example, Persistent Chat policy for specific user).
   - To control Persistent Chat for all users who are not specifically controlled through a user policy, select or clear the **Enable Persistent Chat** check box.

6. Click **Commit**.

1.4.9.8.1.4 Apply a Persistent Chat Policy to a User or User Group

Apply a Persistent Chat Policy to a User or User Group

Deploying Persistent Chat Server > Configuring Persistent Chat Server > Enable Persistent Chat Server Policy >

Topic Last Modified: *2012-10-06*

If a user has been enabled for Lync Server 2013, you can apply appropriate policies to specific users to enable or disable them for Persistent Chat Server.

Note:

To configure and use Persistent Chat Server, you must first use Topology Builder to add Persistent Chat Server support to the topology, and then publish the topology. For details, see Adding Persistent Chat Server to Your Deployment in the Deployment documentation.
To configure Persistent Chat Server configuration settings, see Configure Persistent Chat Server Options Globally or for Persistent Chat Server Pool in the Deployment documentation.

Use the procedure in this topic to apply a previously created Persistent Chat user policy to one or more user accounts or user groups.

To apply a Persistent Chat user policy to a user account

1. From a user account that is assigned to the CsPersistentChatAdministrator, CsAdministrator, or CsUserAdministrator role, log on to any computer in your internal deployment.
2. From the **Start** menu, select the Lync Server Control Panel or open a browser window, and then enter the Admin URL. For details about the different methods that you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Users**, and then search on the user account that you want to configure.
4. In the table that lists the search results, click the user account, click **Edit**, and then click **Show details**.
5. In **Edit Lync Server User** under **Persistent Chat policy**, select the Persistent Chat user policy that you want to apply.

   Note:

   The **<Automatic>** settings apply the default effective policy. These settings are applied automatically by the server.

6. Click **Commit**.

1.4.9.8.2 Configure Persistent Chat Server Options Globally or for Persistent Chat Server Pool

Configure Persistent Chat Server Options Globally or for Persistent Chat Server Pool

Deployment > Deploying Persistent Chat Server > Configuring Persistent Chat Server >

Topic Last Modified: *2012-10-06*

In Lync Server 2013 Control Panel, you can use the **Persistent Chat Configuration** section of the **Persistent Chat** page to configure Persistent Chat settings globally where it applies to all Persistent Chat Server pools, or for a specific Persistent Chat Server pool.

Note:

To configure and use Persistent Chat Server, you must first use Topology Builder to add

> Persistent Chat Server support to the topology, and then publish the topology. For details, see Adding Persistent Chat Server to Your Deployment in the Deployment documentation.

To configure Persistent Chat options globally

1. From a user account that is assigned to the CsPersistentChatAdministrator or CsAdministrator role, log on to any computer in your internal deployment.
2. From the **Start** menu, select the Lync Server Control Panel or open a browser window, and then enter the Admin URL. For details about the different methods that you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.

   > **Important:**
   >
   > You can also use Windows PowerShell cmdlets. For details, see Configuring Persistent Chat Server by Using Windows PowerShell Cmdlets in the Deployment documentation.

3. In the left navigation bar, click **Persistent Chat**, and then click **Persistent Chat Configuration**.
4. On the **Persistent Chat Configuration** page, click **New,** and then click **Site configuration**.

   > **Important:**
   >
   > Choose this option if you want the configuration to be applied to all Persistent Chat Server pools deployed in the site. Click **Pool Configuration** if you want the configuration to be applied to a specific Persistent Chat Server pool.

5. In **Select a Site**, select the site to be configured for the Persistent Chat Server site configuration.
6. In **New Persistent Chat Configuration**, do the following:
   - In **Name**, specify a name for the new configuration settings. By default, the site name already exists.
   - In **Default chat history**, define the number of chat messages that will be processed for each room upon first request. By default, the number is 30. This is the global default, and administrators can disable chat history per category.

     > **Important:**
     >
     > Persistent Chat Server will cache these messages in memory, so if you increase this number, more messages will be cached. You can always access historical content by search. The default number simply determines the maximum number of messages that you initially see when connecting to a chat room.

   - In **Maximum file size (KB)**, select the maximum file size of each chat history. By default, the number is 20 MB (20,000 KB). This is the maximum size for a file that can be uploaded to any chat room in the system (for which file uploads are enabled by its corresponding **Category** setting).

     > **Important:**
     >
     > This setting is enforced on the server because custom applications or previous Group Chat clients using Office Communications Server 2007 R2 Group Chat Server or Lync Server 2010, Group Chat can post files to a room. The Lync 2013 client does not have file upload/download capability, so if you have a pure Lync 2013 deployment or Lync 2013 client, it is not possible to post files in a Persistent Chat Server chat room.

   - In **Participant update limit**, select the limit for participant updates.

Persistent Chat Server sends roster information (who is connected to a chat room) to all participants until the number of connected users reaches this number. By default, the number is 75. This limit indicates the maximum number of participants in a given room beyond which Persistent Chat Server stops sending roster updates to connected clients about who is present in the room.

- (Optional.) In **Room management URL**, select the room management URL. This is the URL for a web-based custom room management. If you don't need to customize room management, and you simply use the default setting, leave this option blank. After the URL is set, it is applied as both the internal and external room management URL.

  If you want to customize your room creation experience and include your specific business workflow, you can build a custom room management solution by using the Persistent Chat Server Software Development Kit (SDK), host it somewhere, and put the URL here. This URL is sent down to the client, so that when a user tries to view or create a room, he or she is directed to your custom room management solution.

7. Click **Commit**.

To configure Persistent Chat options for a specific Persistent Chat Server pool

1. From a user account that is assigned to the CsPersistentChatAdministrator or CsAdministrator role, log on to any computer in your internal deployment.
2. From the **Start** menu, select the Lync Server Control Panel, or open a browser window, and then enter the Admin URL. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.

> **Important:**
> You can also use Windows PowerShell cmdlets. For details, see Configuring Persistent Chat Server by Using Windows PowerShell Cmdlets in the Deployment documentation.

3. In the left navigation bar, click **Persistent Chat**, and then click **Persistent Chat Configuration**.
4. On the **Persistent Chat Configuration** page, click **New**, and then click **Pool configuration**.
5. In **Select a Service**, select the service associated with the Persistent Chat Server pool to be configured.
6. In **New Persistent Chat Configuration**, do the following:

- In **Name**, specify a name for the new configuration settings. By default, the site pool name already exists.
- In **Default chat history**, define the number of chat messages that will be processed for each room upon first request. By default, the number is 30. This is the global default, and administrators can disable chat history per category.

> **Important:**
> Persistent Chat Server will cache these messages in memory, so if you increase this number, more messages will be cached. You can always access historical content by search. The default number simply determines the maximum number of messages that you initially see when connecting to a chat room.

- In **Maximum file size (KB)**, select the maximum file size of each chat history. By default, the number is 20 MB (20,000 KB). This is the maximum size for a file that can be uploaded to any chat room in the system (for which file uploads are enabled by its corresponding **Category** setting).

Important:
This setting is enforced on the server because custom applications or previous Group Chat clients (Office Communications Server 2007 R2 Group Chat Server or Lync Server 2010, Group Chat) can post files to a room. The Lync 2013 client does not have file upload/download capability, so if you have a pure Lync 2013 deployment or Lync 2013 client, it is not possible to post files in a Persistent Chat Server chat room.

- In **Participant update limit**, select the limit for participant updates. Persistent Chat Server sends roster information (who is connected to a chat room) to all participants until the number of connected users reaches this number. By default, the number is 75. This limit indicates the maximum number of participants in a given room beyond which Persistent Chat Server stops sending roster updates to connected clients about who is present in the room.
- In **Room management URL**, select the room management URL. This is the URL for a web-based room management deployment. If you don’t need to customize room management, and you simply use the default setting, leave this option blank.

  If you want to customize your room creation experience and include your specific business workflow, you can build a custom room management solution by using the Persistent Chat Server Software Development Kit (SDK), host it somewhere, and put the URL here. This URL is sent down to the client so that when a user tries to view/create a room, he or she is directed to your custom room management solution.

7. Click **Commit**.

1.4.9.8.3 Configure Categories

Configure Categories

Deployment > Deploying Persistent Chat Server > Configuring Persistent Chat Server >

Topic Last Modified: *2012-10-06*

In Lync Server 2013 Control Panel, you can use the **Category** section of the **Persistent Chat** page to configure categories. A Persistent Chat room category is a logical structure for organizing chat rooms. A category defines a default set of access control lists (ACLs) for controlling the users and user groups who may create or join the chat rooms. You can use categories enforce ethical walls between different subdivisions within their organizations.

Chat room categories may contain chat rooms, but not other categories. Each category describes its contents with metadata, such as *Name* and *Description*. In addition, the category has properties which can be set to control the behavior of the chat rooms belonging to it, such as if the chat rooms allow *Invitations* or *File Uploads*, or contain *Chat History*.

To configure categories for chat rooms

1. From a user account that is assigned to the CsPersistentChatAdministrator or CsAdministrator role, log on to any computer in your internal deployment.
2. From the **Start** menu, select the Lync Server Control Panel or open a browser window, and then enter the Admin URL. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.

Important:
You can also use Windows PowerShell cmdlets. For details, see Configuring Persistent Chat Server by Using Windows PowerShell Cmdlets in the Deployment documentation.

3. In the left navigation bar, click **Persistent Chat**, and then click **Category**. For multiple Persistent Chat Server pool deployments, select the appropriate pool from the drop-down list.
4. On the **Category** page, click **New** or **Edit**.
5. In **Select a Service**, select the service corresponding to the Persistent Chat Server pool on which the category needs to be created. The service is the Persistent Chat Server pool that the Persistent Chat (client) uses to identify which pool the category belongs to. A category can belong to only one Persistent Chat Server pool, and cannot be moved to another one, or shared with another pool.
6. In **New Category**, do the following:
   6.a. In **Name**, specify a name for the new room category.
   6.b. In **Description**, provide a detailed description for the room category (for example, a room category for Contoso).
   6.c. To control whether invitations can be enabled for chat rooms that belong to this category, select or clear the **Enable invitations** check box. If selected, rooms in this category may have invitations on or off; if cleared, the rooms in this category are not allowed to have invitations. If a room has invitations on, when a new member is added to a room, he or she gets a notification of the new room in their Persistent Chat client.
   6.d. To control file uploads in chat rooms belonging to this category, select or clear the **Enable file upload** check box. If selected, the rooms of this category can enable or disable file uploads; if cleared, the rooms of this category are not allowed to have file uploads.

   Important:
   This setting is enforced on the server because custom applications or previous Group Chat clients that use Office Communications Server 2007 R2 Group Chat Server or Lync Server 2010, Group Chat can post files to a room. The Lync 2013 client does not have file upload/download capability, so if you have a pure Lync 2013 deployment or Lync 2013 client, it is not possible to post files in a Persistent Chat Server chat room.

   6.e. To control chat history, select or clear the **Enable chat history** check box. If selected, room chats become persistent; otherwise, chat messages are not persisted. If compliance is enabled, room chats will be saved in compliance, but users will not be able to access older messages. This option can be used for rooms designated for real-time, ad hoc collaborations that don't need chat history to be persisted.
7. In **Edit Category**, do the following:
   7.a. In **Membership**, in the **Allowed members** section, add or remove users and other Active Directory Domain Services (AD DS) principals (users, distribution groups, organizational units, and so on) that are permitted to be added as members of chat rooms belonging to the category. Principals permitted by a category can search for the rooms in the category (unless the room is hidden, in which case only members of the room can search for it in the directory).
   7.b. In **Membership**, in the **Denied members** section, add or remove users and other Active Directory principals associated with members being denied from the room.
   7.c. In **Membership**, in the **Creators** section, add or remove users and other Active Directory principals associated with creators for the category. A creator is a user who has permissions to create chat rooms and assign chat room managers and members.

8. Click **Commit**.

1.4.9.8.4 Configure Rooms

Configure Rooms

Deployment > Deploying Persistent Chat Server > Configuring Persistent Chat Server >

Topic Last Modified: *2012-10-06*

Configuring Persistent Chat rooms is commonly handled by users or other central teams by using Windows PowerShell command-line interface; an administrator typically does not manage chat rooms. However, if you have to create and manage chat rooms, you can use the Windows PowerShell command-line interface, or add yourself as a member to a chat room and use the Lync 2013 client.

For details about configuring chat rooms by using the Windows PowerShell command-line interface, see "Room Management" in Configuring Persistent Chat Server by Using Windows PowerShell Cmdlets.

Managing Data in Chat Rooms

Persistent Chat Server lets users collaborate by posting messages into Persistent Chat rooms. The data is persisted on the server, and members of the room can have access to the data, including historical data. However, users with different roles have different access to the persisted data, as outlined in the following list.

- Administrators can delete earlier content (for example, content that was posted before a certain date) from any chat room to keep the database from growing too large. Or, they can remove or replace messages that are considered inappropriate for a particular chat room.
- End users, including message authors, cannot delete content from any chat room.
- Chat room managers can disable rooms, but cannot delete rooms. Only administrators can delete a chat room after it has been created.

When a message is deleted, you cannot undo the action. However, deleted messages can be restored if there is a backup. If a Persistent Chat Compliance server is enabled, old messages are persisted in the compliance database.

> **Note:**
>
> This chat room data usage applies to the Lync Server 2013, Persistent Chat Server API application, except for the case when the administrator role is involved. The Persistent Chat Server API cannot be used to do any of the administrator’s operations. You must perform these operations in the Lync Server Management Shell.

1.4.9.8.5 Configure Add-ins for Rooms

Configure Add-ins for Rooms

See Also

Deployment > Deploying Persistent Chat Server > Configuring Persistent Chat Server >

Topic Last Modified: *2013-02-21*

In Lync Server 2013 Control Panel, you can use the **Add-in** section of the **Persistent Chat** page to associate URLs with Persistent Chat rooms. These URLs appear in the Lync 2013 client in the chat room in the conversation extensibility pane. An administrator must add Add-ins to the list of registered add-ins, and chat room managers/Creators have to associate rooms with one of the registered add-ins before users can see this upgrade in their Lync 2013 client.

Add-ins are used to extend the in-room experience. A typical add-in might include a URL pointing to a Silverlight application that intercepts when a stock ticker is posted to a chat room, and shows the stock history in the extensibility pane. Other examples include embedding a OneNote 2013 URL in the chat room as an add-in to include some shared context, such as "Top of mind" or "Topic of the day."

To configure Add-ins for chat rooms

1. From a user account that is assigned to the CsPersistentChatAdministrator or CsAdministrator role, log on to any computer in your internal deployment.
2. From the **Start** menu, select the Lync Server Control Panel or open a browser window, and then enter the Admin URL. For details about the different methods that you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.

Important:
You can also use Windows PowerShell cmdlets. For details, see Configuring Persistent Chat Server by Using Windows PowerShell Cmdlets in the Deployment documentation.

3. In the left navigation bar, click **Persistent Chat**, and then click **Add-in**. For multiple Persistent Chat Server pool deployments, select the appropriate pool from the drop-down list.
4. On the **Add-in** page, click **New**.
5. In **Select a Service**, select the service corresponding to the Persistent Chat Server pool where you need to create the Add-in. Add-ins cannot be moved from one pool to another or shared between different pools.
6. In **New Add-in**, do the following:
   - In **Name**, specify a name for the new add-in.
   - In **URL**, specify the URL to be associated with the add-in. URLs are limited to http and https protocols.
7. Click **Commit**.

Configuring Persistent Chat Server by Using Windows PowerShell Cmdlets

1.4.9.9 Configuring Persistent Chat Server by Using Windows PowerShell Cmdlets

Configuring Persistent Chat Server by Using Windows PowerShell Cmdlets

Microsoft Lync Server 2013 > Deployment > Deploying Persistent Chat Server >

Topic Last Modified: *2012-10-06*

Use the following Windows PowerShell cmdlets to configure management within Lync Server 2013, Persistent Chat Server.

In This Section

- Manage Categories
- Manage Rooms

- Manage Add-ins
- Remove a Message
- Test Persistent Chat Server with a Synthetic Transaction
- Run Backward Compatibility for Persistent Chat Server
- Run, Grant, Get, Remove, or Set Persistent Chat Policy
- Configure Persistent Chat Server
- Get Persistent Chat Server Pool Availability
- Persistent Chat Compliance

1.4.9.9.1 Manage Categories

Manage Categories

Deployment > Deploying Persistent Chat Server > Configuring Persistent Chat Server by Using Windows PowerShell Cmdlets >

Topic Last Modified: *2012-10-06*

To create a new Persistent Chat Server Category

```
New-CsPersistentChatCategory -Name Foo -PersistentChatPoolFqdn client.contoso1b11
```

◆Important:

PersistentChatPoolFqdn is needed only if there is more than one Persistent Chat Server pool.

To make changes to existing Persistent Chat Server Category

```
Set-CsPersistentChatCategory -Identity testCat -AllowedMembers @{Add="sip:user1@c
Set-CsPersistentChatCategory -Identity testCat -Creators @{Add="sip:user1@contoso
```

Windows PowerShell: AllowedMembers, DeniedMembers, and Creators can be set simultaneously. Creators should be the subset of AllowedMembers minus DeniedMembers. You can also set the properties of a category at the same time as the members and creators.

Create, Get, Set, or Remove a Category

To create a new Category

```
New-CsPersistentChatCategory -Name <String> [-PersistentChatPoolFqdn <String>] [-
```

To get a Category

```
Get-CsPersistentChatCategory -Identity <String>
```

or

```
Get-CsPersistentChatCategory -PersistentChatPoolFqdn <String>
```

To set a Category

```
Set-CsPersistentChatCategory -Instance <CategoryObject> [-WhatIf] [-Confirm] [<Co
```

or

```
Set-CsPersistentChatCategory [-Identity] <string> [-Name <string>] [-Description
```

To remove a Category

```
Remove-CsPersistentChatCategory -Instance <CategoryObject> [-Force <Switch Parame
```

or

```
Remove-CsPersistentChatCategory -Identity <String> [-Force <Switch Parameter>] [-
```

1.4.9.9.2 Manage Rooms

Manage Rooms

Deployment > Deploying Persistent Chat Server > Configuring Persistent Chat Server by Using Windows PowerShell Cmdlets >

Topic Last Modified: *2013-02-21*

To create a new Persistent Chat Server room

```
New-CsPersistentChatRoom -Name Foo1 -PersistentChatPoolFqdn client.contoso.com -C
```

Important:

-PersistentChatPoolFqdn is not needed if one of the following is true:

- There is only one Persistent Chat Server pool.
- You provide a pool FQDN to the category.
- You provide a pool FQDN to adding the room.

To make changes to an existing Persistent Chat Server room

```
Set-CsPersistentChatRoom -Identity testCat -Members @{Add="sip:user1@contoso.com"
Set-CsPersistentChatRoom -Identity testCat -Managers @{Add="sip:user2@contoso.com
Set-CsPersistentChatRoom -Identity testCat -Presenters @{Add="sip:user1@contoso.c
```

Windows PowerShell: Members, Managers and Presenters can be set simultaneously. They all should be the subset of AllowedMembers minus DeniedMembers of the host Category. A room that is type=normal cannot include Presenters.

Create, Get, Set, Clear, or Remove a Room

To create a new room

```
New-CsPersistentChatRoom -Name <String> [-PersistentChatPoolFqdn <String>]-Catego
```

To set a room

```
Set-CsPersistentChatRoom -Identity <String> [-Name <String>] [-Category <String>]
```

To get a room

```
Get-CsPersistentChatRoom -Identity <String>
```

or

```
Get-CsPersistentChatRoom -filter <String> [-PersistentChatPoolFqdn <String>] [-Se
```

where –filter supports only Name and Description and helps you find rooms whose Name/ Description matches the keyword string. PoolFqdn searches in a given Persistent Chat Server pool.

To clear a room and clear messages from a room

```
Clear-CsPersistentChatRoom [-Identity] <string> -EndDate <DateTime> [-WhatIf] [-C
```

or

```
Clear-CsPersistentChatRoom [-Instance] <ChatRoomObject> -EndDate <DateTime> [-Wha
```

To remove a room

```
Remove-CsPersistentChatRoom [-Identity] <string> [-Force] [-WhatIf] [-Confirm]  [
```

or

```
Remove-CsPersistentChatRoom [-Instance] <ChatRoomObject> [-Force] [-WhatIf] [-Con
```

1.4.9.9.3 Manage Add-ins

Manage Add-ins

Deployment > Deploying Persistent Chat Server > Configuring Persistent Chat Server by Using Windows PowerShell Cmdlets >

Topic Last Modified: *2012-10-06*

To create a new Persistent Chat Server Add-in

```
New-CsPersistentChatAddin -Name Contoso -PersistentChatPoolFqdn client.contoso.co
```

Create, Get, Set, or Remove an Add-in

To create a new Add-in

```
New-CsPersistentChatAddin -PersistentChatPoolFqdn <String> -Name <String> -Url<St
```

Important:

PersistentChatPoolFqdn <String> is required only if there is more than one Persistent Chat Server pool.

To get an Add-in

```
Get-CsPersistentChatAddin -Identity <String>]
```

or

```
Get-CsPersistentChatAddin -PersistentChatPoolFqdn <String>
```

To set an Add-in

```
Set-CsPersistentChatAddIn -Instance <AddinObject> [-Force <Switch Parameter>] [-C
```

or

```
Set-CsPersistentChatAddIn -Identity <String> [-Name <String>] [-Url<String>] [-Fo
```

To remove an Add-in

```
Remove-CsPersistentChatAddIn -Instance <AddinObject> [-Force <Switch Parameter>]
```

or

```
Remove-CsPersistentChatAddIn -Identity <String> [-Force <Switch Parameter>] [-Con
```

1.4.9.9.4 Remove a Message

Remove a Message

Deployment > Deploying Persistent Chat Server > Configuring Persistent Chat Server by Using Windows PowerShell Cmdlets >

Topic Last Modified: *2012-04-04*

To remove a message

```
Remove-CsPersistentChatMessage -Identity <string> [-UserUri <string>] [-StartDate
```

1.4.9.9.5 Test Persistent Chat Server with a Synthetic Transaction

Test Persistent Chat Server with a Synthetic Transaction

Deployment > Deploying Persistent Chat Server > Configuring Persistent Chat Server by Using Windows PowerShell Cmdlets >

Topic Last Modified: *2012-09-21*

To test Persistent Chat Server for sending and receiving messages in a chat room between two users

```
Test-CsPersistentChatMessage [-Authentication <TrustedServer | Negotiate | Client
    LiveID>] [-ReceiverSipAddress <String>] [-RegistrarPort <Int32>] [-SenderSipA
    [-OutVerboseVariable <String>] [<CommonParameters>]
```

or

```
Test-CsPersistentChatMessage [-Authentication <TrustedServer | Negotiate | Client
    LiveID>] -ReceiverCredential <PSCredential> -ReceiverSipAddress <String> [-Re
    <Int32>] -SenderCredential <PSCredential> -SenderSipAddress <String> [-Target
```

or

```
Test-CsPersistentChatMessage [-Authentication <TrustedServer | Negotiate | Client
    LiveID>] [-Force <SwitchParameter>] [-OutLoggerVariable <String>] [-OutVerbos
    <String>] [<CommonParameters>]
```

1.4.9.9.6 Run Backward Compatibility for Persistent Chat Server

Run Backward Compatibility for Persistent Chat Server

Topic Last Modified: *2013-02-21*

The Lync Server 2013, Persistent Chat Server endpoint provides a way to create a simple URL that points to a Persistent Chat Server pool. This is useful for legacy clients (Microsoft Office Communications Server 2007 R2 Group Chat Server or Lync Server 2010, Group Chat) because users can enter a simple URL in the manual configuration when trying to point the legacy client to a computer running Lync 2013, Persistent Chat. This endpoint isn’t used by Persistent Chat, and is required for legacy clients only. This is useful for the interim period where rooms may be migrated, but the Lync 2013 clients have not been deployed throughout the organization. Users running Lync 2010 Group Chat (client) can then still connect to the Persistent Chat Server Back End Server.

You don’t need to create multiple Persistent Chat Server endpoints; you just need one for each Persistent Chat Server pool. Administrators can create multiple endpoints (one per pool), but legacy clients can be configured to connect to only one pool at a time. In the usual or mainstream scenario, the legacy deployment is one pool only. A new deployment generally migrates that pool to a new Lync Server 2013 and might add some new additional Persistent Chat Server pools.

This mainstream scenario generally follows this pattern:

- You administer users with one Lync Server 2010, Group Chat pool, and your Lync 2010 Group Chat clients connect to that pool by using some well-known user (either default sip:ocschat@<*domainName*>.com, or a similar one). The users are SIP-enabled Active Directory Domain Services (AD DS), and the Lookup service registers with them to receive incoming requests.
- Subsequently, you install a Lync Server 2013 Persistent Chat Server and Persistent Chat Server pool.
- During a time when users are generally offline (for example, a weekend):
  - Turn off Lync Server 2010, Group Chat.
  - Migrate data from the Lync Server 2010, Group Chat pool to the Lync Server 2013 Persistent Chat Server pool.
  - Delete the well-known user from the Active Directory Domain Services (AD DS).
  - Create a new *legacy endpoint* with the same SIP URI as the previously deleted well-known user.
  - Start the Lync Server 2013, Persistent Chat Servers.
- Users log back on by using their Lync 2010 Group Chat (client) and connect to their data without needing to change any configuration.
- At a later time, you can decommission the Lync Server 2010, Group Chat. Subsequently, you can deploy Lync Server 2013, Persistent Chat Server, and install new Lync Server 2013 Persistent Chat Server pools.

For details about migrating from Lync Server 2010, Group Chat to Lync Server 2013, Persistent Chat Server, see Migration from Lync Server 2010, Group Chat or Office Communications Server 2007 R2 Group Chat to Lync Server 2013, Persistent Chat Server.

To run backward compatibility (to create a Persistent Chat Server endpoint that points to a Persistent Chat Server pool, which can be used by legacy Group Chat pool clients):

```
New-CsPersistentChatEndpoint -SipAddress <CO name, ex. persistentchat@contoso.com
```

Next, configure Persistent Chat clients to use that SIP address as their contact object. The SIP address is created with the **New-CsPersistentChatEndpoint** cmdlet for a specific Persistent Chat Server pool.

To add the Persistent Chat Server endpoint by using Windows PowerShell command-line interface, consider the following example. In this case, you are configuring the contact object to be named "persistentchat" on the "contoso.com" topology, where the pool fully qualified domain name (FQDN) is "pcpool.contoso.com":

```
New-CsPersistentChatEndpoint -SipAddress sip:persistentchat@contoso.com -Persiste
```

Concepts

Topic Last Modified: *2012-10-06*

To create a new Persistent Chat configuration

```
New-CsPersistentChatConfiguration -Identity <XdsIdentity> [-DefaultChatHistory <I
```

To get Persistent Chat configuration

```
Get-CsPersistentChatConfiguration [-LocalStore <Switch Parameter>] [-Identity <Xd
```

To remove Persistent Chat configuration

```
Remove-CsPersistentChatConfiguration -Identity <XdsIdentity>
```

To set Persistent Chat configuration

```
Set-CsPersistentChatConfiguration [-DefaultChatHistory <Integer>] [-MaxChatConten
```

For Lync Server 2013, all web service traffic is supported on the Lync Server 2013, Front End Servers. Therefore, the gcweb01 address on Persistent Chat Server is not necessary. We still support internal web service access because we provide the File Upload/ Download Web service to the *internal* website only (not to the *external* website for remote users).

1.4.9.9.9 Get Persistent Chat Server Pool Availability

1.4.9.10 Troubleshooting Persistent Chat Server Configuration using Windows PowerShell Cmdlets

Troubleshooting Persistent Chat Server Configuration using Windows PowerShell Cmdlets

Microsoft Lync Server 2013 > Deployment > Deploying Persistent Chat Server >

Topic Last Modified: *2012-10-06*

Use the following workarounds to resolve Persistent Chat Server configuration issues with Windows PowerShell command-line interface cmdlets.

- If the "principal not provisioned" error message appears, the principal that you tried to add is not available.

  > **Tip:**
  >
  > Workaround — No workaround. This error message means that the principal is not available.

1.4.9.11 Configuring Persistent Chat Server for High Availability and Disaster Recovery

Configuring Persistent Chat Server for High Availability and Disaster Recovery

Microsoft Lync Server 2013 > Planning > Planning for High Availability and Disaster Recovery >

Topic Last Modified: *2012-10-01*

The Lync Server 2013, Persistent Chat Server services use a *stretched pool* configuration for disaster recovery. A stretched pool is a pool that has computers that are distributed between two physical data centers, but are within a single logical Lync Server site.

In This Section

1.4.9.11.1 Required Resources

Required Resources

Planning > Planning for High Availability and Disaster Recovery > Configuring Persistent Chat Server for High Availability and Disaster Recovery >

Topic Last Modified: *2012-10-01*

High availability and disaster recovery for Persistent Chat Server requires additional resources beyond what is typically needed for full operation. Before configuring Persistent Chat Server for high availability and disaster recovery, ensure that you have the following resources in addition to what is required for standard Persistent Chat Server operation. For additional configuration information, see Configuring Persistent Chat Server.

- One dedicated database instance located in the same physical data center in which the home front end of the Persistent Chat Server service is located. This database will serve as the SQL Server mirror for the primary Persistent Chat database. Optionally, designate an additional SQL Server to serve as the mirroring witness if you want an automated failover to the mirror database.
- One dedicated database instance located in the other physical data center. This database will serve as the SQL Server Log Shipping secondary database for the database in the primary data center.
- One dedicated database instance to serve as the SQL Server mirror for the secondary database. Optionally, designate an additional SQL Server to server as the mirroring witness. Both of these must be located in the same physical data center as the secondary database.
- If Persistent Chat Server compliance is enabled, an additional three dedicated database instances are required. Their distribution is the same as those previously outlined for the Persistent Chat database. While it is possible for the compliance database to share the same SQL Server instance as the Persistent Chat database, we recommend standalone instances for high availability and disaster recovery.
- A file share must also be created and designated for the SQL Server Log Shipping transaction logs. This share must have read/write privileges to all the

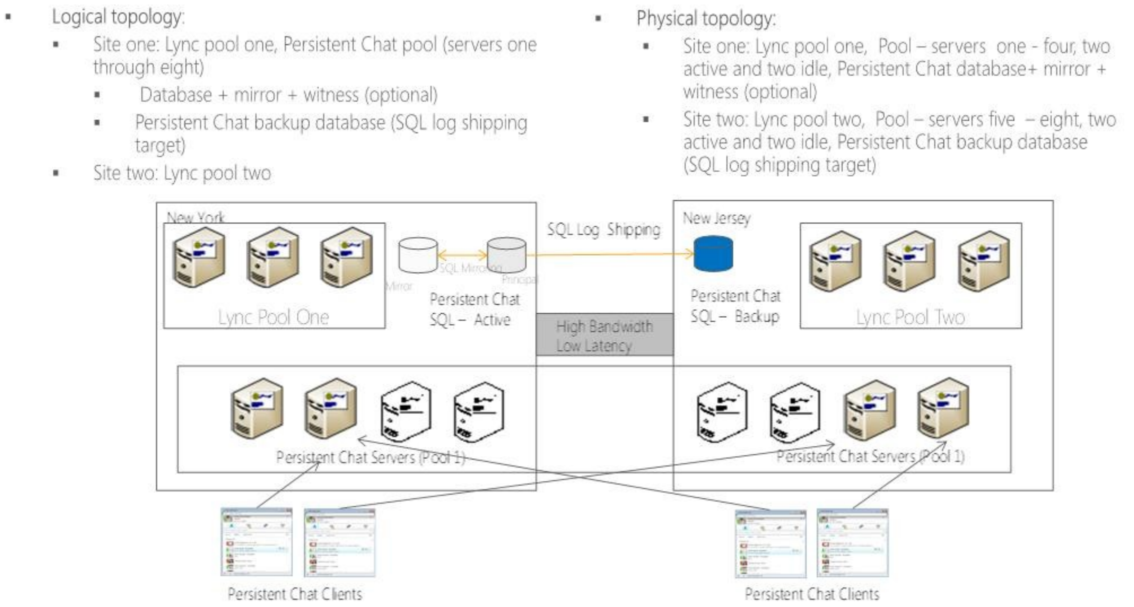
SQL Server services that are running the Persistent Chat databases in both data centers. This share is not defined as part of a FileStore role.

- A file share on the secondary database server to serve as the destination folder for the SQL Server transaction logs that are copied from the primary server file share.

The following figures provide examples about how the entire Persistent Chat Server pool can be configured in the two different stretched pool topologies:

- Stretched Persistent Chat Server pool when data centers are geo-located with high bandwidth/low latency.
- Stretched Persistent Chat Server pool when data centers are geo-located with low bandwidth/high latency.

The following figure shows a stretched Persistent Chat Server pool topology where data centers are geo-located with high bandwidth/low latency.



- Logical topology:
  - Site one: Lync pool one, Persistent Chat pool (servers one through eight)
    - Database + mirror + witness (optional)
    - Persistent Chat backup database (SQL log shipping target)
  - Site two: Lync pool two
- Physical topology:
  - Site one: Lync pool one, Pool – servers one - four, two active and two idle, Persistent Chat database+ mirror + witness (optional)
  - Site two: Lync pool two, Pool – servers five – eight, two active and two idle, Persistent Chat backup database (SQL log shipping target)

1.4.9.11.2 Using Topology Builder to Configure High Availability and Disaster Recovery

Using Topology Builder to Configure High Availability and Disaster Recovery

Planning > Planning for High Availability and Disaster Recovery > Configuring Persistent Chat Server for High Availability and Disaster Recovery >

Topic Last Modified: *2012-10-06*

Perform the following steps within Topology Builder to configure high availability and disaster recovery for Persistent Chat Server.

1. Add the mirror databases and the log shipping secondary database SQL Server stores.
2. Edit the Persistent Chat Server service properties to:
   2.a.Enable mirroring for the primary database.
   2.b.Add the primary mirror SQL Server store.
   2.c.Enable the SQL Server Log Shipping database.
   2.d.Add the SQL Server Log Shipping secondary SQL Server store.
   2.e.Add the SQL Server store mirror for the secondary database.
   2.f.Publish the topology.

1.4.9.11.3 Using a Stretched Persistent Chat Server Pool for Disaster Recovery

Using a Stretched Persistent Chat Server Pool for Disaster Recovery

Planning > Planning for High Availability and Disaster Recovery > Configuring Persistent Chat Server for High Availability and Disaster Recovery >

Topic Last Modified: *2012-10-06*

The disaster recovery solution for Persistent Chat Server is built on a stretched Persistent Chat Server pool. This is similar to metropolitan site resiliency in Lync Server 2010;

however, there is no requirement for a stretched virtual local area network (VLAN). By stretching Persistent Chat Server pool, you essentially configure one pool in the topology logically, but you physically place the servers in the pool in two different data centers. Configure SQL Server mirroring for the database in the same way, and deploy the database and the mirror in the same data center. You need to configure a backup database in the secondary data center (with an optional mirror to provide high availability during disaster recovery). This is the backup database used for failover during disaster recovery.

For details about how to configure SQL Server mirroring for high availability, see SQL Server Mirroring. For details about failing over the database for disaster recovery, see Setting Up SQL Server Log Shipping for the Persistent Chat Server Primary Database and Setting Up SQL Server Log Shipping between the Primary Mirror and the Log Shipping Secondary Database.

1.4.9.11.4 SQL Server Mirroring

SQL Server Mirroring

Planning > Planning for High Availability and Disaster Recovery > Configuring Persistent Chat Server for High Availability and Disaster Recovery >

Topic Last Modified: *2012-09-29*

Establish the SQL Server mirroring session between the primary Persistent Chat database and its mirror. For information about how to deploy SQL Server mirroring, see Deploying SQL Mirroring for Back End Server High Availability.

1.4.9.11.5 Setting Up SQL Server Log Shipping for the Persistent Chat Server Primary Database

Setting Up SQL Server Log Shipping for the Persistent Chat Server Primary Database

Planning > Planning for High Availability and Disaster Recovery > Configuring Persistent Chat Server for High Availability and Disaster Recovery >

Topic Last Modified: *2012-11-12*

Using SQL Server Management Studio, connect to the Persistent Chat Server secondary Log Shipping database instance, and be sure that SQL Server Agent is running.

Using SQL Server Management Studio connected to the Persistent Chat primary database instance, perform the following steps:

1. Be sure that the SQL Server Agent is running.
2. Right-click the mgc database, and then click **Properties**.
3. Under **Select a page**, click **Transaction Log Shipping**.
4. Select the **Enable this as a primary database in a log shipping configuration** check box.
5. Under **Transaction log backups**, click **Backup Settings**.
6. In the **Network path to the backup folder** box, type the network path to the share that you created for the transaction log backup folder.
7. If the backup folder is located on the primary server, type the local path to the backup folder in the **If the backup folder is located on the primary server, type a local path to the folder (example: c:\backup)** box. (If the backup folder is not on the primary server, you can leave this box empty.)

> **Important:**
> If the SQL Server service account on your primary server runs under the local system account, you must create your backup folder on the primary server and specify a local path to that folder.

8. Configure the **Delete files older than** and **Alert if no backup occurs within** parameters.
9. Look at the backup schedule listed in the **Schedule** box under **Backup job**. To customize the schedule for your installation, click **Schedule**, and adjust the SQL Server Agent schedule as required.
10. Under **Compression**, select **Use the default server setting**, and then click **OK**.
11. Under **Secondary server instances and databases**, click **Add**.
12. Click **Connect** and connect to the instance of SQL Server that you have configured as your secondary server.
13. In the **Secondary Database** box, select the **mgc** database from the list.
14. On the **Initialize Secondary database** tab, choose the option **Yes, generate a full backup of the primary database and restore it into the secondary database (and create the secondary database if it doesn't exist)**.
15. On the **Copy Files** tab, in the **Destination folder for copied files** box, type the path of the folder into which the transaction logs backups should be copied. This folder is often located on the secondary server.
16. Note the copy schedule listed in the **Schedule** box under **Copy job**. To customize the schedule for your installation, click **Schedule**, and adjust the SQL Server Agent schedule as required. This schedule should be approximately the same as the backup schedule.
17. On the **Restore** tab, under **Database state when restoring backups**, choose the **No recovery mode** option.
18. Under **Delay restoring backups at least:**, select **0 minutes**.
19. Choose an alert threshold under **Alert if no restore occurs within**.
20. Look at the restore schedule listed in the **Schedule** box under **Restore job**. To customize the schedule for your installation, click **Schedule**, adjust the SQL Server Agent schedule as required, and click **OK**. This schedule should be approximately the same as the backup schedule.
21. On the **Database Properties** dialog box, click **OK** to begin the configuration process.

1.4.9.11.6 Setting Up SQL Server Log Shipping between the Primary Mirror and the Log Shipping Secondary Database

Setting Up SQL Server Log Shipping between the Primary Mirror and the Log Shipping Secondary Database

See Also

Planning > Planning for High Availability and Disaster Recovery > Configuring Persistent Chat Server for High Availability and Disaster Recovery >

Topic Last Modified: *2013-02-21*

Perform the following steps for log shipping to continue if the primary Persistent Chat database is failed over to its mirror database.

1. Manually fail over the primary Persistent Chat database to the mirror. This is done by using the Lync Server Management Shell and the **Invoke-CsDatabaseFailover** cmdlet. For details, see "Using Lync Server Management Shell Cmdlets" in Deploying SQL Mirroring for Back End Server High Availability.
2. Using the SQL Server Management Studio, connect to the primary Persistent

Chat Server mirror instance.

3. Be sure that the SQL Server Agent is running.
4. Right-click the mgc database, and then click **Properties**.
5. Under **Select a page**, click **Transaction Log Shipping**.
6. Select the **Enable this as a primary database in a log shipping configuration** check box.
7. Under **Transaction log backups**, click **Backup Settings**.
8. In the **Network path to the backup folder** box, type the network path to the share you created for the transaction log backup folder.
9. If the backup folder is located on the primary server, type the local path to the backup folder in the **If the backup folder is located on the primary server, type a local path to the folder** box. (If the backup folder is not on the primary server, you can leave this box empty.)

> **Important:**
> If the SQL Server service account on your primary server runs under the local system account, you must create your backup folder on the primary server and specify a local path to that folder.

10. Configure the **Delete files older than** and **Alert if no backup occurs within** parameters.
11. Look at the backup schedule listed in the **Schedule** box under **Backup job**. To customize the schedule for your installation, click **Schedule**, and adjust the SQL Server Agent schedule, as required.

> **Important:**
> Use the same settings that you used for the primary database.

12. Under **Compression**, select **Use the default server setting**, and click **OK**.
13. Under **Secondary server instances and databases**, click **Add**.
14. Click **Connect**, and connect to the instance of SQL Server that you have configured as your secondary server.
15. In the **Secondary Database** box, select the **mgc** database from the list.
16. On the **Initialize Secondary database** tab, select the option **No, the secondary database is initialized**.
17. On the **Copy Files** tab, in **Destination folder for copied files**, type the path of the folder into which the transaction logs backups should be copied, and click **OK**. This folder is often located on the secondary server.
18. Open the **Script Configuration** drop-down list, and select **Script Configuration to New Query Window**.
19. In the new query window, in **Database Properties**, click **OK** to begin the configuration process.
20. Select and run the first half of the query (see step 18) up to the line: -- ****** End: Script to be run at Primary: ******.

> **Important:**
> Manually running this script is necessary because SQL Server Management Studio does not support multiple primary databases in a SQL Server Log Shipping configuration.

21. Select **Cancel** to close the Log File shipping configuration panel and to establish a working setup that correctly implements the log file shipping for both the primary and mirrored database (in case of failover).
22. Manually fail back the primary Persistent Chat database to the primary. This is done by using the Lync Server Management Shell, and the **Invoke-CsDatabaseFailover** cmdlet. For details, see "Using Lync Server Management Shell Cmdlets" in Deploying SQL Mirroring for Back End Server High Availability.

1.4.10 Deploying Clients and Devices

Deploying Clients and Devices

Microsoft Lync Server 2013 > Deployment >

Topic Last Modified: *2013-01-15*

This section outlines the procedures for deploying Lync Server 2013 clients and devices.

In This Section

- Deploying Lync Clients
- Deploying the Lync VDI Plug-in
- Deploying Lync Web App
- Deploying Devices
- Deploying Mobile Clients
- Deploying Lync Windows Store App
- Using Lync Connectivity Analyzer

1.4.10.1 Deploying Lync Clients

Deploying Lync Clients

Microsoft Lync Server 2013 > Deployment > Deploying Clients and Devices >

Topic Last Modified: *2012-10-03*

Lync 2013 introduces a different approach to client deployment. In a departure from previous releases, Lync 2013 no longer has its own installer. Instead, Lync is included with the Office 2013 setup program. To deploy Lync 2013 to your users, you can use Office 2013 installation methods and customization tools.

- **Office 2013 Windows Installer** is a Windows Installer-based installation package that consists of multiple MSI files. A language-neutral core MSI package is combined with one or more language-specific packages to make a complete product. Setup assembles the individual packages and performs customization and maintenance tasks during and after installation of Office on users' computers. The topics in this section describe how to use and customize the Office 2013 Windows Installer to deploy Lync 2013.
- **Office 2013 Click-to-Run** is an installation program that streams Office setup files to the user from the Microsoft Office 365 portal. Administrators can customize installation by using the Office Deployment Tool for Click-to-Run. Because Office 2013 Click-to-Run is primarily used in the Microsoft Office 365 environment, this installation method is not described in detail in this section. Detailed information about using and customizing Click-to-Run installation is available in the Office 2013 Resource Kit documentation. Administrators can also download the Office 2013 Click-to-Run program and language source files to an on-premises location, which is useful when you want to minimize the demand on the network or prevent users from installing software from the Internet because of corporate security requirements.

The topics in this section focus on how to deploy clients by using the Office 2013 MSI-based installer. Your primary reference should be the Office 2013 Resource Kit documentation, which describes in detail how to prepare your infrastructure, customize setup, and deploy Office 2013. However, you should use the Office documentation in conjunction with topics in this section, which point out deployment considerations that are specific to Lync 2013.

Note:

- The Online Meeting Add-in for Lync 2013, which supports meeting management from within the Outlook messaging and collaboration client, installs automatically with Lync 2013.
- The Office 2013 setup program does not uninstall previous versions of Lync or Office Communicator. The Lync 2013 client installs side-by-side with other Lync or Office Communicator clients

In This Section

- Customizing Client Installation
- Customizing Lync Behavior and the User Interface
- Customizing the Online Meeting Add-in
- Configuring the Meeting Join Page
- Configuring Supported Client Versions
- Configuring Enhanced Presence Privacy Mode

1.4.10.1.1 Customizing Client Installation

Customizing Client Installation

Deployment > Deploying Clients and Devices > Deploying Lync Clients >

Topic Last Modified: *2012-10-03*

Enterprise administrators can customize the Office 2013 Windows Installer-based (.msi) installation by using the methods discussed in this section. Because no single tool provides all customization options, you'll likely use a combination of these methods in your Lync 2013 deployment. At a minimum, you might use the tools described in the following sections:

- Using the Office Customization Tool (OCT) to customize setup options and features for Lync and other Office programs.
- Using Config.xml to Perform Installation Tasks to specify the path of the network installation point and perform silent installation.
- Using Setup Command-Line Options to specify the Config.xml file to use during installation.
- Configuring Client Bootstrapping Policies by using the Group Policy Object Editor MMC snap-in.

There will probably be other options you'll want to configure as you deploy the Office suite of products. The topics in this section give an overview of these customization tools and discuss Lync-specific considerations. Included are links to detailed Office help for each tool.

1.4.10.1.1.1 Using the Office Customization Tool (OCT)

Using the Office Customization Tool (OCT)

Deploying Clients and Devices > Deploying Lync Clients > Customizing Client Installation >

Topic Last Modified: *2012-10-02*

The Office Customization Tool (OCT) is part of the Setup program and is the recommended tool for many customizations. By using the OCT, you customize Office and save your customizations in a Setup customization .msp file. You place the file in the Updates folder on the network installation point. When you install Office, Setup looks for a Setup customization file in the Updates folder and applies the customizations. The Updates folder can be used only to deploy software updates during an initial installation of Office 2013.

The OCT is part of setup and it is included in volume license versions of the product. You run the OCT by typing `setup.exe /admin` at the command line from the root of the network installation point that contains the Office 2013 source files. For example, use the following:

```
\\server\share\Office15\setup.exe /admin
```

Administrators use the OCT to create a setup customization .msp file. As in the Microsoft Office 2010 OCT, administrators can customize the following areas:

- **Setup** Used to specify default installation location on the client and default organization name, additional network installation sources, product key, end-user license agreement, display level, earlier versions of Office to remove, custom programs to run during installation, security settings, and Setup properties.
- **Features** Used to configure user settings and to customize how Office features are installed. Administrators can use the OCT to specify initial default values of Office application settings for users. Users can modify most of the settings after the installation.
- **Additional content** Used to add or remove files, add or remove registry entries, and configure shortcuts.
- **Outlook** Used to customize a user's default Outlook profile, specify Exchange settings, add accounts, remove accounts and export settings, and specify Send\Receive groups.

For information about the OCT, see http://go.microsoft.com/fwlink/p/?linkid=267516.

1.4.10.1.1.2 Using Config.xml to Perform Installation Tasks

Using Config.xml to Perform Installation Tasks

Deploying Clients and Devices > Deploying Lync Clients > Customizing Client Installation >

Topic Last Modified: *2012-10-02*

Although the Office Customization Tool (OCT) is the primary tool for customization installation, administrators can use the Config.xml file to specify additional installation instructions that are not available in the OCT. The following customizations can only be made by using the Config.xml file:

- Specify the path of the network installation point.
- Select the products to install.
- Configure logging and the location of the Setup customization file and software updates.
- Specify installation options, such as user name.
- Copy the local installation source (LIS) to the user's computer without installing Office.
- Add or remove languages from the installation.

We recommend that you use the Config.xml file to configure Lync 2013 silent installation.

By default, the Config.xml file that is stored in the core product folder (for example, \*product*.WW) directs Setup to install that product. For example, the Config.xml file in the following folder installs Lync 2013:

- \\server\share\Lync15\Lync.WW \Config.xml

The Config.xml elements most commonly used for Lync 2013 installation are listed in the following table.

Config.xml elements

Element	Description
Configuration	Top-level element (required). Contains the Product attribute, for example: Product=Lync
OptionState	Specifies how specific product features are handled during installation. Use the following attributes to prevent installation of Business Connectivity Services, which includes shared components that interfere with Outlook 2010: • Id="LOBiMain" • State="Absent" • Children="Force"
Display	The level of UI that Setup displays to the user. Typical attributes include the following: • CompletionNotice="Yes" | "No"(default) • AcceptEula="Yes" | "No"(default)
Logging	Options for the kind of logging that Setup performs. Typical attributes include the following: • Type ="Off" | "Standard"(default) | "Verbose" • Template=”*filename*.txt” (the name of the log file)
Setting	Specifies values for Windows Installer properties. Typical attributes include the following: • Setting Id="*name*" (the name of the Windows Installer property) • Value="*value*" (the value to assign to the property)
DistributionPoint	The fully qualified path of the network installation point from which the installation is to run. Includes the Location attribute: • Location=”*path*”

The following example shows a Config.xml file for a typical silent installation of Lync 2013.

```
<Configuration Product="Lync">
  <OptionState Id="LOBiMain" State="Absent" Children="Force" />
  <Display Level="None" CompletionNotice="No" AcceptEula="Yes" />
  <Logging Type="verbose" Path="%temp%" Template="LyncSetupVerbose(*).log" />
  <Setting Id="SETUP_REBOOT" Value="Never" />
  <DistributionPoint Location="\\server\share\Lync15" />
</Configuration>
```

Detailed information about using the Config.xml file to perform Office installation and maintenance tasks is available at http://go.microsoft.com/fwlink/p/?linkid=267514.

To customize the Config.xml file

1. Open the Config.xml file by using a text editor tool, such as Notepad.
2. Locate the lines that contain the elements you want to change.
3. Modify the element entry with the silent options that you want to use. Make sure that you remove the comment delimiters, "<!--" and "-->". For example, use the following syntax:

```
< DistributionPoint Location="\\server\share\Lync15" />
```

4.Save the Config.xml file.

1.4.10.1.1.3 Using Setup Command-Line Options

Using Setup Command-Line Options

[Deploying Clients and Devices](#) > [Deploying Lync Clients](#) > [Customizing Client Installation](#) >

Topic Last Modified: *2012-10-03*

The Setup.exe command line is used for very few operations in Office setup. Instead of using the Setup command-line options, you’ll typically use the Office Customization Tool and the Config.xml file for product setup and feature customization.

The Office Setup.exe command line recognizes the command-line options described in the following table.

Office Setup Command-Line Options

Setup Command-Line Option	Description
/admin	Runs the Office Customization Tool to create a Setup customization file (.msp file).
/adminfile [path]	Applies the specified Setup customization file to the installation. You can specify a path of a specific customization file (.msp file) or to the folder where you store customization files.
/config [path]	Specifies the Config.xml file that Setup uses during the installation. Use the /config option to specify the Config.xml file you customized for Lync 2013 installations, for example: `/config \\server\share\Lync15\Lync.WW\Config.xml`
/modify Lync	Used with a modified Config.xml file to run Setup in maintenance mode and make changes to an existing Office installation. For example, you can use the /modify option to add or remove Lync features.
/repair Lync	Runs Setup from the user’s computer to repair Lync.
/uninstall Lync	Runs Setup to remove Lync from the user’s computer.

For details about using the setup command-line options, see http://go.microsoft.com/fwlink/p/?linkid=267515.

1.4.10.1.1.4 Configuring Client Bootstrapping Policies

Configuring Client Bootstrapping Policies

Deploying Clients and Devices > Deploying Lync Clients > Customizing Client Installation >

Topic Last Modified: *2013-02-21*

The Group Policy Management Console (GPMC) and the Group Policy Object Editor are tools that you use to manage Group Policy. Included with the Office Group Policy Administrative Template are Lync 2013.admx (ADMX) and .adml (ADML) Administrative Templates, which contain the registry-based policy settings that you configure for Group Policy objects in the domain. ADML files are language-specific complements to ADMX files. Each ADMX and ADML file contains the policy settings for a single Office application. For more information, see "Office 2013 Administrative Template files (ADMX, ADML)" in the Office 2013 documentation at http://go.microsoft.com/fwlink/p/?linkid=267516.

For Lync 2013, there are several client bootstrapping policies that you should consider configuring before users sign in to the server for the first time. For example, the default servers and security mode that the client should use until sign-in is complete. You can use Group Policy to establish these settings in users' computer registries before they sign in and begin receiving in-band provisioning settings from the server. The following table lists the Group Policy settings that are available for Lync 2013.

Group Policy Settings for Lync 2013

Group Policy setting	Description
Specify Server (ConfigurationMode)	Specifies how Lync 2013 identifies the transport and server to use during sign-in. Within this setting, you specify the following: • ServerAddressExternal: Specifies the server name or IP address used by clients and federated contacts when connecting from outside the external firewall. • ServerAddressInternal: Specifies the server name or IP address used when clients connect from inside the organization's firewall. • Transport: Specifies either Transmission Control Protocol (TCP) or Transport Layer Security (TLS).
Additional server versions supported (ConfiguredServerCheckValues)	Specifies a list of server version names separated by semi-colons that Lync Server 2013 will log on to, in addition to the server versions that are supported by default.
Disable automatic upload of sign-in failure logs (DisableAutomaticSendTracing)	Automatically uploads sign-in failure logs to Lync Server for analysis. No logs are automatically uploaded if sign-in is successful. If this policy is not configured, the following happens: • For Lync Online users: Sign-in failure logs are automatically uploaded. • For Lync on-premises users: A confirmation dialog box is shown to the user before upload. When this setting is disabled, sign-in logs are automatically uploaded to the Lync Server for both

	Lync on-premises and Lync Online users. When this setting is enabled, sign-in logs are never uploaded automatically.
Disable HTTP fallback for SIP connection (DisableHttpConnect)	Prevents Lync Server from trying to connect to the server by using HTTP, if TLS or TCP are unavailable. By default, Lync first attempts to connect to the server by using TLS or TCP and, if neither of these transport methods is successful, Lync tries to connect by using HTTP. Use this policy to disable the fallback HTTP connection attempt.
Require logon credentials (DisableNTCredentials)	Requires the user to provide logon credentials for Lync rather than automatically using Windows credentials during sign-in to a SIP server.
Disable server version check (DisableServerCheck)	If you set this policy to 1, prevents Lync from checking the server name and version before signing in. By default, Lync makes these checks before signing in.
Enable using BITS to download Address Book Service files (EnableBitsForGalDownload)	Enables Lync to use Background Intelligent Transfer Service (BITS) to download the Address Book Services files.
Configure SIP security mode (EnableSIPHighSecurityMode)	Enables Lync to send and receive instant messages more securely. This policy has no effect on Windows .NET or Microsoft Exchange Server services. If you do not configure this policy setting, Lync can use any transport. But if it does not use TLS and if the server authenticates users, Lync must use either NTLM or Kerberos authentication.
Global Address Book Download Initial Delay (GalDownloadInitialDelay)	Specifies the time period before a download of the global address list (GAL) occurs. The default value is 60 minutes, which means the server delays the download of GAL file for a random period of between 0 and 60 minutes.
Prevent users from running Microsoft Lync (PreventRun)	Prevents users from running Lync. You can configure this policy setting under both Computer Configuration and User Configuration, but the policy setting under Computer Configuration takes precedence.
Allow storage of user passwords (SavePassword)	Enables Lync to store passwords.
Configure SIP compression mode (SipCompression)	Specifies when to turn on SIP compression. By default, SIP compression is enabled based on the adapter speed. Note that setting this policy might cause an increase in sign-in time.
Trusted Domain List (TrustModelData)	Lists the trusted domains that do not match the prefix of the customer SIP domain.

Policies configured on the server take precedence over Group Policy settings and client options configured by the user. The following table summarizes the order in which settings take precedence when a conflict occurs.

Group Policy Precedence

Precedence	Location or Method of Setting
1	Lync Server 2013 in-band provisioning
2	HKEY_LOCAL_MACHINE\SOFTWARE\Policies\Microsoft\Office\15.0\Lync
3	HKEY_CURRENT_USER\SOFTWARE\Policies\Microsoft\Office\15.0\Lync
4	The Lync - Options dialog box in Lync 2013

⊟To define Group Policy settings by using the Lync 2013 administrative template files

1. Create a root-level folder to contain all language-neutral ADMX files. For example, create the root folder for the central store on your domain controller at this location:
   `%systemroot%\sysvol\domain\policies\PolicyDefinitions`

Note:
This procedure assumes that you want to manage multiple computers in your domain. In this case, you store the templates in a central store in the Sysvol folder on the primary domain controller. This provides a replicated central storage location for domain Administrative Templates.

2. Create a subfolder for each language that you'll use. These subfolders will contain the language-specific ADML resource files. For example, create a subfolder for United States English (EN-US) at this location:
   `%systemroot%\sysvol\domain\policies\PolicyDefinitions\EN-US`

1.4.10.1.2 Customizing Lync Behavior and the User Interface

Customizing Lync Behavior and the User Interface

Deployment > Deploying Clients and Devices > Deploying Lync Clients >

Topic Last Modified: *2013-02-20*

This section describes how to add custom features to Lync 2013.

- Configuring Media Port Range Settings
- Adding Commands to Lync Menus
- Integrating a Third-Party Collaboration Application with Lync
- Configuring Custom Presence States
- Adding a Custom Link to Lync Error Messages
- Adding Custom Text to Instant Messages
- Starting Lync from Another Application

1.4.10.1.2.1 Configuring Media Port Range Settings

Configuring Media Port Range Settings

Deploying Clients and Devices > Deploying Lync Clients > Customizing Lync Behavior and the User Interface >

Topic Last Modified: *2012-10-18*

Media port range settings can significantly impact client performance and should be configured. You can configure these settings by using Lync Server Management Shell.

Media Port Range Settings

Setting	Description	Lync Server Management Shell cmdlet	Cmdlet parameters
Portrange\Enabled	Specifies whether the port ranges sent by the server should be used by the client for media and signaling. Used in conjunction with the subvalues MinMediaPort and MaxMediaPort.	**CsConferencingConfiguration**	ClientMediaPortRange Enabled
Portrange \MinMediaPort	Specifies the starting port number to use for media. Combines with MaxMediaPort to specify the range of ports. The recommended minimum range is 40 ports.	**CsConferencingConfiguration**	ClientMediaPort (represents the starting port number to use for client media)
Portrange \MaxMediaPort	Specifies the highest port number to use for media. Combines with MinMediaPort to specify the range of ports. The recommended minimum range is 40 ports.	**CsConferencingConfiguration**	ClientMediaPortRange (indicates the total number of ports available for client media; default is 40)

⊟To Configure Media Port Range Settings

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the following cmdlet:

```
Get-CsConferencingConfiguration
```

   This cmdlet returns the conferencing configuration settings.
3. Run the following cmdlet with the parameters and values you want to change (for details about the parameters for this cmdlet, see the Lync Server Management Shell documentation):

```
Set-CsConferencingConfiguration
```

Note:
You can create additional sets of conferencing configuration settings for specific sites. Use the **New- CsConferencingConfiguration** cmdlet with a site identity. When you create new conferencing configuration settings for sites, the site settings take precedence over the global settings. For details, see

the Lync Server Management Shell documentation.

1.4.10.1.2.2 Adding Commands to Lync Menus

Adding Commands to Lync Menus

Deploying Clients and Devices > Deploying Lync Clients > Customizing Lync Behavior and the User Interface >

Topic Last Modified: *2013-02-20*

You can add custom commands to Lync 2013 menus and pass the SIP Uniform Resource Identifier (URI) of the current user and selected contacts to the application that the custom command starts.

The custom commands that you add can appear on one or more of the following menus:

- The Tools menu, on the menu bar in the Lync main window
- The shortcut menu for contacts in the Contacts list
- The More Options menu, in the Conversation window
- The shortcut menu for people listed in the Conversation window participant list
- The options menu in a contact card

You can define custom commands for two types of applications—applications that do either of the following:

- Apply only to the current user and are started on the local computer.
- Involve additional users, such as an online collaboration program, and must be started on each user's computer.

The custom command can be invoked in the following ways:

- Select one or more users, and then choose the custom command.
- Start a two-party or multiparty conversation, and then choose the custom command.

To add a custom command

Use the registry settings in the following table to add a command to the menus. These entries are placed in the registry at the following location:

HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Office\15.0\Lync\CustomCommands

Custom Command Registry Entries

Name	Type	Data
Name	REG_SZ	Name of the application as it appears on the menu.
ApplicationType	DWORD	0 = Executable (default) **Note:** Requires ApplicationInstallPath. 1 = Protocol
ApplicationInstallPath	REG_SZ	Full path of the executable. **Note:** Must be specified if

		ApplicationType is 0 (Executable).
Path	REG_SZ	Full path to be started along with any parameters, including the default parameters *%user-id%* and *%contact-id%*.
SessionType	DWORD	0 = Local session. The application is started on the local computer. 1 = Two-party session (default). Lync 2013 starts the application locally and then sends a desktop notification to the other user. The other user clicks the notification to start the application on their computer. 2 = Multiparty session. Lync 2013 starts the application locally and then sends desktop notifications to the other users. The other user clicks the notification to start the specified application on their computer.
ExtensibleMenu	REG_SZ	A list of the menus where this command will appear, separated by semicolons. Possible values are: MainWindowActions MainWindowRightClick ConversationWindowActions ConversationWindowRightClick ContactCardMenu If ExtensibleMenu is not defined, the default values of MainWindowRightClick and ConversationWindowActions are used.

For example, the following Registry Editor (.REG) file shows the results of adding a Contoso Sales Contact Manager menu item to Actions menu in the Conversation window:

```
Windows Registry Editor Version 5.00
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Office\15.0\Lync\CustomCommands\{1F9F07C6-
"Name"="Contoso Sales Contact Manager"
"HelpMessage"="The Contoso Sales Contact Manager is not installed. Contact the He
"ApplicationType"=dword:00000000
```

```
"ApplicationInstallPath"="C:\\cscm.exe"
"Path"="C:\\cscm.exe %user-id% %contact-id%"
"SessionType"=dword:00000001
"ExtensibleMenu"="ConversationWindowActions;MainWindowRightClick"
```

To access a custom command

To access a custom command after it is added, do one of the following, depending on the ExtensibleMenu values that you define:

- **MainWindowActions** In the Lync main window, click **Tools**, and then click your custom command.
- MainWindowRightClick In the Lync main window, right-click a contact, and then click your custom command.
- **ConversationWindowActions** In the Conversation window, click the **More Options** icon, and then click your custom command.
- **ConversationWindowRightClick** In the Conversation window, right-click a contact name, and then click your custom command.
- **ContactCardMenu** In a person's contact card, click the options icon, and then click your custom command.

1.4.10.1.2.3 Integrating a Third-Party Collaboration Application with Lync

Integrating a Third-Party Collaboration Application with Lync

Deploying Clients and Devices > Deploying Lync Clients > Customizing Lync Behavior and the User Interface >

Topic Last Modified: *2013-02-20*

You can integrate Lync 2013 with any third-party online collaboration application by adding information about the application to the registry. You can use Lync 2013 to start data conferencing sessions hosted on an in-house server, an Internet-based service, or both. The collaboration or data conferencing session can be started from the Contacts list or from an existing instant messaging, voice, or video session. Lync 2013 acts only as the vehicle for starting the application. Any existing Lync 2013 conversations remain active after the online collaboration session has begun.

The following sections describe how to integrate Lync 2013 with Internet-based and server-based collaboration applications.

Integrating an Internet-Based Collaboration Application with Lync 2013

Generally, the steps involved in integrating a third-party collaboration application are as follows:

1. Information about the application is added to the registry.
2. The organizer signs in to Lync 2013 and selects contacts for data sharing and collaboration. Or, the organizer may already be in a conversation and decide to add data conferencing.
3. Lync 2013 reads the registry, starts the collaboration application, and then sends a custom SIP message—an appINVITE—to the selected participants.
4. Participants accept the invitation, and the collaboration application is started on each person's computer. Lync 2013 uses the registry to determine which collaboration application to use, and then starts that application by using the parameters included in the appINVITE message.

The following table describes the registry entries required to integrate an Internet-based collaboration application with Lync 2013. These entries are placed in the registry in the following location:

- HKEY_LOCAL_MACHINE\Software\Microsoft\Office\15.0\Lync\SessionManager\Apps\Parameters

Registry Entries for an Internet-based Collaboration Application

Name	Type	Data
Name	REG_SZ	The application name for Lync 2013 menus.
SmallIcon	REG_SZ	Path to 16-pixel x 16-pixel icon, BMP or PNG.
Path	REG_SZ	Participant path for starting the online collaboration application.
OriginatorPath	REG_SZ	Organizer path for starting the online collaboration application. This path can contain one or more custom parameters as defined in the Parameters subkey. For example, `https://meetserv.adatum.com/cc/%param1%/join?id=%param2%&role=present&pw=%param3%`
SessionType	DWORD	0 = Local session. The application is started on the local computer. 1 = Two-party session (default). Lync 2013 starts the application locally, and then sends a system notification to the other user. The other user clicks the notification and starts the specified application on their computer. 2 = Multiparty session. Lync 2013 starts the application locally, and then sends system notifications to the other users, prompting them to start the specified application on their own computer.
ExensibleMenu	REG_SZ	A list of the menus where this command will appear, separated by semi-colons. Possible values are: • MainWindowActions • MainWindowRightClick • ConversationWindowActions • ConversationWindowButton • ConversationWindowRightClick If ExtensibleMenu is not defined, the default values of MainWindowRightClick and

		ConversationWindowActions are used.

The following table describes the registry entries for parameters. These entries are place at HKEY_CURRENT_USER\Software\Microsoft\Office\15.0\Lync\SessionManager\Apps \Parameters.

Registry Entries for an Internet-based Collaboration Application

Name	Type	Data
Param1	REG_SZ	Used in tokenized format (%Parm1%) to add user-specific values to the OriginatorPath registry key.
Param2	REG_SZ	See Param1.
Param3	REG_SZ	See Param1.

The following example registry settings integrate ADatum Collaboration Client with Lync 2013:

```
Windows Registry Editor Version 5.00
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Office\15.0\Lync\SessionManager]
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Office\15.0\Lync\SessionManager\Apps]
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Office\15.0\Lync\SessionManager\Apps\{C3F6
"Path"="https://meetingservice.adatum.com/cc/%param1%/meet/%param2%"
"OriginatorPath"="https://meetserv.adatum.com/cc/%param1%/join?id=%param2%&role=p
"SessionType"=dword:00000002
"ApplicationType"=dword:00000001
"LiveServerIntegration"=dword:00000000
"Name"="ADatum Online Collaboration Service"
"Extensiblemenu"="MainWindowActions;MainWindowRightClick;ConversationWindowAction
[HKEY_CURRENT_USER\Software\Microsoft\Office\15.0\Lync\SessionManager]
[HKEY_CURRENT_USER\Software\Microsoft\Office\15.0\Lync\SessionManager\Apps]
[HKEY_CURRENT_USER\Software\Microsoft\Office\15.0\Lync\SessionManager\Apps\Parame
[HKEY_CURRENT_USER\Software\Microsoft\Office\15.0\Lync\SessionManager\Apps\Parame
"Param1"="meetserv"
"Param2"="admin"
"Param3"="abcdefg123"
```

Integrating a Server-Based Collaboration Application with Lync 2013

The settings to add commands for starting a server-based collaboration application from within Lync 2013 are similar to those described in the previous section, Integrating an Internet-Based Collaboration Application with Lync 2013. However, the OriginatorPath is not required, and some values are changed. Registry entries are placed in the following location:

- HKEY_LOCAL_MACHINE\Software\Microsoft\Office\15.0\Lync\SessionManager \Apps\Parameters

Registry Entries for a Server-based Collaboration Application

Name	Type	Data
Name	REG_SZ	Name of the application as it appears on the menu.
ApplicationType	DWORD	Value = 1. Sets the application type to

		protocol. The other possible values do not apply in this case. If not present, ApplicationType is set to 0 (executable).
Path	REG_SZ	Protocol used to start the collaboration application. For Live Meeting 2007, the value of Path is set to `meet:%conf-uri%`.
SessionType	DWORD	0 = Local session. The application is started on the local computer. 1 = Two-party session (default). Lync 2013 starts the application locally, and then sends a system notification to the other user. The other user clicks the notification and starts the specified application on their computer. 2 = Multiparty session. Lync 2013 starts the application locally, and then sends system notifications to the other users, prompting them to start the specified application on their computer.
MCUType	REG_SZ	DATA = The type of server.
ExtensibleMenu	REG_SZ	A list of the menus where this command will appear, separated by semicolons. Possible values are: • MainWindowActions • MainWindowRightClick • ConversationWindowActions • ConversationWindowButton • ConversationWindowRightClick If ExtensibleMenu is not defined, the default values of MainWindowRightClick and ConversationWindowActions are used.

The following example adds commands to start ADatum Collaboration Client from within Lync 2013:

```
Windows Registry Editor Version 5.00
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Office\15.0\Lync\SessionManager]
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Office\15.0\Lync\SessionManager\Apps]
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Office\15.0\Lync\SessionManager\Apps\{2787
"Path"="meet:%conf-uri%"
"SessionType"=dword:00000002
"LiveServerIntegration"=dword:00000001
"ApplicationType"=dword:00000001
"Name"="ADatum Collaboration Client"

Configuring Custom Presence States

Deploying Clients and Devices > Deploying Lync Clients > Customizing Lync Behavior and the User Interface >

Topic Last Modified: *2013-01-10*

To define custom presence states in Lync 2013, create an XML custom presence configuration file, and then specify its location by using the Lync Server Management Shell cmdlets **New-CSClientPolicy** or **Set-CSClientPolicy** with the parameter CustomStateURL.

Configuration files have the following properties:

- Custom presence states can be configured with the Available, Busy, and Do Not Disturb presence indicators.
- The availability attribute determines which presence indicator is associated with the status text of the custom state. In the example later in this topic, the status text Working from Home is displayed to the right of the green (Available) presence indicator.
- The maximum length of the status text is 64 characters.
- A maximum of four custom presence states can be added.
- The CustomStateURL parameter specifies the location of the configuration file. In Lync 2013, SIP high security mode is enabled by default, so you will need to store the custom presence configuration file on a web server that has HTTPS enabled. Otherwise, Lync 2013 clients will be unable to connect to it. For example, a valid address would be `https://lspool.corp.contoso.com/ClientConfigFolder/CustomPresence.xml`.

Note:

Although it is not recommended in a production environment, you can test a configuration file that is located on a non-HTTPS file share by using the EnableSIPHighSecurityMode registry setting to disable SIP high security mode on the client. Then you can use the CustomStateURL registry setting to specify a non-HTTPS location for the configuration file. Note that Lync 2013 honors Lync 2010 registry settings, but the registry hive has been updated. You would create the registry settings as follows:

- HKEY_LOCAL_MACHINE\SOFTWARE\Policies\Microsoft\Office\15.0\Lync\EnableSIPHighSecurityMode
  Type: DWORD
  Value data: 0
- HKEY_LOCAL_MACHINE\SOFTWARE\Policies\Microsoft\Office\15.0\Lync\CustomStateURL
  Type: String (REG_SZ)
  Value data (examples): file://\\lspool.corp.contoso.com\LSFileShare\ClientConfigFolder\Presence.xml or file:///c:/LSFileShare/ClientConfigFolder/Group_1_Pres.xml

Localize your custom presence state by specifying one or more locale ID (LCID) schema in the XML configuration file. The example later in this topic shows localization into English - United States (1033), Norwegian - Bokmål (1044), French - France (1036), and Turkish (1055). For a list of LCIDs, see Locale IDs Assigned by Microsoft at http://go.microsoft.com/fwlink/p/?linkid=157331.

To add custom presence states to Lync 2013

1. Create an XML configuration file that uses the format of the following example:

```
<?xml version="1.0"?>
<customStates xmlns="http://schemas.microsoft.com/09/2009/communicator
  <customState ID="1" availability="online">
    <activity LCID="1033">Working from Home</activity>
    <activity LCID="1044">activity 2 for 1044</activity>
    <activity LCID="1055">activity 3 for 1055</activity>
  </customState>
  <customState ID="2" availability="busy">
    <activity LCID="1033">In a Live Meeting</activity>
    <activity LCID="1036">Equivalent French String for - In a Live Mee
  </customState>
  <customState ID="3" availability="busy">
    <activity LCID="1033">Meeting with Customer</activity>
    <activity LCID="1055">meeting with client</activity>
    <activity LCID="1036">Equivalent French String for - Meeting with
  </customState>
  <customState ID="4" availability="do-not-disturb">
    <activity LCID="1033">Interviewing</activity>
  </customState>
</customStates>
```

2. Save the XML configuration file to a web server with HTTPS enabled. In this example, the file is named Presence.xml and saved to the location https://lspool.corp.contoso.com/ClientConfigFolder/CustomPresence.xml.
3. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
4. In the Lync Server Management Shell, define the location of your XML configuration file by using a command similar to the following:

```
New-CsClientPolicy -Identity ContosoCustomStates
-CustomStateURL "https://lspool.corp.contoso.com/ClientConfigFolder/Cu
```

5. Use the **Grant-CSClientPolicy** cmdlet to assign this new policy to users.

For details, see New-CsClientPolicy and Grant-CsClientPolicy in the Lync Server Management Shell documentation.

Note:

- By default, Lync Server 2013 updates client policies and settings every three hours.
- If you want to continue using Group Policy settings from previous releases, such as CustomStateURL, Lync 2013 will recognize the settings if they are located in the new policy registry hive (HKEY_LOCAL_MACHINE\SOFTWARE\Policies\Microsoft\Office\15.0\Lync). However, server-based client policies take precedence.

1.4.10.1.2.5 Adding a Custom Link to Lync Error Messages

Adding a Custom Link to Lync Error Messages

Deploying Clients and Devices > Deploying Lync Clients > Customizing Lync Behavior and the User Interface >

Topic Last Modified: *2013-02-20*

Customize Lync 2013 error messages by adding a link to your own troubleshooting or help desk information. To do this, use the **New-CSClientPolicy** or **Set-CSClientPolicy** Lync Server Management Shell cmdlets with the CustomLinkInErrorMessages parameter. The text of the custom link is "Click here for support topics from your administrator," and it cannot be customized.

For example, the following command causes the custom link to appear in the footnote area of every Lync 2013 error message and sets the link destination to http://contoso.com/help/LyncHelpDesk.aspx:

```
New-CsClientPolicy -Identity LyncErrorLink -CustomLinkInErrorMessages "http://con
```

Use **Grant-CSClientPolicy** to assign this new policy to users. For details, see **New-CSClientPolicy** and **Grant-CSClientPolicy** in the Lync Server Management Shell documentation.

1.4.10.1.2.6 Adding Custom Text to Instant Messages

Adding Custom Text to Instant Messages

Deploying Clients and Devices > Deploying Lync Clients > Customizing Lync Behavior and the User Interface >

Topic Last Modified: *2013-02-20*

Add a disclaimer or warning to the beginning of every Lync 2013 instant messaging (IM) conversation by using the **New-CSClientPolicy** or **Set-CSClientPolicy** Lync Server Management Shell cmdlets with the IMWarning parameter.

The command in the following example adds a security reminder at the top of the Conversation window whenever a new IM conversation begins:

```
New-CsClientPolicy -Identity IMSecurityNotice -IMWarning
"Remember, security is everyone's responsibility. Keep it confidential."
```

Use **Grant-CSClientPolicy** to assign this new policy to users. For details, see **New-CSClientPolicy** and **Grant-CSClientPolicy** in the Lync Server Management Shell documentation.

1.4.10.1.2.7 Starting Lync from Another Application

Starting Lync from Another Application

Deploying Clients and Devices > Deploying Lync Clients > Customizing Lync Behavior and the User Interface >

Topic Last Modified: *2013-02-20*

You can use command-line parameters to quick-start Lync 2013. For example, if a user clicks a phone number in another application, the application can start an instance of Lync 2013 and initiate a call to that number.

Lync 2013 can also recognize a semicolon-delimited list of contact names for multiparty conferencing.

If Lync 2013 is configured to automatically sign in when started, then starting Lync 2013 with command-line parameters will open the Lync main window. If Lync is not configured to automatically sign in when started, the sign-in window opens.

The following table shows the available parameters.

Lync 2013 Command-Line Parameters

Extension	Format of Data	Action
tel:	tel URI	Opens the Conversation window for an audio call but does not dial the specified number.
callto:	tel:, sip:, or typeable tel URI	Opens the Conversation window for an audio call but does not dial the specified number.
sip:	SIP URI	Opens the Conversation window with the specified SIP Uniform Resource Identifier (URI) in the participant list.
Sips:	SIP URI	If Lync 2013 is configured to use the Transport Layer Security (TLS) protocol, functions exactly like sip:. If TLS is not being used, displays a dialog box informing the user that a higher level of security is required.
conf:	SIP URI of conference to join	If URI is self, instantiates the focus and brings up roster-only view. Otherwise, brings up roster view but does not send INVITE.
im:	SIP URI	Displays an instant messaging (IM)-only Conversation window with the SIP URI. Accepts multiple SIP URIs specified inside angle brackets (<>) without any separator. `im:<sip:user1@host><sip:user2@host>`

The following table provides examples of these command-line parameters.

Command-Line Parameter Examples

Instance	Results
Tel:+14255550101	Opens a phone-only view with +14255550101.
Callto:tel:+ 14255550101	Opens a phone-only view with +14255550101.
Callto:sip:kazuto@litwareinc.com	Opens a phone-only view with kazuto@litwareinc.com.
sip:kazuto@litwareinc.com	Opens a Conversation window with kazuto@litwareinc.com.
conf:sip:https://meet.contoso.com/kazuto/7322994	Opens a Conversation window and displays meeting audio join options.

1.4.10.1.3 Customizing the Online Meeting Add-in

Customizing the Online Meeting Add-in

Deployment > Deploying Clients and Devices > Deploying Lync Clients >

Topic Last Modified: *2012-06-28*

The Online Meeting Add-in for Lync 2013 supports meeting management from within the Outlook messaging and collaboration client. There are several ways you can customize the behavior of the add-in. Among these are new options for adding logos and text to the body of online meeting invitations.

- Updating the Outlook Enable List

- Configuring the Meeting Invitation

1.4.10.1.3.1 Updating the Outlook Enable List

Updating the Outlook Enable List

Deploying Clients and Devices > Deploying Lync Clients > Customizing the Online Meeting Add-in >

Topic Last Modified: *2013-01-07*

You can ensure that Online Meeting Add-in for Microsoft Lync 2013 always remains enabled for users by creating a policy that includes it in the Add-in Management List for Outlook. The Add-in Management List policy is included in the Office administrative template files for the Group Policy Management Console. It creates a registry key under HKCU\Software\Policies\Microsoft\Office\15.0\Outlook15\Resiliency\AddinList. You can add a value for the ucaddin.dll to this key, and configure the ucaddin.dll value so that it is always enabled and so that users cannot manually disable it

⊟To Add ucaddin.dll to the Outlook Add-in List

- To the AddinList registry key, located under HKCU\Software\Policies\Microsoft\Office\15.0\Outlook15\Resiliency\AddinList, add the following value:
  - Registry Type = REG_SZ
  - Name = ucaddin.dll
  - Value = 1 (specifies that the add-in is always enabled and cannot be managed by the end user)

1.4.10.1.3.2 Configuring the Meeting Invitation

Configuring the Meeting Invitation

Deploying Clients and Devices > Deploying Lync Clients > Customizing the Online Meeting Add-in >

Topic Last Modified: *2012-10-03*

You can customize meeting invitations sent by the Online Meeting Add-in for Lync 2013 by including the following optional items in the body of the meeting invitation:

- **Your organization's logo** Add your organization's logo to meeting invitations by using the Logo URL option. If meeting invitations will be sent to people external to your organization, the image should be located at a publicly available URL. The supported image formats are GIF and JPG. Although Lync Server 2013 stores the URL with no size restrictions on the image, for best results, the maximum size of the image should be 30 pixels high by 188 pixels wide.
- **A Custom Help or Support Link** Add a URL for your organization's help or support team website. If meeting invitations will be sent to people external to your organization, the URL should be publicly available. The maximum URL length is 1 KB.
- **Legal disclaimer text** Add a URL for legal text or a disclaimer that will be displayed in all meeting invitations. If meeting invitations will be sent to people external to your organization, the URL should be publicly available. The maximum URL length is 1 KB.
- **Custom footer text** Add text that will be rendered as a custom footer in the invitation. The maximum length of text that can be added is 2 KB.

You can configure these options by using either Lync Server Control Panel or Lync Server Management Shell.

To Customize the Meeting Invitation by using Lync Server Control Panel

1. From a user account that is a member of the RTCUniversalServerAdmins group (or has equivalent user rights), or assigned to the CsServerAdministrator or CsAdministrator role, log on to any computer that is in the network in which you deployed Lync Server 2013.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Conferencing** and then click **Meeting Configuration**.
4. On the **Meeting Configuration** page, click **New**, and then do one of the following:
   - To create a site-level policy, click **Site configuration**. In the **Select a Site** search field, type all or part of the name of the site for which you want to define meeting join settings. In the resulting list of sites, click the site you want, and then click **OK**.
   - To create a pool-level policy, click **Pool configuration**. In the **Select a Service** search field, type all or part of the name of the pool service for which you want to define meeting join settings. In the resulting list of services, click the pool you want, and then click **OK**.
5. Do any of the following:
   - In the **Logo URL** field, type the URL for your organization’s logo image.
   - In the **Help URL** field, type the URL to your organization’s help or support site.
   - In the **Legal text** field, type the URL to the legal text or disclaimer that you want to include in meeting invitations.
   - In the **Custom footer text** field, type footer text, up to 2 KB.

To Customize the Meeting Invitation by using Lync Server Management Shell

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the **New-CsMeetingConfiguration** or **Set-CsMeetingConfiguration** cmdlet to create or configure the meeting invitation options. For example, run:

```
New-CsMeetingConfiguration -Identity site:Redmond -EnableInviteCustomi
```

1.4.10.1.4 Configuring the Meeting Join Page

Configuring the Meeting Join Page

See Also

Microsoft Lync Server 2013 > Deployment > Deploying Conferencing >

Topic Last Modified: *2012-12-14*

When a user clicks a meeting link in a meeting request, the meeting join page detects whether a Lync 2013 client is already installed on the user’s computer. If a client is already installed, the client opens and joins the meeting. If a client is not installed, by default the 2013 version of Lync Web App opens.

You can modify the behavior of the meeting join page if you want to allow users to join meetings with Office Communicator 2007 R2 or Lync 2010 Attendant. These configuration options have been removed from the Lync Server 2013 Control Panel, but you configure them by using the Set-CsWebServiceConfiguration cmdlet.

Meeting Join Page Set-CsWebServiceConfiguration Parameters

Set-CsWebServiceConfiguration Parameter	Description
ShowJoinUsingLegacyClientLink	If set to True, users joining a meeting by using a client application other than Lync will be given the opportunity to join the meeting by using Office Communicator 2007 R2. The default value is False.
ShowAlternateJoinOptionsExpanded	When set to True then alternate options for joining an online conference (such as Office Communicator 2007 R2) will automatically be expanded and shown to users. When set to False (the default value) these options will be available, but the user will have to display the list of options for themselves.

To configure the meeting join page by using Lync Server 2013 Management Shell

1. Start the Lync Server 2013 Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. To view the web service configuration settings, run the following cmdlet:

   ```
   Get-CsWebServiceConfiguration
   ```

3. Run the following command, with the parameters set to True or False, depending on your preference (for details about the parameters for this cmdlet, see Set-CsWebServiceConfiguration in the Lync Server 2013 Management Shell documentation):

   ```
   Set-CsWebServiceConfiguration -Identity global -ShowJoinUsingLegacyCli
   ```

Set-CsWebServiceConfiguration

1.4.10.1.5 Configuring Supported Client Versions

Configuring Supported Client Versions

Deployment > Deploying Clients and Devices > Deploying Lync Clients >

Topic Last Modified: *2012-12-14*

In Lync Server 2013, you can set up client version policies to specify the versions of clients that are supported in your environment. Additionally, you can use the global client version configuration to specify a default action for clients that do not already have a version policy defined and, therefore, are not explicitly supported or restricted.

You can also use client version policies to manage client updates. When you set a client version policy and use the options **Allow and upgrade** and **Block and upgrade**, clients will receive updated software from the Windows Server Update Service (if you are using this service) or from Microsoft Update.

Client Version Policy Settings

The default client version policy requires that all clients run Lync. If clients in your environment are running earlier versions of Communicator, you may need to reconfigure the Client Version rules to prevent clients and devices from being unexpectedly blocked or updated when connecting to Lync Server 2013. You can modify the default rule, or you can add a rule higher in the Client Version Policy list to override the default rule. Additionally, as Cumulative Updates (CUs) are released, you should configure the Client Version Policy to require the latest updates. For details, see Specifying the Client Applications That Can Be Used to Log On to Lync Server 2013 in the Operations documentation.

1.4.10.1.6 Configuring Enhanced Presence Privacy Mode

Configuring Enhanced Presence Privacy Mode

See Also

Deployment > Deploying Clients and Devices > Deploying Lync Clients >

Topic Last Modified: *2012-10-18*

With enhanced presence privacy mode, users can restrict their presence information so that it is visible only to the contacts listed in their Lync 2013 Contacts list. The **New-CsPrivacyConfiguration** and **Set-CsPrivacyConfiguration** cmdlets have an EnablePrivacyMode parameter controls this option. When EnablePrivacyMode is set to True, the option to restrict presence information to contacts becomes available in the Lync 2013 Status options. When EnablePrivacyMode is set to False, users can choose either to always allow everyone to see their presence information or to adhere to any future changes the administrator makes to the privacy mode.

> **Important:**
>
> Lync 2013 and Lync 2010 privacy settings are not honored by previous versions (Microsoft Office Communicator 2007 R2 or Microsoft Office Communicator 2007). If previous versions of Office Communicator are allowed to sign in, a Lync 2013 user's status, contact information, or picture could be viewed by someone who has not been authorized to view it. Additionally, a Lync 2013 user's privacy settings are reset if he or she later signs in with previous version of Communicator.
>
> For these reasons, in a migration scenario, before you enable enhanced presence privacy mode:
>
> - Ensure that every user has Lync 2013 installed.
> - Define a client version policy rule to prevent previous versions of Communicator from signing in.

To enable enhanced presence privacy mode

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Run the following command:

```
Get-CsPrivacyConfiguration | Set-CsPrivacyConfiguration -EnablePrivacy
```

   This command enables privacy mode for all the privacy configuration settings currently in use in the organization.

Get-CsPrivacyConfiguration
New-CsPrivacyConfiguration
Set-CsPrivacyConfiguration

1.4.10.2 Deploying the Lync VDI Plug-in

Deploying the Lync VDI Plug-in

Microsoft Lync Server 2013 > Deployment > Deploying Clients and Devices >

Topic Last Modified: *2012-10-03*

The Lync 2013 client supports audio and video in a Virtual Desktop Infrastructure (VDI) environment. A user can connect an audio or video device (for example, a headset or a camera) to the local computer (for example, a thin client or repurposed computer). The user can connect to the virtual machine, sign in to the Lync 2013 client that is running on the virtual machine, and participate in real-time audio and video communications as though the client is running locally.

The Lync VDI Plug-in is a stand-alone application that installs on the local computer and allows the use of local audio and video devices with the Lync 2013 client running on the virtual machine. The plug-in does not require Lync to be installed on the local computer. After the user signs in to the Lync 2013 client that is running on the virtual machine, Lync prompts the user to re-enter his or her credentials to establish a connection with the Lync VDI Plug-in that is running on the local computer. After this connection is established, the user is ready to make and receive audio and video calls.

In This Section

1.4.10.2.1 Lync VDI Plug-in Prerequisites

Lync VDI Plug-in Prerequisites

Deployment > Deploying Clients and Devices > Deploying the Lync VDI Plug-in >

Topic Last Modified: *2013-02-20*

In a virtual desktop infrastructure (VDI) environment, the virtual machines and the user’s local computer must meet the requirements outlined in this section.

Note:

Refer to your virtualization solution provider for details about how to install and deploy the virtualized environment. For information about deploying a virtualized environment based on Hyper-V and Remote Desktop Services, see the following articles in the Microsoft TechNet Library:

- Hyper-V at http://go.microsoft.com/fwlink/p/?linkid=247514
- Remote Desktop Services in Windows Server 2008 R2 at http://go.microsoft.com/fwlink/p/?linkid=247513

The following are requirements for the virtual machines running on the data center computer:

- Virtual machines must be configured with Windows 8, Windows 7, or Windows Server 2008 R2 with the latest service packs.

The following are requirements for the user and the user's local computer:

- The user must be homed on Lync Server 2013.
- The local computer must be running Windows Embedded Standard 7 with SP1, Windows 7 with SP1, or Windows 8.
- If you are using Remote Desktop Services, the Lync VDI plug-in bitness (that is, whether the application is 32-bit or 64-bit) must match the local computer's operating system bitness. The bitness of the operating system on the local computer and the operating system on the virtual machine do not need to match. If you are using another virtualization solution or platform, refer to guidance from your virtualization solution provider about bitness requirements.
- The local computer must be running the latest version of the remote desktop client. Install the latest updates of Remote Desktop Services client from Microsoft or the latest remote desktop client software from your virtualization solution provider. For the latest Remote Desktop Services updates, see http://go.microsoft.com/fwlink/p/?LinkId=268032.
- On the local computer, the remote desktop client settings must be configured so that audio plays on the local computer and remote recording is disabled. To configure these settings for Remote Desktop Connection in Windows, see the next section, "To configure Remote Desktop Connection settings."

To configure Remote Desktop Connection settings

To prepare Remote Desktop Connection in Windows for the Lync VDI plug-in, follow these steps.

1. If the local computer is running Windows 8, skip this step. If the local computer is running Windows 7 with SP1, install the latest Windows 8 version of the Remote Desktop Services client, available at http://go.microsoft.com/fwlink/p/?LinkId=268032.
2. Start the Remote Desktop Services client by clicking **Start**, and then clicking **Remote Desktop Connection**.
3. Click **Options**.
4. Click the **Local Resources** tab. Under **Remote audio**, click **Settings**, and then do the following:
   - Under **Remote audio playback**, select **Play on this computer**.
   - Under **Remote audio recording**, select **Do not record**.
   - Click **OK**.
5. Click the **Experience** tab. Under **Performance**, clear the **Persistent bitmap caching** check box.
6. Click the **General** tab. In **Computer**, type the name of the virtual machine, and then click **Connect**.

1.4.10.2.2 Preparing Your Environment for VDI

Preparing Your Environment for VDI

Deployment > Deploying Clients and Devices > Deploying the Lync VDI Plug-in >

Topic Last Modified: *2013-02-22*

To prepare the environment for the Lync VDI plug-in, the administrator must perform the following steps.

1. In Lync Server 2013, ensure that EnableMediaRedirection is set to TRUE for

all VDI users. For details, see the Help topics for the New-CsClientPolicy cmdlet and the Set-CsClientPolicy cmdlet.

2. On the data center computer, install the Lync 2013 client on all virtual machines.
3. On the local computers, install the Lync VDI plug-in.

1.4.10.2.3 Signing In and Using Lync 2013 on the Virtual Machine

Signing In and Using Lync 2013 on the Virtual Machine

Deployment > Deploying Clients and Devices > Deploying the Lync VDI Plug-in >

Topic Last Modified: *2012-10-03*

After the VDI plug-in is enabled, the following steps occur when the user signs in to Lync 2013.

1. The user types his or her credentials in to the Lync 2013 client running on the virtual machine.
2. After Lync detects the availability of the VDI plug-in, Lync prompts the user to re-enter his or her credentials. In this dialog box, we recommend that the user select the **Save my password** check box so that he or she will not be required to enter credentials during subsequent sign in.
3. Lync begins pairing with the VDI plug-in. Before pairing is complete, the client displays two icons in the Lync status bar. The icon in the lower left indicates that no audio devices are available, and the blinking icon in the lower right indicates that the VDI pairing is in progress, as shown:

4. After VDI pairing is successful, the icons change to indicate the audio device that will be used for calls and the VDI pairing success:

5. After Lync pairs with the VDI plug-in, the user can see his or her presence on Lync compatible devices that are connected to the local computer. The user can now place and answer calls as usual.

1.4.10.2.4 Troubleshooting the Lync VDI Plug-in

Troubleshooting the Lync VDI Plug-in

Deployment > Deploying Clients and Devices > Deploying the Lync VDI Plug-in >

Topic Last Modified: *2012-10-10*

Troubleshooting Issues with Installing the Lync VDI Plug-in on a Thin Client

If there are issues with installing the VDI plug-in on a thin client, check the following:

- Ensure that there is sufficient space in the folder that you specified in the TEMP and TMP system variables.
- Ensure that write-protect is turned off. Refer to your device manufacturer’s documentation for instructions.

Troubleshooting Issues with Pairing

When VDI plug-in pairing fails, the pairing icon in the lower right displays as a red “X” as shown:

The following are possible reasons for failures and the corrective actions you can take.

- **The user entered incorrect credentials during sign-in.**
  The user should sign out of Lync and sign in again with the correct credentials. The pairing dialog box will reappear and show whether pairing is successful.
- **Another instance of the remote desktop client is running.**
  If they are using Remote Desktop Connection in Windows, users should do the following:
  .1. Start Task Manager: Press **Alt+Ctrl+Delete**, and then click **Start Task Manager**.
  .2. Click the **Processes** tab and look for all processes named **mstsc.exe** in the list.
  .3. Highlight each **mstsc.exe** process and then click **End Process**.
  .4. Start a new remote desktop session and try connecting again.
- **The necessary files did not install correctly.**
  After the plug-in is installed on the local computer, the following files should be present under C:\Program Files\Microsoft Office\Office15 (or the appropriate drive letter):
  .1. LyncVdiPlugin.dll
  .2. UcVdi.dll
  If there are any issues with VDI pairing, check to make sure that these files are present on the local computer.
- **The Lync client is running on the local computer.**
  To use the Lync VDI plugin, a Lync client must not be running on the local computer, otherwise pairing will fail. As a best practice, the user should not install a Lync client on the local computer.

1.4.10.2.5 Known Limitations for VDI

Known Limitations for VDI

Deployment > Deploying Clients and Devices > Deploying the Lync VDI Plug-in >

Topic Last Modified: *2012-12-14*

The following are known limitations when you are using Lync 2013 in a VDI environment:

- There is limited support for Call Delegation and Response Group Agent Anonymization features.
- There is no support for the following features:
  - Integrated Audio Device and Video Device tuning pages.
  - Multi-view video.
  - Recording of conversations.
  - Joining meetings anonymously (that is, joining Lync meetings hosted by an organization that does not federate with your organization).
  - Using the Lync VDI plug-in along with a Lync Phone Edition device.
  - Call continuity in case of a network outage.
  - Customized ringtones and music on hold features.
- The Lync VDI plug-in is not supported in an Office 365 environment.

1.4.10.3 Deploying Lync Web App

Deploying Lync Web App

See Also

Microsoft Lync Server 2013 > Deployment > Deploying Clients and Devices >

Topic Last Modified: *2013-03-04*

Lync Web App is an Internet Information Services (IIS) web client that installs with Lync Server 2013 and is enabled by default. No additional steps are necessary to either enable Lync Web App on the server or deploy the web client to users. Whenever a user clicks a meeting URL but does not have the Lync 2013 client installed, the user is presented with the option to join the meeting by using the latest version of Lync Web App.

The voice, video, and sharing features in Lync Web App require a Microsoft ActiveX control. You can either install the ActiveX control in advance or allow users to install it when prompted, which happens the first time they use Lync Web App or the first time they access a feature that requires the ActiveX control.

Note:

In Lync Server 2013 Edge Server deployments, an HTTPS reverse proxy in the perimeter network is required for Lync Web App client access. You must also publish simple URLs. For details, see Setting Up Reverse Proxy Servers and Planning for Simple URLs.

Enabling Multi-Factor Authentication for Lync Web App

The Lync Server 2013 version of Lync Web App supports multi-factor authentication. In addition to user name and password, you can require additional authentication methods, such as smart cards or PINs, to authenticate external users when they sign in to Lync meetings. You can enable multi-factor authentication by deploying Active Directory Federation Service (AD FS) federation server and enabling passive authentication in Lync Server 2013. After AD FS is configured, external users who attempt to join Lync meetings are presented with an AD FS multi-factor authentication webpage that contains the user name and password challenge along with any additional authentication methods that you have configured.

Important:

The following are important considerations if you plan to configure AD FS for multi-factor authentication:

- If you use hardware load balancers, enable cookie persistence on the load balancers so that all requests from the Lync Web App client are handled by the same Front End Server.
- When you establish a relying party trust between Lync Server and AD FS servers, assign a token life that is long enough to span the maximum length of your Lync meetings. Typically, a token life of 240 minutes is sufficient.

To Configure Multi-Factor Authentication

1. Install an AD FS federation server role. For details, see the Active Directory Federation Services 2.0 Deployment Guide at http://go.microsoft.com/fwlink/p/?linkid=267511
2. Create certificates for AD FS. For more information, see the "Federation server certificates" section of the Plan for and deploy AD FS for use with single sign-on topic at http://go.microsoft.com/fwlink/p/?LinkId=285376.
3. From the Windows PowerShell command-line interface, run the following command:

   ```
   add-pssnapin Microsoft.Adfs.powershell
   ```

4. Establish a partnership by running the following command:

```
Add-ADFSRelyingPartyTrust -Name ContosoApp -MetadataURL https://lyncpo
```

5. Set the following relying party rules:

```
$IssuanceAuthorizationRules = '@RuleTemplate = "AllowAllAuthzRule" =>
$IssuanceTransformRules = '@RuleTemplate = "PassThroughClaims" @RuleNa
```

```
Set-ADFSRelyingPartyTrust -TargetName ContosoApp -IssuanceAuthorizatio
```

```
Set-CsWebServiceConfiguration -UseWsFedPassiveAuth $true -WsFedPassive
```

BranchCache Configuration

The BranchCache feature in Windows 7 and Windows Server 2008 R2 can interfere with Lync Web App web components. To prevent issues for Lync Web App users, make sure that BranchCache is not enabled.

For details about disabling BranchCache, see the BranchCache Deployment Guide, which is available in Word format at the Microsoft Download Center at http://go.microsoft.com/fwlink/p/?LinkId=268788 and in HTML format in the Windows Server 2008 R2 Technical Library at http://go.microsoft.com/fwlink/p/?LinkId=268789.

Verifying Lync Web App Deployment

You can use the Test-CsUcwaConference cmdlet to verify that a pair of test users can participate in a conference using the Unified Communications Web API (UCWA). For details about this cmdlet, see Test-CsUcwaConference in the Lync Server Management Shell documentation.

Troubleshooting Plug-in Installation on Windows Server 2008 R2

If installation of the plug-in fails on a computer running Windows Server 2008 R2, you may need to modify the Internet Explorer security setting or the DisableMSI registry key setting.

To modify the security setting in Internet Explorer

1. Open Internet Explorer.
2. Click **Tools**, click **Internet Options**, and then click **Advanced**.
3. Scroll down to the **Security** section.
4. Clear **Do not save encrypted pages to disk**, and then click **OK**.

> **Note:**
> If selected, this setting will also cause an error when trying to download an attachment from Lync Web App.

5. Rejoin the meeting. The plug-in should download without errors.

To modify the DisableMSI Registry setting

1. Click **Start**, and then click **Run**.
2. To access the Registry Editor, type **regedit**.
3. Navigate to HKEY_LOCAL_MACHINE\Software\Policies\Microsoft\Windows\Installer.
4. Edit or add the DisableMSI registry key of type REG_DWORD and set it to 0.
5. Rejoin the meeting.

1.4.10.5 Deploying Mobile Clients

Deploying Mobile Clients

Microsoft Lync Server 2013 > Deployment > Deploying Clients and Devices >

Topic Last Modified: *2013-02-19*

Lync 2013 apps for mobile clients provide instant messaging (IM), enhanced presence, and telephony for users in your organization who are connecting from a smartphone or a phone running a Professional edition of Windows Mobile. You can instruct your users to install Lync 2013 by directing them to the app marketplace for their mobile phone.

Note:

Lync Server 2013 also supports Lync 2010 for mobile clients. For details, refer to the following articles in the Lync Server 2010 TechNet library:

- "Planning for Mobile Clients" at http://go.microsoft.com/fwlink/p/?LinkID=235955.
- "Deploying Mobile Clients" at http://go.microsoft.com/fwlink/p/?LinkID=236068.

1.4.10.5.1 Deploying Lync for Windows Phone

Deploying Lync for Windows Phone

Deployment > Deploying Clients and Devices > Deploying Mobile Clients >

Topic Last Modified: *2013-02-19*

This section describes how to deploy Lync 2013 for Windows Phone for your mobile users.

- Installing Lync for Windows Phone
- Removing Lync for Windows Phone

1.4.10.5.1.1 Installing Lync for Windows Phone

Installing Lync for Windows Phone

Deploying Clients and Devices > Deploying Mobile Clients > Deploying Lync for Windows Phone >

Topic Last Modified: *2013-02-19*

Lync 2013 for Windows Phone is a user-installable application that is available in the Windows Phone Marketplace.

Installing Lync for Windows Mobile

You can instruct your users to install Lync 2013 for Windows Phone on their devices by directing them to the Windows Phone Marketplace at http://go.microsoft.com/fwlink/p/?linkid=231901.

Verifying Mobile Client Installation

After you configure the client and sign in successfully, use the following tests to verify that your installation of Lync 2013 is working correctly on your mobile device.

Search for a contact in the corporate directory

1. In the Contacts list, tap **Search** at the bottom.
2. Search for a contact that exists only in the global address list.
3. Verify that the contact name appears in the search results.

Test instant messaging and presence

1. In the Contacts list, tap a contact.
2. In the contact card, tap the **IM** icon.
3. Verify that an instant messaging (IM) window appears and that you can type and send an IM.

Test dial-out conferencing

1. In Outlook, schedule a Lync meeting.
2. On the mobile device, open the meeting invitation.
3. Click the link in the meeting to join.
4. Answer the call from the conference service and verify that you are connected to meeting audio.

Test push notifications

1. On user A’s mobile device, sign in to Lync with user A’s account.
2. Open another application on the mobile device.
3. On a different client, sign in to Lync with user B’s account.
4. Send an IM from user B to user A.
5. Verify that the IM notification appears on user A’s mobile device.

1.4.10.5.1.2 Removing Lync for Windows Phone

Removing Lync for Windows Phone

Deploying Clients and Devices > Deploying Mobile Clients > Deploying Lync for Windows Phone >

Topic Last Modified: *2013-02-19*

To remove the Lync 2013 for Windows Phone application from the mobile device, perform the following steps:

1. On the mobile device, from the start screen, swipe to see the application list.
2. Tap and hold the Lync application, and then select **Uninstall**.

1.4.10.5.2 Deploying Lync for iPhone and iPad

Deploying Lync for iPhone and iPad

Deployment > Deploying Clients and Devices > Deploying Mobile Clients >

Topic Last Modified: *2013-02-19*

This section describes how to deploy Lync 2013 for iPhone and Lync 2013 for iPad for your mobile users.

- Installing Lync for iPhone and iPad

1.4.10.5.2.1 Installing Lync for iPhone and iPad

Installing Lync for iPhone and iPad

Deploying Clients and Devices > Deploying Mobile Clients > Deploying Lync for iPhone and iPad >

Topic Last Modified: *2013-02-19*

Lync 2013 for iPhone and Lync 2013 for iPad are user-installable applications that are available in the Apple App Store.

Installing Lync for iPhone and Lync for iPad

You can instruct your users to install Lync 2013 for iPhone and Lync 2013 for iPad by directing them to the App Store from their devices. The App Store for each device is also available online.

- Lync for iPhone is available in the App Store at < http://www.apple.com/iphone/from-the-app-store/>
- Lync for iPad is available in the App Store at < http://www.apple.com/ipad/from-the-app-store/>

Verifying Mobile Client Installation

After you configure the client and sign in successfully, use the following tests to verify that your Lync installation is working correctly on your mobile device.

Search for a contact in the corporate directory

1. In the Contacts list, tap inside the search bar at the top, and begin typing the name of a contact that exists only in the global address list (GAL).
2. Verify that the contact name appears in the search results.

Test instant messaging and presence

1. In the Contacts list, tap a contact.
2. In the contact card, tap the **IM** icon.
3. Verify that an instant messaging (IM) window appears and that you can type and send an IM.

Test dial-out conferencing

1. In Outlook, schedule a Lync meeting.
2. On the mobile device, open the meeting invitation.
3. Click the link in the meeting to join.
4. Answer the call from the conference service and verify that you are connected to the meeting audio.

Test push notifications

1. On user A’s mobile device, sign in to Lync with user A’s account.
2. Open another application on the mobile device.
3. On a different client, sign in to Lync with user B’s account.
4. Send an IM from user B to user A.
5. Verify that the IM notification appears on user A’s mobile device.

1.4.10.5.2.2 Removing Lync for iPhone and iPad

Removing Lync for iPhone and iPad

Deploying Clients and Devices > Deploying Mobile Clients > Deploying Lync for iPhone and iPad >

Topic Last Modified: *2013-02-19*

To remove Lync 2013 for iPhone or Microsoft Lync 2010 for iPad from the device, perform the following steps:

1. On the mobile device home screen, tap and hold the Lync icon.
2. When the tiles begin to shake and the **X** appears, tap the **X** to delete the application.

1.4.10.6 Deploying Lync Windows Store App

Deploying Lync Windows Store App

Microsoft Lync Server 2013 > Deployment > Deploying Clients and Devices >

Topic Last Modified: *2013-02-19*

Before making Lync Windows Store app available to users, make sure that your deployment meets the Lync Windows Store App Requirements. For details about configuring Lync Server 2013 to support Lync Windows Store app, see the NextHop Blog article, "Lync Server Autodiscover and the Lync Windows Store App," at http://go.microsoft.com/fwlink/?LinkId=271966. After your server environment is configured correctly, you can direct users to download the Lync app from the Windows Store by searching for "Lync."

Known Issues that Can Prevent Sign-in

The time and date are not set accurately on the device running Lync Windows Store app

The time setting on the device must be synchronized with the time setting on the server. This is particularly important for devices such as Microsoft Surface, and other devices running Windows RT that are not joined to a domain. To set the time on these devices automatically from a time server, run the following command from an elevated command prompt on the device:

```
w32tm /resync
```

Lync Windows Store app cannot access the Lync server or services

Lync Windows Store app may not be able to access the Lync server or services through network adapters, such as 4G LTE USB modems, that do not register with Windows 8 as physical devices. Lync Windows Store app may have this issue even when the desktop apps and browsers are able to access other servers and web sites.

Use Lync Windows Store app logs to troubleshoot issues

You can use the logs generated on the device to troubleshoot issues. The logs are stored in the following folder:

%LocalAppData%\Packages\Microsoft.LyncMX_8wekyb3d8bbwe\LocalState\Tracing

Before you get the logs from a user, make sure that logging is turned on, and then ask the user to save the logs so that all the information stored in memory is also saved to files on the hard drive.

To turn on logging

1. Open Lync Windows Store app on the device.
2. Swipe from the right side of the screen. If you're using a mouse, point to the upper-right corner of the screen and then move the mouse pointer down the screen.
3. Select **Settings**, select **Options**, and then set **Diagnostic Logs** to **On**.
4. If **Diagnostic Logs** was off previously, you must restart Lync. To restart Lync, do one of the following:
   - Restart the device.
   - End the Lync task and launch the app again. To end the task, open the Windows Task Manager, select **Lync**, and then tap **End task**. If Lync is not listed, tap **More details** and look for Lync under **Background processes**.

To save the logs

1. Open Lync Windows Store app on the device.
2. Try signing in.
3. Swipe from the right side of the screen. If you're using a mouse, point to the upper-right corner of the screen and then move the mouse pointer down the screen.
4. Select **Settings**, select **About**, and then select **Save logs**.

1.4.10.7 Using Lync Connectivity Analyzer

Using Lync Connectivity Analyzer

Microsoft Lync Server 2013 > Deployment > Deploying Clients and Devices >

Topic Last Modified: *2013-01-15*

Microsoft Lync Connectivity Analyzer helps Lync administrators determine whether the deployment and configuration of their on-premises Lync Server environment meets the requirements to support connections from Lync app from Windows Store for Windows 8 and Windows RT, and from Lync apps on mobile devices.

Lync Connectivity Analyzer attempts to connect to your on-premises Lync Server by using the same services and protocols that are used by Lync Windows Store app and Lync mobile apps. You can perform the connection tests over your internal network or over an external network that connects to Lync Server. Lync Connectivity Analyzer provides a report with detailed information about each connection step to help you validate your configuration and troubleshoot connection problems.

Lync Connectivity Analyzer tests the following Lync Server components:

- Autodiscover service

- Authentication Broker (Reach) service
- Mobility (MCX) service
- WebTicket service

Lync Connectivity Analyzer tests the configuration of the following other components:

- Publication of DNS records for Autodiscover URLs
- Certificates
- Proxy servers

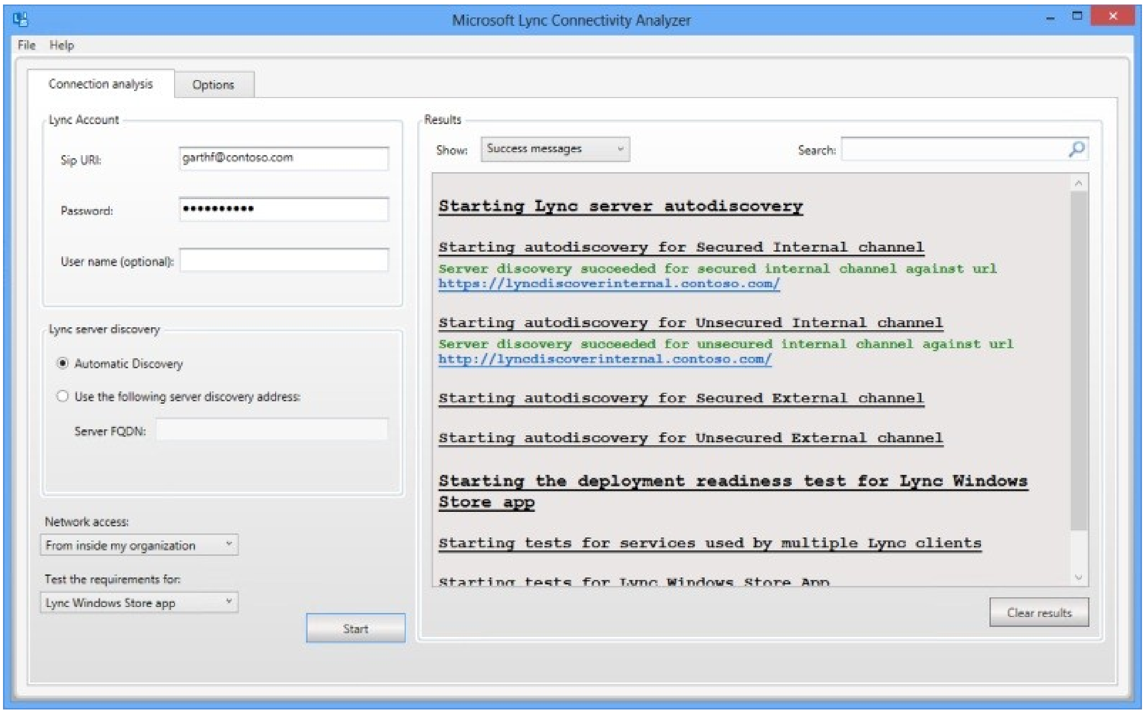
You can download Lync Connectivity Analyzer from the Microsoft Download Center at http://go.microsoft.com/fwlink/?LinkId=277056.

Note:
Lync Connectivity Analyzer cannot be used to test accounts for Office 365 Lync servers.

To Analyze Your Connectivity

1. Enter the credentials for a valid Lync account that will be used by the tool to test the connection:
   - In **SIP URI**, enter the SIP sign-in address for the Lync connection in the format **user@domain.com**.
   - In **Password**, enter the password associated with this account.
   - In **User name (optional)**, enter a user name if applicable. The user name is also known as the User Principal Name (UPN). If the user name and the SIP URI are the same, you do not need to enter a user name. If they are not the same, enter the user name in the format **user@domain.com** or **domain\user**, as appropriate.
   - Under **Lync server discovery**, select the type of test to perform:
     - If you want the tool to discover the Lync server automatically, select **Automatic discovery**.
     - If you want the tool to bypass the autodiscover test, or if you know the name of the server you would like to connect to, select **Use the following server discovery address**, and then in **Server FQDN**, specify the fully qualified domain name (FQDN) of the Lync server—for example, **lync.company.com**.
2. Under **Network access**, choose **From inside my organization** if you are running Lync Connectivity Analyzer from a computer connected to your internal network. Otherwise, choose **External (Internet)**. Lync Connectivity Analyzer always performs both internal and external tests, but specifying whether you are inside or outside of your own network helps the tool interpret whether certain failures are expected.
3. Under **Test the requirements for**, select whether to perform connectivity tests for **Lync Windows Store app** or **Lync mobile apps**.
4. Click **Start**.

The following figure shows sample results from Lync Connectivity Analyzer.



Lync Account

Sip URI: garthf@contoso.com

Password: •••••••••••

User name (optional):

Lync server discovery

```

Components Tested by Lync Connectivity Analyzer

Lync Connectivity Analyzer attempts to discover the Lync server and establish a connection by using the same steps used by Lync Windows Store app and Lync mobile apps. It performs the tests as described in this section.

If **Automatic discovery** is selected, Lync Connectivity Analyzer does the following:

- Queries Domain Name Service (DNS) for autodiscover URLs.
- Attempts discovery by using the secured internal channel. For example, **HTTPS://lyncdiscoverinternal.company.com/**.
- Attempts discovery by using the unsecured internal channel. For example, **HTTP://lyncdiscoverinternal.company.com/**.
- Attempts discovery by using the secured external channel. For example, **HTTPS://lyncdiscover.company.com**.
- Attempts discovery by using the unsecured external channel. For example, **HTTP://lyncdiscover.company.com**.

If **Use the following server discovery address** is selected, Lync Connectivity Analyzer does the following:

- Queries DNS for the server’s FQDN.
- Attempts discovery by using the secured channel. For example, **HTTPS://serverFQDN/**.
- Attempts discovery by using the unsecured channel. For example, **HTTP://serverFQDN/**.

If **Lync Windows Store app** is selected under **Test the requirements for**, Lync Connectivity Analyzer does the following:

- Verifies that the WebTicket service is available and tests authentication of the Lync account credentials.
- Verifies that the Authentication Broker (Reach) service is available.

If **Lync mobile apps** is selected under **Test the requirements for**, Lync Connectivity Analyzer does the following:

- Verifies that the WebTicket service is available and tests authentication of the Lync account credentials.
- Verifies that the Mobility (MCX) service is available.

While performing these tests, Lync Connectivity Analyzer validates the certificates installed on Lync Server, hardware load balancers, proxy servers, and the computer on which you are running the tests.

Other Resources

Microsoft also provides Microsoft Remote Connectivity Analyzer, a web-based connectivity test tool, which is available at https://testconnectivity.microsoft.com/. Lync Connectivity Analyzer and Remote Connectivity Analyzer differ in the following ways:

- Remote Connectivity Analyzer can test connectivity for Microsoft Exchange and Outlook, in addition to Microsoft Lync.
- Remote Connectivity Analyzer completes the SIP sign-in, whereas Lync Connectivity Analyzer only validates the account credentials, without signing in.
- Remote Connectivity Analyzer tests connections only from outside of your organization's network because it runs from a public web server.
- Remote Connectivity Analyzer does not test the availability of Authentication Broker (Reach), Mobility (MCX), and WebTicket services.
- Lync Connectivity Analyzer tests the Autodiscover service.
- Remote Connectivity Analyzer can connect to any version of Lync Server, whereas Lync Connectivity Analyzer can connect successfully only to Lync Server 2010 with Cumulative Updates for Lync Server 2010: February 2012 (at a minimum), or the latest version of Lync Server.

The following documentation describes the requirements and procedures for deploying and configuring Lync Server to support Lync Windows Store app and Lync mobile clients:

- Deploying Clients and Devices
- Planning for Mobility
- Deploying Mobility

1.4.11 Planning and Deploying Unified Contact Store

Planning and Deploying Unified Contact Store

Microsoft Lync Server 2013 > Deployment >

Topic Last Modified: *2012-06-14*

Unified contact store is a feature that provides a consistent contact experience across Microsoft Office products. This feature enables users to store all contact information in Exchange 2013 so that the information is available globally across Lync, Exchange, Outlook, and Outlook Web Access.

In This Section

- Requirements for Unified Contact Store
- Deploying Unified Contact Store

1.4.11.1 Requirements for Unified Contact Store

Requirements for Unified Contact Store

Microsoft Lync Server 2013 > Deployment > Planning and Deploying Unified Contact Store >

Topic Last Modified: *2012-10-01*

The following list describes the requirements for implementing unified contact store in Lync Server 2013:

- You must be running Microsoft Lync Server 2013 and Exchange 2013.
- Users must use Lync 2013 to initiate the migration of contacts from Lync Server 2013 to Exchange 2013.
- User mailboxes must be migrated to Exchange 2013.
- You must have server-to-server authentication configured between Lync Server 2013 and Exchange 2013.

> **Note:**
>
> For detailed requirements about setting up authentication between Lync Server 2013 and Exchange 2013, see Managing Server-to-Server Authentication (Oauth) and Partner Applications in the Operations documentation.

1.4.11.2 Deploying Unified Contact Store

Deploying Unified Contact Store

Microsoft Lync Server 2013 > Deployment > Planning and Deploying Unified Contact Store >

Topic Last Modified: *2012-10-07*

Enabling unified contact store in Lync Server 2013 does not require any topology settings. Enabling unified contact store for users requires the following:

- Unified contact store policy is enabled (default is enabled).
- Users log in with Lync 2013 at least once.

After a user’s contacts have been migrated, which happens automatically when a user logs in with Lync 2013, the user can access and manage their Lync contacts from Lync 2013, Outlook 2013, or Outlook Web Access. The user does not have to be logged in to Lync to manage their contacts from Outlook or Outlook Web Access.

> **Important:**
>
> If a user logs in from Lync 2010 after migration, contacts and groups are available and up-to-date, but the user cannot manage (that is, add, delete, move, tag, untag, or modify) those contacts.

- Enable Users for Unified Contact Store
- Migrate Users to Unified Contact Store
- Roll back Migrated Users

1.4.11.2.1 Enable Users for Unified Contact Store

Enable Users for Unified Contact Store

Deployment > Planning and Deploying Unified Contact Store > Deploying Unified Contact Store >

Topic Last Modified: *2012-10-07*

When you deploy Lync Server 2013 and publish the topology, unified contact store is enabled for all users by default. You do not need to take any additional action to enable unified contact store after you deploy Lync Server 2013. However, you can use the **Set-CsUserServicesPolicy** cmdlet to customize which users have unified contact store available. You can enable this feature globally, by site, by tenant, or by individuals or groups of individuals.

To enable users for unified contact store

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Do any of the following:
   - To enable unified contact store globally for all Lync Server users, at the command line, type:

     ```
     Set-CsUserServicesPolicy -Identity global -UcsAllowed $True
     ```

   - To enable unified contact store for the users at a specific site, at the command line, type:

     ```
     New-CsUserServicesPolicy -Identity site:<site name> -UcsAllo
     ```

     For example:

     ```
     New-CsUserServicesPolicy -Identity site:Redmond -UcsAllowed
     ```

   - To enable unified contact store by tenant, at the command line, type:

     ```
     Set-CsUserServicesPolicy -Tenant <tenantId> -UcsAllowed $Tru
     ```

     For example:

     ```
     Set-CsUserServicesPolicy -Tenant "38aad667-af54-4397-aaa7-e9
     ```

   - To enable unified contact store for specific users, at the command line, type:

     ```
     New-CsUserServicesPolicy -Identity "<policy name>" -UcsAllow
     Grant-CsUserServicesPolicy -Identity "<user display name>" -
     ```

     Note:
     You can also use user alias or SIP URI instead of the user display name.

     For example:

     ```
     New-CsUserServicesPolicy -Identity "UCS Enabled Users" -UcsA
     Grant-CsUserServicesPolicy -Identity "Ken Myer" -PolicyName
     ```

     Note:
     In the preceding example, the first command creates a new per-user policy named *UCS Enabled Users* with the UcsAllowed flag set to True. The second command assigns the policy to the user with the display name Ken Myer, which means that Ken Myer is now enabled for unified contact store.

1.4.11.2.2 Migrate Users to Unified Contact Store

Migrate Users to Unified Contact Store

[Deployment](#) > [Planning and Deploying Unified Contact Store](#) > [Deploying Unified Contact Store](#) >

Topic Last Modified: *2012-10-15*

A user's contacts are automatically migrated to the Exchange 2013 server when the user:

- Has been assigned a user services policy that has UcsAllowed set to True.
- Has been provisioned with an Exchange 2013 mailbox and has signed into the mailbox at least once.
- Logs in by using a Lync 2013 rich client.

If the user logs in with a Lync 2010 or earlier client, or if the user is not connected to an Exchange 2013 server, the user services policy is ignored and the user's contacts remain in Lync Server.

You can determine whether a user's contacts have been migrated by using either of the following methods:

- Check the following registry key on the client computer: HKEY_CURRENT_USER\Software\Microsoft\Office\15.0\Lync\<SIP URL>\UCS If the user's contacts are stored in Exchange 2013, this key contains a value of InUCSMode with a value of 2165.
- Run the **Test-CsUnifiedContactStore** cmdlet. At the Lync Server Management Shell command line, type:

  ```
  Test-CsUnifiedContactStore -UserSipAddress "sip:kenmyer@litwareinc.com"
  ```

  If **Test-CsUnifiedContactStore** succeeds, the user's contacts were migrated to unified contact store.

1.4.11.2.3 Roll back Migrated Users

Roll back Migrated Users

Deployment > Planning and Deploying Unified Contact Store > Deploying Unified Contact Store >

Topic Last Modified: *2012-10-07*

If you need to roll back the unified contact store feature, roll back the contacts only if you move the user back to Exchange 2010 or Lync Server 2010. To roll back, disable the policy for the user, and then run the **Invoke-CsUcsRollback** cmdlet. Just running **Invoke-CsUcsRollback** alone is not enough to ensure permanent rollback, because unified contact store migration will be initiated again if the policy is not disabled. For example, if a user is rolled back because Exchange 2013 is rolled back to Exchange 2010, and then the user’s mailbox is moved to Exchange 2013, the unified contact store migration will be initiated again seven days after the rollback, as long as unified contact store is still enabled for the user in the user services policy.

> **Important:**
>
> The **Move-CsUser** cmdlet automatically rolls back the user's contact store from Exchange 2013 to Lync Server 2013 in the following situations:
>
> - When users are moved from Lync Server 2013 to Lync Server 2010.
> - When users are migrated cross premises, such as when a user is moved from Lync Online to Lync Server 2013 on-premises, or vice versa.

> **Important:**
>
> Importing unified contact store data from a backup database can cause unified contact store data and user data to become corrupted if the unified contact store mode changed between the export and the import. For example:
>
> - If you export contact lists before the users' contacts are migrated to Exchange 2013 and then, after the migration, import the same data, the unified contact store data and contact lists will be corrupted.
> - If you export userdata after you migrate users to Exchange 2013, roll back the migration, and then for some reason you import the data from after the migration, the unified contact store data and contact lists will be corrupted.

> **Important:**
>
> Before you move an Exchange mailbox from Exchange 2013 to Exchange 2010, the

Exchange administrator must make sure that the Lync Server administrator has first rolled back the Lync Server user contacts from Exchange 2013 to Lync Server. To roll back unified contact store contacts to Lync Server, see procedure "To roll back unified contact store contacts from Exchange 2013 to Lync Server 2013," later in this section.

The following procedure describes how to roll back user contacts. If you use the **Move-CsUser** cmdlet to move users between Lync Server 2013 and Lync Server 2010, you can skip these steps because the **Move-CsUser** cmdlet automatically rolls back unifed contact store when it moves users from Lync Server 2013 to Lync Server 2010. **Move-CsUser** does not disable unified contact store policy, so the migration to unified contact store will recur if the user is moved back to Lync Server 2013.

To roll back user contacts from Lync Server 2013 to Lync Server 2010

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Disable unified contact store for the users to be rolled back so that they will not be remigrated after rollback. (Perform this step only if you want to make sure that users will not remigrate in the future.) To disable unified contact store for individual users, at the command line, type:

   ```
   Set-CsUserServicesPolicy -Identity "<policy name>" -UcsAllowed $False
   ```

   For example:

   ```
   Set-CsUserServicesPolicy -Identity "UCS Enabled Users" -UcsAllowed $Fa
   ```

3. Before moving a user from Lync Server 2013 to Lync Server 2010, roll back the Buddy List for the specified users on Lync Server.

   Important:
   If this step is omitted, the Buddy List will be lost.

4. Roll back the specified users. At the command line, type:

   ```
   Invoke-CsUcsRollback -Identity "<user display name>"
   ```

   For example:

   ```
   Invoke-CsUcsRollback -Identity "Ken Myer"
   ```

   Important:
   We do not recommend using the –Force option to force the rollback. If you use this option, the users' contacts will be lost.

To roll back unified contact store contacts from Exchange 2013 to Lync Server 2013

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Disable unified contact store for the users to be rolled back so that they will not be remigrated after rollback. To disable unified contact store for individual users, at the command line, type:

   ```
   Set-CsUserServicesPolicy -Identity "<policy name>" -UcsAllowed $False
   ```

   For example:

   ```
   Set-CsUserServicesPolicy -Identity "UCS Enabled Users" -UcsAllowed $Fa
   ```

3. Roll back the specified users. At the command line, type:

   ```
   Invoke-CsUcsRollback -Identity "<user display name>"
   ```

   For example:

   ```
   Invoke-CsUcsRollback -Identity "Ken Myer"
   ```

Important:
You must first roll back the Lync Server user, and then move the Exchange 2013 mailbox. The Exchange administrator is blocked from rolling back Exchange until the Lync Server rollback is complete. We do not recommend using the –Force option to force the rollback. If you use this option, the users' contacts will be lost.

4. After you roll back the user to Lync Server, the Exchange administrator can roll back the Exchange user from Exchange 2013 to Exchange 2010.

1.4.12 Managing Server-to-Server Authentication (Oauth) and Partner Applications

Managing Server-to-Server Authentication (Oauth) and Partner Applications

See Also

Microsoft Lync Server 2013 > Deployment >

Topic Last Modified: *2013-01-22*

Microsoft Lync Server 2013 must be able to securely, and seamlessly, communicate with other applications and server products. For example, you can configure Lync Server 2013 so that contact data and/or archiving data is stored in Microsoft Exchange Server 2013; however, this can only be done if Lync Server and Exchange are able to securely communicate with one another. Likewise, you can schedule a Lync Server conference from within Microsoft SharePoint Server; again, however, this can only be done if the two servers (SharePoint and Lync Server) trust one another. Although it's possible to use one authentication mechanism for Lync-to-Exchange communication and a separate mechanism for Lync-to-SharePoint communication, a better and more efficient approach is to use a standardized method for all server-to-server authentication and authorization.

Using a single, standardized method for server-to-server authentication is the approach taken by Lync Server 2013. For the 2013 release, Lync Server 2013 (as well as other Microsoft Server products, including Exchange 2013 and Microsoft SharePoint Server) support the OAuth (Open Authorization) protocol for server-to-server authentication and authorization. With OAuth, a standard authorization protocol used by a number of major websites, user credentials and passwords are not passed from one computer to another. Instead, authentication and authorization is based on the exchange of security tokens; these tokens grant access to a specific set of resources for a specific amount of time.

OAuth authentication typically involves three parties: a single authorization server and the two realms that need to communicate with one another. (You can also do server-to-server authentication without using an authorization server, a process that will be discussed later in this document.) Security tokens are issued by the authorization server (also known as a security token server) to the two realms that need to communicate; these tokens verify that communications originating from one realm should be trusted by the other realm. For example, the authorization server might issue tokens that verify that users from a specific Lync Server 2013 realm are able to access a specified Exchange 2013 realm, and vice-versa.

Note:
A realm is simply a security container. By default, Lync Server 2013 uses your default SIP domain as its OAuth realm.

Lync Server 2013 supports three server-to-server authentication scenarios. With Lync Server 2013 you can:

- Configure server-to-server authentication between an on-premise installation of Lync Server 2013 and an on-premises installation of Exchange 2013 and/or

Microsoft SharePoint Server.

- Configure server-to-server authentication between a pair of Office 365 components (for example, between Microsoft Exchange 365 and Microsoft Lync Server 365, or between Microsoft Lync Server 365 and Microsoft SharePoint 365).
- Configure server-to-server authentication in a cross-premises environment (that is, server-to-server authentication between an on-premises server and an Office 365 component).

Note that, at this point in time, only Exchange 2013, SharePoint Server, and Lync Server 2013 support server-to-server authentication; if you are not running one of these servers then you will not be able to fully implement OAuth authentication.

It should also be pointed out that you do not need to use server-to-server authentication: server-to-server authentication is not required in order to deploy Lync Server 2013. If Lync Server 2013 does not need to communicate with other servers (such as Exchange 2013) then server-to-server authentication is not needed.

However, server-to-server authentication is required if you want to use some of Lync Server's new features, such as the "unified contact store." With unified contact store, Lync Server 2013 contact information is stored in Exchange 2013 instead of in Lync Server; this enables users to have a single set of contacts that is readily accessible from within Lync, Microsoft Outlook, or Microsoft Outlook Web Access. Because the unified contact store requires Lync Server 2013 to share information with Exchange 2013, you must use server-to-server authentication in order to deploy the feature. Server-to-server authentication is also required if you choose to use Exchange archiving, in which the transcripts of instant messaging sessions are saved as Exchange 2013 emails rather than as individual database records.

For the Office 365 version of Lync Server to communicate with its Exchange counterpart, Lync Server 2013 must first obtain a security token from the authorization server. Lync Server then uses that security token to identify itself to Exchange 365. The Office 365 version of Exchange must go through the same process in order to communicate with Lync Server 2013.

However, for on-premises server-to-server authentication between two Microsoft servers there is no need to use a third-party token server. Server products such as Lync Server 2013 and Exchange 2013 have a built-in token server that can be used for authentication purposes with other Microsoft servers (such as SharePoint server) that support server-to-server authentication. For example, Lync Server 2013 can issue and sign a security token by itself, then use that token to communicate with Exchange 2013. In a case like this, there is no need for a third-party token server.

In order to configure server-to-server authentication for an on-premises implementation of Lync Server 2013 you must do two things:

- Assign a certificate to Lync Server's built-in token issuer.
- Configure the server that Lync Server 2013 will communicate with to be a "partner application." For example, if Lync Server 2013 needs to communicate with Exchange 2013 then you will need to configure Exchange to be a partner application.

Note:

A "partner application" is any application that Lync Server 2013 can directly exchange security tokens with, without having to go through a third-party security token server.

Assigning a Server-to-Server Authentication Certificate to Microsoft Lync Server 2013
Configuring Microsoft Lync Server 2013 in a Cross-Premises Environment

1.4.12.1 Assigning a Server-to-Server Authentication Certificate to Microsoft Lync Server 2013

Assigning a Server-to-Server Authentication Certificate to Microsoft Lync Server 2013

Microsoft Lync Server 2013 > Deployment > Managing Server-to-Server Authentication (Oauth) and Partner Applications >

Topic Last Modified: *2012-10-01*

To determine whether or not a server-to-server authentication certificate has already been assigned to Microsoft Lync Server 2013, run the following command from the Lync Server 2013 Management Shell:

```
Get-CsCertificate -Type OAuthTokenIssuer
```

If no certificate information is returned you must assign a token issuer certificate before you can use server-to-server authentication. As a general rule, any Lync Server 2013 certificate can be used as your OAuthTokenIssuer certificate; for example, your Lync Server 2013 default certificate can also be used as the OAuthTokenIssuer certificate. (The OAUthTokenIssuer certificate can also be any Web server certificate that includes the name of your SIP domain in the Subject field.) The primary two requirements for the certificate used for server-to-server authentication are these: 1)the same certificate must be configured as the OAuthTokenIssuer certificate on all of your Front End Servers; and, 2) the certificate must be at least 2048 bits.

If you do not have a certificate that can be used for server-to-server authentication you can obtain a new certificate, import the new certificate, and then use that certificate for server-to-server authentication. After you have requested and obtained the new certificate you can then log on to any one of your Front End Servers and use a Windows PowerShell command similar to this one to import and assign that certificate:

```
Import-CsCertificate -Identity global -Type OAuthTokenIssuer -Path C:\Certificate
```

In the preceding command the Path parameter represents the full path to the certificate file, and the Password parameter represents the password that was assigned to the certificate. This procedure should be run just one time: Lync Server's replication service will then automatically create a set of scheduled tasks that will decrypt and deploy the certificate to all your Front End Servers.

Alternatively, you can use an existing certificate as your server-to-server authentication certificate. (As noted, the default certificate can be used as the server-to-server authentication certificate.) The following pair of Windows PowerShell commands retrieve the value of the default certificate's Thumbprint property, then use that value to make the default certificate the server-to-server authentication certificate:

```
$x = (Get-CsCertificate -Type Default).Thumbprint
Set-CsCertificate -Identity global -Type OAuthTokenIssuer -Thumbprint $x
```

In the preceding command, the retrieved certificate is configured to function as the global server-to-server authentication certificate; that means that the certificate will be replicated to, and used by, all your Front End Servers. Again, this command should only be run one time, and only on one of your Front End Servers. Although all Front End Servers must use the same certificate, you should not configure the OAuthTokenIssuer certificate on each Front End Server. Instead, configure the certificate once, then let Lync Server's replication server take care of copying that certificate to each server.

The Set-CsCertificate cmdlet takes the certificate in question and immediately configures that certificate to act as the current OAuthTokenIssuer certificate. (Lync Server 2013 keeps two copies of a certificate type: the current certificate and the previous certificate.)

If you need the new certificate to immediately begin to act as the OAuthTokenIssuer certificate then you should use the Set-CsCertificate cmdlet.

You can also use the Set-CsCertificate cmdlet to "roll" a new certificate. "Rolling" a certificate simply means that you configure a new certificate to become the current OAuthTokenIssuer certificate at a specified point in time. For example, this command retrieves the default certificate and then configure that certificate to take over as the current OAuthTokenIssuer certificate as of July 1, 2012:

```
$x = (Get-CsCertificate -Type Default).Thumbprint
Set-CsCertificate -Identity global -Type OAuthTokenIssuer -Thumbprint $x -Effecti
```

On July 1, 2012 the new certificate will be configured as the current OAuthTokenIssuer certificate and the "old" OAuthTokenIssuer certificate will be configured as the previous certificate.

If you do not want to use Windows PowerShell you can also use the Certificates MMC console to export a certificate from one Front End Server and then import that same certificate on all your other Front End Servers. If you do this, make sure that you export the private key along with the certificate itself.

Caution:

In this case, the procedure must be performed on each Front End Server. When exporting and importing certificates in this manner Lync Server 2013 will not replicate that certificate to each Front End Server.

After the certificate has been imported to all your Front End Servers, that certificate can then be assigned by using the Lync Server Deployment Wizard instead of Windows PowerShell. To assign a certificate by using the Deployment Wizard, complete the following steps on a computer where the Deployment Wizard has been installed:

1. Click Start, click All Programs, click **Microsoft Lync Server 2013 (Technical Preview)**, and then click **Lync Server Deployment Wizard**.
2. In the Deployment Wizard, click **Install or Update Lync Server System**.
3. On the **Lync Server 2013 (Technical Preview)** page, click the **Run** button under the heading **Step 3: Request, Install or Assign Certificates**. (Note: If you have already installed certificates on this computer then the **Run** button will be labeled **Run Again**.)
4. In the Certificate Wizard, select the **OAuthTokenIssuer** certificate and then click **Assign**.
5. In the Certificate Assignment wizard, on the **Certificate Assignment** page, click **Next**.
6. On the **Certificate Store** page, select the certificate to be used for server-to-server authentication and then click **Next**.
7. On the Certificate Assignment Summary page, click **Next**.
8. On the Executing Commands page, click **Finish**.
9. Close the Certificate Wizard and the Deployment Wizard.

1.4.12.2 Configuring an On-Premises Partner Application for Microsoft Lync Server 2013

Configuring an On-Premises Partner Application for Microsoft Lync Server 2013

Microsoft Lync Server 2013 > Deployment > Managing Server-to-Server Authentication (Oauth) and Partner Applications >

Topic Last Modified: *2013-02-04*

After you have assigned the OAuthTokenIssuer certificate you must then configure your

Microsoft Lync Server 2013 partner applications. (The procedure about to be discussed configures both Microsoft Exchange Server 2013 and Microsoft SharePoint to act as partner applications.) To configure an on-premises partner application, you must start by copying the following Windows PowerShell script and pasting the code into Notepad (or any other text editor):

```
if ((Get-CsPartnerApplication -ErrorAction SilentlyContinue) -ne $Null)
   {
       Remove-CsPartnerApplication app
   }
$exch = Get-CsPartnerApplication microsoft.exchange -ErrorAction SilentlyContinue
if ($exch -eq $null)
   {
      New-CsPartnerApplication -Identity microsoft.exchange -MetadataUrl https://
    }
else
    {
       if ($exch.ApplicationIdentifier -ne "00000002-0000-0ff1-ce00-000000000000"
          {
             Remove-CsPartnerApplication microsoft.exchange
New-CsPartnerApplication -Identity microsoft.exchange -MetadataUrl https://atl-ex
           }
        else
           {
             Set-CsPartnerApplication -Identity microsoft.exchange -ApplicationTr
           }
     }
$shp = Get-CsPartnerApplication microsoft.sharepoint -ErrorAction SilentlyContinu
if ($shp -eq $null)
   {
      New-CsPartnerApplication -Identity microsoft.sharepoint -MetadataUrl http:/
    }
else
    {
       if ($shp.ApplicationIdentifier -ne "00000003-0000-0ff1-ce00-000000000000")
          {
             Remove-CsPartnerApplication microsoft.sharepoint
             New-CsPartnerApplication -Identity microsoft.sharepoint -MetadataUrl
           }
        else
           {
             Set-CsPartnerApplication -Identity microsoft.sharepoint -Application
            }
   }
Set-CsOAuthConfiguration -ServiceName 00000004-0000-0ff1-ce00-000000000000
```

After copying the code, save the script using a .PS1 file extension (for example, C:\Scripts \ServerToServerAuth.ps1). Note that, before you run this script, you must replace the metadata URLs https://atl-exchange-001.litwareinc.com/autodiscover/metadata/json/1 and http://atl-sharepoint-001.litwareinc.com/jsonmetadata.ashx with the metadata URLs used by your Exchange 2013 and SharePoint servers, respectively. See the product documentation for Exchange 2013 and SharePoint for information on how you can identify the respective product's metadata URL.

If you look at the last line of the script you will notice that the Set-CsOAuthConfiguration cmdlet is called using this syntax:

```
Set-CsOAuthConfiguration -ServiceName 00000004-0000-0ff1-ce00-000000000000
```

Because the Realm parameter was not used when calling Set-CsOAuthConfiguration the realm will automatically be set to the fully qualified domain name (FQDN) of your organization (for example, litwareinc.com). If your realm name is different from your organization name then you should include the realm name, like this:

```
Set-CsOAuthConfiguration -ServiceName 00000004-0000-0ff1-ce00-000000000000 -Realm
```

After making these changes you can then execute the script, and configure both Exchange 2013 and SharePoint as partner applications, by running the script file from within the Lync Server 2013 Management Shell. For example:

```
C:\Scripts\ServerToServerAuth.ps1
```

Note that you can run this script even if you do not have both Exchange 2013 and SharePoint Server installed:, no problems will occur if you, say, configure SharePoint Server as a partner application even though you do not have SharePoint Server installed.

When you run this script you might receive an error message similar to the following:

```
New-CsPartnerApplication : Cannot bind parameter 'MetadataUrl' to the target. Exc
```

This error message typically means one of two things: 1) that one of the URLs specified in the script is not valid (that is, one of your metadata URLs is not an actual metadata URL); or, 2) one of the metadata URLs could not be contacted. If this happens, verify that the URLs are correct and are accessible, and the re-run the script.

After creating the partner application for Lync Server 2013 you must then configure Lync Server to be a partner application for Exchange 2013. You can configure partner applications for Exchange 2013 by running the script Configure-EnterprisePartnerApplication.ps1; all you need to do is specify the metadata URL for Lync Server and indicate that Lync Server is the new partner application.

To configure Lync Server as a partner application for Exchange, open the Exchange Management Shell and run a command similar to this

```
"c:\Program Files\Microsoft\Exchange Server\V15\Scripts\Configure-EnterprisePartn
```

1.4.12.3 Configuring Microsoft Lync Server 2013 in a Cross-Premises Environment

Configuring Microsoft Lync Server 2013 in a Cross-Premises Environment

Microsoft Lync Server 2013 > Deployment > Managing Server-to-Server Authentication (Oauth) and Partner Applications >

Topic Last Modified: *2012-10-02*

In a cross-premise configuration, some of your users are homed on an on-premises installation of Microsoft Lync Server 2013 while other users are homed on the Office 365 version of Lync Server. In order to configure server-to-server authentication in a cross-premises environment, you must first configure your on-premises installation of Lync Server 2013 to trust the Office 365 Authorization server. The initial step in this process can be carried out by running the following Lync Server Management Shell script:

```
$TenantID = (Get-CsTenant -DisplayName "Fabrikam.com").TenantId
$sts = Get-CsOAuthServer microsoft.sts -ErrorAction SilentlyContinue
   if ($sts -eq $null)
      {
         New-CsOAuthServer microsoft.sts -MetadataUrl "https://accounts.accesscon
      }
   else
      {
         if ($sts.MetadataUrl -ne  "https://accounts.accesscontrol.windows.net/$T
            {
               Remove-CsOAuthServer microsoft.sts
               New-CsOAuthServer microsoft.sts -MetadataUrl "https://accounts.acc
            }
        }
```

```
$exch = Get-CsPartnerApplication microsoft.exchange -ErrorAction SilentlyContinue
if ($exch -eq $null)
   {
      New-CsPartnerApplication -Identity microsoft.exchange -ApplicationIdentifie
    }
else
    {
       if ($exch.ApplicationIdentifier -ne "00000002-0000-0ff1-ce00-000000000000"
          {
             Remove-CsPartnerApplication microsoft.exchange
             New-CsPartnerApplication -Identity microsoft.exchange -ApplicationId
          }
       else
          {
             Set-CsPartnerApplication -Identity microsoft.exchange -ApplicationTr
          }
   }
Set-CsOAuthConfiguration -ServiceName 00000004-0000-0ff1-ce00-000000000000
```

Keep in mind that the realm name for a tenant is typically different than the organization name; in fact, the realm name is almost always the same as the tenant ID. Because of that, the first line in the script is used to return the value of the TenantId property for the specified tenant (in this case, fabrikam.com) and then assign that name to the variable $TenantId:

```
$TenantID = (Get-CsTenant -DisplayName "Fabrikam.com").TenantId
```

After the script completes you must then configure a trust relationship between Lync Server 2013 and the authorization server, and a second trust relationship between Exchange 2013 and the authorization server. This can only be done by using the Microsoft Online Services cmdlets.

Note:

If you have not installed the Microsoft Online Services cmdlets you will need to do two things before proceeding. First, download and install the 64-bit version of the Microsoft Online Services Sign-in Assistant. After installation is complete, download and install the 64-bit version of the Microsoft Online Services Module for Windows PowerShell. Detailed information for installing and using the Microsoft Online Services Module can be found on the Office 365 web site. These instructions will also tell you how to configure single sign-on, federation, and synchronization between Office 365 and Active Directory.

After you have configured Office 365, and after you have created Office 365 service principals for Lync Server 2013 and Exchange 2013, you will then need to register your credentials with these service principals. In order to do this, you must first obtain an X.509 Base64 saved as a .CER file. This certificate will then be applied to the Office 365 service principals.

When you have obtained the X.509 certificate, start the Microsoft Online Services Module (click **Start**, click **All Programs**, click **Microsoft Online Services**, and then click **Microsoft Online Services Module for Windows PowerShell**). After the Services Module opens, type the following to import the Microsoft Online Windows PowerShell module containing the cmdlets that can be used to manage service principals:

```
Import-Module MSOnlineExtended
```

When the module has been imported, type the following command and then press ENTER in order to connect to Office 365:

```
Connect-MsolService
```

After you press ENTER, a credentials dialog box will appear. Enter your Office 365 user name and password in the dialog box, and then click OK.

As soon as you are connected to Office 365 you can then run the following command in order to return information about your service principals:

```
Get-MsolServicePrincipal
```

You should get back information similar to this for all your service principals:

```
ExtensionData        : System.Runtime.Serialization.ExtensionDataObject
AccountEnabled       : True
Addresses            : {}
AppPrincipalId       : 00000004-0000-0ff1-ce00-000000000000
DisplayName          : Microsoft Lync Server
ObjectId             : aada5fbd-c0ae-442a-8c0b-36fec40602e2
ServicePrincipalName : LyncServer/litwareinc.com
TrustedForDelegation : True
```

The next step is to import, encode, and assign the X.509 certificate. To import and encode the certificate, use the following Windows PowerShell commands, being sure to specify the complete file path to your .CER file when you call the Import method:

```
$certificate = New-Object System.Security.Cryptography.X509Certificates.X509Certi
$certificate.Import("C:\Certificates\Office365.cer")
$binaryValue = $certificate.GetRawCertData()
$credentialsValue = [System.Convert]::ToBase64String($binaryValue)
```

After the certificate has been imported and encoded, you can then assign the certificate to your Office 365 service principals. To do that, first use the Get-MsolServicePrincipal to retrieve the value of the AppPrincipalId property for both the Lync Server and the Microsoft Exchange service principals; the value of the AppPrincipalId property will be used to identify the service principal being assigned the certificate. With the AppPrincipalId property value for Lync Server 2013 in hand, use the following command to assign the certificate to the Office 365 version of Lync Server (the StartDate and EndDate properties should correspond to the validity period for the certificate):

```
New-MsolServicePrincipalCredential -AppPrincipalId 00000004-0000-0ff1-ce00-000000
```

You should then repeat the command, this time using the AppPrincipalId property value for Exchange 2013.

If you later need to delete that certificate, you can do so by first retrieving the KeyId for the certificate:

```
Get-MsolServicePrincipalCredential -AppPrincipalId 00000004-0000-0ff1-ce00-000000
```

That command will return data like this one:

```
Type      : Asymmetric
Value     :
KeyId     : bc2795f3-2387-4543-a95d-f92c85c7a1b0
StartDate : 6/1/2012 8:00:00 AM
EndDate   : 5/31/2013 8:00:00 AM
Usage     : Verify
```

You can then delete the certificate by using a command similar to this:

```
Remove-MsolServicePrincipalCredential -AppPrincipalId 00000004-0000-0ff1-ce00-000
```

In addition to assigning a certificate you must also configure the Exchange Online Service Principal and configure your on-premise version of Lync Server 2013 as an Office 365 service principal. That can be done by carrying out the following two commands:

```
Set-MSOLServicePrincipal -AppPrincipalID 00000002-0000-0ff1-ce00-000000000000 -Ac
$lyncSP = Get-MSOLServicePrincipal -AppPrincipalID 00000004-0000-0ff1-ce00-000000
$lyncSP.ServicePrincipalNames.Add("00000004-0000-0ff1-ce00-000000000000/lync.cont
Set-MSOLServicePrincipal -AppPrincipalID 00000004-0000-0ff1-ce00-000000000000 -Se
```

1.4.13 Updating From the Evaluation Version of Lync Server 2013

Updating From the Evaluation Version of Lync Server 2013

Microsoft Lync Server 2013 > Deployment >

Topic Last Modified: *2012-06-20*

If you have installed the Evaluation version of Microsoft Lync Server 2013, you will eventually need to update that installation a licensed copy of the software; that's because the evaluation version expires 180 days after it was installed. However, you will not need to completely uninstall the evaluation version and then install the licensed version. Instead, after you have obtained a valid licensing key, you can update the evaluation version of Lync Server 2013 by carrying out the following procedure on each computer acting as a Lync Server Front End Server, Director, or Edge Server. Note that you do not have to update computers carrying out other server roles, such as a Monitoring Server or Archiving Server.

Updating from the Evaluation Version of Microsoft Lync Server 2013

To update a computer from the evaluation version of Lync Server 2013 to the licensed version of the software:

Updating from the Evaluation Version of Microsoft Lync Server 2013

1. Log on to the computer as a local administrator.
2. Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. In the Lync Server Management Shell, type the following command and then press ENTER:

   ```
   msiexec.exe /fvomus server.msi EVALTOFULL=1 /qb
   ```

   Note that you might need to specify the full path to the file server.msi. This file can be found in the Setup folder of the Lync Server Volume media installation files.
4. After Setup finishes running, type the following from the command prompt and then press ENTER:

   ```
   Enable-CsComputer
   ```
5. Repeat this procedure on any other Front End Server, Director, or Edge Server running an evaluation copy of Lync Server. This procedure should also be performed on any Branch Office Servers that were deployed by using the Lync Server media installation files.

If you are not sure if the evaluation version of Lync Server is running on a given computer you can verify that by running the following command from within the Lync Server Management Shell:

```
Get-CsServerVersion
```

The Get-CsServerVersion cmdlet will analyze the local computer and report back one of the following:

- That the Lync Server volume license key has been installed on the computer, meaning that no updating is necessary.
- That the Lync Server evaluation license key has been installed, meaning that

the computer must be updated.

- That no volume license key is required on the computer. Updating from the evaluation version to the licensed version is only required on Front End Servers, Directors, and Edge Servers.

1.4.14 Deploying Remote Call Control

Deploying Remote Call Control

Microsoft Lync Server 2013 > Deployment >

Topic Last Modified: *2012-10-20*

This section guides you through the process of deploying remote call control functionality to users in your organization.

> **Note:**
> Although remote call control features are available to remote users while they are outside of your organization’s firewall, details about deploying external access scenarios are beyond the scope of this documentation. For details about deploying external user access, see Deploying External User Access in the Deployment documentation.

- Configuring Lync Server 2013 to Route to a SIP/CSTA Gateway
- Configure a Static Route for Remote Call Control
- Configure a Trusted Application Entry for Remote Call Control
- Define a SIP/CSTA Gateway IP Address (only if the gateway is configured to use TCP)
- Enable Lync Users for Remote Call Control
- Remote Call Control and Phone Number Normalization
- Remove a Legacy Authorized Host (Optional) (only if you are migrating users previously enabled for remote call control)

Planning for Remote Call Control

1.4.14.1 Configuring Lync Server 2013 to Route to a SIP/CSTA Gateway

Configuring Lync Server 2013 to Route to a SIP/CSTA Gateway

Microsoft Lync Server 2013 > Deployment > Deploying Remote Call Control >

Topic Last Modified: *2012-10-05*

A SIP/CSTA gateway is a gateway between SIP and a computer-supported telecommunications application (CSTA). A SIP/CSTA gateway provides the interface between an existing private branch exchange (PBX) and Lync Server for routing remote call control requests to the PBX. After you install a SIP/CSTA gateway, you must perform the following procedures on each Lync Server pool for which you want to configure remote call control:

- Configure a Static Route for Remote Call Control
- Configure a Trusted Application Entry for Remote Call Control

1.4.14.2 Configure a Static Route for Remote Call Control

Configure a Static Route for Remote Call Control

See Also

Topic Last Modified: *2012-09-22*

Remote call control requires that every Lync Server pool is configured with a path from that pool to the SIP/CSTA gateway that connects to the private branch exchange (PBX). This path requires that each pool has one static route for each gateway to which the pool will proxy SIP call control messages associated with calls to the PBX. If you configure a global static route for remote call control, each pool that is not configured with a static route at the pool level will use the global static route.

To configure a static route for remote call control

1. Log on to a computer where Lync Server Management Shell is installed as a member of the RTCUniversalServerAdmins group or a role-based access control (RBAC) role to which you have assigned the **New-CsStaticRoute** cmdlet.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. To create a static route and put it in the variable $TLSRoute or $TCPRoute, do one of the following:

Tip:

To match child domains of a domain, you can specify a wildcard value in the MatchUri parameter. For example, ***.contoso.net**. That value matches any domain that ends with the suffix **contoso.net**.

- For a Transport Layer Security (TLS) connection, type the following at the command prompt:

```
$TLSRoute = New-CsStaticRoute -TLSRoute -Destination <gatewa
```

For example:

```
$TLSRoute = New-CsStaticRoute -TLSRoute -Destination rccgate
```

If UseDefaultCertificate is set to False, you must specify TLSCertIssuer and TLSCertSerialNumber parameters. These parameters indicate the name of the certification authority (CA) that issued the certificate used in the static route, and the serial number of that TLS certificate, respectively. For details about these parameters, see Lync Server Management Shell Help by typing the following at the command prompt:

```
Get-Help New-CsStaticRoute -Full
```

- For a Transmission Control Protocol (TCP) connection, type the following at the command prompt:

Note:

If you specify a fully qualified domain name (FQDN), you must configure a Domain Name System (DNS) A record first.

```
$TCPRoute = New-CsStaticRoute -TCPRoute -Destination <gatewa
```

For example:

```
$TCPRoute = New-CsStaticRoute -TCPRoute -Destination 192.168
```

The following are default values for optional parameters for static routes:

- Enabled = True
- MatchOnlyPhoneUri = False
- ReplaceHostInRequestUri = False

We strongly recommend that you do not change these default values. However, if you must change any of these parameters, see Lync Server Management Shell Help by typing the following at the command prompt:

```
Get-Help New-CsStaticRoute -Full
```

4. To persist a newly created static route in the Central Management store, run one of the following, as appropriate:

```
Set-CsStaticRoutingConfiguration -Route @{Add=$TLSRoute}
```

```
Set-CsStaticRoutingConfiguration -Route @{Add=$TCPRoute}
```

Define a SIP/CSTA Gateway IP Address

1.4.14.3 Configure a Trusted Application Entry for Remote Call Control

Configure a Trusted Application Entry for Remote Call Control

See Also

Microsoft Lync Server 2013 > Deployment > Deploying Remote Call Control >

Topic Last Modified: *2012-10-22*

The SIP/CSTA gateway must be configured as a trusted application in order for Lync Server to apply a static route to route calls to the gateway.

Important:
If you are migrating users from a previous version of Lync Server deployment, be sure that you removed all existing trusted application entries (previously known as authorized host entries) you created for the SIP/CSTA gateway before following the procedures in this topic. For details, see Remove a Legacy Authorized Host (Optional).

To configure a trusted application entry for the SIP/CSTA gateway

1. Log on to the computer where Lync Server Management Shell is installed as a member of the RTCUniversalServerAdmins group or a role-based access control (RBAC) role to which you have assigned the **New-CsTrustedApplicationPool** cmdlet.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. To create a trusted application entry, do one of the following:
   - For a Transport Layer Security (TLS) connection, type the following at the command prompt:

     ```
     New-CsTrustedApplicationPool -Identity <FQDN of the SIP/CSTA
     ```

     For example:

     ```
     New-CsTrustedApplicationPool -Identity rccgateway.contoso.ne
     ```

   - For a Transmission Control Protocol (TCP) connection, type the following at the command prompt:

     ```
     New-CsTrustedApplicationPool -Identity <IP address or FQDN o
     ```

     For example:

     ```
     New-CsTrustedApplicationPool -Identity 192.168.0.240 -Regist
     ```

4. To add the trusted application to the pool, do one of the following:
   - For a TLS connection, type the following at the command prompt:

     ```
     New-CsTrustedApplication -ApplicationID <application name> -
     ```

     For example:

```
New-CsTrustedApplication -ApplicationID RccGateway-1 -Truste
```

- For a TCP connection, type the following at the command prompt:

```
New-CsTrustedApplication -ApplicationID <application name> -
```

  For example:

```
New-CsTrustedApplication -ApplicationID RccGateway-1 -Truste
```

5. To implement the published changes you have made to the topology, type the following at the command prompt:

```
Enable-CsTopology
```

If Lync Server will connect to the SIP/CSTA gateway that you deployed for remote call control by using a Transmission Control Protocol (TCP) connection, then you must define the IP address of the gateway in Topology Builder. This step is not necessary for gateways that support Transport Layer Security (TLS) connections. For any gateway that supports TLS connections, you can skip this procedure and continue deployment of remote call control by following the steps in Enable Lync Users for Remote Call Control.

⊟To define the SIP/CSTA gateway IP address by using Topology Builder

1. Log on to the computer where Topology Builder is installed as a member of the Domain Admins group and the RTCUniversalServerAdmins group.
2. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Topology Builder**.
3. Choose the option to download an existing topology.
4. Expand the **Trusted application servers** node.
5. Right-click the trusted application pool that you created, as described in Configure a Trusted Application Entry for Remote Call Control, and then click **Edit Properties**.
6. Clear the **Enable replication of configuration data to this pool** check box.
7. Click **Limit service usage to selected IP addresses**. The default setting is **Use all configured IP addresses**.
8. In the **Primary IP address** text box, enter the IP address of the SIP/CSTA gateway.
9. To update the topology in the Central Management store, in the console tree, click **Lync Server**, and then, from the **Actions** pane, click **Publish**.

1.4.14.5 Enable Lync Users for Remote Call Control

Enable Lync Users for Remote Call Control

Microsoft Lync Server 2013 > Deployment > Deploying Remote Call Control >

Topic Last Modified: *2012-09-21*

You can configure Lync users for remote call control by using in-band provisioning policies that are server-based. You can manage in-band provisioning settings by using Lync Server Control Panel or the Lync Server Management Shell command-line interface. These tools replace the Windows Management Instrumentation (WMI) snap-in that was used to manage Group Policy settings in earlier releases.

If you prefer to let users to configure their own remote call control settings in Lync, you can configure remote call control settings for users on the server without specifying **Line Server URI** and **Line URI** values. Be sure that you communicate the appropriate **Line Server URI** and **Line URI** values to your users, and provide your users with the instructions to configure these settings. For the procedure to manually configure remote call control in Lync Server, see "Set Phones options and numbers" at http://go.microsoft.com/fwlink/p/?linkid=210132 in the Lync client documentation on the Microsoft Office website.

If you have an existing Communications Server 2007 R2 or Communications Server 2007 deployment, Communicator 2007 R2 and Communicator 2007 clients will continue to use Group Policy during side-by-side migration. However, if you want policy settings to carry over to Lync clients, you need to configure the equivalent Lync Server in-band provisioning settings.

Note:

To enable a user for remote call control, you need to provide the user with both a Line URI and a Line Server URI. As described in Deployment Tasks for Remote Call Control, you need to be sure to use the syntax that is required by the gateway for these settings.
Be sure that the domain in the Line Server URI is the same as the destination domain that you specified in the MatchUri parameter when you configured the static route to the gateway.
The Line URI specifies the phone number assigned to the user in E.164 format, with the "TEL:" prefix (for example, tel:+14255550150). If you want to configure an extension number, then the format is tel:+14255550150;ext=111. If you previously configured the user's Line URI and the value has not changed, you do not need to specify the Line URI when you enable the user for remote call control.

⊟To enable remote call control for Lync-enabled users by using Management Shell

1. Log on to a computer where Lync Server Management Shell is installed as a member of the RTCUniversalServerAdmins group or as a role-based access control role to which you have assigned the **Set-CsUser** cmdlet.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. To use the **Set-CsUser** cmdlet to configure remote call control for an existing Lync-enabled user, do the following:

   ```
   Set-CsUser -Identity <User ID> -EnterpriseVoiceEnabled $false -LineSer
   ```

   For example:

   ```
   Set-CsUser -Identity "Katie Jordan" -EnterpriseVoiceEnabled $false -Li
   ```

⊟To configure users for remote call control by using Lync Server Control Panel

1. From a user account that is assigned to the CsUserAdministrator role or the CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Admin URL to open the Lync Server Control Panel. For details about the different methods you can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.
3. In the left navigation bar, click **Users**.
4. In the **Search users** box, type all (or the first portion) of the display name, first name, last name, Security Accounts Manager (SAM) account name, SIP address, or line Uniform Resource Identifier (URI) of the user account that you want, and then click **Find**.
5. In the table, click the user account that you want to modify.
6. On the **Edit** menu, click **Modify**.
7. In **Telephony**, do one of the following:
   - To enable remote call control to enable the user to control their private branch exchange (PBX) phone from Lync 2013 to make PC-to-PC audio calls and PC-to-phone calls, click **Remote call control**. In **Line URI**, specify the telephone number of the user. In **Line Server URI**, specify the SIP URI of the SIP/CSTA gateway.
   - To enable remote call control, but disable PC-to-PC audio calls, and to enable only the user to control their PBX phone from Lync 2013 to make PC-to-phone calls, click **Remote call control only**. In **Line URI**, specify the telephone number of the user. In **Line Server URI**, specify the SIP URI of the SIP/CSTA gateway.
8. When you are finished, click **Commit**.

1.4.14.6 Remote Call Control and Phone Number Normalization

Remote Call Control and Phone Number Normalization

Microsoft Lync Server 2013 > Deployment > Deploying Remote Call Control >

Topic Last Modified: *2012-09-22*

Lync clients download phone number normalization rules as part of the Address Book Service (ABS) file download. In remote call control scenarios, Address Book Service phone number normalization rules are applied to both incoming and outgoing remote call control calls. For incoming calls to a remote call control-enabled user, the phone number of the caller is first normalized to E.164 format by either the SIP/CSTA gateway or private branch exchange (PBX). When Lync Server 2013 receives the call from the gateway, it performs reverse number lookup (RNL) on the phone number of the caller against the normalized number in the callee’s Microsoft Office Outlook Contacts list or the global address list (GAL) that is stored in the Address Book Service. If reverse number lookup successfully finds a match, the caller is identified by name in the incoming call notification.

For outgoing remote call control calls, Lync applies the Address Book Service phone number normalization rules to the dialed number before routing the call to the SIP/CSTA gateway.

For details about creating phone number normalization rules for remote call control, see Dial Plans and Normalization Rules in the Planning documentation.

Migrating Phone Number Normalization Rules

If you are migrating users previously enabled for remote call control, see the following topics in the Migration documentation:

- For Lync Server 2010, see Migrate Address Book in the Migration

documentation.
- For Communications Server 2007 R2, see Migrate Address Book in the Migration documentation.

1.4.14.7 Remove a Legacy Authorized Host (Optional)

Remove a Legacy Authorized Host (Optional)

See Also

Microsoft Lync Server 2013 > Deployment > Deploying Remote Call Control >

Topic Last Modified: *2012-09-05*

When you migrate remote call control to a Lync Server deployment, you must remove legacy authorized host entries (known as *trusted application entries* in Lync Server) for any SIP/CSTA gateways in your legacy deployment. You must use the administrative tools to remove authorized host entries from those deployments, respectively.

1.4.15 Deploying Mobility

Deploying Mobility

Microsoft Lync Server 2013 > Deployment > Deploying External User Access >

Topic Last Modified: *2012-09-08*

When you deploy the Lync Server 2013 mobility feature, mobile users can use supported mobile devices for Lync functionality such as instant messaging (IM), presence, and contacts.

For details about requirements for deploying the mobility feature, see Planning for Mobility.

This section guides you through the steps for deploying and verifying the mobility and automatic discovery features.

- Creating DNS Records for the Autodiscover Service
- Modifying Certificates for Mobility
- Configuring the Reverse Proxy for Mobility
- Configuring Autodiscover for Mobility with Hybrid Deployments
- Verifying Your Mobility Deployment
- Configuring for Push Notifications
- Configuring Mobility Policy

1.4.15.1 Creating DNS Records for the Autodiscover Service

Creating DNS Records for the Autodiscover Service

Deployment > Deploying External User Access > Deploying Mobility >

Topic Last Modified: *2012-10-05*

To support autodiscovery for Lync Mobile users, you need to create the following Domain Name System (DNS) records:

- An internal DNS record to support mobile users who connect from within your organization's network
- An external, or public, DNS record to support mobile users who connect from the Internet

Or

- An external, or public, DNS record to support mobile users who connect from the Internet

You must create an internal DNS record and an external DNS record for each SIP domain.

The DNS records can be either A (host) records or CNAME records. The following procedures describe how to create internal and external DNS records. For more details about the DNS requirements for mobile users, see Technical Requirements for Mobility.

⊟To create DNS CNAME records

1. Log on to a DNS server as follows:
   - To create an internal DNS record, log on to a DNS server in your network as a member of the Domain Admins group or a member of the DnsAdmins group.
   - To create an external DNS record, connect to your public DNS provider.
2. Open the DNS administrative snap-in: Click **Start**, click **Administrative Tools**, and then click **DNS**.
3. Do one of the following:
   - For an internal DNS record, in the console tree of the DNS server, expand **Forward Lookup Zones** for your Active Directory domain (for example, contoso.local).

Note:
This domain is the Active Directory domain where your Lync Server 2013 Director pool and Front End pool are installed.

   - For an external DNS record, in the console tree of the DNS server, expand **Forward Lookup Zones** for your SIP domain (for example, contoso.com).
4. Verify that a host A record exists for your Director pool as follows:
   - For an internal DNS record, a host A record should exist for the internal Web Services fully qualified domain name (FQDN) for your Director pool (for example, lyncwebdir01.contoso.local).
   - For an external DNS record, a host A record should exist for the external web services FQDN for your Director pool (for example, lyncwebextdir.contoso.com).
5. Verify that a host A record exists for your Front End pool as follows:
   - For an internal DNS record, a host A record should exist for the internal Web Services FQDN for your Front End pool (for example, lyncwebpool01.contoso.local).
   - For an external DNS record, a host A record should exist for the external Web Services FQDN for your Front End pool (for example, lyncwebextpool01.contoso.com).
6. For an internal DNS record, in the console tree of your DNS server, expand **Forward Lookup Zones** for your SIP domain (for example, contoso.com).

Note:
If you are creating an external DNS record, **Forward Lookup Zones** is already expanded for your SIP domain from step 3.

7. Right-click the SIP domain name, and then click **New Alias (CNAME)**.
8. In **Alias name**, type one of the following:
   - For an internal DNS record, type lyncdiscoverinternal as the host name for the internal Autodiscover Service URL.
   - For an external DNS record, type lyncdiscover as the host name for the external Autodiscover Service URL.

9. In **Fully qualified domain name (FQDN) for target host**, do one of the following:
   - For an internal DNS record, type or browse to the internal Web Services FQDN for your Director pool (for example, lyncwebdir01.contoso.local), and then click **OK**.
   - For an external DNS record, type or browse to the external Web Services FQDN for your Director pool (for example, lyncwebextdir.contoso.com), and then click **OK**.

   Note:
   If you do not use a Director, use the internal and external Web Services FQDN for the Front End pool, or, for a single server, the FQDN for the Front End Server or Standard Edition server.

   Important:
   You must create a new Autodiscover CNAME record in the forward lookup zone of each SIP domain that you support in your Lync Server 2013 environment.

To create DNS A records

1. Log on to a DNS server as follows:
   - To create an internal DNS record, log on to a DNS server in your network as a member of the Domain Admins group or a member of the DnsAdmins group.
   - To create an external DNS record, connect to your public DNS provider.
2. Open the DNS administrative snap-in: Click **Start**, click **Administrative Tools**, and then click **DNS**.
3. Do one of the following:
   - For an internal DNS record, in the console tree of the DNS server, expand **Forward Lookup Zones** for your Active Directory domain (for example, contoso.local).

     Note:
     This domain is the Active Directory domain where your Lync Server 2013 Director pool and Front End pool are installed.
   - For an external DNS record, in the console tree of the DNS server, expand **Forward Lookup Zones** for your SIP domain (for example, contoso.com).
4. Verify that a host A (for IPv6, AAAA) record exists for your Director pool as follows:
   - For an internal DNS record, a host A (for IPv6, AAAA) record should exist for the internal Web Services FQDN for your Director pool (for example, lyncwebdir01.contoso.local).
   - For an external DNS record, a host A (for IPv6, AAAA) record should exist for the external Web Services FQDN for your Director pool (for example, lyncwebextdir.contoso.com).
5. Verify that a host A (for IPv6, AAAA) record exists for your Front End pool as follows:
   - For an internal DNS record, a host A (for IPv6, AAAA) record should exist for the internal Web Services FQDN for your Front End pool (for example, lyncwebpool01.contoso.local).
   - For an external DNS record, a host A (for IPv6, AAAA) record should exist for the external Web Services FQDN for your Front End pool (for example, lyncwebextpool01.contoso.com).
6. For an internal DNS record, in the console tree of your DNS server, expand **Forward Lookup Zones** for your SIP domain (for example, contoso.com).

   Note:
   If you are creating an external DNS record, **Forward Lookup Zones** is already expanded for your SIP domain from step 3.

7. Right-click the SIP domain name, and then click **New Host (A or AAAA)**.
8. In **Name**, type the host name as follows:
   - For an internal DNS record, type lyncdiscoverinternal as the host name for the internal Autodiscover Service URL.
   - For an external DNS record, type lyncdiscover as the host name for the external Autodiscover Service URL.

   Note:
   The domain name is assumed from the zone in which the record is defined and, therefore, does not need to be entered as part of the A record.
9. In **IP Address**, type the IP address as follows:
   - For an internal DNS record, type the internal Web Services IP address of the Director (or, if you use a load balancer, type the virtual IP (VIP) of the Director load balancer).

     Note:
     If you do not use a Director, type the IP address of the Front End Server or Standard Edition server, or, if you use a load balancer, type the VIP of the Front End pool load balancer.
   - For an external DNS record, type the external or public IP address of the reverse proxy.
10. Click **Add Host**, and then click **OK**.
11. To create an additional A record, repeat steps 8 through 10.

    Important:
    You must create a new Autodiscover A record in the forward lookup zone of each SIP domain that you support in your Lync Server 2013 environment.
12. When you are finished creating A (for IPv6, AAAA) records, click **Done**.

1.4.15.2 Modifying Certificates for Mobility

Modifying Certificates for Mobility

Deployment > Deploying External User Access > Deploying Mobility >

Topic Last Modified: *2012-10-18*

The certificates for your Director pool, Front End pool, and reverse proxy require additional subject alternative name entries to support secure connections with mobile clients. For details about certificate requirements for mobility, see Technical Requirements for Mobility.

Note:
You can use the **Get-CsCertificate** cmdlet to view information about the currently assigned certificates. However, the default view truncates the properties of the certificate and does not display all values in the SubjectAlternativeNames property. You can use the **Get-CsCertificate** , **Request-**CsCertificate and the **Set-CsCertificate** cmdlets to view some information and to request and assign certificates. However, it’s not the best method to use if you are unsure of the properties of the subject alternative names (SAN) on the current certificate. To view the certificate and all property members, it is suggested to use the Certificates snap-in the *Microsoft Management Console (MMC)* or to use the Lync Server Deployment Wizard. In the Lync Server Deployment Wizard, you can use the Certificate Wizard to view the certificate properties. The procedures for viewing, requesting and assigning a certificate using the Lync Server Management Shell and the *Microsoft Management Console (MMC)* are detailed in the following procedures. To use the Lync Server Deployment Wizard, see details here if you have deployed the optional Director or Director pool: Configure Certificates for the Director. For the Front End Server or Front End pool, see the details here: Configure Certificates for Servers
The initial steps in this procedure are preparation steps, to orient you as to what role the current certificates play. By default, the certificates will not have a

lyncdiscover.<sipdomain> or lyncdiscoverinternal.<internal domain name> entry unless you have previously installed Mobility Services or have prepared your certificates in advance. This procedure uses the example SIP domain name 'contoso.com' and the example internal domain name 'contoso.net'.
The default certificate configuration for Lync Server 2013 and Lync Server 2010 is to use a single certificate (named 'Default') with the purposes Default (for all purposes except for the web services), WebServicesExternal and WebServicesInternal. An optional configuration is to use separate certificates for each purpose. Certificates can be managed by using the Lync Server Management Shell and Windows PowerShell cmdlets, or by using the Certificate Wizard in the Lync Server Deployment Wizard.

To update certificates with new subject alternative names using the Lync Server Management Shell

1. Log on to the computer using an account that has local administrator rights and permissions.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Find out what certificates have been assigned to the server and for which type of use. You need this information in the next step to assign the updated certificate. At the command line, type:

```
Get-CsCertificate
```

4. Look in the output from the previous step to see whether a single certificate is assigned for multiple uses or whether a different certificate is assigned for each use. Look in the Use parameter to find out how a certificate is used. Compare the Thumbprint parameter for the displayed certificates to see if the same certificate has multiple uses.
5. Update the certificate. At the command line, type:

```
Set-CsCertificate -Type <type of certificate as displayed in the Use p
```

For example, if the **Get-CsCertificate** cmdlet displayed a certificate with Use of Default, another with a Use of WebServicesInternal, and another with a Use of WebServicesExternal, and they all had the same Thumbprint value, at the command line, type:

```
Set-CsCertificate -Type Default,WebServicesInternal,WebServicesExterna
```

Important:
If a separate certificate is assigned for each use (the Thumbprint value is different for each certificate), it is important that you do not run the **Set-CsCertificate** cmdlet with multiple types. In this case, run the **Set-CsCertificate** cmdlet separately for each use. For example:

```
Set-CsCertificate -Type Default -Thumbprint <Certificate Thumbprint>
Set-CsCertificate -Type WebServicesInternal -Thumbprint <Certificate T
Set-CsCertificate -Type WebServicesExternal -Thumbprint <Certificate T
```

6. To view the certificate, click **Start**, click **Run...**. Type MMC to open the Microsoft Management Console.
7. From the MMC menu, select **File**, select **Add/Remove snap-in...**, select Certificates. Click **Add**. When prompted, select **Computer account**, then click **Next**.
8. If this is the computer where the certificate is located, select **Local computer**. If the certificate is located on another computer, select **Another computer**, type in the fully qualified domain name of the computer or click **Browse** In **Enter the object name to select**, type the name of the computer. Click **Check Names**. When the name of the computer is resolved, it will be underlined. Click **OK**, then click **Finish**. Click **OK** to commit the selection and close the **Add or Remove Snap-ins** dialog.
9. To view the properties of the certificate, expand **Certificates**, expand **Personal**, and select **Certificates**. Select the certificate to view, right-click on

the certificate and select **Open**.

10. In the **Certificate** view, select **Details**. From here, you can select the certificate subject name by selecting **Subject** and the assigned subject name and associated properties are displayed.
11. To view the assigned subject alternative names, select **Subject Alternative Name**. All assigned subject alternative names are displayed. The subject alternative names that are found in the property are of type **DNS Name** by default. You should see the following members (all of which should be fully qualified domain names as represented in DNS host (A or, if IPv6 AAAA) records:
    - Pool name for this pool, or the single server name if this is not a pool
    - Server name that the certificate is assigned to
    - Simple URL records, typically meet and dialin
    - Web services internal and Web services external names (for example, webpool01.contoso.net, webpool01.contoso.com), based on choices made in Topology Builder and over-ridden web services selections.
    - If already assigned, the lyncdiscover.<sipdomain> and lyncdiscoverinternal.<sipdomain> records.

    The last item is what you are most interested in – if there is a lyncdiscover and lyncdiscoverinternal SAN entry.

    Once you have this information, you can close the certificate view and the MMC.
12. If an Autodiscover Service subject alternative name is missing, and you are using a single Default certificate for the Default, WebServicesInternal and WebServiceExternal types, do the following:
    - At the Lync Server Management Shell command line prompt, type:

      ```
      Request-CsCertificate -New -Type Default,WebServicesInterna
      ```

      If you have many SIP domains, you cannot use the new AllSipDomain parameter. Instead, you must use DomainName parameter. When you use the DomainName parameter, you must define the FQDN for the lyncdiscoverinternal and lyncdiscover records. For example:

      ```
      Request-CsCertificate -New -Type Default,WebServicesInterna
      ```

    - To assign the certificate, type the following:

      ```
      Set-CsCertificate -Type Default,WebServicesInternal,WebServi
      ```

      Where “Thumbprint” is the thumbprint displayed for the newly issued certificate.

13. For a missing internal Autodiscover subject alternative names when using separate certificates for Default, WebServicesInternal, and WebServicesExternal, do the following:
    - At the Lync Server Management Shell command line prompt, type:

      ```
      Request-CsCertificate -New -Type WebServicesInternal -Ca dc\
      ```

      If you have many SIP domains, you cannot use the new AllSipDomain parameter. Instead, you must use DomainName parameter. When you use the DomainName parameter, you must use an appropriate prefix for the SIP domain FQDN. For example:

      ```
      Request-CsCertificate -New -Type WebServicesInternal -Ca dc\
      ```

    - For a missing external Autodiscover subject alternative name, at the command line, type:

      ```
      Request-CsCertificate -New -Type WebServicesExternal -Ca dc\
      ```

      If you have many SIP domains, you cannot use the new AllSipDomain parameter. Instead, you must use DomainName parameter. When you use the DomainName parameter, you must use an appropriate prefix for the SIP domain FQDN. For example:

```
Request-CsCertificate -New -Type WebServicesExternal -Ca dc\
```

- To assign the individual certificate types, type the following:

```
Set-CsCertificate -Type Default -Thumbprint <Certificate Thu
Set-CsCertificate -Type WebServicesInternal -Thumbprint <Cer
Set-CsCertificate -Type WebServicesExternal -Thumbprint <Cer
```

Where “Thumbprint” is the thumbprint displayed for the newly issued individual certificates.

1.4.15.3 Configuring the Reverse Proxy for Mobility

Configuring the Reverse Proxy for Mobility

See Also

Deployment > Deploying External User Access > Deploying Mobility >

Topic Last Modified: *2012-09-08*

If you want to use automatic discovery for mobile device clients, you need to modify an existing or create a new web publishing rule for the reverse proxy whether or not you update the subject alternative name lists on the reverse proxy certificates.

If you decide to use HTTPS for initial Lync Server 2013 Autodiscover Service requests and update the subject alternative names lists on the reverse proxy certificates, you need to assign the updated public certificate to the Secure Sockets Layer (SSL) Listener on your reverse proxy. For details about the required subject alternative name entries, see Technical Requirements for Mobility. You then need to modify the existing listener for the external web services or create a new web publishing rule for the external Autodiscover Service URL. If you do not already have a web publishing rule for the external Lync Server 2013 Web Services URL for your Front End pool, you also need to publish a rule for that.

Note:

The reverse proxy publishing rule and listener can service both the external web services and the Autodiscover Service, as long as the certificate assigned to the listener contains the necessary subject name and subject alternative names for both. For details on the default configuration of the web listener and publishing rule, see Setting Up Reverse Proxy Servers for more details.

If you decide to use HTTP for initial Autodiscover Service requests so that you do not need to update subject alternative names for the reverse proxy, you need to create or modify a web publishing rule for port 80.

The procedures in this section describe how to create or modify the web publishing rules in Microsoft Forefront Threat Management Gateway 2010 for automatic discovery.

Note:

These procedures assume that you have installed the Standard Edition of Forefront Threat Management Gateway (TMG) 2010. If you are using another reverse proxy, the procedures are similar, but will need to be mapped to the documentation for the third-party product.

To create a web publishing rule for the external Autodiscover URL

1. Click **Start**, point to **Programs**, point to **Microsoft Forefront TMG**, and then click **Forefront TMG Management**.
2. In the left pane, expand **ServerName**, right-click **Firewall Policy**, point to **New**, and then click **Web Site Publishing Rule**.

3. On the **Welcome to the New Web Publishing Rule** page, type a display name for the new publishing rule (for example, LyncDiscoveryURL).
4. On the **Select Rule Action** page, select **Allow**.
5. On the **Publishing Type** page, select **Publish a single Web site or load balancer**.
6. On the **Server Connection Security** page, select **Use SSL to connect to the published Web server or server farm**.
7. On the **Internal Publishing Details** page, in **Internal Site name**, type the fully qualified domain name (FQDN) of your Director pool (for example, lyncdir01.contoso.local). If you are creating a rule for the external Web Services URL on the Front End pool, type the FQDN of the Front End pool (for example, lyncpool01.contoso.local).
8. On the **Internal Publishing Details** page, in **Path (optional)**, type **/*** as the path of the folder to be published, and then select **Forward the original host header**.
9. On the **Public Name Details** page, do the following:
   - Under **Accept Requests for**, select **This domain name**.
   - In **Public Name**, type **lyncdiscover.**<*sipdomain*> (the external Autodiscover Service URL). If you are creating a rule for the external Web Services URL on the Front End pool, type the FQDN for the external Web Services on your Front End pool (for example, lyncwebextpool01.contoso.com).
   - In **Path**, type **/***.
10. On **Select Web Listener** page, in **Web Listener**, select your existing SSL Listener with the updated public certificate.
11. On the **Authentication Delegation** page, select **No delegation, but client may authenticate directly**.
12. On the **User Set** page, select **All Users**.
13. On the **Completing the New Web Publishing Rule Wizard** page, verify that the web publishing rule settings are correct, and then click **Finish**.
14. In the Forefront TMG list of web publishing rules, double-click the new rule you just added to open **Properties**.
15. On the **To** tab, do the following:
   - Select **Forward the original host header instead of the actual one**.
   - Select **Requests appear to come from the Forefront TMG computer**.
16. On the **Bridging** tab, configure the following:
   - Select **Web server**.
   - Select **Redirect requests to HTTP port**, and type **8080** for the port number.
   - Select **Redirect requests to SSL port**, and type **4443** for the port number.
17. Click **OK**.
18. Click **Apply** in the details pane to save the changes and update the configuration.
19. Click **Test Rule** to verify that your new rule is set up correctly.

⊟To modify an existing web publishing rule to add the external Autodiscover SAN and URL

1. Click **Start**, point to **Programs**, point to **Microsoft Forefront TMG**, and then click **Forefront TMG Management**.

   Important:

   You will repeat the modification for each publishing rule and listener that you have. Typically, this will be one rule and listener for the Front End pools and one for the optional Directors or Director pools, if you have deployed them.

2. In the left pane, expand **ServerName**, right-click **Firewall Policy**, click the applicable rule. On the **Tasks** tab, click **Edit Selected rule**.
3. On the **Public Name** tab, in **This rule applies to**, select **Requests for the following Web sites**.
4. Click **Add**, type the name of the new Autodiscover site (for example, "lyncdiscover.contoso.com"), and then click **OK**.

5. On the **Listener** tab, click **Select Certificate** and assign the new certificate with the added Autodiscover SAN entries. Close the Listener and Web Publishing properties.
6. Click **Apply** in the details pane to save the changes and update the configuration.
7. Click **Test Rule** to verify that your new rule is set up correctly.

⊟To create a web publishing rule for port 80

1. Click **Start**, point to **Programs**, point to **Microsoft Forefront TMG**, and then click **Forefront TMG Management**.
2. In the left pane, expand **ServerName**, right-click **Firewall Policy**, point to **New**, and then click **Web Site Publishing Rule**.
3. On the **Welcome to the New Web Publishing Rule** page, type a display name for the new publishing rule (for example, Lync Autodiscover (HTTP)).
4. On the **Select Rule Action** page, select **Allow**.
5. On the **Publishing Type** page, select **Publish a single Web site or load balancer**.
6. On the **Server Connection Security** page, select **Use non-secured connections to connect to the published Web server or server farm**.
7. On the **Internal Publishing Details** page, in **Internal Site name**, type the internal Web Services FQDN for your Front End pool (for example, lyncpool01.contoso.local).
8. On the **Internal Publishing Details** page, in **Path (optional)**, type **/*** as the path of the folder to be published, and then select **Forward the original host header instead of the one specified in the Internal site name field**.
9. On the **Public Name Details** page, do the following:
   - Under **Accept Requests for**, select **This domain name**.
   - In **Public Name**, type **lyncdiscover.**<*sipdomain*> (the external Autodiscover Service URL).
   - In **Path**, type **/***.
10. On **Select Web Listener** page, in **Web Listener**, select a Web Listener or use the New Web Listener Definition Wizard to create a new one.
11. On the **Authentication Delegation** page, select **No delegation, and client cannot authenticate directly**.
12. On the **User Set** page, select **All Users**.
13. On the **Completing the New Web Publishing Rule Wizard** page, verify that the web publishing rule settings are correct, and then click **Finish**.
14. In the Forefront TMG list of web publishing rules, double-click the new rule you just added to open **Properties**.
15. On the **Bridging** tab, configure the following:
    - Select **Web server**.
    - Select **Redirect requests to HTTP port**, and type **8080** for the port number.
    - Verify that **Redirect requests to SSL port** is not selected.
16. Click **OK**.
17. Click **Apply** in the details pane to save the changes and update the configuration.
18. Click **Test Rule** to verify that your new rule is set up correctly.
19. Verify that the external Autodiscover Service URL is not defined on any other web publishing rule.

1.4.15.4 Configuring Autodiscover for Mobility with Hybrid Deployments

Configuring Autodiscover for Mobility with Hybrid Deployments

See Also

Deployment > Deploying External User Access > Deploying Mobility >

Topic Last Modified: *2013-01-24*

Hybrid Deployments are configurations that use both the Microsoft Lync Online cloud service and the on premises deployment. In this type of configuration, the Autodiscover service must be able to locate where the user is actually located. That is to say, Autodiscover aids in finding the user account and where the server that hosts the user's account is, regardless if it is in the on premises deployment or in the Lync Online deployment.

For example, if a user's account is hosted on a server in Lync Online, the attempt to locate the user will happen as follows, in a process known as *discoverability*:

- User initiates a connection attempt to the on premises deployment, **contoso.com**.
- The attempt is sent to lyncdiscover.contoso.com, the DNS name associated with the Autodiscover service.
- Autodiscover refers to the assumed registrar pool at the contoso.com on premises deployment and is given information on the user's actual home server hosted in Lync Online. Autodiscover then sends the user a referral to the **lync.com** online Autodiscover service.
- The user initiates a connection attempt to the lync.com online Autodiscover service and is able to locate the user's account and the user's home server.

To enable mobile clients to discover the deployment where the user home server is located, you must configure the Autodiscover service with a new uniform resource locator (URL). Do the following to configure the Autodiscover service.

⊟Configuring Autodiscover for Hybrid Deployments

1. You use Get-CsHostingProvider to retrieve the value of the attribute ProxyFQDN.
2. From the Lync Server Management Shell, type

   ```
   Set-CsHostingProvider -Identity [identity] -AutodiscoverUrl https://we
   ```

   Where [identity] is replaced with the domain name of the shared SIP address space.

Set-CsHostingProvider

1.4.15.5 Verifying Your Mobility Deployment

Verifying Your Mobility Deployment

See Also

Deployment > Deploying External User Access > Deploying Mobility >

Topic Last Modified: *2013-02-12*

```
Some information in this topic pertains to Cumulative Updates for Lync Server 201
```

After you deploy the Lync Server Mobility Service and Lync Server Autodiscover Service, run a test transaction to verify that your deployment works correctly. You can run **Test-CsUcwaConference** to test the ability of two users who are using Lync 2013 Mobile clients to create, join and communicate in a conference. To use this test transaction, you need two actual users or test users, and their full credentials.

You use **Test-CsMcxP2PIM** to test sending an instant message between two users who are using Lync 2010 Mobile. Similar to **Test-CsUcwaConference**, you use two actual users or two predefined test users.

⊟To test conferencing for Lync 2013 Mobile clients

1. Log on as a member of the CsAdministrator role on any computer where Lync Server Management Shell and Ocscore are installed.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. At the command line, type:

   ```
   Test-CsUcwaConference -TargetFqdn <FQDN of Front End pool> -Authentica
   ```

   You can set credentials in a script and pass them to the test cmdlet. For example:

   ```
   $passwd1 = ConvertTo-SecureString "Password01" -AsPlainText -Force
   $passwd2 = ConvertTo-SecureString "Password02" -AsPlainText -Force
   $testuser1 = New-Object Management.Automation.PSCredential("contoso\Us
   $testuser2 = New-Object Management.Automation.PSCredential("contoso\Us
   Test-CsUcwaConference -TargetFqdn pool01.contoso.com -Authentication N
   ```

⊟To test person-to-person instant messaging (IM) for Lync 2010 Mobile

1. Log on as a member of the CsAdministrator role on any computer where Lync Server Management Shell and Ocscore are installed.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. At the command line, type:

   ```
   Test-CsMcxP2PIM -TargetFqdn <FQDN of Front End pool> -Authentication <
   ```

   You can set credentials in a script and pass them to the test cmdlet. For example:

   ```
   $passwd1 = ConvertTo-SecureString "Password01" -AsPlainText -Force
   $passwd2 = ConvertTo-SecureString "Password02" -AsPlainText -Force
   $tuc1 = New-Object Management.Automation.PSCredential("contoso\UserNam
   $tuc2 = New-Object Management.Automation.PSCredential("contoso\UserNam
   Test-CsMcxP2PIM -TargetFqdn pool01.contoso.com -Authentication Negotia
   ```

1.4.15.6 Configuring for Push Notifications

Configuring for Push Notifications

See Also

Deployment > Deploying External User Access > Deploying Mobility >

Topic Last Modified: *2013-02-12*

Push notifications, in the form of badges, icons, or alerts, can be sent to a mobile device even when the mobile application is inactive. Push notifications notify a user of events such as a new or missed IM invitation and voice mail. The Lync Server 2013 Mobility Service sends the notifications to the cloud-based Lync Server Push Notification Service, which then sends the notifications to the Apple Push Notification Service (APNS) (for an Apple device running the Lync 2010 Mobile client) or the Microsoft Push Notification Service (MPNS) (for a Windows Phone device running the Lync 2010 Mobile or the Lync 2013 Mobile client).

Important:

If you use Windows Phone with Lync 2010 Mobile or Lync 2013 Mobile client, push notification is an important consideration.
If you use Lync 2010 Mobile on Apple devices, push notification is an important consideration.
If you use Lync 2013 Mobile on Apple devices, you no longer need push notification.

Configure your topology to support push notifications by doing the following:

- If your environment has a Lync Server 2010 or Lync Server 2013 Edge Server, you need to add a new hosting provider, Microsoft Lync Online, and then set up hosting provider federation between your organization and Lync Online.
- If your environment has a Office Communications Server 2007 R2 Edge Server, you need to set up direct SIP federation with push.lync.com.

  Note:

  Push.lync.com is a Microsoft Office 365 domain for Push Notification Service.
- To enable push notifications, you need to run the **Set-CsPushNotificationConfiguration** cmdlet. By default, push notifications are turned off.
- Test the federation configuration and push notifications.

To configure for push notifications with Lync Server 2013 or Lync Server 2010 Edge Server

1. Log on to a computer where Lync Server Management Shell and Ocscore are installed as a member of the RtcUniversalServerAdmins group.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Add a Lync Server online hosting provider. At the command line, type:

   ```
   New-CsHostingProvider -Identity <unique identifier for Lync Online hos
   ```

   For example:

   ```
   New-CsHostingProvider -Identity "LyncOnline" -Enabled $True -ProxyFqdn
   ```

   Note:

   You cannot have more than one federation relationship with a single hosting provider. That is, if you have already set up a hosting provider that has a federation relationship with sipfed.online.lync.com, do not add another hosting provider for it, even if the identity of the hosting provider is something other than LyncOnline.
4. Set up hosting provider federation between your organization and the Push Notification Service at Lync Online. At the command line, type:

   ```
   New-CsAllowedDomain -Identity "push.lync.com"
   ```

To configure for push notifications with Office Communications Server 2007 R2 Edge Server

1. Log on to the Edge Server as a member of the RtcUniversalServerAdmins group.

2. Click **Start**, click **All Programs**, click **Administrative Tools**, and then click **Computer Management**.
3. In the console tree, expand **Services and Applications**, right-click **Microsoft Office Communications Server 2007 R2**, and then click **Properties**.
4. On the **Allow** tab, click **Add**.
5. In the **Add Federated Partner** dialog box, do the following:
   - In **Federated partner domain name**, type **push.lync.com**.
   - In **Federated partner Access Edge Server**, type **sipfed.online.lync.com**.
   - Click **OK**.

To enable push notifications

1. Log on to a computer where Lync Server Management Shell and Ocscore are installed as a member of the CsAdministrator role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Enable push notifications. At the command line, type:

```
Set-CsPushNotificationConfiguration -EnableApplePushNotificationServic
```

4. Enable federation. At the command line, type:

```
Set-CsAccessEdgeConfiguration -AllowFederatedUsers $True
```

To test federation and push notifications

1. Log on to a computer where Lync Server Management Shell and Ocscore are installed as a member of the CsAdministrator role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Test the federation configuration. At the command line, type:

```
Test-CsFederatedPartner -TargetFqdn <FQDN of Access Edge server used f
```

   For example:

```
Test-CsFederatedPartner -TargetFqdn accessproxy.contoso.com -Domain pu
```

4. Test push notifications. At the command line, type:

```
Test-CsMcxPushNotification -AccessEdgeFqdn <Access Edge service FQDN>
```

   For example:

```
Test-CsMcxPushNotification -AccessEdgeFqdn accessproxy.contoso.com
```

Other Resources

Test-CsFederatedPartner
Test-CsMcxPushNotification

1.4.15.7 Configuring Mobility Policy

Configuring Mobility Policy

See Also

Deployment > Deploying External User Access > Deploying Mobility >

Topic Last Modified: *2013-02-13*

```
Some information in this topic pertains to Cumulative Updates for Lync Server 201
```

Lync Server 2013 provides mobility policies that determine who can use mobility features, Call via Work, voice over IP (VoIP) or video, and whether WiFi will be required for either VoIP or video. The Call via Work feature enables a mobile user to make and receive calls on a mobile phone by using a work phone number instead of the mobile phone number.

This feature prevents the called party from seeing the caller's mobile phone number and enables a user to avoid outbound calling charges. Configuring VoIP and video makes it possible for users to receive and make VoIP calls and video. Settings for WiFi usage define if a user's device will be required to use a WiFi network over a cellular data network.

By default, mobility, Call via Work, and the VoIP and video features are enabled. The settings to require WiFi for VoIp and video are disabled. Administrators can determine who has access to these features by running a cmdlet. You can turn options off globally, by site, or by user.

To be able to use mobility features and Call via Work, users must meet the following prerequisites:

- Users must be enabled for Lync Server 2013.
- Users must be enabled for Enterprise Voice.
- Users must be assigned a mobility policy that has the **EnableMobility** option set to True.

For users to be able to use Call via Work, they must meet the following two additional prerequisites:

- Users must be assigned a voice policy that has the **Enable simultaneous ringing of phones** option selected.
- Users must be assigned a mobility policy that has the **EnableOutsideVoice** option set to True.

Note:

Users who are not enabled for Enterprise Voice can use their mobile devices to make Lync to Lync Voice over IP (VoIP) calls, or can join conferences by using the Click to Join link on their mobile devices, if you assign those users the appropriate options for voice policy. For details, see Defining Your Mobility Requirements.

For details about enabling users for Lync Server 2013, see Disable or Re-Enable User Account for Lync Server. For details about enabling users for Enterprise Voice, see Enable Users for Enterprise Voice. For details about setting voice policy options, see Modify a Voice Policy and Configure PSTN Usage Records.

To modify global mobility policy

1. Log on to any computer where Lync Server Management Shell and Ocscore are installed as a member of the CsAdministrator role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Turn off access to mobility and Call via Work globally. At the command line, type:

```
Set-CsMobilityPolicy -EnableMobility $False -EnableOutsideVoice $False
```

Note:

You can turn off Call via Work without turning off access to mobility. However, you cannot turn off mobility without also turning off Call via Work.

To modify mobility policy by site

1. Log on to any computer where Lync Server Management Shell and Ocscore are installed as a member of the CsAdministrator role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Create a site-level policy, and turn off VoIP and video, and enable Require

WiFi for IP Audio and for IP Video by site. At the command line, type:

```
New-CsMobilityPolicy -Identity site:<site identifier> -EnableIPAudioVi
```

To modify mobility policy by user

1. Log on to any computer where Lync Server Management Shell and Ocscore are installed as a member of the CsAdministrator role.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Create user level mobility policies and turn off mobility and Call via Work by user. At the command line, type:

```
New-CsMobilityPolicy -Identity <policy name> -EnableMobility $False -E
Grant-CsMobilityPolicy -Identity <user identifier> -PolicyName <policy
```

You can turn off Call via Work without turning off access to mobility. However, you cannot turn off mobility without also turning off Call via Work.

For example:

```
New-CsMobilityPolicy "tag:disableOutsideVoice" -EnableOutsideVoice $Fa
Grant-CsMobilityPolicy -Identity -MobileUser1@contoso.com -PolicyName
```

1.4.16 Health Configuration in Lync Server 2013

Health Configuration in Lync Server 2013

Microsoft Lync Server 2013 > Deployment >

Topic Last Modified: *2012-10-22*

Between various websites, Microsoft Knowledge Base articles, and Lync Server Resource Kit tools, administrators who encounter problems when running Lync Server are never far from a way to solve those problems.

Obviously there is no way to guarantee that you will never encounter problems with Lync Server 2013 because Lync Server can be affected by many things—like network crashes and hardware failures—that the product itself cannot control. By implementing health monitoring, administrators can identify potential problems before they turn into actual problems. For example, administrators can use Lync Server monitoring to identify trends and tendencies. For example, a steady increase in the number of audio/video conferences might suggest a need to add capacity before the system becomes overloaded.

In a similar fashion, administrators can use System Center Operations Manager to do such things as issue real-time alerts when specified events occur, and to run synthetic transactions that proactively test the system. Synthetic transactions are used in Lync

Server to verify that users are able to successfully complete common tasks such as logging on to the system, exchanging instant messages, or making calls to a phone located on the public switched telephone network (PSTN). For example, periodically running these tests can alert you to potential problems with users logging on to Lync Server, and give you a chance to correct the problem before your support team is flooded with calls from users unable to make a connection. By using System Center Operations Manager to run these synthetic transactions, administrators can routinely monitor their deployment of Lync Server continuously for 24 hours every day without having to do much of anything beyond responding to any alerts that might be issued.

> **Note:**
>
> For Lync Server 2013, the Management Pack for System Center Operations Manager is also able to detect "external" issues that can adversely affect Lync Server. For example, administrators can be notified if Internet Information Services (IIS) goes offline, system resources on a Lync Server computer fall below a specified amount, or a Lync Server computer experiences a hardware failure.

Health configuration in Lync Server 2013 is built around System Center Operations Manager and the use of Lync Server Management Packs. These Management Packs include a number of new features and enhancements, including:

- **Scenario availability from any location.** The Lync Server 2010 Management Pack introduced the concept of monitoring end user scenario availability with synthetic transactions. In Lync Server 2013, these agents have more synthetic transactions and can be run from a variety of locations inside the enterprise, from remote geographic locations outside of the enterprise, against branch office appliances and against Lync Server 2010 deployments to add coverage to legacy Edge deployments.
- **Synthetic transaction logs.** When a synthetic transaction fails, administrators have access to HTML logs to help determine what failed. This includes understanding which action failed, the latency of each action, the command-line used to run the test, and the error that was encountered.
- **Increased call reliability coverage.** The Lync Server 2010 Management Pack introduced call reliability alerting to detect severe connectivity issues that affect the audio calls of end users. The Lync Server 2013 Management Packs add coverage for peer-to-peer instant messaging (IM) and other basic conferencing features to maximize coverage while reducing noise.
- **Dependency monitoring.** Lync Server scenarios can fail due to a variety of external factors such as IIS being offline, limited CPU and memory resources, and disk issues. The new management packs check several critical dependencies to ensure administrators are aware of their impact.
- **Enhanced reporting.** A set of reports to help administrators estimate scenario availability, plan for capacity, and see which components are experiencing the most issues.

The Management Packs also include a variety of features to help detect and diagnose provide real-time visibility into the health your Lync Server deployment. These features are listed in the following table.

Management Pack Features

Feature	Description
Synthetic Transactions	Windows PowerShell cmdlets that can be run from various locations to ensure that end user scenarios such as sign-in, presence, IM, and conferencing are readily available to end users.
Call Reliability Alerts	Database queries for Call Detail Records (CDR). These records are written by Front

	End Servers to reflect whether end users were able to connect to a call or why a call was terminated. These queries result in alerts that indicate when a wide range of end users are experiencing connectivity issues for peer-to-peer calls or basic conferencing functionality.
Media Quality Alerts	Database queries that look at Quality of Experience (QoE) reports published by clients at the end of each call. These queries result in alerts that pinpoint scenarios where users are likely to be experiencing poor media quality during calls and conferences. The data is built upon key metrics such as packet latency and loss, metrics that are known to directly contribute to call quality.
Component Health	Individual server components raise alerts by using event logs and performance counters. These alerts indicate failure conditions that can severely impact one or more end user scenarios. These alerts can also indicate a variety of other failure conditions, including services not running, high failure rates, high message latency, or connectivity issues.
Dependency Health	Failures can occur for a variety of external reasons. The management packs now monitor and collect data for some of the critical external dependencies that might indicate severe issues, including IIS availability, CPU and memory usage of servers and processes, and disk metrics.

The alerts issued by the system have been classified into three general categories:

- **High-priority Alerts.** These alerts indicate conditions that will cause service outages for large groups of users. For example, a component failure on a single machine is not a high-priority alert because Lync Server 2013 has built-in high availability features. Instead, high-priority alerts represent problems serious enough "to wake up administrators at night." Outages detected by synthetic transactions and offline services (for example, audio/video conferencing) qualify as high-priority alerts.
- **Medium-priority alerts.**. These alerts indicate conditions that affect a subset of users or indicate call quality degradation. That includes problems such as component failures, latency in call establishment, or degraded audio quality in call. Alerts in this category are stateful and indicate the current status of the issue. For example, suppose your call establishment times exceed the alert threshold. If call establishment times return to normal, these alerts will be auto-resolved in System Center Operations Manager. The expectation for these alerts is that an administrator will look at them on the same business day.
- **Other alerts.** These are alerts from components that might affect a specific user or subset of users. For example, perhaps the Address Book service could not parse the Active Directory entry of a given user. The expectation for these alerts is that administrators will get to them when they have time available.

- Using Rich Logging for Synthetic Transactions
- Using Microsoft SQL Server 2008 R2 as Your System Center Operations Manager Database

1.4.16.1 Configuring Lync Server to Work With System Center Operations Manager

Configuring Lync Server to Work With System Center Operations Manager

Microsoft Lync Server 2013 > Deployment > Health Configuration in Lync Server 2013 >

Topic Last Modified: *2012-10-22*

In order to configure your Microsoft Lync Server 2013 infrastructure to work with System Center Operations Manager you must do three things:

- Identify and configure your primary System Center Operations Manager management server. Configuring the management server includes installing System Center Operations Manager 2012 or System Center Operations Manager 2007 R2, as well as setting up a back-end database using SQL Server. The actual version of SQL Server that you need to be use depends on the version of System Center Operations Manager you are using. For details, see Configuring the Primary Management Server.
- Identify and configure the Lync Server computers that you want to monitor. To monitor a Lync Server computer by using System Center Operations Manager you must install the System Center Operations Manager agent files, and configure each server to act as a proxy.
- Identify and configure the computers that you want to act as Lync Server *watcher nodes*. Watcher nodes are computers that periodically run Lync Server synthetic transactions, which are Windows PowerShell cmdlets that verify that key Lync Server components, such as the ability to log on to the system or the ability to exchange instant messages are working as expected.

The topics in this section contain instructions for carrying out each of these tasks.

In This Section

- Configuring the Primary Management Server
- Installing the Lync Server 2013 Management Packs
- Configuring the Lync Server Computers That Will Be Monitored
- Installing and Configuring Watcher Nodes

1.4.16.1.1 Configuring the Primary Management Server

Configuring the Primary Management Server

Deployment > Health Configuration in Lync Server 2013 > Configuring Lync Server to Work With System Center Operations Manager >

Topic Last Modified: *2012-10-22*

In order to take full advantage of the new health monitoring capabilities included in Microsoft Lync Server 2013 administrators must first designate a computer to act as your primary management server; on that computer you must then install System Center Operations Manager 2007 R2 or System Center Operations Manager 2012. In addition, you must install a supported version of SQL Server to function as your Operations Manager back-end database. If you are using System Center Operations Manager 2012 you can use any of the following versions of SQL Server as your back-end database:

- SQL Server 2008 R2 Service Pack 1
- SQL Server 2008 R2 Service Pack 2

If you are using System Center Operations Manager 2007 R2 it is recommended that you install either SQL Server 2005 Service Pack 4 or SQL Server 2008 Service Pack 3. You can also use SQL Server 2008 R2 as the backend database for System Center Operations Manager 2007 R2. See Appendix 1 of this documentation for more information on configuring SQL Server 2008 R2 to work with System Center Operations Manager 2007 R2.

When you install System Center Operations Manager 2012 or System Center Operations Manager 2007 R2 you need to install all the components of that product, including:

- Operational database
- Server
- Console
- Windows PowerShell cmdlets
- Web console
- Reporting
- Data warehouse

These components and their installation will not be discussed in detail in this document. For details about System Center Operations Manager 2007 R2, see the Operations Manager 2007 R2 documentation at http://go.microsoft.com/fwlink/p/?linkid=257526 and the System Center Operations Manager 2012 documentation at http://go.microsoft.com/fwlink/p/?linkid=257527. You should follow those instructions if you are going to use SQL Server 2005 or SQL Server 2008 Service Pack 1 as your back-end database.

If you are using System Center Operations Manager 2012 then you can use SQL Server 2012 as your back-end database. For details about SQL Server 2012, see Books Online for SQL Server 2012 at http://go.microsoft.com/fwlink/p/?LinkId=257528.

Keep in mind that you can only have a single Root Management Server per Lync Server deployment. Also, while you can use either System Center Operations Manager 2012 or System Center Operations Manager 2007 R2, you cannot run the two applications simultaneously—you must choose one or the other. For example, if you are running System Center Operations Manager 2012 then all your System Center agents must also be runningSystem Center Operations Manager 2012. You cannot have some agents running System Center Operations Manager 2012 and other agents running System Center Operations Manager 2007 R2.

1.4.16.1.2 Installing the Lync Server 2013 Management Packs

Installing the Lync Server 2013 Management Packs

Deployment > Health Configuration in Lync Server 2013 > Configuring Lync Server to Work With System Center Operations Manager >

Topic Last Modified: *2012-10-22*

By itself, System Center Operations Manager has the ability to monitor only a small portion of the Windows operating system. However, you can extend the capabilities of System Center Operations Manager by installing management packs, software that dictates which items System Center Operations Manager can monitor, including how those items should be monitored and how alerts should be triggered and reported. Microsoft Lync Server 2013 includes two System Center Operations Manager management packs that provide the following capabilities:

- The Component and User Management Pack (Microsoft.LS.2013.Monitoring.ComponentAndUser.mp) tracks Lync Server issues recorded in event logs, registered by performance counters, or logged in the call detail records (CDR) or the Quality of Experience (QoE) databases. For critical problems, System Center Operations Manager can be configured to immediately notify administrators via email, instant message, or Short Message Service (SMS) messaging. SMS is the technology used to send text messages from one mobile device to another.

  Note:

  For more information on configuring Operations Manager notification, see Configuring Notification in the TechNet Library at http://go.microsoft.com/fwlink/p/?linkid=268785.

- The Active Monitoring Pack (Microsoft.LS.2013.Monitoring.ActiveMonitoring.mp) proactively tests key Lync Server components such as logging on to the system, exchanging instant messages, or making calls to a phone located on the public switched telephone network (PSTN). These tests are conducted using the Lync Server synthetic transaction cmdlets. For example, the **Test-CsIM** cmdlet is used to simulate an instant messaging conversation between a pair of test users. If this simulated messaging conversation fails an alert will be generated.

The two management packs included with Lync Server 2013 include a large number of enhancements over the management packs used with Microsoft Lync Server 2010. For example, the Lync Server 2013 Component Management Pack is not limited to monitoring Lync Server itself. In addition to monitoring event logs and performance counters for Lync Server, the Component Management pack can also track the performance of, and issue alerts for, crucial items such as:

- **Internet Information Services (IIS)** Alerts will be issued if Internet Information Services goes offline. This is important, because the Lync Server web services rely on IIS.
- **Process usage** Alerts will be issued if system resources (such as available memory) begin to run low. These alerts will be issued even if Lync Server is not responsible for the high system usage.
- **Computer failure events** Alerts will be issued in case of a hardware or software issue that threatens the viability of a server. For example, Lync Server administrators will be notified if a server appears to be in danger of experiencing a hard disk failure.

The new management packs also feature enhanced reporting. New reports for Lync Server 2013 include:

- **End to End Scenario Availability Report** This report details the availability/uptime for key Lync Server services such as registration or presence.
- **Capacity Report** Using performance counter information, this report shows trends for system components such as memory availability and processor usage.
- **Component Report** This report lists the top alert generators grouped by Lync Server component.

In addition to these predesigned reports, the management packs for Lync Server 2013 automatically report alerts for both Call Reliability (metrics measured by Call Detail Recording) and QoE states (metrics measured by Quality of Experience). If you have enabled Call Detail Recording, you can review Call Reliability alerts by completing the following procedure from the System Center Operations Manager console:

- Expand **Monitoring**, expand **Microsoft Lync Server 2013 Health**, expand **Call**

Reliability and Media Quality, and then click **Call Reliability**.

To view Quality of Experience alerts, complete this procedure from the System Center Operations Manager console:

- Expand **Monitoring**, expand **Microsoft Lync Server 2013 Health**, expand **Call Reliability and Media Quality**, and then expand **Media Quality**.

The management packs for Lync Server 2013 now use machine-level discovery instead of the central discovery mechanism used in Microsoft Lync Server 2010. This means that each System Center agent essentially discovers itself and reports its existence to the Central Management Server. Using machine-level discovery simplifies administration of your System Center infrastructure and also allows different versions of the Lync Server management packs (for example, management packs for Lync Server 2010 and management packs for Lync Server 2013) to coexist.

1.4.16.1.2.1 Using the Lync Server 2010 Management Packs in a Coexistence Scenario

Using the Lync Server 2010 Management Packs in a Coexistence Scenario

Health Configuration in Lync Server 2013 > Configuring Lync Server to Work With System Center Operations Manager > Installing the Lync Server 2013 Management Packs >

Topic Last Modified: *2012-10-22*

Many customers adopt a rollout program inside of their enterprises in which users are progressively migrated from Microsoft Lync Server 2010 to Lync Server 2013. The administrators at these companies will care about monitoring both versions of Lync Server to help ensure that all of their end users are getting the best possible communication experience. For this scenario, the Lync Server 2013 Management Pack supports a side-by-side migration path with the Lync Server 2010 Management Pack.

In the Lync Server 2010, Lync Server computers were discovered through the topology document stored with the Central Management store. In this configuration, a single computer would report the existence of all the other Lync Server computers.

The management packs for Lync Server 2013 now use machine-level discovery instead of the central discovery mechanism that was used in Lync Server 2010. This means that each System Center agent essentially discovers itself and reports its existence to System Center Operations Manager. Using machine-level discovery simplifies administration of your System Center infrastructure and also enables different versions of the Lync Server management packs (for example, management packs for Lync Server 2010 and management packs for Lync Server 2013) to coexist more easily.

To support this migration, you will first need to upgrade your existing Lync Server 2010 monitoring to avoid gaps in coverage. To do this, elect an existing Lync Server 2010 computer to service the Central Discovery script for the Lync Server 2010 before upgrading your Central Management store to Lync Server 2013. This is a four-step process:

1. Upgrade the Lync Server 2010 Management Packs to Cumulative Update 7.
2. Instruct a Lync Server 2010 computer to run the Central Discovery script.
3. Override the Central Discovery Candidate in the Microsoft Lync Server 2010 Management Pack.
4. Verify that the new Central Discovery Candidate has been discovered.

Instructing a Lync Server 2010 Computer

to Run the Central Discovery script

To nominate a non-Central Management store computer (for example, a Lync Server Front End) server to handle central discovery, you will need to create the following registry key on the non-Central Management store server:

HKLM\Software\Microsoft\Real-Time Communications\Health\CentralDiscoveryCandidate

You can create this registry key by completing the following procedure:

1. Click **Start** and then click **Run**.
2. In the **Run** dialog box, type **regedit** and then press ENTER.
3. In Registry Editor, expand **HKEY_LOCAL_MACHINE**, expand **SOFTWARE**, expand **Microsoft**, and then expand **Real-Time Communications**.
4. Right-click **Health**, click **New**, and then click **Key**. If the **Health** key does not exist, then right-click **Real-Time Communications**, point to **New**, and then click **Key**. When the new key is created, type Health, and then press ENTER. After the new key has been created, type **CentralDiscoveryCandidate** and then press ENTER to rename the key.

It may take the computer several hours to pick up this change. To make the change take effect immediately, stop and then restart the Health Agent service. To restart the Health Agent service, complete the following procedure on the Lync Server 2010 computer:

1. Click **Start**, click **All Programs**, click **Accessories**, right-click **Command Prompt**, and then click **Run as administrator**.
2. In the console window, type the following command and then press ENTER:

   ```
   Net stop HealthService
   ```

3. You will see a message that states "The System Center Management service is stopping," followed by a second message that tells you that the service has been stopped. After the service has stopped, you can restart it by typing the following command and pressing ENTER:

   ```
   Net start HealthService
   ```

Overriding the Central Discovery Candidate in the Lync Server 2010 Management Pack

After instructing a Lync Server 2010 computer to report on Lync Server 2010 computers, you will need to inform the Lync Server 2010 Management Pack about this change as well. To do this, you will need to create an override in the Management Pack. That can be done by completing the following procedure:

1. In the Operations Manager console, click **Authoring**.
2. On the Authoring tab, expand **Management Pack Objects**, click **Object Discoveries**, and then click **Scope**.
3. In the **Scope Management Pack Objects** dialog box, select the item with the Target **LS Discovery Candidate** and then click **OK**. Note that LS Discovery Candidate will appear only if you have installed the Lync Server 2010 Management Pack.
4. In the Operations Manager console, right-click **LS Discovery Candidate**, point to **Overrides**, point to **Override the Object Discovery**, and then click **For all objects of class: LS Discovery Candidate**.
5. In the **Override Properties** dialog box, select the **Override** check box next to the parameter **Central Discovery WatcherNode Fqdn**. Type the fully qualified domain name of the Lync Server 2010 computer in the **Override Value** and **Effective Value** boxes. Select the **Enforced** check box and click **OK**.

After you have created the override, you need to restart the health service on the Root Management Server. To restart the health service, complete the following procedure on the Root Management Server:

1. Click **Start**, click **All Programs**, click **Accessories**, right-click **Command Prompt**, and then click **Run as administrator**.
2. In the console window, type the following command, and then press ENTER:

```
Net stop HealthService
```

3. You will see a message stating that "The System Center Management service is stopping," followed by a second message that tells you that the service has been stopped. After the service has stopped, you can then restart it by typing the following command and pressing ENTER:

```
Net start HealthService
```

Verifying that the New Central Discovery Candidate Was Discovered

The final step before upgrading Central Management store is to make sure that the new central discovery candidate was discovered by the Lync Server 2010 Management Pack. To do this, open the Operations Manager console and then click Monitoring. On the Monitoring tab, expand **Microsoft Lync Server 2010 Health**, expand **Topology Discovery**, and then click **Discovery State View**. Verify that a row in the display has a **Path** that lists the fully qualified domain name of the central discovery candidate. You should also verify that the computer state is reported as **Healthy**.

1.4.16.1.2.2 Importing the Lync Server 2013 Management Packs

Importing the Lync Server 2013 Management Packs

Health Configuration in Lync Server 2013 > Configuring Lync Server to Work With System Center Operations Manager > Installing the Lync Server 2013 Management Packs >

Topic Last Modified: *2012-10-22*

You can extend the capabilities of System Center Operations Manager by installing management packs—software that dictates which items System Center Operations Manager can monitor, and how those items should be monitored and how alerts should be triggered and reported. Lync Server 2013 includes two System Center Operations Manager management packs that provide the following capabilities:

- The Component and User Management Pack (Microsoft.LS.2013.Monitoring.ComponentAndUser.mp) tracks Lync Server issues recorded in event logs, registered by performance counters, or logged in the call detail records (CDR) or the Quality of Experience (QoE) databases. For critical problems, System Center Operations Manager can be configured to immediately notify administrators via email, instant message, or Short Message Service (SMS) messaging. SMS is the technology used to send text messages from one mobile device to another.)

  > **Note:**
  >
  > For details about configuring Operations Manager notification, see the Configuring Notification in the TechNet Library at http://go.microsoft.com/fwlink/p/?LinkId=268785.

- The Active Monitoring Management Pack (Microsoft.LS.2013.Monitoring.ActiveMonitoring.mp) proactively tests key Lync Server components such as signing into to the system, exchanging instant messages, or making calls to a phone located on the public switched telephone network (PSTN). These tests are conducted using the Lync Server synthetic transaction cmdlets. For example, you can use the **Test-CsIM** cmdlet to simulate an instant messaging (IM) conversation between a pair of test users. If this simulated messaging conversation fails an alert is generated.

You need to import the management packs. If you do not import the management packs, you cannot use Operations Manager to monitor Lync Server events or run Lync Server synthetic transactions.

The Component and User Management Pack is only used to monitor Lync Server 2013. If you are in a coexistence scenario, where you have both Lync Server 2013 and Lync Server 2010 installed, you should continue to use the Lync Server 2010 management packs for your Lync Server 2010 computers.

Note:
Management packs for Lync Server 2010 include the Lync Server 2010 Monitoring Management Pack and the Lync Server 2010 Group Chat Monitoring Management Pack.

You can use one of the following tools to import management packs:

- **System Center Operations Manager** With this method, you use the the Operations Manager to add monitoring for Lync Server.
- **Operations Manager Shell** You can use the Operations Manager Shell to import directly or to troubleshoot any issues you encounter when you import management packs by using the System Center Operations Manager console.

Importing the Management Packs by Using System Center Operations Manager

1. Download the files Microsoft.LS.2013.Monitoring.ActiveMonitoring.mp and Microsoft.LS.2013.Monitoring.ComponentAndUser.mp.
2. In System Center Operations Manager, click **Administration**.
3. In the **Administration** pane, right-click **Management Packs**, and then click **Import Management Packs**.
4. In the **Select Management Packs** dialog box, click **Add**, and then click **Add from disk**.
5. In the **Online Catalog Connection** dialog box, click **Cancel** to prevent Operations Manager from going online to see if any dependencies exist for the Lync Server management packs. If you are using System Center Operations Manager 2012, click **No**.
6. In the **Select Management Packs to import** dialog box, locate and select the files **Microsoft.LS.2013.Monitoring.ActiveMonitoring.mp** and **Microsoft.LS.2013.Monitoring.ComponentAndUser.mp** and then click **Open**. To select multiple files in the dialog box, click the first file, hold down the Ctrl key and then click the second file.
7. In the **Select Management Packs** dialog box, click **Install**. If you get an error message and installation fails, that typically means that the management pack files are in a folder protected by the Windows User Account Control. If this occurs, copy the files to a different folder and then restart the import and installation process.
8. In the **Select Management Packs** dialog box, click **Close**. Note that the import and installation process might require several minutes to complete.

Importing Management Packs by Using the Operations Manager Shell

In general it is easier to import the management packs by using the Operations Manager.However, if an error occurs and the import fails, the console does not always provide adequate error reports. By comparison, the Operations Manager Shell, provides detailed information. If you are using Operations Manager and you run into problems importing a management pack, import the pack by using the Operations Manager Shell . The Operations Manager Shell provides more information that might help you determine why the import failed.

If you are using System Center Operations Manager 2007 R2, complete the following procedure:

1. Click **Start**, click **All Programs**, click **System Center Operations Manager 2007 R2**, and then click **Operations Manager Shell**.
2. In the Operations Manager Shell, type the following command at the command prompt, using the actual path to your copy of the file Microsoft.LS.2013.Monitoring.ActiveMonitoring.mp, and then press ENTER:
   ```
   MPImport.exe D:\MP\Microsoft.LS.2013.Monitoring.ActiveMonitoring.mp
   ```
3. After you import the first management pack, repeat the process using the path to your copy of the file Microsoft.LS.2013.Monitoring.ComponentAndUser.mp:
   ```
   MPImport.exe D:\MP\Microsoft.LS.2013.Monitoring.ComponentAndUser.mp
   ```
4. Close the Operations Manager Shell.

If you are using System Center Operations Manager 2012, complete this procedure instead:

1. Click **Start**, click **All Programs**, click **Microsoft System Center 2012**, click **Operations Manager**, and then click **Operations Manager Shell**.
2. In the Operations Manager Shell, type the following command at the command prompt, using the actual path to your copy of the file Microsoft.LS.2013.Monitoring.ActiveMonitoring.mp, and then press ENTER:
   ```
   Import-SCOMManagementPack -FullName "D:\MP\ Microsoft.LS.2013.Monitori
   ```
3. After you have imported the first management pack, repeat the process using the path to your copy of the file Microsoft.LS.2013.Monitoring.ComponentAndUser.mp:
   ```
   Import-SCOMManagementPack -FullName "D:\MP\ Microsoft.LS.2013.Monitori
   ```

1.4.16.1.3 Configuring the Lync Server Computers That Will Be Monitored

Configuring the Lync Server Computers That Will Be Monitored

Deployment > Health Configuration in Lync Server 2013 > Configuring Lync Server to Work With System Center Operations Manager >

Topic Last Modified: *2012-10-20*

Because Lync Server 2013 does not use the central discovery process used in Microsoft Lync Server 2010, each Lync Server 2013 computer that you want to monitor must be able to self-report its existence to the management server. To make this possible, you must install the Operations Manager agent files on each of the computers to be monitored. After the agent files have been installed, you must configure the computer to act as a System Center proxy. Note that these procedures should be carried out after you have installed and configured Lync Server on these computers.

1.4.16.1.3.1 Installing a Certificate on a Watcher Node Located Outside the Perimeter Network

Installing a Certificate on a Watcher Node Located Outside the Perimeter Network

Health Configuration in Lync Server 2013 > Configuring Lync Server to Work With System Center Operations Manager > Configuring the Lync Server Computers That Will Be Monitored >

Topic Last Modified: *2012-10-22*

System Center Operations Manager agents running in a perimeter network (such as a Lync Server Edge Server), outside of the enterprise (such as an external synthetic transaction watcher node), or across an Active Directory Domain Services (AD DS) trust boundary, might require the configuration of a System Center Operations Manager Gateway Server. This server role allows agents that do not have a trust relationship with the Root Management Server to raise alerts. For details, see "Managing Gateway Servers in Operations Manager 2007" in the System Center Operations Manager TechNet Library at http://go.microsoft.com/fwlink/p/?LinkId=268703.

If you deploy an agent in one of these locations, you will also need to request and configure a certificate that enables the watcher node to send alerts to System Center Operations Manager. To simplify this process, the Operations Manager team has created a set of utilities that enable you to request and install the correct type of certificate on the watcher node computer. For details, and to download these utilities, see the "Obtaining Certificates for Non-Domain Joined Agents Made Easy With Certificate Generation Wizard" blog article at http://go.microsoft.com/fwlink/p/?LinkId=267421.

1.4.16.1.3.2 Installing the Operation Manager Agent Files

Installing the Operation Manager Agent Files

Health Configuration in Lync Server 2013 > Configuring Lync Server to Work With System Center Operations Manager > Configuring the Lync Server Computers That Will Be Monitored >

Topic Last Modified: *2012-10-20*

To install the Operations Manager agent files on the computer, complete the following steps.

1. On your System Center setup media, double-click **SetupOM.exe**.
2. In System Center Operation Manager setup, click **Install Operations Manager Agent**.
3. In System Center Setup wizard, on the **Welcome to the System Center Operations Manager Setup** wizard page, click **Next**.
4. On the **Destination Folder** page, select the folder where the Operations Manager Agent files will be installed, and then click **Next**.
5. On the **Management Group Configuration** page, select **Specify Management Group information**, and then click **Next**.
6. On the **Management Group Configuration** page, type the name of your Operations Manager Management Group in the **Management Group Name** box, and then type the host name of your Operations Manager server (for example, atl-scom-001) in the **Management Server** box. If you have changed the port number used by Operations Manager, then type the new port number in the Management Server Port box. Otherwise, leave the port at the default value of 5723 and click **Next**.
7. On the **Agent Action Account** page, select **Local System**, and then click **Next**.
8. On the **Microsoft Update** page, select **I don't want to use Microsoft Update**,

and then click **Next**.

9. On the **Ready to Install** page, click **Install**.
10. On the **Completing the System Center Operations Manager Setup wizard** page, click **Finish**.
11. Click **Exit**.

If you are using System Center 2007 R2, you can verify that the agent has been created by clicking **Start**, clicking **All Programs**, clicking **System Center Operations Manager 2007 R2**, and then clicking **Operations Manager Shell**. In the Operations Manager Shell, type the following Windows PowerShell command, and then press ENTER:

```
Get-Agent
```

A list of all your Operations Manager agents will appear onscreen.

If you are using System Center 2012, run this command from the Operations 2012 Manager Shell:

```

Get-SCOMAgent
```

1.4.16.1.3.3 Configuring the Lync Server Computer to Participate in System Center Discovery

Configuring the Lync Server Computer to Participate in System Center Discovery

Health Configuration in Lync Server 2013 > Configuring Lync Server to Work With System Center Operations Manager > Configuring the Lync Server Computers That Will Be Monitored >

Topic Last Modified: *2012-10-20*

To make sure that your new Lync Server agent participates in discovery process for System Center Operations Manager, you must complete the following procedure on each computer where the System Center Operations Manager console has been installed:

1. On the **Administration** tab, click **Agent Managed**.
2. Right-click the name of the computer, and then click **Properties**. In the **Properties** dialog box, on the **Security** tab, select **Allow this agent to act as a proxy and discover managed objects on other computers**, and then click **OK**.

After completing step 2, reboot the Health Agent service. (Rebooting the service will “force” discovery of the new machine. If you do not reboot the service, it could take as long as 4 hours before the new machine is discovered by System Center Operations Manager.). After the service has rebooted, verify that no error events are being recorded in the Operations Manager event log on that computer.

1.4.16.1.4 Installing and Configuring Watcher Nodes

Installing and Configuring Watcher Nodes

Deployment > Health Configuration in Lync Server 2013 > Configuring Lync Server to Work With System Center Operations Manager >

Topic Last Modified: *2012-10-22*

Watcher nodes are computers that periodically run Lync Server synthetic transactions. *Synthetic transactions* are Windows PowerShell cmdlets that verify that key end user scenarios—such as the ability to sign in to the system, or the ability to exchange instant messages—are working as expected. For Lync Server 2013, System Center Operations Manager can run the synthetic transactions shown in the following table. There are three different synthetic transaction types shown in the table:

- **Default**. These are the synthetic transactions that a watcher node will run by default. When you create a new watcher node, you have the option of specifying which synthetic transactions that node will run. (That's the purpose of the Tests parameter used by the **New-CsWatcherNodeConfiguration** cmdlet.) If you do not use the Tests parameter when the watcher node is created, it will automatically run all the Default synthetic transactions and will not run any of the Non-default synthetic transactions. That means, for example, that the watcher node will be configured to run the Test-CsAddressBookService test, but will not be configured to run the Test-CsExumConnectivity test.
- **Non-default**. As the name implies, Non-default synthetic transactions are tests that watcher nodes do not run by default. However, the watcher node can be enabled to run any of the Non-default synthetic transactions. You can do this when you create the watcher node (by using the **New-CsWatcherNodeConfiguration** cmdlet), or at any time after that. Many of the Non-default synthetic transactions require extra setup steps. For details, see Special Setup Instructions for Synthetic Transactions.
- **Extended**. Extended tests are a special type of Non-default synthetic transaction. Unlike other synthetic transactions, Extended tests can be run multiple times during each pass. This can be useful when verifying behavior such as multiple public switched telephone network (PSTN) voice routes for a pool. This can be configured simply by adding multiple instances of an Extended test to a watcher node.

For details about the process of adding other synthetic transactions to a watcher node, see Managing Watcher Nodes. You can use the Lync Server Management Shell to remove synthetic transactions from a watcher node.

The synthetic transactions available to watcher nodes include the following:

Cmdlet Name (Test Name)	**Description**	**Synthetic Transaction Type**
Test-CsAddressBookService (ABS)	Confirms that users are able to look up users that aren't in their contact list.	Default
Test-CsAddressBookWebQuery (ABWQ)	Confirms that users are able to look up users that aren't in their contact list via HTTP.	Default
Test-CsIM (IM)	Confirms that users are able to send peer-to-peer instant messages.	Default
Test-CsP2PAV (P2PAV)	Confirms that users are able to place peer-to-peer audio calls (signaling only).	Default
Test-CsPresence (Presence)	Confirms that users are able to view other users' presence.	Default
Test-CsRegistration (Registration)	Confirms that users are able sign in to Lync.	Default
Test-CsAudioConferencingProvider	Not used with the on-premises version of Lync	Extended

(ACP)	Server 2013	
Test-CsPstnPeerToPeerCall (PSTN)	Confirms that users are able to place and receive calls with people outside of the enterprise (PSTN numbers).	Non-default, Extended
Test-CsAVConference (AvConference)	Confirms that users are able to create and participate in an audio/video conference.	Default
Test-CsAVEdgeConnectivity (AVEdgeConnectivity)	Confirms that the A/V Edge servers are able to accept connections for peer-to-peer calls and conference calls.	Non-default
Test-CsDataConference (DataConference)	Confirms that users can participate in a data collaboration conference, an online meeting that includes activities such as whiteboards and polls.	Non-default
Test-CsExumConnectivity (ExumConnectivity)	Confirms that a user can connect to Exchange Unified Messaging (UM).	Non-default
Test-CsGroupIM (GroupIM)	Confirms that users are able to send instant messages in conferences and participate in instant message conversations with three or more people.	Default
Test-CsGroupIM – TestJoinLauncher (JoinLauncher)	Confirms that users are able to create and join scheduled meetings via a web address link.	Non-default
Test-CsMCXP2PIM (MCXP2PIM)	Confirms that mobile device users are able to register and send instant messages.	Non-default
Test-CsPersistentChatMessage (PersistentChatMessage)	Confirms that users can exchange messages by using the Persistent Chat service.	Non-default
Test-CsUnifiedContactStore (UnifiedContactStore)	Confirms that a user's contacts can be accessed through the unified contact store. The unified contact store provides a way for users to maintain a single set of contacts that can be accessed by using Lync 2013, Outlook, and/or Outlook Web Access.	Non-default
Test-CsXmppIM (XmppIM)	Confirms that an instant message can be sent across the XMPP (Extensible	Non-default

	Messaging and Presence Protocol) gateway.	

You do not need to install watcher nodes in order to use System Center Operations Manager. If you do not install these nodes, you can still get real-time alerts from Lync Server 2013 components when an issue occurs. (The Component and User Management Pack does not use watcher nodes.) However, watcher nodes are required if you want to monitor end-to-end scenarios by using the Active Monitoring Management pack.

Note:

Administrators can also run synthetic transactions manually, without needing to use, or install, Operations Manager. For details about the various Test-Cs cmdlets, see the Lync Server 2013 Cmdlets Index.

Depending on the size of your deployment, synthetic transactions may use a large amount of computer memory and processor time. For this reason, we recommend that you use a dedicated computer as a watcher node. For example, you should not configure a Front End Server to act as a watcher node. Watcher nodes should meet the same basic hardware requirements as any other computer that plays a role in your Lync Server.

Note:

A legacy Microsoft Lync Server 2010 watcher node cannot be collocated on the same machine with a Lync Server 2013 watcher node. This is because the core system files for Lync Server 2010 and Lync Server 2013 cannot be installed on the same computer. However, Lync Server 2013 watcher nodes can simultaneously monitor both Lync Server 2013 and Lync Server 2010. The Default synthetic transactions are supported on both product versions.

Lync Server 2013 watcher nodes may be deployed inside or outside of an enterprise to help verify:

- Connectivity to pools for users inside the enterprise.
- Connectivity through perimeter networks for remote users who work outside the enterprise.
- Connectivity to branch office appliances.
- Connectivity to Lync Server 2010 inside the enterprise and through perimeter networks.

Different authentication options are available for inside and outside of the enterprise to help simplify administration. For details, see Configuring a Watcher Node to Run Synthetic Transactions.

To configure a computer to act as a watcher node, you must complete the following steps after you have installed System Center Operations Manager and imported the Lync Server 2013 management packs.

Before you install the Lync Server 2013 core files and the System Center agent files, you should also make sure that the watcher node computer meets all the prerequisites for installing Lync Server 2013. In addition, the watcher node computer should also have the following items installed:

- The full version of .NET Framework 4.5.
- Windows Identity Foundation.
- Windows PowerShell 3.0.

As soon as all these prerequisites have been met, you can configure the watcher node by:

- Installing the Lync Server 2013 core files on the watcher node computer.
- Installing System Center Operations Manager agent on the watcher node computer.

- Running the Watchernode.msi executable file.
- Using the **CsWatcherNodeConfiguration** cmdlets to configure test users to be employed by the watcher node.

1.4.16.1.4.1 Installing the Lync Server 2013 Core Files and the RTCLocal Database

Installing the Lync Server 2013 Core Files and the RTCLocal Database

Health Configuration in Lync Server 2013 > Configuring Lync Server to Work With System Center Operations Manager > Installing and Configuring Watcher Nodes >

Topic Last Modified: *2012-10-20*

To install the Lync Server 2013 core files on a computer, complete the following procedure. The RTCLocal database is automatically installed when you install the core files. Note that you do not need to install SQL Server on the watcher nodes. Instead, SQL Server Express is automatically installed for you.

To install the Lync Server 2013 core files and the RTCLocal database:

1. On the watcher node computer, click **Start**, click **All Programs**, click **Accessories**, right-click **Command Prompt**, and then click **Run as administrator**.
2. In the console window, type the following command and then press ENTER, using the appropriate path to your Lync Server setup files:

   ```
   D:\Setup.exe /BootstrapLocalMgmt
   ```

To verify that the core Lync Server components were successfully installed, click **Start**, click **All Programs**, click **Lync Server 2013**, and then click **Lync Server Management Shell**. In the Lync Server 2013 Management Shell, type the following Windows PowerShell command, and then press ENTER:

```
Get-CsWatcherNodeConfiguration
```

The first time you run this command, you no data is returned because you have not configured any watcher node computers yet. As long as the command runs without returning an error, you can assume that the Lync Server setup completed successfully.

If your watcher node computer is located inside your perimeter network, you can run the following command to verify the installation of Lync Server 2013:

```
Get-CsPinPolicy
```

You will receive information similar to the following, depending on the number of personal identification number (PIN) policies configured for use in your organization:

```
Identity              : Global
Description           :
MinPasswordLength     : 5
PINHistoryCount       : 0
AllowCommonPatterns   : False
PINLifetime           : 0
MaximumLogonAttempts  :
```

If you see information about your PIN policies, it means that you have successfully installed the core components.

1.4.16.1.4.2 Installing the Operation Manager Agent Files on a Watcher Node

Installing the Operation Manager Agent Files on a Watcher Node

Health Configuration in Lync Server 2013 > Configuring Lync Server to Work With System Center Operations Manager > Installing and Configuring Watcher Nodes >

Topic Last Modified: *2012-10-20*

Similar to setting up a Lync Server to report component alerts, a Lync Server 2013 watcher node requires System Center Operations Manager agent files to be installed. This will enable the synthetic transactions to be run and for alerts to be reported to the System Center Operations Manager Root Management Server.

To install the agent files, follow the same procedures listed in the following sections:

1. Installing a Certificate on a Watcher Node Located Outside the Perimeter Network
2. Installing the Operation Manager Agent Files
3. Configuring the Lync Server Computer to Participate in System Center Discovery

1.4.16.1.4.3 Configuring a Watcher Node to Participate in System Center Discovery

Configuring a Watcher Node to Participate in System Center Discovery

Health Configuration in Lync Server 2013 > Configuring Lync Server to Work With System Center Operations Manager > Installing and Configuring Watcher Nodes >

Topic Last Modified: *2012-10-22*

To make sure that your watcher node participates in the discovery process for System Center Operations Manager, you must complete the following procedure on a computer where the System Center Operations Manager console has been installed:

1. On the **Administration** tab, click **Agent Managed**.
2. Right-click the name of the watcher node computer, and then click **Properties**. In the **Properties** dialog box, on the **Security** tab, select **Allow this agent to act as a proxy and discover managed objects on other computers**, and then click **OK**.

After configuring the watcher node to act as a proxy, reboot the watcher node computer. After the computer has rebooted, verify that no error events are being recorded in the Operations Manager event log on that computer. After the computer has been running for 15 minutes or so, use the Operations Manager console to verify that your Lync Server computers are listed under the **Lync** category.

1.4.16.1.4.4 Configuring a Watcher Node to Run Synthetic Transactions

Configuring a Watcher Node to Run Synthetic Transactions

Health Configuration in Lync Server 2013 > Configuring Lync Server to Work With System Center Operations Manager > Installing and Configuring Watcher Nodes >

Topic Last Modified: *2012-10-20*

After the System Center agent files have been installed, you must next configure the watcher node itself. The steps you take to configure a watcher node will vary depending on whether your watcher node computer lies inside your perimeter network or outside your perimeter network.

When you configure a watcher node, you must also choose the type of authentication method to be employed by that node. Lync Server 2013 enables you to choose one of two authentication methods: Trusted Server or Credential Authentication. The differences between these two methods are outlined in the following table:

Configuration	Description	Locations Supported
Trusted Server	Uses a certificate to impersonate an internal server and bypass authentication challenges. This is useful for administrators who would prefer to manage a single certificate instead of many user passwords on each watcher node.	Inside the enterprise. Note that, with this method, the watcher node must be in the same domain as the pools being monitored. If the watcher node and the monitored pools are in different domains, use Credential Authentication instead.
Credential Authentication	Stores user names and passwords securely in Windows Credential Manager on each watcher node. This mode requires more password management, but is the only option for watcher nodes located outside of the enterprise. These watcher nodes cannot be treated as an endpoint trusted for authentication.	Outside the enterprise. Inside the enterprise.

Configuring a Watcher Node to Use Trusted Server Authentication

Configuring Lync Server to Work With System Center Operations Manager > Installing and Configuring Watcher Nodes > Configuring a Watcher Node to Run Synthetic Transactions >

Topic Last Modified: *2012-10-22*

If your watcher node computer lies inside the perimeter network, using Trusted Server authentication can greatly reduce administration taxes to maintaining a single certificate rather than numerous user account passwords.

The first step in configuring Trusted Server authentication is to create a trusted application pool to host the watcher node computer. After the trusted application pool has been created, you must then configure synthetic transactions on that watcher node to run as a trusted application.

> **Note:**
> A trusted application is an application that is given trusted status to run as part of Lync Server 2013, but that is not a built-in part of the product. Trusted status means that the application will not be challenged for authentication each time it runs.

To create a trusted application pool, open the Lync Server 2013 Management Shell and run a command similar to this:

```
New-CsTrustedApplicationPool -Identity atl-watcher-001.litwareinc.com -Registrar
```

> **Note:**
> For details about the parameters used in the preceding command, type the following at the Lync Server Management Shell prompt:
> Get-Help New-CsTrustedApplicationPool -Full | more

After creating the trusted application pool, configure the watcher node computer to run synthetic transactions as a trusted application. This is done by using the **New-CsTrustedApplication** cmdlet and a command similar to this:

```
New-CsTrustedApplication -ApplicationId STWatcherNode -TrustedApplicationPoolFqdn
```

When the preceding command completes and the trusted application has been created, run Enable-CsTopology to make sure that the changes take effect:

```
Enable-CsTopology
```

After running Enable-CsTopology, we recommend that you restart the computer.

To verify that the new trusted application has been created, type the following at the Lync Server Management Shell prompt:

```
Get-CsTrustedApplication -Identity "atl-watcher-001.litwareinc.com/urn:applicatio
```

Configuring a Default Certificate on the Watcher Node

Each watcher node must have a Default certificate assigned by using the Lync Server Deployment Wizard.

To assign a Default certificate

1. Click **Start**, click **All Programs**, click **Lync Server**, and then click **Lync Server Deployment Wizard**.
2. In the Lync Server Deployment Wizard, click **Install or Update Lync Server System** and then click **Run** under the heading **Request, Install, or Assign Certificate**.

   > **Note:**
   > If the **Run** button is disabled, you may need to first click **Run** under **Install Local Configuration Store**.

3. Do one of the following:
   - If you already have a certificate that can be used as the Default certificate, click **Default** in the Certificate wizard and then click **Assign**. Follow the steps in the Certificate Assignment wizard to assign that certificate.
   - If you need to request a certificate for use the Default certificate, click **Request** and then follow the steps in the Certificate Request wizard to request that certificate. If you use the default values for the Web Server certificate, you get a certificate that you can assign as the Default certificate.

Installing and Configuring a Watcher Node

After you have restarted the watcher node computer and configured a certificate, you need to run the file Watchernode.msi. (You must run Watchernode.msi on a computer where both the Operations Manager agent files and the Lync Server 2013 core components are installed.)

To install and configure a watcher node

1. Open the Lync Server Management Shell by clicking **Start**, clicking **All Programs**, clicking **Lync Server**, and then clicking **Lync Server Management Shell**.
2. In the Lync Server Management Shell, type the following command and then press ENTER (specify the actual path to your copy of Watchernode.msi):

```
C:\Tools\Watchernode.msi Authentication=TrustedServer
```

> **Note:**
> You can also run Watchernode.msi from a command window. To open a command window, click **Start**, right-click **Command Prompt**, and then click **Run as administrator**. When the command window opens, type the same preceding command.

Note that the name/value pair in the preceding command Authentication=TrustedServer is case-sensitive. You must type it exactly as shown. The following command fails because it does not use the correct letter casing:

```
C:\Tools\Watchernode.msi authentication=trustedserver
```

You can use TrustedServer mode only with computers that are located within the perimeter network. When a watcher node is running in TrustedServer mode, administrators do not have to maintain test user passwords on the computer.

Configuring a Watcher Node to Use Credential Authentication

Configuring Lync Server to Work With System Center Operations Manager > Installing and Configuring Watcher Nodes > Configuring a Watcher Node to Run Synthetic Transactions >

Topic Last Modified: *2012-10-20*

If your watcher node computer lies outside the perimeter network, then you must follow a slightly different procedure in order to configure that watcher node to run synthetic transactions. Specifically, you should not create a trusted application pool and a trusted application, and you must install a certificate that enables the watcher node to send alerts to a computer inside the perimeter network. This means that you will need to complete two separate tasks:

- Update the membership in the computer's RTC Local Read-only Administrators Group
- Install the watcher node configuration files

Updating Membership in the RTC Local Read-Only Administrators Group

If your watcher node lies outside the perimeter network, you must add the Network

Service account to the RTC Local Read-only Administrators group on the watcher node computer. To do this, complete the following procedure on the watcher node:

1. Click **Start**, right-click **Computer**, and then click **Manage**.
2. In Server Manager, expand **Configuration**, expand **Local Users and Groups**, and then click **Groups**.
3. In the Groups pane, double-click **RTC Local Read-only Administrators**.
4. In the **RTC Local Read-only Administrators Properties** dialog box, click **Add**.
5. In the **Select Users, Computers, Service Accounts, or Groups** dialog box, click **Locations**.
6. In the **Locations** dialog box, select the name of the watcher node computer, and then click **OK**.
7. In the **Enter object names to select** box, type **Network Service**, and then click **OK**.
8. In the **RTC Local Read-only Administrators Properties** dialog box, click **OK**, and then close **Server Manager**.

Restart the watcher node computer.

Installing the Watcher Node Configuration Files

After the watcher node computer has restarted, your next step is to run the file Watchernode.msi. To run this file, open the Lync Server 2013 Management Shell by clicking **Start**, clicking **All Programs**, clicking **Lync Server 2013**, and then clicking **Lync Server Management Shell**. In the Lync Server Management Shell, type the following command and then press ENTER (be sure and specify the actual path to your copy of Watchernode.msi):

```
C:\Tools\Watchernode.msi Authentication=Negotiate
```

Note:

As noted previously, Watchernode.msi can also be run from a command window. To open a command window, click **Start**, right-click **Command Prompt**, and then click **Run as administrator**. When the command window opens, type the same command as shown earlier.

The Negotiate mode is used any time the watcher node cannot be set up as a trusted application pool. In this mode, administrators will need to manage test user passwords on the watcher node.

1.4.16.1.4.5 Configuring Watcher Node Test Users and Configuration Settings

Configuring Watcher Node Test Users and Configuration Settings

Health Configuration in Lync Server 2013 > Configuring Lync Server to Work With System Center Operations Manager > Installing and Configuring Watcher Nodes >

Topic Last Modified: *2012-10-22*

After configuring the computer that will act as a watcher node, you must:

1. Create the test accounts to be used by these watcher nodes. If you are using the Negotiate authentication method, you must also use the Set-CsTestUserCredential cmdlet to enable these test accounts for use on the watcher node.
2. Update the watcher node configuration settings.

This section covers:

- Configuring Test User Accounts
- Configuring a Basic Watcher Node with the Default Synthetic Transactions
- Configuring Extended Tests
- Adding and Removing Synthetic Transactions
- Viewing and Testing the Watcher Node Configuration

Configuring Test User Accounts

Test users do not need to represent actual people, but they must be valid Active Directory Domain Services (AD DS) accounts; in addition, these accounts must be enabled for Lync Server 2013, they must have valid SIP addresses, and they should be enabled for Enterprise Voice (to use the Test-CsPstnPeerToPeerCall synthetic transaction). If you use the TrustedServer authentication method, then all you need to do is to make sure that these accounts exist and have been configured as specified here. You should assign at least three test users for each pool that you want to test.

If you are using the Negotiate authentication method, you must also use the **Set-CsTestUserCredential** cmdlet and the Lync Server Management Shell to enable these test accounts to work with the synthetic transactions. You can do this by running a command similar to the following. (These commands assume that the three Active Directory user accounts have already been created and that those accounts have been enabled for Lync Server 2013.):

```
Set-CsTestUserCredential -SipAddress "sip:watcher1@litwareinc.com" -UserName "lit
Set-CsTestUserCredential -SipAddress "sip:watcher2@litwareinc.com" -UserName "lit
Set-CsTestUserCredential -SipAddress "sip:watcher3@litwareinc.com" -UserName "lit
```

Note that you must include not only the SIP address but also the user name and password. If you do not include the password Set-CsTestUserCredential will prompt you to enter that information. The user name can be specified using the domain name\user name format shown above, or by using the format user name@domain name; for example:

```
-UserName "watcher3@litwareinc.com"
```

To verify that the test user credentials were created, run these commands from within the Lync Server Management Shell:

```
Get-CsTestUserCredential -SipAddress "sip:watcher1@litwareinc.com"
Get-CsTestUserCredential -SipAddress "sip:watcher2@litwareinc.com"
Get-CsTestUserCredential -SipAddress "sip:watcher3@litwareinc.com"
```

Information similar to this should be returned for each user:

```
UserName                        Password
--------                        --------
Litwareinc\watcher1              System.Security.SecureString
```

Configuring a Basic Watcher Node with the Default Synthetic Transactions

After the test users have been created you can then create a watcher node by using a command similar to this:

```
New-CsWatcherNodeConfiguration -TargetFqdn "atl-cs-001.litwareinc.com" -PortNumbe
```

This command creates a new watcher node that uses the default settings and runs the default set of synthetic transactions. The new watcher node also uses the test users watcher1@litwareinc.com, watcher2@litwareinc.com, and watcher3@litwareinc.com. If the watcher node is using TrustedServer authentication, the three test accounts can be any valid user accounts enabled for Active Directory and Lync Server. If the watcher node is using the Negotiate authentication method, you must also enable these user accounts for watcher node by using the **Set-CsTestUserCredential** cmdlet.

Configuring Extended Tests

If you want to enable the public switched telephone network (PSTN test), which verifies connectivity with the public switched telephone network, you will need to do some additional configuration when setting up the watcher node. First, you need to associate your test users with the PSTN test type. To do that, run a command similar to this from within the Lync Server Management Shell:

```
$pstnTest = New-CsExtendedTest -TestUsers "sip:watcher1@litwareinc.com", "sip:wat
```

Note that the results of this command must be stored in a variable. In this example, that's a variable named $pstnTest.

At this point, you can use the **New-CsWatcherNodeConfiguration** cmdlet to associate the test type (stored in the variable $pstnTest) to a Lync Server 2013 pool. For example, the following command creates a new watcher node configuration for the pool atl-cs-001.litwareinc.com, adding the three test users that were created previously, and also adding the PSTN test type:

```
New-CsWatcherNodeConfiguration -TargetFqdn "atl-cs-001.litwareinc.com" -PortNumbe
```

Note that the preceding command will fail if you have not installed the Lync Server core files and the RTCLocal database on the watcher node computer.

To test multiple voice policies, you need to create an extended test for each policy by using the **New-CsExtendedTest** cmdlet. The users assigned to this test should be configured with the desired voice policies. The extended tests are then passed to the **New-CsWatcherNodeConfiguration** cmdlet by using a command similar to the following:

```
-ExtendedTests @{Add=$pstnTest1,$pstnTest2,$pstnTest3}
```

If New-CsWatcherNodeConfiguration is called without using the Tests parameter, that means that only the Default synthetic transactions (and the specified extended synthetic transaction) will be enabled for the new watcher node. This means that the watcher node will test the following components:

- Registration
- IM
- GroupIM
- P2PAV (peer-to-peer audio/video sessions)
- AvConference (audio/conferencing)
- Presence
- ABS (Address Book service)
- ABWQ (Address Book web service)
- PSTN (PSTN gateway calls, specified as an extended test. By default, PSTN is disabled. The test is enabled in this case only because the command enabled PSTN by using the ExtendedTests parameter.)

This also means that the following components will not be tested by default:

- AVEdgeConnectivity
- MCXP2PIM (mobile device instant messaging)
- ExumConnectivity (Exchange Unified Messaging)
- JoinLauncher

- PersistentChatMessage
- DataConference
- XmppIM
- UnifiedContactStore

Adding and Removing Synthetic Transactions

After a watcher node has been configured, you can use the **Set-CsWatcherNodeConfiguration** cmdlet to add or remove synthetic transactions from the node. For example, to add the PersistentChatMessage test to the watcher node, use the Add method and a command similar to this:

```
Set-CsWatcherNodeConfiguration -Identity "atl-cs-001.litwareinc.com" -Tests @{Add
```

Multiple tests can be added by separating the test names by using commas. For example:

```
Set-CsWatcherNodeConfiguration -Identity "atl-cs-001.litwareinc.com" -Tests @{Add
```

Note that an error will occur if one or more of these tests (for example, DataConference) has already been enabled on the watcher node. In this case, you will receive an error message similar to the following:

```
Set-CsWatcherNodeConfiguration : There is a duplicate key sequence 'DataConferenc
```

When this error occurs, no changes will be applied. The command should be rerun with the duplicate test removed.

To remove a synthetic transaction from a watcher node, use the Remove method instead of the Add method. For example, this command removes the ABWQ test from a watcher node:

```
Set-CsWatcherNodeConfiguration -Identity "atl-cs-001.litwareinc.com" -Tests @{Rem
```

You can also use the Replace method to replace all the currently-enabled tests with one or more new tests. For example, if you only want a watcher node to run the IM test, you can configure that by using this command:

```
Set-CsWatcherNodeConfiguration -Identity "atl-cs-001.litwareinc.com" -Tests @{Rep
```

When you run the preceding command, all synthetic transactions on the specified watcher node will be disabled except for IM.

Viewing and Testing the Watcher Node Configuration

If you want to view the tests that have been assigned to a watcher node, use a command similar to this:

```
Get-CsWatcherNodeConfiguration -Identity "atl-cs-001.litwareinc.com" | Select-Obj
```

The preceding command will return information similar to this, depending on the synthetic transactions that have been assigned to the node:

```
Registration
IM
GroupIM
P2PAV
AvConference
```

```
Presence
PersistentChatMessage
DataConference
```

Tip:

To view the synthetic transactions in alphabetical order, use this command instead: Get-CsWatcherNodeConfiguration –Identity "atl-cs-001.litwareinc.com" | Select-Object –ExpandProperty Tests | Sort-Object

To verify that a watcher node has been created, type the following command from within the Lync Server Management Shell:

```
Get-CsWatcherNodeConfiguration
```

You will receive information similar to this:

```
Identity      : atl-cs-001.litwareinc.com
TestUsers     : {sip:watcher1@litwareinc.com, sip:watcher2@litwareinc.com ...}
ExtendedTests : {TestUsers=IList<System.String>;Name=PSTN Test; Te...}
TargetFqdn    : atl-cs-001.litwareinc.com
PortNumber    : 5061
```

To verify that the watcher node has been configured correctly, type the following command from within the Lync Server Management Shell:

```
Test-CsWatcherNodeConfiguration
```

The preceding command will test each watcher node in your deployment and tell you information, such as whether:

- The required Registrar role been installed.
- The required registry key was created for you when you ran Set-CsWatcherNodeConfiguration.
- Your servers are running the correct version of Lync Server.
- Your ports been configured correctly.
- Your assigned test users have the required credentials.

1.4.16.1.4.6 Managing Watcher Nodes

Managing Watcher Nodes

Health Configuration in Lync Server 2013 > Configuring Lync Server to Work With System Center Operations Manager > Installing and Configuring Watcher Nodes >

Topic Last Modified: *2012-10-20*

In addition to modifying the synthetic transactions that are executed on a watcher node, administrators can also use the **Set-CsWatcherNodeConfiguration** cmdlet to carry out two other important tasks: enabling and disabling the watcher node, and configuring the watcher node to use either internal URLs or external URLs when running its tests.

By default, watcher nodes are designed to periodically run all their enabled synthetic transactions. Sometimes, however, you may need to suspend those transactions. For example, if the watcher node is temporarily disconnected from the network, then there is no reason to run the synthetic transactions. Without network connectivity, those transactions are guaranteed to fail. If you want to temporarily disable a watcher node, run a command similar to this from the Lync Server Management Shell:

```
Set-CsWatcherNodeConfiguration -Identity "atl-watcher-001.litwareinc.com" -Enable
```

This command will disable the execution of synthetic transactions on the watcher node atl-watcher- 001.litwareinc.com. To resume execution of the synthetic transactions, set the Enabled property back to True ($True):

```
Set-CsWatcherNodeConfiguration -Identity "atl-watcher-001.litwareinc.com" -Enable
```

Note:

The Enabled property can be used to turn watcher nodes on or off. If you want to permanently delete a watcher node, use the **Remove-CsWatcherNodeConfiguration** cmdlet:

Remove-CsWatcherNodeConfiguration –Identity "atl-watcher-001.litwareinc.com"

That command removes all the watcher node configuration settings from the specified computer, which prevents the computer from automatically running synthetic transactions. However, the command does not uninstall the System Center agent files or the Lync Server 2013 system files.

By default, watcher nodes use an organization's external URLs when conducting their tests. However, watcher nodes can also be configured to use the organization's internal URLs. This enables administrators to verify URL access for users located inside the perimeter network. To configure a watcher node to use internal URLs instead of external URLs, set the UseInternalWebUrls property to True ($True):

```
Set-CsWatcherNodeConfiguration -Identity "atl-watcher-001.litwareinc.com" -UseInt
```

If you reset this property to the default value of False ($False), the watcher will then use the external URLs:

```
Set-CsWatcherNodeConfiguration -Identity "atl-watcher-001.litwareinc.com" -UseInt
```

1.4.16.1.4.7 Special Setup Instructions for Synthetic Transactions

Special Setup Instructions for Synthetic Transactions

Health Configuration in Lync Server 2013 > Configuring Lync Server to Work With System Center Operations Manager > Installing and Configuring Watcher Nodes >

Topic Last Modified: *2013-01-22*

Most synthetic transactions can run on a watcher node as-is; that is, as soon as the synthetic transaction has been added to the watcher node configuration settings, the watcher node can begin using the synthetic transaction during its test passes. However, this is not true for all synthetic transactions. The exceptions—synthetic transactions that require special setup instructions—are discussed in the following sections.

Dealing With Server Timeout Errors

In some cases you might find that your synthetic transactions are failing with server timeout errors (error code 504). These errors are typically due to firewall problems. When a synthetic transaction is executed, that transaction runs under the MonitoringHost.exe process; in turn, MonitoringHost.exe starts an instance of the PowerShell.exe process. If either MonitoringHost.exe or PowerShell.exe is blocked by your firewall then the synthetic transaction will fail and will generate a 504 error.

To resolve this issue, you should manually create inbound firewall rules for both MonitoringHost.exe and PowerShell.exe.

Data Conferencing Synthetic Transactions

If your watcher node computer is located outside your perimeter network, you will probably not be able to run the Data Conferencing Synthetic Transaction unless you first disable the Internet Explorer proxy settings for the Network Service account. To disable the proxy settings for this service, complete the following procedure:

1. On the watcher node computer, click **Start**, click **All Programs**, click **Accessories**, right-click **Command Prompt**, and then click **Run as administrator**.
2. In the console window, type the following command and then press ENTER:

```
bitsadmin /util /SetIEProxy NetworkService NO_PROXY
```

The following message will appear in the command window:

```
BITSAdmin is deprecated and is not guaranteed to be available in future versions
Internet proxy settings for account NetworkService set to NO_PROXY.
(connection = default)
```

This message means that you have disabled the Internet Explorer proxy settings for the Network Service account.

Exchange Unified Messaging Synthetic Transactions

The Exchange Unified Messaging (UM) synthetic transaction verifies that test users can connect to voicemail accounts homed in Exchange. These test users will need to be preconfigured with voicemail accounts before they can use the Exchange UM tests.

Persistent Chat Synthetic Transactions

To use the Persistent Chat synthetic transaction, administrators must first create a channel and give the test users permissions to use it. The Test-CsPersistentChatMessage cmdlet can be used to properly configure these test users:

```
$cred1 = Get-Credential "litwareinc\kenmyer"
$cred2 = Get-Credential "litwareinc\pilar"
Test-CsPersistentChatMessage -TargetFqdn atl-cs-001.litwareinc.com -SenderSipAddr
```

This setup task must be run from inside the enterprise:

- If run from a nonserver machine, the user who runs the cmdlet must be a member of the PersistentChatAdministrators role for Role-Based Access Control (RBAC).
- If run from the server itself, the user who runs the cmdlet should be a member of the RTCUniversalServerAdmins group.

In the preceding command, the Setup parameter was included and set to True ($True). If you include the Setup parameter, Test-CsPersistentChatMessage will create a special Persistent Chat room and populate that room with the test users. This helps to ensure that there is actually a chat room available for testing purposes. Note that the Setup parameter should be run only from a Front End Server.

The chat room that is created by Test-CsPersistentChatMessage can be deleted only by an administrator.

PSTN Peer-to-Peer Call Synthetic Transactions

The Test-CsPstnPeerToPeerCall synthetic transaction verifies the ability to place and receive calls via the public switched telephone network (PSTN).

To run this synthetic transaction, administrators must configure:

- Two test users (a caller and a receiver) enabled for Enterprise Voice.
- Direct Inward Dialing (DID) numbers for each user account.
- Voice policies and voice routes that enable calls to the receiver's number to reach the PSTN gateway.
- A PSTN gateway that accepts calls, and media that route calls backs to a receiver's home pool based on the number dialed.

Unified Contact Store Synthetic Transactions

The Unified Contact Store synthetic transaction verifies that Lync Server 2013 is able to retrieve contacts on behalf of a user from Microsoft Exchange Server 2013.

To use this synthetic transaction, the following conditions must be met:

- Managing Server-to-Server Authentication (Oauth) and Partner Applications must be configured between Lync Server 2013 and Exchange 2013.
- Test users must have a valid Exchange 2013 mailbox.

After these conditions are met, administrators can run the following command to verify that the user with the SIP address kenmyer@litwareinc.com can retrieve his contacts from the unified contact store:

```
Test-CsUnifiedContactStore -TargetFqdn atl-cs-001.litwareinc.com -UserSipAddress
```

Note the use of the Setup parameter used in the preceding command. If the Setup parameter is included when running Test-CsUnifiedContactStore then the specified user's contacts (in this case, sip:kenmyer@litwareinc.com) will be moved to the unified contact store. (Of course, if the user's contacts are already in the Unified Contact Store then they do not have to be moved.) The Setup parameter is typically used only one time (the first time Test-CsUnifiedContactStore is executed), and should only be used with test users; that is, with user accounts that will never actually be logged on to Lync Server. After your test user has been migrated to the unified contact store, you can verify that the user's contacts can be retrieved by calling Test-CsUnifiedContactStore without the Setup parameter:

```
Test-CsUnifiedContactStore -TargetFqdn atl-cs-001.litwareinc.com -UserSipAddress
```

XMPP Synthetic Transactions

The XMPP (Extensible Messaging and Presence Protocol) IM synthetic transaction requires that the XMPP feature be configured with one or more federated domains.

To enable the XMPP synthetic transaction, an XmppTestReceiverMailAddress parameter must be provided with a user account at a routable XMPP domain. For example:

```
Set-CsWatcherNodeConfiguration -Identity pool0.contoso.com -Tests @{Add="XmppIM"}
```

In this example, a Lync Server 2013 rule will need to exist to route messages for litwareinc.com to an XMPP gateway.

1.4.16.2 Using Rich Logging for Synthetic Transactions

Using Rich Logging for Synthetic Transactions

Microsoft Lync Server 2013 > Deployment > Health Configuration in Lync Server 2013 >

Topic Last Modified: *2012-10-22*

Synthetic transactions (introduced in Microsoft Lync Server 2010) provide a way for administrators to verify that users are able to successfully complete common tasks such as logging on to the system, exchanging instant messages, or making calls to a phone located on the public switched telephone network (PSTN). These tests (which are packaged as a set of Lync Server Windows PowerShell cmdlets) can be conducted manually by an administrator, or they can be automatically run by an application such as System Center Operations Manager.

In Lync Server 2010, synthetic transactions proved extremely useful in helping administrators to identify problems with the system. For example, the **Test-CsRegistration** cmdlet could alert administrators to the fact that some users were having difficulty registering with Lync Server. However, the synthetic transactions were somewhat less useful in helping administrators determine why these users were having difficulty registering with Lync Server. This was due to the fact that the synthetic transactions did not provide detailed logging information that could help administrators troubleshoot problems with Lync Server. At best, the verbose output from a synthetic transaction provided step-by-step information that might enable an administrator to make an educated guess as to where a problem likely occurred.

In Microsoft Lync Server 2013, synthetic transactions have been re-architected to provide rich logging. "Rich logging" means that, for each activity that a synthetic transaction undertakes, information such as this will be recorded:

- The time that the activity started
- The time that the activity finished
- The action that was performed (for example, creating, joining, or leaving a conference; signing on to Lync Server; sending an instant message; and so on)
- Informational, verbose, warning, or error messages generated when the activity ran
- SIP registration messages
- Exception records or diagnostic codes generated when the activity ran
- The net result of running the activity

This information is automatically generated each time a synthetic transaction is run. However, the information is not automatically displayed or saved to a log file. Instead, administrators who are manually running a synthetic transaction can use the OutLoggerVariable parameter to specify a Windows PowerShell variable in which the information will be stored. From there, administrators can then use a pair of methods that enable them to save and/or view the rich log in either XML or HTML format.

For example, Lync Server 2010 administrators might run the **Test-CsRegistration** cmdlet by using a command similar to the following:

```
Test-CsRegistration -TargetFqdn atl-cs-001.litwareinc.com
```

Administrators have the option of including the OutLoggerVariable parameter followed by a variable name of their choosing:

```
Test-CsRegistration -TargetFqdn atl-cs-001.litwareinc.com -OutLoggerVariable Regi
```

Note:

Do not preface the variable name with the $ character. Use a variable name like RegistrationTest and not $RegistrationTest.

The preceding command outputs content similar to the following:

```
Target Fqdn   : atl-cs-001.litwareinc.com
Result        : Failure
Latency       : 00:00:00
Error Message : This machine does not have any assigned certificates.
Diagnosis     :
```

However, much more detailed information is available for this failure than just the error message shown above. To access that information in HTML format, use a command similar to this in order to save the information stored in the variable RegistrationTest to an HTML file:

```
$RegistrationTest.ToHTML() | Out-File C:\Logs\Registration.html
```

Alternatively, you can use the ToXML() method to save the data to an XML file:

```
$RegistrationTest.ToXML() | Out-File C:\Logs\Registration.xml
```

These files can then be viewed using Internet Explorer, Visual Studio, or any other application capable of opening HTML/XML files.

Synthetic transactions run from inside of System Center Operations Manager will automatically generate these log files for failures. However, these logs will not be generated if the execution fails before Windows PowerShell is able to load and run the synthetic transaction.

Important:

By default, Lync Server 2013 saves log files to a folder that is not shared. To make these logs readily accessible, you should share this folder (for example, \\atl-watcher-001.litwareinc.com\WatcherNode.

1.4.16.3 Using Microsoft SQL Server 2008 R2 as Your System Center Operations Manager Database

Using Microsoft SQL Server 2008 R2 as Your System Center Operations Manager Database

Microsoft Lync Server 2013 > Deployment > Health Configuration in Lync Server 2013 >

Topic Last Modified: *2012-10-22*

To use SQL Server 2008 R2 as your back-end database, complete the steps detailed in this topic.

Configuring SQL Server 2008 R2 and SQL Server Reporting Services

Before you begin installing System Center Operations Manager you must make two changes to your SQL Server 2008 R2 and your SQL Server Reporting Services configuration. (These changes are required only if you are using SQL Server 2008 R2 as your Operations Manager database.) First, do the following on the computer that will host your Operations Manager database:

1. Click **Start** and then click **Run**.
2. In the **Run** dialog box, type **C:\Program Files\Microsoft SQL Server\MSRS10_50.ARCHINST\Reporting Services\ReportServer** and then press

ENTER.

3. In the **ReportServer** folder, open the file **rsreportserver.config** in Notepad or any other text editor.
4. Near the beginning of the file you will see a series of "Add Key" nodes. Find the entry that begins **<Add Key="SecureConnectionLevel"** and set the value to **0**:

```
<Add Key="SecureConnectionLevel" Value="0"/>
```

5. Save the file **rsreportserver.config** and then close your text editor.

After updating the Report Server configuration file you must then assign the correct certificate to SQL Server Reporting Services. To do that:

1. Click **Start**, click **All Programs**, click **Microsoft SQL Server 2008 R2**, click **Configuration Tools**, and then click **Reporting Services Configuration Manager**.
2. In the **Reporting Services Configuration Connection** dialog box, make sure that the name of your server appears in the **Server Name** box. Select the SQL Server instance that will host your Operations Manager database (for example, **ARCHINST**) from the **Report Server Instance** drop-down list and then click **Connect**.
3. In Reporting Services Configuration Manager, click **Web Service URL**.
4. On the **Web Service URL** page, select the certificate to be used for your Reporting Services from the **SSL Certificate** dropdown list and then click **Apply**. After a few seconds, you will see a pair of URLs listed under **Report Server Web Service URLs**.
5. Click both of the URLs to verify that you can access SQL Server Reporting Services.
6. Close Reporting Services Configuration Manager.

Creating a System Center Operations Manager database for use with SQL Server 2008 R2

If you want to configure System Center Operations Manager to use a SQL Server 2008 R2 database, you will need to "manually" create the Operations Manager database on the computer running SQL Server 2008 R2. (Again, these steps are not required if you are using UNRESOLVED_TOKEN_VAL(nm-sql-2005) or UNRESOLVED_TOKEN_VAL(nm-sql-2008) as your back-end database.)

To manually create an Operations Manager database do the following:

1. On the System Center Operations Manager 2007 R2 setup media, in the SupportTools\AMD64 folder, double-click **DBCreateWizard.exe**.
2. In the Database Configuration Wizard, on the **Welcome to the Database Configuration Wizard** page, click **Next**.
3. On the **Database Information** page leave all the settings as-is and then click **Next**
4. On the **Management Group Configuration** page type a name for your Management Group (for example, **Lync Server Monitoring**) in the **Management Group name** box and then click **Next**.
5. On the **Operations Manager Error Reports** page click **Next**.
6. On the **Summary** page click **Finish**.

Creating a System Center Operations Manager data warehouse for use with SQL Server 2008 R2

Microsoft Lync Server 2013 ships with three new System Center Operations Manager reports:

- **End to End Scenario Availability Report** This report details the availability/ uptime for key Lync Server services such as registration or presence.
- **Capacity Report** Using performance counter information, this report shows trends for system components such as memory availability and processor usage.
- **Component Report** This report lists the top alert generators grouped by Lync Server component.

In order to use these new reports you must install a System Center Operations Manager data warehouse. (A data warehouse provides for long-term storage of operations data.) To use a data warehouse with SQL Server 2008 R2 you must carry out the following steps on the computer that hosts your SQL Server database:

1. On the System Center Operations Manager setup media, in the Setup \SupportTools\AMD64 folder, double-click **DBCreateWizard.exe**.
2. In the Database Configuration Wizard, on the **Welcome to the Database Configuration Wizard** page, click **Next**.
3. On the **Database Information** page, select **Operations Manager Data Warehouse Database** from the **Database Type** dropdown list and then click **Next**.
4. On the **Summary** page click **Finish**.

Installing the System Center Operations Manager console

The Operations Manager console is the primary tool used to manage System Center Operations Manager. Before you install the Operations Manager console, make sure that you have installed a supported version of SQL Server along with the SQL Server Reporting Service. It is also recommended that you run SQL Server's Reporting Services Configuration Manager to verify that the Reporting Service has been correctly installed and configured.

To install the System Center Operations Manager console:

1. On the System Center Operations Manager setup media, double-click **SetupOM.exe**.
2. In System Center Operations Manager 2007 R2 Setup, click **Check Prerequisites**.
3. In the System Center Operations Manager Prerequisite Viewer, select the System Center components to be installed: (**Server**; **Console**; and **PowerShell**) and then click **Check**. Verify that no blocking issues have been reported and then click **Close**. If a blocking issue has been reported, correct the problem and then click **Check** to re-run the prerequisite testing.
4. In System Center Operations Manager Setup, click **Install Operations Manager**.
5. In the System Center Operations Manager Setup wizard, on the **Welcome to the System Center Operations Manager Setup Wizard** page, click **Next**.
6. On the **End-User License Agreement** page, select **I accept the terms in the license agreement** and then click **Next**.
7. On the **Product Registration** page, type your name in the **User Name** box and name of your organization in the **Organization** box. Type your System Center Operations Manager product key in the **Enter your 25 digit CD Key** box and then click **Next**.
8. On the **Custom Setup** page select the System Center options to be installed and then click **Next**. You should select **Management Server**, **User Interfaces**, and **Web Console** to be installed. **Database** should not be selected and should not be installed.
9. On the **SC Database Server Instance** page, verify that the name of the computer where the Operations Manager databases are installed appears in

the **System Center Database Server** box. Click **Next**.

10. On the **Management Server Action Account** page, select **Domain or Local Computer Account** and then enter the appropriate values in the **User Account**, **Password**, and **Domain or local computer** boxes. Click **Next**.
11. On the **SDK and Config Service Account** page, select **Domain or Local Computer Account** and then enter the appropriate values in the **User Account**, **Password**, and **Domain or local computer** boxes. Click **Next**.
12. On the **Operations Manager Error Reports** page click **Next**.
13. On the **Customer Experience Improvement Program** page click **Next**.
14. On the **Ready to Install the Program** page, click **Install**.
15. On the **Completing the System Center Operations Manager Setup** page, clear the **Backup Encryption Key** and **Start the console checkboxes** and then click **Finish**.
16. In System Center Operations Manager Setup click **Exit**.

Installing System Center Reporting Services

After installing and configuring the System Center Operations Manager console you must then install System Center Reporting Services. If you are using SQL Server 2008 R2 as your Operations Manager back-end database, that means that you must first make a temporary change to the security group associated with SQL Server Reporting Services. If you are using SQL Server 2008 R2, you must do the following:

1. Click **Start**, point to **Administrative Tools**, and then click **Server Manager**.
2. In Server Manager, expand **Configuration**, expand **Local Users and Groups**, and then click **Groups**.
3. Locate the following group, where atl-sc-001 represents the name of your computer and ARCHINST represents the SQL Server instance for the System Center database: **SQLServerReportServerUser$atl-sc-001$MSRS10_50.ARCHINST**.
4. Right-click the group and then click **Rename**. Rename the group by deleting **_50** from the group name. For example: **SQLServerReportServerUser$atl-sc-001$MSRS10.ARCHINST**.
5. Close Server Manager.

At this point you are ready to install System Center Reporting Services. To do this:

1. On the System Center Operations Manager 2007 R2 Setup media, double-click **SetupOM.exe**.
2. In System Center Operations Manager 2007 R2 Setup, click **Install Operations Manager Reporting**.
3. In the System Center Operations Manager 2007 R2 Reporting Setup wizard, on the **Welcome to Operations Manager Reporting Setup** page, click **Next**.
4. On the **End-user License Agreement** page select **I accept the terms of the license agreement** and then click **Next**.
5. On the **Product Registration** page, ensure that your name and the name of your organization appear in the **User Name** and **Organization** boxes and then click **Next**.
6. On the **Custom Setup** page, click **Reporting Server** and select **This component, and all dependent components, will be installed on local disk drive**. Click **Data Warehouse** and select **This component will not be available**, and then click **Next**.
7. On the **Connect to the Root Management Server** page, type the name of your Operations Manager root management server in the **Root Management Server** box and then click **Next**.
8. On the **Connect to the Operations Manager Data Warehouse** page, type the SQL Server instance where your data warehouse is located in the **SQL Server Instance** box. (If your data warehouse is located in the Default instance then simply type the server name; for example: atl-sql-001.) Verify that the database name **OperationsManagerDW** appears in the **Name** box,

and that port **1433** appears in the **SQL Server port** box. Click **Next**.

9. On the **SQL Server Reporting Instance** page, select your SQL Server reporting server from the **Enter the SQL Server Reporting Services Server** dropdown list and then click **Next**.
10. On the **Data Warehouse Write Account** page, enter the name and password of the user to be initially assigned write permissions to the data warehouse in the **User Account** and **Password** boxes. Select the user's domain from the **Domain** dropdown list and then click **Next**.
11. On the **Data Reader Account** page, enter the name and password of the user account to be used when SQL Reporting Services queries the data warehouse in the **User Account** and **Password** boxes. Select the account domain from the **Domain** dropdown list and then click **Next**.
12. On the **Operational Data Reports** page, click **Next**.
13. On the **Microsoft Update** page, click **Next**.
14. On the **Ready to Install the Program** page, click **Install**.
15. On the **Completing the Operations Manager Reporting Components Setup Wizard** page, click **Finish**.
16. In System Center Operations Manager 2007 R2 Setup, click **Exit**.

After System Center reporting has been installed you then use the following procedure to reset the name of the security group associated with SQL Server reporting. Again, this procedure is only required if you are using SQL Server:

1. Click **Start**, point to **Administrative Tools**, and then click **Server Manager**.
2. In Server Manager, expand **Configuration**, expand **Local Users and Groups**, and then click **Groups**.
3. Locate the following group, where atl-sc-001 represents the name of your computer and ARCHINST represents the SQL Server instance for the archiving and monitoring databases: **SQLServerReportServerUser$atl-sc-001$MSRS10.ARCHINST**.
4. Right-click the group and then click **Rename**. Rename the group by adding **_50** to the end of the group name, right before the SQL Server instance name. For example: **SQLServerReportServerUser$atl-sc-001$MSRS10_50.ARCHINST**.
5. Close Server Manager.

If the System Center Operations Console is open you will need to close the application and then restart it; if you do not do this the **Reporting** tab will not appear in the Operations Console user interface. Note that, after restarting the Operations Console the first time, it could take several minutes before all the Monitoring Reports appear on the **Reporting** tab.

1.4.17 Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013

Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013

Microsoft Lync Server 2013 > Planning > Planning for Exchange Server Integration >

Topic Last Modified: *2012-10-10*

Exchange and Lync Server have a long history of integration and compatibility. This integration is most noticeable within their respective client application. For example, Lync presence information can be reported in Microsoft Outlook; likewise, Lync can use Outlook calendar to automatically update that presence information. (For example, Lync can change your status to Busy any time your calendar shows that you have a meeting scheduled.) Although you do not have to run Exchange in order to run Lync Server (or vice-versa) there's little doubt that using the two products together epitomizes the very definition of the term "better together."

This is especially true with the release of Microsoft Lync Server 2013 and Microsoft Exchange Server 2013. In addition to features, such as unified messaging and IM and presence, that are found in Microsoft Exchange Server 2010 and Microsoft Lync Server 2010, the 2013 releases of the server products include a number of new capabilities. These capabilities include such things as:

- **Lync Archiving Integration**. In Lync Server 2013 administrators still have the option of having instant messaging and Web conferencing transcripts archived to SQL Server (the same way these transcripts were archived in Lync Server 2010). Alternatively, however, administrators can choose to have transcripts archived to Exchange 2013, storing those transcripts in the individual user mailboxes in the same way in which Exchange archives communications. That means a single repository for all your electronic communications (from both Exchange and Lync Server), which makes it much easier to search for and retrieve those archived communications should the need arise.
- **Unified Contact Store**. In Lync Server 2010, users had to maintain separate contact lists in Outlook and Lync; in fact, to ensure that you had the same contacts available in both products you had to maintain duplicate contact lists, one for Outlook and one for Lync. With Lync Server 2013, however, user contacts can be stored in Exchange 2013 and the unified contact store. Using a single contact store enables users to maintain just one set of contacts, with that same set of contacts being available in Lync 2013, Outlook 2013, and Outlook Web Access 2013.
- **High resolution photos**. Lync 2010 could only display small photos of your contacts; that's because those photos were stored in Active Directory, and Active Directory imposes a 48 pixel by 48 pixel size limitation on stored photos. With Lync Server 2013, however, photos can be stored in Microsoft Exchange; that allows for high-resolution photos as large as 648 pixels by 648 pixels. As you might expect, Lync 2013 has been upgraded to allow for the display of these high-resolution photographs.

Keep in mind that these new features require the use of both Lync Server 2013 and Exchange 2013. In addition to that, users who hope to take full advantage of these new capabilities must have accounts on Lync Server 2013 and Exchange 2013, and must be using the latest versions of the client software (e.g., Lync 2013). For example, the unified contact store is not available to users who have been homed on Lync Server 2010; likewise, high-resolution photos cannot be displayed in Lync 2010.

This documentation provides information on integrating Lync Server 2013 and Exchange 2013. including step-by-step information on enabling new features such archiving Integration and the unified contact store. What this documentation does not do is discuss the initial setup and configuration of these two products. For details about deploying Lync Server 2013 see the Lync Server 2013 Tech Center at http://go.microsoft.com/fwlink/p/?LinkId=246127. For details about deploying Exchange 2013 see the Exchange 2013 Tech Center at http://go.microsoft.com/fwlink/p/?LinkId=268528.
Prerequisites for Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013

Configuring Partner Applications in Microsoft Lync Server 2013 and Microsoft Exchange Server 2013

Configuring Microsoft Lync Server 2013 to Use Microsoft Exchange Server 2013 Archiving

Configuring Microsoft SharePoint Server 2013 to Search for Archived Microsoft Lync Server 2013 Data

Configuring Microsoft Lync Server 2013 to Use the Unified Contact Store

Configuring the Use of High-Resolution Photos in Microsoft Lync Server 2013

Configuring Microsoft Exchange Server 2013 Unified Messaging for Microsoft Lync Server 2013 Voicemail

Integrating Microsoft Lync Server 2013 and Microsoft Outlook Web App 2013

1.4.17.1 Prerequisites for Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013

Prerequisites for Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013

Planning > Planning for Exchange Server Integration > Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 >

Topic Last Modified: *2012-10-10*

Before you can integrate Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 you must ensure that all the prerequisite steps have been completed. As you might expect, integration cannot take place until both Exchange 2013 and Lync Server 2013 are fully installed and up and running. For details about installing Exchange, see the Exchange 2013 Planning and Deployment documentation at http://go.microsoft.com/fwlink/p/?LinkId=268539. For details about installing Lync Server 2013, see the planning and deployment documentation at http://go.microsoft.com/fwlink/p/?LinkId=254806.

After the servers are up and running you must assign server-to-server authentication certificates to both Lync Server 2013 and Exchange 2013; these certificates allow Lync Server and Exchange to exchange information and to communicate with one another. When you install Exchange 2013, a self-signed certificate with the name Microsoft Exchange Server Auth Certificate is created for you. This certificate, which can be found in the local computer certificate store, should be used for server-to-server authentication on Exchange 2013. For details about assigning certificates in Exchange 2013, see "Configure Mail Flow and Client Access" at http://go.microsoft.com/fwlink/p/?LinkId=268540.

For Lync Server 2013 you can use an existing Lync Server certificate as your server-to-server authentication certificate; for example, your default certificate can also be used as the OAuthTokenIssuer certificate. Lync Server 2013 allows you to use any Web server certificate as the certificate for server-to-server authentication provided that:

- The certificate includes the name of your SIP domain in the Subject field.
- The same certificate is configured as the OAuthTokenIssuer certificate on all of your Front End Servers.
- The certificate has a length of at least 2048 bits.

For details about server-to-server authentication certificates for Microsoft Lync Server 2013, see Assigning a Server-to-Server Authentication Certificate to Microsoft Lync Server 2013.

After the certificates have been assigned you must then configure the autodiscover service on Exchange 2013. In Exchange 2013, the autodiscover service configures user profiles and provides access to Exchange services when users log on to the system. Users present the autodiscover service with their email address and password; in turn, the services provide the user with information such as:

- Connection information for both internal and external connectivity to Exchange 2013.
- The location of the user’s Mailbox server.
- URLs for Outlook features such as free/busy information, Unified Messaging, and the offline address book.

- Outlook Anywhere server settings.

The autodiscover service must be configured before you can integrate Lync Server 2013 and Exchange 2013. You can verify whether or not the autodiscover service has been configured by running the following command from the Exchange Management Shell and checking the value of the AutoDiscoverServiceInternalUri property:

```
Get-ClientAccessServer
```

If this value is blank, you must assign a URI to the autodiscover service. Typically this URI will look similar to this:

```
https://autodiscover.litwareinc.com/autodiscover/autodiscover.xml
```

You can assign the autodiscover URI by running a command similar to this:

```
Get-ClientAccessServer | Set-ClientAccessServer -AutoDiscoverServiceInternalUri "
```

For details about the autodiscover service, see "Understanding the Autodiscover Service" at http://go.microsoft.com/fwlink/p/?LinkId=268542.

After the autodiscover service has been configured you must then modify the Lync Server OAuth configuration settings; this ensures that that Lync Server knows where to find the autodiscover service. To modify the OAuth configuration settings in Lync Server 2013, run the following command from within the Lync Server Management Shell. When running this command, be sure that you specify the URI to the autodiscover service running on your Exchange server, and that you use **autodiscover.svc** to point to the service location instead of **autodiscover.xml** (which points to the XML file used by the service):

```
Set-CsOAuthConfiguration -Identity global -ExchangeAutodiscoverUrl "https://autod
```

Note:

The Identity parameter in the preceding command is optional; that's because Lync Server only allows you to have a single, global collection of OAuth configuration settings. Among other things, that means that you can configure the autodiscover URL by using this slightly-simpler command:
Set-CsOAuthConfiguration–ExchangeAutodiscoverUrl "https://autodiscover.litwareinc.com/autodiscover/autodiscover.svc"
If you are unfamiliar with the technology, OAuth is a standard authorization protocol used by a number of major websites. With OAuth, user credentials and passwords are not passed from one computer to another. Instead, authentication and authorization is based on the exchange of security tokens; these tokens grant access to a specific set of resources for a specific amount of time.

In addition to configuring the autodiscover service, you must also create a DNS record for the service that points to your Exchange server. For example, if your autodiscover service is located at autodiscover.litwareinc.com you will need to create a DNS record for autodiscover.litwareinc.com that resolves to the fully qualified domain name of your Exchange server (for example, atl-exchange-001.litwareinc.com).

1.4.17.2 Configuring Partner Applications in Microsoft Lync Server 2013 and Microsoft Exchange Server 2013

Configuring Partner Applications in Microsoft Lync Server 2013 and Microsoft Exchange Server 2013

Planning > Planning for Exchange Server Integration > Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 >

Topic Last Modified: *2012-11-12*

Server-to-server authentication typically involves three entities: the two servers that need to communicate with one another, and a third-party security token server. If two servers (for example, Server A and Server B) need to communicate, then both of those servers typically start by contacting a token server and obtain a mutually-trusted security token. Server A then present that security token to Server B (and vice-versa) as a way to guarantee both its authenticity and its trustworthiness.

However, that's a general rule. Lync Server 2013, Microsoft Exchange Server 2013, and Microsoft SharePoint Server 2013 do not need to use a third-party token server when communicating with one another; that's because these server products can create security tokens that can be accepted by one another without the need for a separate token server. (This capability is only available in Lync Server 2013, Exchange 2013, and SharePoint Server 2013. If you need to set up server-to-server authentication with other servers, including other Microsoft server products, then you will need to do so by using a third-party token server.)

In order to set up server-to-server authentication between Lync Server and Exchange you must do two things: 1) you must assign the appropriate certificates to each server; and, 2) you must configure each server to be a partner application of the other server: that means you must configure Lync Server 2013 to be a partner application for Exchange 2013, and you must configure Exchange 2013 to be a partner application for Lync Server 2013.

Configuring Lync Server 2013 to be a Partner Application for Exchange 2013

The easiest way to configure Lync Server 2013 to be a partner application with Exchange 2013 is to run the Configure-EnterprisePartnerApplication.ps1 script, a Windows PowerShell script that ships with Exchange 2013. To run this script, you must provide the URL for the Lync Server authentication metadata document; this will typically be the fully qualified domain name of the Lync Server 2013 pool followed by the suffix /metadata/json/1. For example:

```
https://atl-cs-001.litwareinc.com/metadata/json/1
```

To configure Lync Server as a partner application, open the Exchange Management Shell and run a command similar to this (assuming that Exchange has been installed on drive C: and that it uses the default folder path):

```
"C:\Program Files\Microsoft\Exchange Server\V15\Scripts\Configure-EnterprisePartn
```

After configuring the partner application it is recommended that you stop and restart Internet Information Services (IIS) on your Exchange mailbox and client access servers. You can restart IIS by using a command similar to this, which restarts the service on the computer atl-exchange-001:

```
iisreset atl-exchange-001
```

This command can be run from within the Exchange Management Shell or from any other command window run under administrator privileges.

Configuring Exchange 2013 to be a Partner Application for Lync Server 2013

After you have configured Lync Server 2013 to be a partner application for Exchange 2013, you must then configure Exchange to be a partner application for Lync Server. This can be done by using the Lync Server Management Shell and specifying the authentication metadata document for Exchange; this will typically be the URI of the Exchange autodiscover service followed by the suffix /metadata/json/1. For example:

```
https://autodiscover.litwareinc.com/autodiscover/metadata/json/1
```

In Lync Server, partner applications are configured by using the New-CsPartnerApplication cmdlet. In addition to specifying the metadata URI you should also set the application trust level to Full; this will allow Exchange to represent both itself and any authorized user in the realm. For example:

```
New-CsPartnerApplication -Identity Exchange -ApplicationTrustLevel Full -Metadata
```

Alternatively, you can create a partner application by copying and modifying the script code found in the Lync Server 2013 server-to-server authentication documentation. See the article Managing Server-to-Server Authentication (Oauth) and Partner Applications for more information.

If you have successfully configured partner applications for both Lync Server and Exchange that means that you have also successfully configured server-to-server authentication between the two products. Lync Server 2013 includes a Windows PowerShell cmdlet, Test-CsExStorageConnectivity, that enables you to verify that server-to-server authentication has been correctly configured and that the Lync Server Storage Service can connect to Exchange 2013. The cmdlet does this by connecting to the mailbox of an Exchange 2013 user, writing an item into the Conversation History folder for that user, and then, optionally, deleting that item.

To test the integration of Lync Server 2013 and Exchange 2013, run a command similar to this from within the Lync Server Management Shell:

```
Test-CsExStorageConnectivity -SipUri "sip:kenmyer@litwareinc.com"
```

In the preceding command, the SipUri represents the SIP address of a user with an account on Exchange 2013; your command will fail in this is not a valid user account.

If the test succeeds and connectivity has been established, you can then proceed to configure optional features such as archiving integration and the unified contact store.

1.4.17.3 Configuring Microsoft Lync Server 2013 to Use Microsoft Exchange Server 2013 Archiving

Configuring Microsoft Lync Server 2013 to Use Microsoft Exchange Server 2013 Archiving

Planning > Planning for Exchange Server Integration > Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 >

Topic Last Modified: *2012-10-04*

Microsoft Lync Server 2013 gives administrators the option of having instant messaging and Web conferencing transcripts archived to a user's Microsoft Exchange Server 2013 mailbox rather than a SQL Server database. If you enable this option, transcripts are written to the Purges folder in the user's mailbox. The Purges folder is a hidden folder found in the Recoverable Items folder. Although this folder is not visible to end-users, the folder is indexed by the Exchange search engine and can be discovered by using Exchange mailbox search and/or Microsoft SharePoint Server 2013. Because information is stored in the same folder used by the Exchange In-Place Hold feature (responsible for archiving email and other Exchange communications), administrators can use a single tool to search for all the electronic communications archived for a user.

In order to archive transcripts to Exchange 2013 you must begin by configuring server-to-server authentication between the two servers. After server-to-server authentication is in place you can then carry out the following tasks in Microsoft Lync Server 2013 (note that, depending on your setup and configuration, you might not need to complete all of these tasks):

1. Enable Exchange archiving by modifying your Lync Server archiving configuration settings. This step is required for all deployments.
2. Enable archiving for internal and/or external communications for your users. This step is required for all deployments.
3. Configure the ExchangeArchivingPolicy property for each user. This step is only required in Lync Server and Exchange are located in different forests.

Step 1: Enabling Exchange Archiving

Archiving in Lync Server is primarily managed by using the archiving configuration settings. When you install Lync Server 2013 you are automatically given a single, global collection of these settings. (Administrators can optionally create new collections of archiving settings at the site scope.) By default, archiving is not enabled in the global settings, nor is Exchange archiving enabled in these settings. In order to use Exchange archiving administrators must configure both the EnableArchiving and the EnableExchangeArchiving properties in these configuration settings. The EnableArchiving property can be set to one of three possible values:

- **None**. Archiving is disabled. This is the default value. If EnableArchiving is set to None then nothing will be archived in either your Lync Server archiving database or in Exchange 2013.
- **ImOnly**. Only instant message transcripts are archived. If Exchange archiving is enabled these transcripts will be archived in Exchange 2013. If Exchange archiving is disabled then these transcripts will be archived to Lync Server.
- **ImAndWebConf**. Both instant message transcripts and Web conferencing transcripts are archived. If Exchange archiving is enabled these transcripts will be archived in Exchange 2013. If Exchange archiving is disabled then these transcripts will be archived to Lync Server.

The EnableExchangeArchiving property is a Boolean value: set EnableExchangeArchiving to True ($True) to enable Exchange archiving or set EnableExchangeArchiving to False ($False) to disable Exchange archiving. For example, this command enables the archiving of instant messaging transcripts and also enables Exchange archiving:

```
Set-CsArchivingConfiguration -Identity "global" -EnableArchiving ImOnly -EnableEx
```

To disable Exchange archiving, use a command similar to the following, which enables instant messaging archiving but disables archiving to Exchange (in other words, transcripts will be archived to Lync Server):

```
Set-CsArchivingConfiguration -Identity "global" -EnableArchiving ImOnly -EnableEx
```

Note:

If the EnableArchiving property is set to None then Lync Server will not archive instant messaging and Web conferencing transcripts at all. In that case, the server will simply ignore the value configured for EnableExchangeArchiving.

Exchange archiving can also be enabled (or disabled) by using the Lync Server Control Panel. To do that, complete the following procedure:

1. In Control Panel, click **Monitoring and Archiving**, and then click **Archiving Configuration**.
2. On the **Archiving Configuration** tab, double-click the collection of archiving

settings to be modified (for example, the **Global** collection).

3. In the **Edit Archiving Setting** pane, click the **Archiving setting** dropdown list and select either **Archive IM sessions** (to archive just instant messaging sessions) or **Archive IM and web conferencing sessions** (to archive both instant messaging and Web conferencing sessions).
4. After choosing the items to be archived, select the **Exchange Server integration** checkbox to enable Exchange archiving. To disable Exchange archiving, clear this checkbox.

Note:

The **Exchange Server integration** checkbox will not be available if the **Archiving setting** is set to **Disable archiving**. You must enable archiving first and then enable Exchange archiving.

If Lync Server 2013 and Exchange 2013 are located in the same forest then archiving for individual users (or at least for users who have email accounts on Exchange 2013) is managed by using Exchange In-Place Hold policies. If you have users who are homed on a previous version of Exchange then archiving for those users will be managed by using Lync Server archiving policies. Note that only users with accounts on Exchange 2013 can have their Lync transcripts archived to Exchange.

If Lync Server 2013 and Exchange 2013 are located in different forests then archiving for individual users is managed by configuring the ExchangeArchivingPolicy property for each individual user account. See Step 3 for more information.

Step 2: Enabling the Archiving of Internal and/or External Communications

After you have enabled archiving (and Exchange archiving) you must then modify the appropriate archiving policies to ensure that user sessions are actually archived. Note that simply enabling archiving (Step 1) does not cause Lync Server to begin archiving instant messaging and Web conferencing transcripts. Instead, you must use archiving policies to enable internal and/or external archiving. When you install Lync Server 2013 you also install a single, global archiving policy that contains two properties:

- **ArchiveInternal**. When set to True ($True) indicates that internal communication sessions involving only users who have Active Directory accounts in your organization) will be archived.
- **ArchiveExternal**. When set to True ($True) indicates that internal communication sessions (sessions involving at least one user who does not have an Active Directory account in your organization) will be archived.

By default, both of these property values are set to False, meaning that neither internal nor external communication sessions are archived. To modify the global policy, you can use the Lync Server Management Shell and the Set-CsArchivingPolicy cmdlet. This command enables the archiving of both internal and external communication sessions:

```
Set-CsArchivingPolicy -Identity "global" -ArchiveInternal $True -ArchiveExternal
```

Alternatively, you can use the New-CsArchivingPolicy to create a new policy at either the site scope or the per-user scope. For example, this command creates a new per-user archiving policy named RedmondArchivingPolicy:

```
New-CsArchivingPolicy -Identity "RedmondArchivingPolicy" -ArchiveInternal $True -
```

If you create a per-user policy you will then need to assign that policy to the appropriate users. For example:

```
Grant-CsArchivingPolicy -Identity "Ken Myer" -PolicyName  "RedmondArchivingPolicy
```

Archiving policies can also be managed by using the Lync Server Control Panel. Within the Control Panel, click **Monitoring and Archiving** and then click **Archiving Policy**. To modify an existing policy, double-click the policy (e.g., Global) and then, in the **Edit Archiving Policy** pane, select or clear the **Archive internal communications** and the **Archive external communications** checkboxes as needed. To create a new archiving policy, click **New** and then select either **Site policy** or **User policy**. If you create a new user policy then you must access the appropriate user accounts (from the **Users** tab) and assign those users the new policy.

Step 3: Configuring the ExchangeArchivingPolicy Property

If Lync Server 2013 and Exchange 2013 are located in different forests then it is not enough to simply enable Exchange archiving in the archiving configuration settings; that will not result in instant messaging and Web conferencing transcripts being archived in Exchange. Instead, you must also configure the ExchangeArchivingPolicy property on each of the relevant Lync Server user accounts. This property can be set to one of four possible values:

1. Uninitialized. Indicates that archiving will be based on the In-Place Hold settings configured for the user's Exchange mailbox; if In-Place Hold has not been enabled on the user's mailbox then the user will have his or her messaging and Web conferencing transcripts archived in Lync Server.
2. **UseLyncArchivingPolicy**. Indicates that the user's instant messaging and Web conferencing transcripts should be archived in Lync Server rather than in Exchange.
3. **NoArchiving**. Indicates that the user's instant messaging and Web conferencing transcripts should not be archived at all. Note that this setting overrides any Lync Server archiving policies assigned to the user.
4. **ArchivingToExchange**. Indicates that the user's instant messaging and Web conferencing transcripts should be archived to Exchange regardless of the In-Place Hold settings that have (or have not) been assigned to the user's mailbox.

For example, to configure a user account so that instant messaging and Web conferencing transcripts are always archived to Exchange you can use a command similar to this from the Lync Server Management Shell:

```
Set-CsUser -Identity "Ken Myer" -ExchangeArchivingPolicy ArchivingToExchange
```

If you want to set the same archiving policy for a group of users (for example, all the users homed on a specified Registrar pool) you can use a command similar to this:

```
Get-CsUser -Filter {RegistrarPool -eq "atl-cs-001.litwareinc.com"} | Set-CsUser -
```

Note that you must use the Lync Server Management Shell (and Windows PowerShell) in order to configure value of the ExchangeArchivingPolicy property. This property is not exposed to administrators in the Lync Server Control Panel.

If you would like to view a list of all the users who have been assigned a specific archiving policy then you can use a command similar to the following, which returns the Active Directory display name of all the users who have had the ExchangeArchivingPolicy property set to Uninitialized:

```
Get-CsUser | Where-Object {$_.ExchangeArchivingPolicy -eq "Uninitialized"} | Sele
```

Likewise, this command returns the display name of the users who have not have the ExchangeArchivingPolicy property set to UseLyncArchivingPolicy:

```
Get-CsUser | Where-Object {$_.ExchangeArchivingPolicy -ne "UseLyncArchivingPolicy
```

1.4.17.4 Configuring Microsoft SharePoint Server 2013 to Search for Archived Microsoft Lync Server 2013 Data

Configuring Microsoft SharePoint Server 2013 to Search for Archived Microsoft Lync Server 2013 Data

Planning > Planning for Exchange Server Integration > Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 >

Topic Last Modified: *2013-02-04*

One of the major advantages to storing instant messaging and Web conferencing transcripts in Microsoft Exchange Server 2013 instead of Microsoft Lync Server 2013 is the fact that storing data in the same location enables administrators to use a single tool to search for archived Exchange data and/or archived Lync Server data. Because all the data is stored in the same place (Exchange) any tool that can search for archived Exchange data can also search for archived Lync Server data.

One tool that makes it easy to search for archived data is Microsoft SharePoint Server 2013. If you would like to use SharePoint to search for Lync Server data, you must first complete all the steps involved in configuring Exchange archiving in Lync Server. After Exchange 2013 and Lync Server 2013 have been successfully integrated you must then install the Exchange Web Services Managed API Version 2.0 on your SharePoint Server; the setup program for that API can be downloaded from the Microsoft Downloads Center (http://go.microsoft.com/fwlink/p/?LinkId=258305). The downloaded file (EWSManagedAPI.msi) can be saved to any folder on your SharePoint server.

After the file has been downloaded complete the following procedure on the SharePoint server:

1. Open a command window by clicking **Start**, clicking **All Programs**, clicking **Accessories**, right-clicking **Command Prompt**, and then clicking **Run as administrator**.
2. In the command window, use the **cd** command to change the current directory to the folder where the file EWSManagedAPI.msi has been saved. For example, if you have saved the file to C:\Downloads type the following command in the command window and then press ENTER:
   ```
   cd C:\Downloads
   ```
3. To install the API, type the following command then press ENTER:
   ```
   msiexec /I EwsManagedApi.msi addlocal="ExchangeWebServicesApi_Feature,
   ```
4. After the API has been installed, reset IIS by typing the following command and pressing ENTER:
   ```
   iisreset
   ```

After Exchange Web Services has been installed you must then configure server-to-server authentication between SharePoint Server 2013 and Exchange 2013. To do this, first open the SharePoint 2013 Management Shell and run the following set of command:

```
New-SPTrustedSecurityTokenIssuer -Name "Exchange" -MetadataEndPoint "https://auto
$service = Get-SPSecurityTokenServiceConfig
$service.HybridStsSelectionEnabled = $True
$service.AllowMetadataOverHttp = $False
$service.AllowOAuthOverHttp = $False
$service.Update()
```

Note:

Be sure and use the URI for your autodiscover service. Do not use the sample URI https://autodiscover.litwareinc.com/autodiscover/metadata/json/1.

After you have created the token issuer and configured the token service, run these commands, making sure to substitute the URL of your SharePoint site for the sample URL http://atl-sharepoint-001:

```
$exchange = Get-SPTrustedSecurityTokenIssuer "Exchange"
$app = Get-SPAppPrincipal -Site "https://atl-sharepoint-001" -NameIdentifier $exc
$site = Get-SPSite  "https://atl-sharepoint-001"
Set-SPAppPrincipalPermission -AppPrincipal $app -Site $site.RootWeb -Scope "SiteS
```

To configure server-to-server authentication for Exchange 2013, open the Exchange Management Shell and run a command similar to this (assuming that Exchange has been installed on drive C: and that it uses the default folder path):

```
"C:\Program Files\Microsoft\Exchange Server\V15\Scripts\Configure-EnterprisePartn
```

After configuring the partner application it is recommended that you stop and restart Internet Information Services (IIS) on all your Exchange mailbox and client access servers. You can restart IIS by using a command similar to this, which restarts the service on the computer atl-exchange-001:

```
iisreset atl-exchange-001
```

This command can be run from within the Exchange Management Shell or from any other command window.

Next, run a command similar to the following, which gives the specified user (in this example, kenmyer) the right to do discovery on Exchange:

```
Add-RoleGroupMember "Discovery Management" -Member "kenmyer"
```

After server-to-server authentication has been established between Exchange and SharePoint your next step is to create an eDiscovery site in SharePoint. That can be done by running commands similar to these from the SharePoint Management Shell:

```
$template = Get-SPWebTemplate | Where-Object {$_.Title -eq "eDiscovery Center"}
New-SPSite -Url "https://atl-sharepoint-001/sites/discovery" -OwnerAlias "kenmyer
```

Note:

"eDiscovery" is short for "electronic discovery," and typically refers to the process of looking through electronic archives for items that can be "reasonably calculated to lead to admissible evidence" in a court of law.

When the new site is ready, the next step is to configure Exchange 2013 to act as a result source for SharePoint. You can do that by completing the following procedure from the SharePoint 2013 Central Administration page:

1. On the Central Administration page click **Manage Service Applications** and then click **Search Service Application**.
2. On the Search Service Application: Search Administration page click **Result Sources** and then click **New Result Source**.
3. In the **New Result Source** pane enter a name for the new result source (for example, **Microsoft Exchange**) in the **Name** box. Select **Exchange** as the result source **Protocol**, and then enter the web services source URL for your Exchange server in the **Exchange Source URL** box. The source URL should look similar to this: https://atl-exchange-001.litwareinc.com/ews/exchange.asmx
4. Make sure that **Use Autodiscover** is not selected, and then click **OK**.

Finally, create a new eDiscovery case and a new eDiscovery set by completing the following procedure from the SharePoint Discovery site (for example, https://atl-sharepoint-001/sites/discovery):

1. On the Site Contents page click **Create a new case**.
2. On the Site Contents: New SharePoint Site page, enter the user's email alias (for example, **kenmyer**) in the **Title** box, then add that same URL to the **Web Site Address** box. That will result in a URL similar to this: https://atl-sharepoint-001/sites/eDiscovery/kenmyer
3. Click **Create**.
4. When the eDiscovery set page appears, click **new item** under **Identity and Preserve: Discovery Sets**.
5. On the New: Discovery Set page, enter the user's email alias in the **Discovery Set Name** box. Enter **eDiscovery Lync*** in the **Filter** box and then click **Add & Manage Sources**.
6. On the Add & Manage Sources page, enter the user's email alias in the first textbox under **Mailboxes**. Click the check mailbox icon located next to the textbook to verify that SharePoint can connect to the specified mailbox.
7. Click **OK**.
8. On the eDiscovery set page, click **Save** to save the new eDiscovery set.

At this point you can search the specified mailbox (kenmyer) and/or enable In-Place holds the same way you would for any other SharePoint content or result source.

1.4.17.5 Configuring Microsoft Lync Server 2013 to Use the Unified Contact Store

Configuring Microsoft Lync Server 2013 to Use the Unified Contact Store

Planning > Planning for Exchange Server Integration > Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 >

Topic Last Modified: *2013-01-16*

The unified contact store enables users to maintain a single contacts list and then have those contacts available in multiple applications, including Microsoft Lync 2013, Microsoft Outlook 2013, and Microsoft Outlook Web App 2013. When you enable the unified contact store for a user that user's contacts are not stored in Microsoft Lync Server 2013 and then retrieved using the SIP protocol. Instead, his or her contacts are stored in Microsoft Exchange Server 2013 and are retrieved by using Exchange Web Services.

Note:

Technically, contact information is stored in a pair of folders found in the user's Exchange 2013 mailbox. The contacts themselves are stored in a folder named Lync Contacts which is visible to end users; metadata about the contacts are stored in a subfolder that is not visible to end users.

Enabling the Unified Contact Store for a User

If you have already configured server-to-server authentication between Lync Server 2013 and Exchange 2013 then you have also enabled the use of the unified contact store; no additional server configuration is required. However, additional user account configuration is required in order to move a user's contacts into the unified contact store. By default, user contacts are kept in Lync Server and not in the unified contact store.

Access to the unified contact store is managed by using Lync Server user services policies.

User server policies have only a single property (UcsAllowed); this property is used to determine the location where a user's contacts are stored. If a user is managed by a user services policy where UcsAllowed has been set to True ($True) then the user's contacts will be stored in in the unified contact store. If the user is managed by a user services policy where UcsAllowed has been set to False ($False) then his or her contacts will be stored in Lync Server.

When you install Lync Server 2013 a single user services policy (configured at the global scope) is installed as well. The UcsAllowed value in this policy is set to True, meaning that, by default, user contacts will be stored in the unified contact store (assuming this has been deployed and configured). If you want to migrate all of your user contacts to the unified contact store you do not have to do anything at all.

If you would prefer not to migrate all your contacts to the unified contact store you can disable the unified contact store for all users by setting the UcsAllowed property in the global policy to False:

```
Set-CsUserServicesPolicy -Identity global -UcsAllowed $False
```

After you have disabled the unified contact store in the global policy you can then create a per-user policy that enables the use of the unified contact store; this allows you to have some users keep their contacts in the unified contact store while other users continue to keep their contacts in Lync Server. You can create a per-user user services policy by using a command similar to this:

```
New-CsUserServicesPolicy -Identity "AllowUnifiedContactStore" -UcsAllowed $True
```

After you have created the new policy you must then assign that policy to any user who should have access to the unified contact store. Per-user policies can be assigned to users by using commands similar to this:

```
Grant-CsUserServicesPolicy -Identity "Ken Myer" -PolicyName "AllowUnifiedContactS
```

After the policy has been assigned Lync Server will begin to migrate the user's contacts to the unified contact store. After migration is complete, the user will then have his or her contacts stored in Exchange rather than Lync Server. If the user happens to be logged on to Lync 2013 at the time migration completes, a message box will appear and he or she will be asked to log off of Lync and then log back on in order to finalize the process. Users who have not been assigned this per-user policy will not have their contacts migrated to the unified contact store. That’s because those users are being managed by the global policy, and use of the unified contact store has been disabled in the global policy.

You can verify that a user's contacts have successfully been migrated to the unified contact store by running the Test-CsUnifiedContactStore cmdlet from within the Lync Server Management Shell:

```
Test-CsUnifiedContactStore -UserSipAddress "sip:kenmyer@litwareinc.com" -TargetFq
```

If Test-CsUnifiedContactStore succeeds that means that the contacts for the user sip:kenmyer@litwareinc.com have been migrated to the unified contact store.

Rolling Back the Unified Contact Store

If you need to remove a user's contacts from the unified contact store (for example, if the user needs to be rehomed on Microsoft Lync Server 2010 and thus can no longer use the unified contact store) you must do two things. First, you must assign the user a new user services policy, one that prohibits storing contacts in the unified contact store. (That is, a policy where the UcsAllowed property has been set to $False.) If you do not have such a policy you can create one using a command similar to this:

```
New-CsUserServicesPolicy -Identity NoUnifiedContactStore -UcsAllowed $False
```

You can then assign this new per-user policy (NoUnifiedContactStore) by using a command like this:

```
Grant-CsUserServicesPolicy -Identity "Ken Myer" -PolicyName NoUnifiedContactStore
```

The preceding command assigns the new policy to the user Ken Myer, and also prevents Ken's contacts from being migrated to the unified contact store.

Note:

In some cases you can achieve the same net effect by simply unassigning the user's current user services policy. For example, suppose Ken Myer has a per-user user services policy the enables the unified contact store, but your global policy prohibits the use of the unified contact store. In that case, you could unassign Ken's per-user services policy. When you do that, Ken will automatically be managed by the global policy, and thus will no longer have access to the unified contact store.
To unassign a previously-assigned per-user policy, use the same command as shown before, but this time set the PolicyName parameter to a null value:
Grant-CsUserServicesPolicy –Identity "Ken Myer" –PolicyName $Null

The terminology "prevents Ken's contacts from being migrated to the unified contact store" is important to keep in mind when working with the unified contact store. Simply assigning Ken a new user services policy will not move his contacts out of the unified contact store. When a user logs on to Lync Server 2013, the system checks the user's user services policy to see whether his or her contacts should be kept in the unified contact store. If the answer is yes (that is, if the UcsAllowed property is set to $True) then those contacts will be migrated to the unified contact store (assuming that those contacts are not already in the unified contact store). If the answer is no, then Lync Server simply ignores the user's contacts and moves on to its next task. That means that Lync Server will not automatically move a user's contacts from out of the unified contact store, regardless of the value of the UcsAllowed property.

That also means that, after assigning the user a new user services policy, you must then run the Invoke-CsUcsRollback cmdlet in order to move the user's contacts out of Exchange 2013 and back to Lync Server 2013. For example, after assigning Ken Myer a new user services policy you can then move his contacts out of the unified contact store by using the following command:

```
Invoke-CsUcsRollback -Identity "Ken Myer"
```

If you change the user services policy but do not run the Invoke-CsUcsRollback cmdlet Ken's contacts will not be removed from the unified contact store. What if you run Invoke-CsUcsRollback but do not change Ken Myer's user services policy? In that case, Ken's contacts will be temporarily removed from the unified contact store. The fact that this removal is temporary is important to keep in mind. After Ken's contacts have been removed from the unified contact store, Lync Server 2013 will wait 7 days and then check to see which user services policy has been assigned to Ken. If Ken is still assigned a policy that enables the user of the unified contact store, then his contacts will automatically be moved back to into the contact store. To permanently remove contacts from the unified contact store you must change the user services policy in addition to running the Invoke-CsUcsRollback cmdlet.

1.4.17.6 Configuring the Use of High-Resolution Photos in Microsoft Lync Server 2013

Configuring the Use of High-Resolution Photos in Microsoft Lync Server 2013

Planning > Planning for Exchange Server Integration > Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 >

Topic Last Modified: *2012-10-22*

Microsoft Lync Server 2010 provided the ability for users to view photos of their contacts (and to make their own photos available to others). Typically these photos were stored as part of the user's thumbnailPhoto attribute in Active Directory. That placed a serious limitation on the size and resolution of the photos: the thumbnailPhoto attribute can only hold a photograph with a maximum size of 48 pixels by 48 pixels.

In Microsoft Lync Server 2013, however, photos can be stored in a user's Microsoft Exchange Server 2013 mailbox; that allows for photo sizes up to 648 pixels by 648 pixels. In addition to that, Exchange 2013 can automatically resize these photos for use in different products as needed. Typically that means three different photo sizes and resolutions:

- 48 pixels by 48 pixels, the size used for the Active Directory thumbnailPhoto attribute. If you upload a photo to Exchange 2013 Exchange will automatically create a 48 pixel by 48 pixel version of that photo and update the user's thumbnailPhoto attribute. Note, however, that the reverse is not true: if you manually update the thumbnailPhoto attribute in Active Directory the photo in the user's Exchange 2013 mailbox will not automatically be updated.
- 96 pixels by 96 pixels, for use in Microsoft Outlook 2013 Web App, Microsoft Outlook 2013, Microsoft Lync Web App, and Lync 2013.
- 648 pixels by 648 pixels for use in Lync 2013 and Microsoft Lync Web App.

Note:

If you have the resources, it is recommended that you upload 648x648 photos; that provides the maximum resolution and optimal picture quality in any of the Office 2013 applications. Each JPEG photo with a size of 648x648 and a depth of 24 bits results in a file size of approximately 240 kilobytes. That means you will need approximately 1 megabyte of disk space for every 4 user photos.

High-resolution photos, which are accessed by using Exchange Web Services, can be uploaded by users who are running Outlook 2013 Web App; users are only allowed to update their own photo. Administrators, however, can update the photo for any user by using the Exchange Management Shell and a series of Windows PowerShell commands similar to the following:

```
$photo = ([Byte]] $(Get-Content -Path "C:\Photos\Kenmyer.jpg" -Encoding Byte -Rea
Set-UserPhoto -Identity "Ken Myer" -PictureData $photo -Confirm:False
Set-UserPhoto -Identity "Ken Myer" -Save -Confirm:False
```

The first command in the preceding example uses the Get-Content cmdlet to read the contents of the file C:\Photos\Kenmyer.jpg and store that data in a variable named $photo. In the second command, the Exchange cmdlet Set-UserPhoto is used to upload the photo and attach that photo to Ken Myer's user account.

Note:

In this example, Ken Myer's Active Directory display name is used as the user account Identity. You can also reference a user account by using other identifiers such as the user's SMTP address or his or her User Principal Name. See the documentation for the Set-UserPhoto cmdlet at http://go.microsoft.com/fwlink/p/?LinkId=268536 for more information

Uploading the photo does not equate to assigning that photo to Ken Myer's user account. Instead, uploading the photo simply results in a preview of that photo to be displayed on the Outlook Web App Options page. To actually assign that photo to the user account the user must click **Save** on the Options page or the administrator must execute the third command in the example. That third command uses the Save parameter to assign the photo to Ken Myer's user account:

```
Set-UserPhoto -Identity "Ken Myer" -Save -Confirm:False
```

To verify that the new photo has been assigned to the user account, Ken Myer can log on to Lync 2013, select **Options**, and then select **My Picture**. The newly-uploaded photo should be displayed as Ken's personal photo. Alternatively, administrators can verify the photo for any user by starting Internet Explorer and navigating to a URL similar to this:

```
https://atl-mail-001.litwareinc.com/ews/Exchange.asmx/s/GetUserPhoto?email=kenmye
```

If the administrator can view the photo using Internet Explorer but the user cannot view his or her photo in Lync 2013, that typically indicates a connectivity problem with Exchange Web Services or with the Exchange autodiscover service.

1.4.17.7 Configuring Microsoft Exchange Server 2013 Unified Messaging for Microsoft Lync Server 2013 Voicemail

Configuring Microsoft Exchange Server 2013 Unified Messaging for Microsoft Lync Server 2013 Voicemail

Planning > Planning for Exchange Server Integration > Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 >

Topic Last Modified: *2013-02-04*

Microsoft Lync Server 2013 enables you to have voicemail messages stored in Microsoft Exchange Server 2013; those voicemail messages will then appear as email messages in your users' Inboxes. This capability was also found in the 2010 editions of Lync Server and Exchange; however, the process of configuring this "unified messaging" has been simplified in in the 2013 editions thanks to the introduction of the UM Call Router component. This component is installed on the Exchange 2013 Client Access server, and all calls to Exchange unified messaging (such as a voicemail) are first routed through the Call Router and then are redirected to the appropriate Mailbox server.

If you have already configured server-to-server authentication between Lync Server 2013 and Exchange 2013 then you are ready to setup unified messaging. To do so, you must first create and assign a new unified messaging dial plan on your Exchange server. For example, these two commands (run from within the Exchange Management Shell) configure a new 3-digit dial plan for Exchange:

```
New-UMDialPlan -Name "RedmondDialPlan" -VoIPSecurity "Secured" -NumberOfDigitsInE
Set-UMDialPlan "RedmondDialPlan" -ConfiguredInCountryOrRegionGroups "Anywhere,*,*
```

In the first command in the example, the VoIPSecurity parameter, and the parameter value "Secured" indicate that the signaling channel is encrypted by using Transport Layer Security (TLS). The URIType "SipName" indicates that messages will be sent and received using the SIP protocol, and the CountryOrRegionCode of 1 indicates that the dial plan applies to the US.

In the second command, the parameter value passed to the ConfiguredInCountryOrRegionGroups parameter specifies the in-country groups that can be used with this dial plan. The parameter value "Anywhere,*,*,*" sets the following:

- Group name ("Anywhere")
- AllowedNumberString (*, a wildcard character indicating that any number string is allowed)

- DialNumberString (*, a wildcard character indicating that any dialed number is allowed)
- TextComment (*, a wildcard character indicating that any text command is allowed)

Note:

Creating a new dial plan will also create a Default Mailbox Policy.

After creating and configuring the new dial plan you must add the new dial plan to your unified messaging server and then modify the startup mode of that server; in particular, you must set the startup mode to "Dual". You can perform both of these tasks from within the Exchange Management Shell:

```
Set-UmService -Identity "atl-exchangeum-001.litwareinc.com" -DialPlans "RedmondDi
```

After the unified messaging server has been configured you should next run the Enable-ExchangeCertificate cmdlet to ensure that your Exchange certificate is applied to the unified messaging service:

```
Enable-ExchangeCertificate -Server "atl-umserver-001.litwareinc.com" -Thumbprint
```

After the certificate has been correctly assigned you must then stop and restart the MsExchangeUM service on the unified messaging server. This service must be stopped and restarted any time you change the startup mode.

After finishing configuration of the unified messaging server you can then configure the UM Call Router:

```
Set-UMCallRouterSettings -Server "atl-exchange-001.litwareinc.com" -UMStartupMode
Enable-ExchangeCertificate -Server "atl-umserver-001.litwareinc.com" -Thumbprint
```

Because the startup mode has changed you must stop and restart the MsExchangeUMCR service on the computer hosting the UM Call Router.

To complete the unified messaging setup, you then need to create a UM mailbox policy and then use that policy to enable users for unified messaging. You can create a mailbox policy by using a command similar to this:

```
New-UMMailboxPolicy -Name "RedmondMailboxPolicy" -AllowedInCountryOrRegionGroups
```

And you can enable a user for unified messaging by using a command similar to this:

```
Enable-UMMailbox -Extensions 100 -SIPResourceIdentifier "kenmyer@litwareinc.com"
```

In the preceding command, the Extensions parameter represents the telephone extension number for the user. In this example, the user has the extension number 100.

After you have enabled his mailbox, the user kenmyer@litwareinc.com should be able to use Exchange unified messaging. You can verify that the user can connect to Exchange UM by running the Test-CsExUMConnectivity cmdlet from within the Lync Server Management Shell:

```
$credential = Get-Credential "litwareinc\kenmyer"
Test-CsExUMConnectivity -TargetFqdn "atl-cs-001.litwareinc.com" -UserSipAddress "
```

If you have a second user who has been enabled for unified messaging you can use the Test-CsExUMVoiceMail cmdlet to verify that this second user can leave a voicemail message for the first user.

```
$credential = Get-Credential "litwareinc\pilar"
Test-CsExUMVoiceMail -TargetFqdn "atl-cs-001.litwareinc.com" -ReceiverSipAddress
```

1.4.17.8 Integrating Microsoft Lync Server 2013 and Microsoft Outlook Web App 2013

Integrating Microsoft Lync Server 2013 and Microsoft Outlook Web App 2013

Planning > Planning for Exchange Server Integration > Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 >

Topic Last Modified: *2013-02-03*

In addition to integrating with Microsoft Outlook 2013, Microsoft Lync Server 2013 can be fully integrated with Microsoft Outlook Web App 2013; among other things, this adds instant messaging and presence to Outlook Web App, and enables your unified contact list to be shared between Outlook Web App and Microsoft Lync 2013. In order to integrate Lync Server 2013 and Outlook Web App, you must first verify that the Unified Communications Managed API 4.0 Runtime has installed in your Microsoft Exchange Server 2013 backend server. You can do this by looking for the existence of the following registry value:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSExchange OWA \InstantMessaging\ImplementationDLLPath

The ImplementationDLLPath should point to the folder location for the file Microsoft.Rtc.Internal.Ucweb.dll. If it does not, or if the registry value does not exist, then you should download and install the UCMA Runtime setup program from the Microsoft Download Center at http://www.microsoft.com/en-us/download/details.aspx?id=34992. Information on how to install the UCMA Runtime can be found on that same web page.

Backward Compatibility

Lync Server 2013 can be integrated with the Microsoft Exchange Server 2010 versions of both unified messaging and Outlook Web App. For more information, see the article Deploying On-Premises Exchange UM to Provide Lync Server 2010 Voice Mail at http://technet.microsoft.com/en-us/library/gg398768.aspx. If you integrate with Exchange 2010 you will not have Lync Server specific features such as the unified contact store and Lync-to-Exchange archiving.

Microsoft Lync 2013 can also be used in conjunction with Exchange 2010 and Outlook 2010. Once again, however, new functionality such as the unified contact store and high-resolution photos will not be available to Lync 2013 users. These new capabilities require both Lync Server 2013 and Exchange 2013.

Creating a Trusted Application Pool for Outlook Web App

If you have installed the Microsoft Exchange Unified Messaging Call Router service and the Microsoft Exchange Unified Messaging service on the same computer then there is no need to create a trusted application pool for Outlook Web App. (This assumes that the server in question is hosting a SipName UM dial plan.) If you are using a single computer to host both of these services then you can skip to the section of this document titled **Enabling Instant Messaging on Outlook Web App**.

Lync Server 2013 can autodiscover any Exchange servers that host a SipName UM dial plan; these servers are automatically added to the Lync Server Known Servers List. There is no need to create a trusted application pool and add these servers to the Known Servers List. In fact, doing so will cause Outlook Web App integration to stop working.

Note:

This is due to the fact that the Lync Server topology will now have two entries for the same computer: the autodiscovered entry, and the manually-added entry. To fix the problem, and to get Outlook Web App working again, use Windows PowerShell to remove the trusted pool and trusted application entries for the server. See the help topics for the Remove-CsTrustedApplicationPool and Remove-CsTrustedApplication cmdlets for more information.

If these two services are running on separate computers then, after you have verified that the Unified Communications Managed API 4.0 Runtime has been installed, you must create a Lync Server trusted application pool and a trusted application associated with Outlook Web App; that will add the server to the Known Servers List. To do that, first run a command similar to this from within the Lync Server Management Shell:

```
New-CsTrustedApplicationPool -Identity atl-owa-001.litwareinc.com -Registrar atl-
```

In the preceding command, atl-owa-001.litwareinc.com is the fully qualified domain name of the Outlook Web App pool; this must be the same name that appears in the Subject Name and Subject Alternative Name (SAN) fields of the certificate that provides access to Outlook Web App. Likewise, atl-cs-001.litwareinc.com is the fully qualified domain name of the Lync Server 2013 pool that will host the new trusted application pool. Note, too that the specified site, Redmond, represents the SiteID of the Lync Server site. The SiteID is not necessarily the same as the site's DisplayName; you can retrieve SiteIDs for your Lync Server sites by running the following command from the Lync Server Management Shell:

```
Get-CsSite | Select-Object DisplayName, SiteID
```

After creating the trusted application pool, use a command similar to the following to configure an application Identity and a port for Outlook Web App:

```
New-CsTrustedApplication -ApplicationId OutlookWebApp -TrustedApplicationPoolFqdn
```

In the preceding command, the ApplicationID is simply a friendly identifier used to distinguish trusted applications. The ApplicationID can be any text string that does not include blank spaces or other prohibited characters. (To ensure that you create a valid identifier, it is recommended that you use only letters and numbers when specifying an ApplicationId.) The value assigned to the Port parameter is also left to the administrator's discretion: this can be any available network port.

After creating the trusted application you must run the following command to enable the changes to your Lync Server topology:

```
Enable-CsTopology
```

Note that you must also add your Exchange client access and mailbox server to all of your SIP Uri dial plans. In turn, this will configure the servers as trusted SIP peers with the ExUmRouting topology for Lync Server.

Enabling Instant Messaging on Outlook Web App

With Lync Server correctly configured you can then begin to configure Outlook Web App. The first step in that process is to enable instant messaging on all your Outlook Web App virtual directories on your front end servers. (There is no need to enable instant messaging for the virtual directories on your backend servers. In fact, it is recommended that you do not enable instant messaging on your backend servers.) Instant messaging can be enabled on the client access servers by running the following command from within the Exchange Management Shell:

```
Get-OwaVirtualDirectory | Set-OwaVirtualDirectory -InstantMessagingEnabled $True
```

Note:

By default, instant messaging is enabled when you install Outlook Web App; that is, the InstantMessagingEnabled property is set to True. However, you must still run the preceding command in order to set the instant messaging type to OCS. By default, InstantMessagingType is set to None.

Next you must add the following two lines to Outlook Web App Web.config file (this file is typically located in the folder C:\Program Files\Microsoft\Exchange Server\V15 \ClientAccess\Owa). These two lines should be added under the <AppSettings> node in the Web.config file, and this procedure should be carried out only on the backend servers where Outlook Web App has been installed:

```
<add key="IMCertificateThumbprint" value="EA5A332496CC05DA69B75B66111C0F78A110D22
<add key="IMServerName" value="atl-cs-001.litwareinc.com"/>
```

In the preceding example, the value for IMCertificateThumbprint must be the thumbprint for the Exchange 2013 certificate that is installed on your backend servers. You can retrieve that information by running the following command from the Exchange Management Shell:

```
Get-ExchangeCertificate
```

Note, too that the value assigned to IMServerName is the fully qualified domain name of the Lync Server pool where you created the trusted application pool for Outlook Web App.

The certificate that you use for Outlook Web App must be a certificate that is trusted by Lync Server. One way to ensure that the certificate will be trusted by both Lync Server and Exchange is to use your internal certificate authority to create a certificate on the mailbox server, making sure that the server FQDN is used for the subject name and that this FQDN appears in the certificate alternate name field. After the certificate has been created it can then be imported to your backend servers. The net result is that the same certificate is used for two purposes: 1) communication between Exchange unified messaging and Lync Server; and, 2) the integration between Outlook Web App and Lync Server.

After you have updated the Web.config file you should then run the following command on the Exchange backend server in order to recycle the Outlook Web App pool:

```
C:\Windows\System32\Inetsrv\Appcmd.exe recycle apppool /apppool.name:"MSExchangeO
```

If the recycle operation succeeds you will see the following message in the Exchange Management Shell:

```
"MSExchangeOWAAppPool" successfully recycled
```

Configuring Outlook Web App Mailbox Policies

At this point you can use the following command to configure instant messaging on the appropriate Outlook Web App mailbox policy (or policies). For example, this command, run on one of your mailbox servers, enables instant messaging on the Default policy:

```
Set-OwaMailboxPolicy -Identity "Default" -InstantMessagingEnabled $True -InstantM
```

And this command enables instant messaging for all your Outlook Web App mailbox policies:

```
Get-OwaMailboxPolicy | Set-OwaMailboxPolicy -InstantMessagingEnabled $True -Insta
```

After the mailbox policy has been enabled then all users managed by that policy will have full integration between Lync Server and Outlook Web App, provided that:

- The user has a mailbox on Exchange 2013.
- The user has been enabled for Lync Server 2013.
- The user has a valid SIP proxy address.

Disabling Instant Messaging in Outlook Web App

As noted previously, instant messaging is enabled by default in Outlook Web App. That means that, if you do not integrate Outlook Web App with Lync Server, users will see blank presence icons and an error message each time they log on to Outlook Web App. To prevent this problem, use the following Exchange Management Shell command to disable instant messaging in Outlook web App:

```
Get-OwaVirtualDirectory | Set-OwaVirtualDirectory -InstantMessagingEnabled $False
```

Verifying Integration With Outlook Web App

To verify that instant messaging and presence have been integrated with Outlook Web App, sign on to Outlook Web App 2013. In the upper right-hand corner of the screen, you will see your Exchange display name. If there is a presence icon next to your name (for example, a green icon indicating that your current status is Available) that indicates that you have successfully integrated Lync Server and Outlook Web App.

After the initial sign-on to Outlook Web App, check to see if an event with the Event ID 112 (and the source MSExchange OWA) has been written to the event log on the mailbox server. This event indicates that the Instant Messaging Endpoint Manager was successfully initialized. If instant messaging does not appear to be working then, on the mailbox server, look for log files in the folder C:\Program Files\Microsoft\Exchange server \V15\Logging\OWA\InstantMessaging. If either the Logging or the InstantMessaging folders do not exist that indicates that integration has failed. In that case, you can use SIPStack tracing on Lync Server (All Levels and All Flags) to try and determine why integration failed.

1.4.17.9 Configuring the Personal Contacts Store on Client Computers

Configuring the Personal Contacts Store on Client Computers

Microsoft Lync Server 2013 > Deployment > Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 >

Topic Last Modified: *2012-10-10*

If you are integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 then it is recommended that you configure the Lync personal contact store on all your client computers; in particular, you should configure Lync to use Exchange as the personal contact store, and, at the same time, ensure that users are not able to override that decision. This can be done by creating and configuring a Registry value on each client computer.

To configure this value on a single computer, complete the following procedure:

1. On the client computer, click Start and then click Run.
2. In the Run dialog box, type regedit and then press ENTER.
3. In Registry Editor, expand HKEY_LOCAL_MACHINE, expand Software, expand Policies, and then expand Microsoft.
4. Right-click Communicator, point to New, and then click DWORD (32-bit) Value.
5. After the new value is created, type PersonalContactStoreOverride and then press ENTER to rename the value.
6. Verify that the value of PersonalContactStoreOverride is set to 0 and then close Registry Editor.

If you need to make this same change on multiple computers you can do so by creating a custom Group Policy object. For details, see the Group Policy documentation at http://go.microsoft.com/fwlink/p/?LinkId=268543.

1.5 Lync Server 2013 Hybrid

Lync Server 2013 Hybrid

Microsoft Lync Server 2013 >

Topic Last Modified: *2013-02-18*

This section describes hybrid configurations for Lync Server 2013, including hybrid Lync Server 2013 deployments and Hybrid Voice deployments.

Overview of Hybrid Deployments

Planning for Hybrid Deployments

Configuring Hybrid Deployments

1.5.1 Overview of Hybrid Deployments

Overview of Hybrid Deployments

Microsoft Lync Server 2013 > Lync Server 2013 Hybrid >

Topic Last Modified: *2013-02-18*

A hybrid deployment is a deployment in which some users are homed on-premises and some users are homed online, but the users share the same domain, such as contoso.com. In Lync Server 2013, you can configure two types of hybrid deployments.

- **Hybrid Lync Server** An on-premises Lync Server configured for hybrid with Lync Online.
- **Hybrid Voice** On-premises Lync Server configured for hybrid with Hosted Voice services.

You can configure your on-premises deployment for hybrid with Lync Online, by using Active Directory Synchronization to keep your on-premises and online users synchronized. You can also configure hybrid deployments for integration with other Microsoft Office 365 applications, including Exchange Online and SharePoint Online. This section guides you through deploying the applications required for a Lync Server hybrid deployment, and then configuring your deployment to enable it.

About Hybrid Deployments

For information about configuring your on-premises Lync Server deployment for hybrid with Lync Online or for Hybrid Voice, see the following topics:

Planning for Hybrid Deployments

Configuring Hybrid Deployments

For more information about Lync Online, see Lync Online at http://go.microsoft.com/fwlink/p/?LinkId=282396.

1.5.2 Planning for Hybrid Deployments

Planning for Hybrid Deployments

Microsoft Lync Server 2013 > Lync Server 2013 Hybrid >

Topic Last Modified: *2013-02-19*

This section provides information about planning for hybrid deployments.

- Planning for Lync Server 2013 Hybrid Deployments
- Supported Lync Server 2013 Hybrid Configurations
- Planning for Hybrid Voice

1.5.2.1 Planning for Hybrid Deployments

Planning for Lync Server 2013 Hybrid Deployments

Microsoft Lync Server 2013 > Lync Server 2013 Hybrid > Planning for Hybrid Deployments >

Topic Last Modified: *2013-02-22*

You should consider the following requirements for users and your network infrastructure while planning for a hybrid deployment.

Requirements

You must have the following available in your environment in order to implement and configure a Lync Server 2013 hybrid deployment.

- An Office 365 tenant running Lync Online 2013.
- An Active Directory Federation Services (AD FS) Server running Windows 2008 R2 SP1 or the latest service pack. For additional system requirements for AD FS, see Active Directory Federation Services 2.0 at http://go.microsoft.com/fwlink/p/?LinkId=151338.
- Lync Server 2013 on-premises deployment.
- A Directory Synchronization server. For details about Directory Synchronization, see Directory Synchronization Tool at http://go.microsoft.com/fwlink/p/?LinkID=231010.

Lync Client Support

There are some differences in the features supported in Lync clients, as well as the features available in on-premises and online environments. Before you decide where you want to home users in your organization, you can view the client support for the various configurations of Lync Server. For details about client support, see the following topics:

- Lync Online client comparison tables at http://go.microsoft.com/fwlink/p/?LinkId=281902.
- Client Comparison Tables
- Mobile Client Comparison Tables

Topology Requirements

To configure your Lync Server 2013 deployment for hybrid with Lync Online, you need to have one of the following supported topologies:

- Microsoft Office Communications Server 2007 R2 with Lync Server 2013 on-premises. The Lync Server 2013 federation Edge Server and the next hop server from the federation Edge Server must be running Lync Server 2013, and there must be a Central Management Store deployed. The Edge Server and pool must be deployed on-premises.

- Microsoft Lync Server 2010 with Lync Server 2013 on-premises. The federation Edge Server and next hop server from the federation Edge Server must be running either Lync Server 2013 or Microsoft Lync Server 2010 with the latest cumulative updates.

> **Important:**
> If a Lync Server 2013 Director is deployed and is the next hop for the Edge Server, the –ProxyPool parameter must be used with the **Move-CsUser** cmdlet to move users from on-premises to Lync Online. For details, see Move Users to Lync Online.

- A Lync Server 2013 deployment with all servers running Lync Server 2013.

For more information about supported topologies, see Supported Lync Server 2013 Topologies.

Requirements for Federation Allowed/ Blocked Lists

The Allowed domains list includes domains that have a partner Edge fully qualified domain name (FQDN) configured. These are sometimes referred to as *allowed partner servers* or *direct federation partners*. You should be familiar with the difference between Open Federation and Closed Federation, referred to as *partner discovery* and *allowed partner domain list*, respectively, in on-premises deployments.

The following requirements must be met to successfully configure a hybrid deployment:

- Domain matching must be configured the same for your on-premises deployment and your Office 365 tenant. If partner discovery is enabled on the on-premises deployment, then open federation must be configured for your online tenant. If partner discovery is not enabled, then closed federation must be configured for your online tenant.
- The Blocked domains list in the on-premises deployment must exactly match the Blocked domains list for your online tenant.
- The Allowed domains list in the on-premises deployment must exactly match the Allowed domains list for your online tenant.
- Federation must be enabled for the external communications for the online tenant, which is configured by using the Lync Online Control Panel.

DNS Settings

When creating DNS SRV records for hybrid deployments, the records, _sipfederationtls._tcp.<domain> and _sip._tls.<domain>, should point to the on-premises Access Proxy.

Firewall Considerations

Computers on your network must be able to perform standard Internet DNS lookups. If these computers can reach standard Internet sites, your network meets this requirement.

Depending on the location of your Microsoft Online Services data center, you must also configure your network firewall devices to accept connections based on wildcard domain names (for example, all traffic from *.outlook.com). If your organization’s firewalls do not support wildcard name configurations, you will have to manually determine the IP address ranges that you would like to allow and the specified ports.

Refer to the Help topic Office 365 URLs and IP address ranges at http://go.microsoft.com/fwlink/p/?LinkId=252942.

Port and Protocol Requirements

In addition to the port requirements for internal Lync Server 2013 communication, you must also configure the following ports.

Protocol / Port	Applications
TCP 443	Open inbound • Active Directory Federation Services (federation server role) For more information, see Understanding AD FS Role Services at http://go.microsoft.com/fwlink/p/?LinkId=281899. • Active Directory Federation Services (proxy server role) • Microsoft Online Services Portal • My Company Portal • Outlook Web App • Lync client (communication to Lync Online from on-premises Lync Server)
TCP 80 and 443	Open inbound • Microsoft Online Services Directory Synchronization Tool
TCP 5061	Open inbound/outbound on the Edge Server
PSOM/TLS 443	Open inbound/outbound for data sharing sessions
STUN/TCP 443	Open inbound/outbound for audio, video, application sharing sessions
STUN/UDP 3478	Open inbound/outbound for audio and video sessions
RTP/TCP 50000-59999	Open outbound for audio and video sessions

Note:

If you need to federate with partners running Office Communications Server 2007, you will need to open inbound/outbound RTP/UDP and RTP/TCP ports 50000-59999. For more information about A/V firewall requirements see, Determine External A/V Firewall and Port Requirements. For more information on ports and protocols, see Port Summary - Scaled Consolidated Edge with Hardware Load Balancers.

User Accounts and Data

In a Lync Server 2013 hybrid deployment, any user that you want to home in Lync Online must first be created in the on-premises deployment, so that the user account is created in Active Directory Domain Services (AD DS). You can then move the user to Lync Online, which will move the user’s contact list.

Important:

If the user is created by using the online portal for Office 365, the user account will not be synchronized with on-premises Active Directory, and the user will not exist in the on-premises Active Directory.

You should also consider the following user-related issues when planning for a hybrid deployment.

- **User contacts** The limit for contacts for Lync Online users is 250. Any contacts beyond that number will be removed from the user's contact list.
- **Instant Messaging and Presence** User contact lists, groups, and access control lists (ACLs) are migrated with the user account.
- **Conferencing data, meeting content, and scheduled meetings** This content is not migrated with the user account. Users must reschedule meetings after their accounts are migrated to Lync Online.

User Policies and Features

- In a Lync Server 2013 hybrid environment, users can be enabled for Instant Messaging, voice, and meetings either on-premises or online, but not both simultaneously.
- **Lync Client** Some users may require a new client version when they are moved to Lync Online. For Office Communications Server 2007 R2, users must be moved to a Lync Server 2013 pool prior to migration to Lync Online. For more information about client support, see Lync Online client comparison tables at http://go.microsoft.com/fwlink/p/?LinkId=281902 and Lync Client Requirements and Limitations at http://go.microsoft.com/fwlink/p/?LinkId=281901 .
- **Enterprise Voice** User level call routing capabilities are migrated.
- **On-premises policies and configuration (non-user)** Online and on-premises policies require separate configuration. You cannot set global policies that apply to both.

1.5.2.2 Supported Lync Server 2013 Hybrid Configurations

Supported Lync Server 2013 Hybrid Configurations

Microsoft Lync Server 2013 > Lync Server 2013 Hybrid > Planning for Hybrid Deployments >

Topic Last Modified: *2013-03-12*

You can configure Lync Server 2013 deployments for integration with Microsoft Exchange Server 2013 and SharePoint Server, both on-premises and online. The features listed in the following table are supported with all clients unless otherwise specified. For more information about client support, see Client Comparison Tables and Lync Online client comparison tables at http://go.microsoft.com/fwlink/p/?LinkId=281902.

Integration with Exchange Server

The following table lists the features supported in a Lync Server 2013 hybrid deployment when integrated with Exchange.

	Exchange on-premises	Exchange Online
Lync Server 2013 on-premises	• IM/Presence in Outlook For more information, see IM and Presence • Schedule and join online meetings through Outlook For more information, see Integrating	• IM/Presence in Outlook For more information, see Configuring On-premises Lync Server 2013 Integration with Exchange Online • Schedule and join online meeting

	Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 • IM/Presence in Outlook Web App For more information, see Configuring Microsoft Lync Server 2013 in a Cross-Premises Environment • Schedule and join online meetings through Outlook Web App • IM/Presence in Mobile Clients • Join online meetings in Mobile clients For more information, see Deploying Mobility • Publish status based on Outlook calendar free/busy information • Contact List (via Unified Contact Store) For more information, see Configuring Microsoft Lync Server 2013 to Use the Unified Contact Store **Note:** Lync Server 2013 and Exchange only. A Lync 2013 client is required. • High-resolution Contact Photo in Lync 2013 client and Lync Web App. For more information, see Configuring the Use of High-Resolution Photos in Microsoft Lync Server 2013 **Note:** Lync Server 2013 only • Meeting delegation Supported only when both users are homed online in the same forest, or both are homed on-premises. • Missed Conversations history and Call Logs are written to user’s exchange mailbox • Archiving Content (IM	through Outlook • IM/Presence in OWA For more information, see Integrating Microsoft Lync Server 2013 and Microsoft Outlook Web App 2013 • Schedule and join online meeting from Outlook Web App For more information, see Integrating Microsoft Lync Server 2013 and Microsoft Outlook Web App 2013 • IM/Presence in Mobile Clients • Join online meeting in Mobile clients • Publish status based on Outlook calendar free/busy information • Contact List (via Unified Contact Store). For more information, see Configuring Microsoft Lync Server 2013 to Use the Unified Contact Store **Note:** Lync Server 2013 only. A Lync 2013 client is required. • High-resolution Contact Photo in Lync 2013 client and Lync Web App. For more information, see Configuring the Use of High-Resolution Photos in Microsoft Lync Server 2013. • Meeting delegation Supported only when both users are homed online in the same forest, or both are homed on-premises. • Missed Conversations history and Call Logs are written to user’s exchange mailbox • Archiving Content (IM and Meeting) in Exchange. For more information,

	and Meeting) in Exchange For more information, see Deployment Checklist for Archiving • Search archived content • Voice mail For more information, see Deploying On-Premises Exchange UM to Provide Lync Server 2013 Voice Mail	see Deployment Checklist for Archiving **Note:** Lync Server 2013 only • Search archived content. For more information, see Configure Exchange for SharePoint eDiscovery Center at http://go.microsoft.com/fwlink/p/?LinkId=285448 **Note:** Lync Server 2013 only • Voice mail. For more information, see Providing Lync Server 2013 Users Voice Mail on Hosted Exchange UM
Lync Online	• IM and Presence in Outlook • Schedule and join online meetings through Outlook • IM/Presence in Mobile clients • Missed Conversations history and Call Logs are written to user’s exchange mailbox • High-resolution Contact Photo in Lync 2013 client. **⚠Warning:** Not supported in Lync Web App when users are homed on Lync Online. • Join online meeting in Mobile clients • Publish status based on Outlook calendar free/busy information • Meeting delegation Supported only when both users are homed online in the same forest, or both are homed on-premises. **Note:** Exchange 2013 only	• IM/Presence in Outlook • Schedule and join online meetings through Outlook • IM/Presence in Outlook Web App • Schedule and join online meeting from Outlook Web App • IM/Presence in Mobile Clients • Join online meeting in Mobile clients • Publish status based on Outlook calendar free/busy information • Missed Conversations history and Call Logs are written to user’s exchange mailbox • Contact List (via Unified Contact Store) **Note:** Lync Server 2013 client Required • High-resolution Contact Photo in Lync 2013 client and Lync Web App • Meeting delegation Supported only when both users are homed

		online in the same forest, or both are homed on-premises. • Archiving Content (IM and Meeting) in Exchange • Search archived content • Voicemail

Integration with SharePoint

The following table lists the features supported in a Lync Server 2013 hybrid deployment when integrated with SharePoint.

	SharePoint on-premises	SharePoint Online
Lync Server 2013 on-premises	• Skills search • Presence in SharePoint	• Presence in SharePoint
Lync Online	• Presence in SharePoint	• Presence in SharePoint

1.5.2.3 Planning for Hybrid Voice

Planning for Hybrid Voice

Microsoft Lync Server 2013 > Lync Server 2013 Hybrid > Planning for Hybrid Deployments >

Topic Last Modified: *2013-03-12*

Many enterprises are actively looking to move their enterprise services to the cloud. The move to the cloud does not happen in single deployment step. It is more of a process performed over time in a phased approach eventually leading to a complete transition to the cloud. We refer to this phased approach while some users are still homed on-premise and other users are moved to Lync Online as a hybrid environment.

While planning a transition to the cloud, there needs to be an approach which allows the following:

- Moves existing functionality to the cloud
- Provides time to validate quality, reliability and the security of the cloud offering
- Continues to allow existing on-premise Lync investments to be utilized

To facilitate the transition to the cloud, hybrid voice allows customers to integrate Lync Online with their on-premise PSTN infrastructure:

- For migrating users from Lync on-premise to Lync Online
- For leveraging existing on-premise PBX infrastructure
- For keeping existing carrier relationships

On-Premise Infrastructure Requirements

Server Roles	Supported versions	Notes
Lync pool	Lync Server 2010: October 2012 cumulative updates or later Lync Server 2013	The Lync pool must be configured as the next hop to the Edge Server. A Lync pool consists of an Enterprise Edition pool, Standard Edition

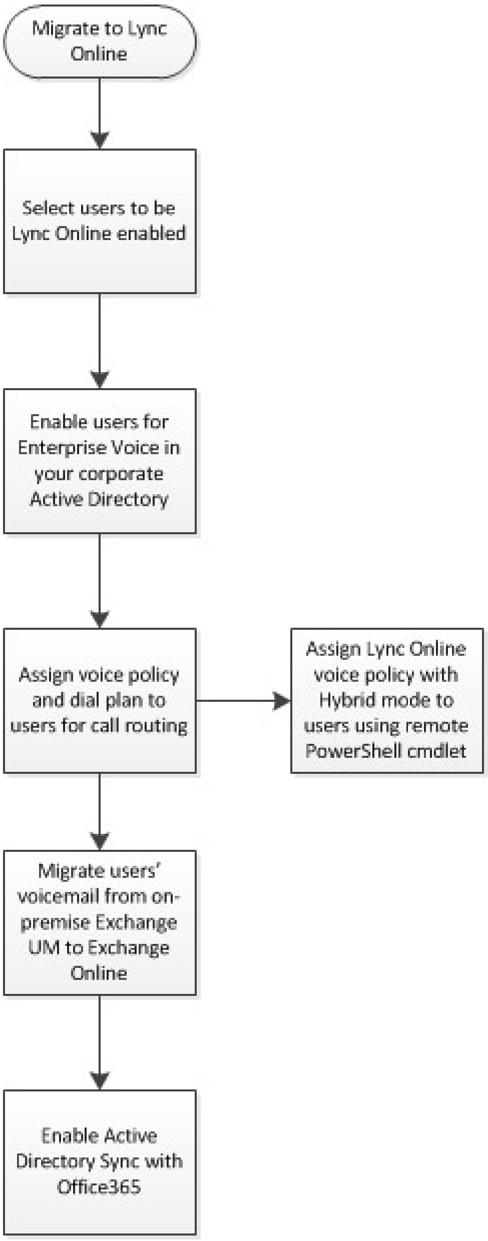
		server or Director
Edge Server	Lync Server 2010: October 2012 cumulative updates or later Lync Server 2013	
Mediation Server	Office Communication Server 2007 R2 Lync Server 2010 Lync Server 2013	E-9-1-1 and Media Bypass for hybrid voice users is only supported with Lync Server 2013Mediation Server.

Feature Summary

Enterprise Voice Functionality	Lync Online Hybrid Voice
Call Hold/Retrieve	yes
Call Transfer	yes
Call Forwarding	yes
Voicemail (Exchange UM Online)	yes
USB Peripherals	yes
Delegation, Team Call	yes
Outside voice – Mobile	yes
Integration with on-premise PBX	yes
Private Line	yes
E-9-1-1	yes
Media bypass	yes
Lync Phone Edition devices	yes
Response Group	no
Call Park	no
Voice Resiliency	no
RCC (remote call control)	no
Analog and common area phones	no
Integration with on-premise Call Center Solutions	no

Deployment Workflow

The following diagram illustrates the workflow to enable users for hybrid voice.



Migrate to Lync Online
Select users to be Lync Online enabled
Enable users for Enterprise Voice in your corporate Active Directory
Assign voice policy and dial plan to users for call routing
Assign Lync Online voice policy with Hybrid mode to users using remote PowerShell cmdlet
Migrate users' voicemail from on-premise Exchange UM to Exchange Online
Enable Active Directory Sync with Office365

1.5.3 Configuring Hybrid Deployments

Configuring Hybrid Deployments

Microsoft Lync Server 2013 > Lync Server 2013 Hybrid >

Topic Last Modified: *2013-02-22*

This section describes the steps necessary for configuring hybrid Lync Server 2013 deployments and Hybrid Voice deployments.

- Configuring an On-premises Deployment for Hybrid with Lync Online
- Configuring Hybrid Voice

Configuring an On-premises Deployment for Hybrid with Lync Online

Microsoft Lync Server 2013 > Lync Server 2013 Hybrid > Configuring Hybrid Deployments >

Topic Last Modified: *2013-02-20*

A hybrid deployment is a deployment in which some users are homed on-premises and some users are homed online, but all users share the same domain, such as user@contoso.com. This section guides you through deploying the applications required for a hybrid deployment, and then configuring your deployment to enable it.

- Overview of the Lync Server 2013 Hybrid Environment
- Steps to Prepare and Deploy Lync Server 2013 Hybrid Environment
- Configure Federation with Lync Online
- Move Users to Lync Online
- Administering Users in a Hybrid Deployment

1.5.3.1.1 Overview of the Lync Server 2013 Hybrid Environment

Overview of the Lync Server 2013 Hybrid Environment

Lync Server 2013 Hybrid > Configuring Hybrid Deployments > Configuring an On-premises Deployment for Hybrid with Lync Online >

Topic Last Modified: *2013-02-19*

Lync Server 2013 hybrid environment refers to a deployment in which there are some users homed to the on-premises Lync Server 2013 and other users homed to Lync Online, but users share the same domain, such as user@contoso.com.

About this Guide

This guide describes the tasks necessary to configure your Lync Server 2013 environment for interoperability with Lync Online, and then to move users from your on-premises deployment to use Lync Online.

Prerequisites

You will need to have the following applications and utilities installed to complete the tasks for configuring a deployment for hybrid. The installers for these files are included on the installation media provided for your deployment, as well as at the links included in the following list.

- Active Directory Federation Services (AD FS) 2.0
- Directory Synchronization tool (DirSync.exe)
- Microsoft Online Services module for Windows PowerShell
- Microsoft Online Services Sign-in Assistant (msoidcli-7.0.msi) is included with the Desktop Setup for Office 365, which can be obtained from the Downloads page linked to from the Admin portal.

Administrator Credentials

When you are asked to provide your administrator credentials, use the username and password provided to you as the administrator account for the Office 365 tenant that was created for you. You will also use these credentials when you configure Active Directory Federation Services (AD FS) 2.0, Directory Synchronization, Single sign-on, and federation.

1.5.3.1.2 Steps to Prepare and Deploy Lync Server 2013 Hybrid Environment

Steps to Prepare and Deploy Lync Server 2013 Hybrid Environment

Lync Server 2013 Hybrid > Configuring Hybrid Deployments > Configuring an On-premises Deployment for Hybrid with Lync Online >

***Topic Last Modified:** 2013-02-22*

The following table lists the steps required to prepare your environment for a hybrid deployment with Microsoft Lync Online and Microsoft Office 365.

Completed?	Step	Description
	Create a tenant account for Office 365 and enable Lync Online	Learn about Office 365 and Lync Online at Office 365. To make sure that your environment is ready for Office 365, see the System Requirements. For details about setting up Office 365, see Getting Started with Office 365 and Set Up Office 365.
	Add your domain and verify ownership	Your domain is sometimes also referred to as your *vanity domain*. You must add your domain to your Office 365 tenant, and then follow the steps to validate the domain with Office 365. This is to confirm that you are the owner of the domain. To add your domain to your Office 365 tenant, follow the steps described at Add your domain to Office 365. Complete all of the steps in each section in the topic, including "Edit DNS records for your Office 365 services."
	Verify environment readiness	You can use the Office 365 Deployment Readiness Tool to identify any issues in your

		Active Directory Domain Services (AD DS) that may cause issues with synchronizing with Office 365. This tool inspects your Active Directory environment, and then provides a report that includes a prerequisite check and an attribute assessment that are specific to the directory synchronization tool requirements. To download the tool, see Microsoft Office 365 Deployment Readiness Tool. For details about using the tool and deploying Office 365, see Microsoft Office 365 Deployment Guide for Enterprises.
	Prepare for Active Directory synchronization	Active Directory synchronization keeps your on-premises Active Directory continuously synchronized with Office 365. This lets you create synchronized versions of each user account and group, and also enables global address list (GAL) synchronization from your local Microsoft Exchange Server environment to Microsoft Exchange Online. To prepare your environment for Active Directory synchronization, follow the steps described in Active Directory synchronization: Roadmap, including setting up single sign-on.
	Create certificates for Active Directory Federation Services (AD FS)	You will need to create the certificates that are used for identity federation with Office 365. For more information, see the “Federation server certificates” section of the Plan for and deploy AD FS for use with single sign-on topic at http://go.microsoft.com/fwlink/p/?LinkId=285376.
	Assign certificates for AD FS	After you create the certificates that are used for

		identity federation with Office 365, you must install and assign them.
	Move pilot users to Lync Online	After you have completed the steps to prepare and configure your environment for Lync Online, you can start moving pilot users to Lync Online. See Move Users to Lync Online.
	Administering users in a hybrid deployment	For details about how to administer users in a hybrid deployment, see Administering Users in a Hybrid Deployment.

1.5.3.1.3 Configure Federation with Lync Online

Configure Federation with Lync Online

See Also

Lync Server 2013 Hybrid > Configuring Hybrid Deployments > Configuring an On-premises Deployment for Hybrid with Lync Online >

Topic Last Modified: *2013-02-19*

Follow the steps in this section to configure interoperability between your on-premises deployment and Lync Online.

Configure Your Edge Service for Federation with Lync Online

Run the following cmdlets:

```
Set-CSAccessEdgeConfiguration -AllowOutsideUsers 1 -AllowFederatedUsers 1 -UseDns
```

```
New-CSHostingProvider -Identity LyncOnline -ProxyFqdn "sipfed.online.lync.com" -E
```

For details about considerations for federation in a hybrid deployment, see Planning for Lync Server 2013 Hybrid Deployments.

1.5.3.1.4 Move Users to Lync Online

Move Users to Lync Online

Lync Server 2013 Hybrid > Configuring Hybrid Deployments > Configuring an On-premises Deployment for Hybrid with Lync Online >

Topic Last Modified: *2013-02-19*

Before you start migrating users to Lync Online, you should backup the user data associated with the account to be moved.

Migrate User Settings to Lync Online

User settings are moved with the user account. Some on-premises settings are not moved with the user account.

Moving Pilot Users to Lync Online

Before you begin to move users to Lync Online, you may want to move a few pilot users to confirm that your environment is correctly configured. You can then verify that Lync features and services function as expected before attempting to move additional users.

To move an on-premises user to your Lync Online tenant, run the following cmdlets in the Lync Server Management Shell, using the administrator credentials for your Microsoft Office 365 tenant. Replace "username@contoso.com" with the information for the user that you want to move.

```
$creds=Get-Credentials
```

```
Move-CsUser -Identity username@contoso.com -Target sipfed.online.lync.com -Creden
```

The format of the URL specified for the **HostedMigrationOverrideUrl** parameter must be the URL to the pool where the Hosted Migration service is running, in the following format:

Https://<Pool FQDN>/HostedMigration/hostedmigrationService.svc. You can determine the URL to the Hosted Migration Service by viewing the URL for the Lync Online Control Panel for your Office 365 tenant account.

To determine the Lync Online Control Panel URL for your Office 365 tenant

1. Login to the Office 365 portal, and then access the Lync Administration Center.
2. Copy the URL in the address bar up to "ync.com." For example, **https://admin.online.lync.com**.
3. Append the following string to the URL: **/HostedMigration/hostedmigrationservice.svc**.
   The resulting URL should look like the following:
   https://admin.online.lync.com/HostedMigration/hostedmigrationservice.svc

Moving Users to Lync Online

You can move multiple users by using the **Get-CsUSer** cmdlet with the –Filter parameter to select the users with a specific property assigned to the user accounts, such as RegistrarPool. You can then pipe the returned users to the **Move-CsUSer** cmdlet, as shown in the following example.

```
Get-CsUser -Filter {UserProperty -eq "UserPropertyValue"} | Move-CsUser -Target s
```

You can also use the –OU parameter to retrieve all users in the specified OU, as shown in the following example.

```
Get-CsUser -OU "cn=hybridusers,cn=contoso.." | Move-CsUser -Target sipfed.online.
```

Verify Lync Online User Settings and

Features

You can verify that the user was moved successfully in the following ways:

- View the status of the user in the Lync Online Control Panel. The visual indicator for on-premises users and online users is different.
- Run the following cmdlet:

```

Get-CsUser -Identity
```

1.5.3.1.5 Administering Users in a Hybrid Deployment

Administering Users in a Hybrid Deployment

Lync Server 2013 Hybrid > Configuring Hybrid Deployments > Configuring an On-premises Deployment for Hybrid with Lync Online >

Topic Last Modified: *2013-02-22*

You can manage user settings and policies for users migrated to Lync Online by using the User Management features available in the Microsoft Office 365 online portal. You must sign in by using a tenant administrator account to perform administration tasks.

Moving Users Back to On-premises

- Run the following cmdlet:

```
$cred=Get-Credentials
Move-CsUser -Identity username@contoso.com -Target localpool.contoso.co
```

The format of the URL specified for the **HostedMigrationOverrideUrl** parameter must be the URL to the pool where the Hosted Migration service is running, in the following format:

Https://<Pool FQDN>/HostedMigration/hostedmigrationService.svc. You can determine the URL to the Hosted Migration Service by viewing the URL for the Lync Online Control Panel for your Office 365 tenant account.

1.5.3.2 Configuring Hybrid Voice

Configuring Hybrid Voice

Microsoft Lync Server 2013 > Lync Server 2013 Hybrid > Configuring Hybrid Deployments >

Topic Last Modified: *2012-06-29*

With Office 365 Lync Online, Microsoft offers customers Lync Server 2013 as an online service. Customers can migrate to Lync Online on their own terms. With an existing deployment of Lync Server on-premises, hybrid voice refers to a customer environment where some users are enabled for Enterprise Voice on-premises (that is, on-premises users) and other users are enabled for hosted Enterprise Voice online (that is, Office 365 users). This hybrid model provides a seamless user experience for users enabled for Enterprise Voice, whether they are enabled on-premises or online. This section guides you through the configuration of Enterprise Voice with Lync Online.

This section assumes that you have already deployed Lync Server on-premises and have enabled users for Enterprise Voice. You have defined at least one gateway peer to provide PSTN connectivity.

This section also assumes that you have configured on-premises Active Directory Federation Services—a Windows Server 2008 service—to federate with the Microsoft Federation Gateway. After Active Directory Federation Services is configured, all Lync Online users whose identities are based on the federated domain can use their existing corporate logon to automatically authenticate to Office 365.

In This Section

- Configure Enterprise Voice to Work with Lync Online
- Configure Online Users for Lync on-premises Enterprise Voice
- Configure Enterprise Voice Applications for Lync Online Users

1.5.3.2.1 Configure Enterprise Voice to Work with Lync Online

Configure Enterprise Voice to Work with Lync Online

Lync Server 2013 Hybrid > Configuring Hybrid Deployments > Configuring Hybrid Voice >

Topic Last Modified: *2013-02-21*

The following steps configure your Enterprise Voice deployment to enable Lync Online users to receive and place calls to the PSTN through your on-premises PSTN gateways.

- Create a Hybrid PSTN Usage
- Create a Hybrid Voice Routing Policy
- Dial Plan for Hybrid Voice Users
- Normalization Rules for Dial Plan

1.5.3.2.1.1 Create a Hybrid PSTN Usage

Create a Hybrid PSTN Usage

Configuring Hybrid Deployments > Configuring Hybrid Voice > Configure Enterprise Voice to Work with Lync Online >

Topic Last Modified: *2013-02-21*

This step creates a usage specifically for your Lync Online users, which is called HybridVoiceUsage. The new PSTN usage must be tag or global scope. You can also use an existing PSTN usage as long as it is tag scope or global scope.

Using Windows PowerShell command-line interface to create a PSTN usage

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. In the Lync Server Management Shell, type the following commands, replacing the placeholders with the correct information for your organization:

   ```
   Set-CSPstnUsage -Usage <String>
   ```

   For example:

   ```
   Set-CSPstnUsage -Usage @{add="HybridVoiceUsage"}
   ```

1.5.3.2.1.2 Create a Hybrid Voice Routing Policy

Create a Hybrid Voice Routing Policy

Configuring Hybrid Deployments > Configuring Hybrid Voice > Configure Enterprise Voice to Work with Lync Online >

Topic Last Modified: *2013-02-21*

This step creates a voice routing policy specifically for your Lync Online users. Perform this procedure at the on-premise central site. If you want to assign an existing voice routing policy to your Lync Online users, skip to Configure Online Users for Lync on-premises Enterprise Voice, and replace the policy tag, HybridVoiceUser, with the name of your voice routing policy.

The voice routing policy is used to route calls to the PSTN through your on-premises PSTN gateway when the Edge Server next hop is a Lync Server 2013 pool or Director. However, if the Edge Server next hop is a Lync Server 2010 pool or Director, then the user's voice policy is used to route calls to the PSTN.

Using Windows PowerShell command-line interface to create a voice routing policy

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. In the Lync Server Management Shell, type the following commands, replacing the placeholders with the correct information for your organization:

   ```
   New-CSVoiceRoutingPolicy -Identity <Tag> -Name <String> -PstnUsages <U
   ```

   For example:

   ```
   New-CSVoiceRoutingPolicy -Identity "tag:HybridVoiceUser" -Name "Hybrid
   ```

1.5.3.2.1.3 Dial Plan for Hybrid Voice Users

Dial Plan for Hybrid Voice Users

Configuring Hybrid Deployments > Configuring Hybrid Voice > Configure Enterprise Voice to Work with Lync Online >

Topic Last Modified: *2012-11-13*

This step creates a dial plan specifically for your Lync Online users. Skip this step if you plan to apply an existing tagged scoped dial plan to your hybrid voice users, instead of creating a new dial plan. Perform this procedure at the on-premise central site.

Using Windows PowerShell command-line interface to create a dial plan

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. In the Lync Server Management Shell, type the following commands, replacing the placeholders with the correct information for your organization:

   ```
   New-CSDialPlan -Identity "tag:HybridVoiceDialplan" -SimpleName "Hybrid
   ```

1.5.3.2.1.4 Normalization Rules for Dial Plan

Normalization Rules for Dial Plan

Configuring Hybrid Deployments > Configuring Hybrid Voice > Configure Enterprise Voice to Work with Lync Online >

Topic Last Modified: *2012-04-28*

Create normalization rules for the dial plan created in the previous section, Dial Plan for Hybrid Voice Users. Skip this step if you plan to apply an existing set of normalization rules to your hybrid voice users, instead of creating new normalization rules. Perform this procedure at the on-premise central site.

Using Windows PowerShell command-line interface to create normalization rules

1. Log on to the computer as a member of the RTCUniversalServerAdmins group, or as a member of the CsVoiceAdministrator, CsServerAdministrator, or CsAdministrator role. For details, see Delegate Setup Permissions.
2. In the Lync Server Management Shell, type the following commands, replacing the placeholders with the correct information for your organization:

   ```
   New-CSVoiceNormalizationRule -Identity <Tag> -Pattern <RegEx String> -
   ```

   For example:

   ```
   New-CSVoiceNormalizationRule -Identity tag:HybridVoiceDialplan/7Digit
   New-CSVoiceNormalizationRule -Identity tag:HybridVoiceDialplan/10Digit
   New-CSVoiceNormalizationRule -Identity tag:HybridVoiceDialplan/11Digit
   ```

1.5.3.2.2 Configure Online Users for Lync on-premises Enterprise Voice

Configure Online Users for Lync on-premises Enterprise Voice

Lync Server 2013 Hybrid > Configuring Hybrid Deployments > Configuring Hybrid Voice >

Topic Last Modified: *2012-04-09*

After creating a voice routing policy and dial plan for your Lync Online users, use the following procedures to enable your Lync Online users for Lync on-premise Enterprise Voice.

- Enable On-Premise Enterprise Voice
- Assign a Voice Routing Policy
- Assign a Dial Plan
- Assign a Lync Online Voice Policy
- Move Voicemail for Lync Online Users to Exchange Online

1.5.3.2.2.1 Enable On-Premise Enterprise Voice

Enable On-Premise Enterprise Voice

Configuring Hybrid Deployments > Configuring Hybrid Voice > Configure Online Users for Lync on-premises Enterprise Voice >

Topic Last Modified: *2012-04-09*

For Lync Online users to place and receive voice calls, they must be enabled for Enterprise Voice on the on-premise Lync Server environment. Perform the following procedures at the central site.

To enable Lync Online users for Enterprise Voice

1. From a user account that is assigned to the CsUserAdministrator role or the CsAdministrator role, log on to any computer in your internal deployment.
2. Open a browser window, and then enter the Administrator URL to open the Lync Server 2013 Control Panel. For details about the different methods you

can use to start Lync Server Control Panel, see Open Lync Server Administrative Tools.

3. In the left navigation bar, click **Users**.
4. In the **Search users** box, type all or the first portion of the display name, first name, last name, Security Accounts Manager (SAM) account name, SIP address, or line Uniform Resource Identifier (URI) of the user account that you want to enable, and then click **Find**.
5. In the table, click the Lync Online user account that you want to enable for Enterprise Voice.
6. Click Line URI, and assign a unique, normalized TEL URI (for example, tel:+14255550200). This will be the user's phone number.
7. Click Commit.
8. To finish enabling a user for Enterprise Voice, ensure that the user is assigned the user-specific hybrid voice policy and dial plan.

1.5.3.2.2.2 Assign a Voice Routing Policy

Assign a Voice Routing Policy

Configuring Hybrid Deployments > Configuring Hybrid Voice > Configure Online Users for Lync on-premises Enterprise Voice >

Topic Last Modified: *2012-06-28*

The user-specific on-premise Lync voice routing policy, created in the step Create a Hybrid Voice Policy, must be assigned to the Lync Online users. Perform the following procedures at the central site. If you are using an existing voice routing policy, replace the placeholder, HybridVoiceUser, with the name of your voice policy

To assign the user-specific hybrid voice policy

1. From a user account that is assigned to the CsUserAdministrator role or the CsAdministrator role, log on to any computer in your internal deployment.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Assign an existing voice policy to a user:

   ```
   Grant-CsVoiceRoutingPolicy -Identity <UserIdParameter> -PolicyName <St
   ```

   For example:

   ```
   Grant-CsVoiceRoutingPolicy -Identity "Bob Kelly" -PolicyName HybridVoi
   ```

In this example, the user with the display name Bob Kelly is assigned to the previously created voice policy with the name HybridVoiceUser.

For details about assigning a user-specific voice policy or about running the Grant-CsVoiceRoutingPolicy cmdlet, see the Lync Server Management Shell documentation.

1.5.3.2.2.3 Assign a Dial Plan

Assign a Dial Plan

Configuring Hybrid Deployments > Configuring Hybrid Voice > Configure Online Users for Lync on-premises Enterprise Voice >

Topic Last Modified: *2012-06-28*

To complete the on-premise configuration for Lync Online users enabled for Enterprise Voice, the on-premise administrator must assign an on-premise dial plan to the Lync Online user. Perform the following procedures at the central site.

To assign a dial plan

1. From a user account that is assigned to the CsUserAdministrator role or the CsAdministrator role, log on to any computer in your internal deployment.
2. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
3. Assign a user-specific dial plan:

   ```
   Grant-CsDialPlan -Identity <UserIdParameter> -PolicyName <String>
   ```

   For example:

   ```
   Grant-CsDialPlan -Identity "Bob Kelly" -PolicyName HybridVoiceDialplan
   ```

In this example, the user with the display name Bob Kelly is assigned the previously created user dial plan with the name HybridVoiceDialplan.

For details about assigning a user dial plan or about running the Grant-CsDialPlan cmdlet, see the Lync Server Management Shell documentation.

1.5.3.2.2.4 Assign a Lync Online Voice Policy

Assign a Lync Online Voice Policy

Configuring Hybrid Deployments > Configuring Hybrid Voice > Configure Online Users for Lync on-premises Enterprise Voice >

Topic Last Modified: *2013-02-21*

The Lync Online users must also be assigned a Lync Online voice policy, also referred to as a Hybrid Voice policy. The tenant administrator assigns the Lync Online voice policy to Lync Online users enabled for on-premises Enterprise Voice by remotely using the PowerShell Lync Server Management Shell cmdlet, **Grant-CsVoicePolicy**. Perform the following procedures. "HybridVoice" is the default name of the Lync Online voice policy.

To assign the user-specific hybrid voice policy

1. Start a Windows PowerShell remote session, not a Lync Server Management Shell.

   Note:
   For details about how to start a Windows PowerShell remote session, see Lync Server Windows PowerShell blog article, "Quick Start: Managing Microsoft Lync Server 2010 Using Remote PowerShell," at http://go.microsoft.com/fwlink/?LinkId=255876.

2. In the Windows PowerShell, type the following command and then press **Enter**:

   ```
   $PSModuleAutoloadingPreference = "None"
   ```

3. Import the following Windows PowerShell command-line interface modules:

   ```
   Import-Module LyncOnlineConnector, Microsoft.PowerShell.Management, Mi
   ```

4. Provide your Administrator’s credentials:

   ```
   $cred=Get-Credential <Administrator URI>
   ```

   You will be prompted to enter the Administrator’s password.

5. Create a Lync Online session, specifying the URL of your Lync Online Control Panel:

   ```
   $CsSession = New-CsOnlineSession -TargetServer <Lync Online Control Pa
   ```

Note:
To determine the URL of your Lync Online Control Panel, follow the steps in **To determine the Lync Online Control Panel URL for your Office 365 tenant** under Move Users to Lync Online.

6. Import all the commands from the newly created session, $CsSession, into the current session:

```
Import-PsSession -Session $CsSession
```

7. Assign the Lync Online policy to your user specified by its SIP URI:

```
Grant-CsVoicePolicy -Identity <SIP URI> -PolicyName HybridVoice
```

For example:

```
Grant-CsVoicePolicy -Identity dorena@contoso.com -PolicyName HybridVoi
```

1.5.3.2.2.5 Move Voicemail for Lync Online Users to Exchange Online

Move Voicemail for Lync Online Users to Exchange Online

Configuring Hybrid Deployments > Configuring Hybrid Voice > Configure Online Users for Lync on-premises Enterprise Voice >

Topic Last Modified: *2012-06-29*

The final step is to move Lync Online users' Unified Messaging to Exchange Online. For procedures for configuring Unified Messaging for Lync Online users, see Set Up Unified Messaging at http://go.microsoft.com/fwlink/?LinkId=255531.

1.5.3.2.3 Configure Enterprise Voice Applications for Lync Online Users

Configure Enterprise Voice Applications for Lync Online Users

Lync Server 2013 Hybrid > Configuring Hybrid Deployments > Configuring Hybrid Voice >

Topic Last Modified: *2013-02-25*

In a hybrid voice environment where Lync Online users are enabled for Enterprise Voice using Lync on-premise, these Lync Online users do not have access to advanced features such as Media Bypass and E-9-1-1 available to on-premise Enterprise Voice users until the tenant administrator configures the web URL on Lync Online. To enable Lync Online users to benefit from on-premise Enterprise Voice Applications, the tenant administrator must perform the following procedures.

To enable Lync Online users for Enterprise voice applications

1. Select the Lync pool to serve the Lync Online users.
2. Configure the Lync Web Service and CPS is enabled (with configured orbit numbers) on the selected pool.
3. Assign Lync Online the URL of the Web Service of the selected Lync pool by running the following remote Windows PowerShell command-line interface cmdlet. To enable Media Bypass and E-9-1-1 for hybrid voice users, Lync Server 2013 pool is required. If your deployment uses Lync Server 2010, then you must upgrade to Lync Server 2013 to enable Media Bypass and E-9-1-1.

```
Set-CSTenantHybridConfiguration
-HybridConfigServiceInternalURL <on-premise Web Service internal URL c
-HybridConfigServiceExternalURL <on-premise Web Service external URL c
```

1.6 Migration

Migration

Microsoft Lync Server 2013 >

Topic Last Modified: *2012-09-18*

This section explains how to migrate from Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server 2010 to Microsoft Lync Server 2013, from Microsoft Lync Server 2010, Group Chat to Microsoft Lync Server 2013, Persistent Chat Server, and from Microsoft Office Communications Server 2007 R2 Group Chat to Persistent Chat Server.

- Migration from Lync Server 2010 to Lync Server 2013
- Migration from Office Communications Server 2007 R2 to Lync Server 2013
- Migration from Lync Server 2010, Group Chat or Office Communications Server 2007 R2 Group Chat to Lync Server 2013, Persistent Chat Server

1.6.1 Migration from Lync Server 2010 to Lync Server 2013

Migration from Lync Server 2010 to Lync Server 2013

Microsoft Lync Server 2013 > Migration >

Topic Last Modified: *2012-09-17*

The topics in this section guide you through the process of migrating from Lync Server 2010 to Lync Server 2013.

◆**Important:**
This document describes the steps generally required to accomplish each phase of migration. It does not address every possible legacy deployment topology or every possible migration scenario. Therefore, you may not need to perform every step described, or you may need to perform additional steps, depending on your deployment. This document also provides examples of verification steps. These verification steps are provided to help you understand what you need to look for to ensure that each phase completes successfully as you progress through your migration. Tailor these verification steps to your specific migration process.

This guide provides information specific to upgrading your existing deployment. It does not explain how to change your existing topology. This guide does not cover the implementation of new features. When a detailed procedure is documented elsewhere, this guide directs you to the appropriate document or document section.

This document defines terms as specified in the following list.

migration

Moving your production deployment from a previous version of Lync Server 2010 to Lync Server 2013.

upgrade

Installing a newer version of software on a server or client computer.

coexistence

The temporary environment that exists during migration when some functionality has been migrated to Lync Server 2013 and other functionality still remains on a prior version of Lync Server 2010.

interoperability

The ability of your deployment to operate successfully during the period of coexistence.

In This Section

1.6.1.1 Before You Begin the Migration

Before You Begin the Migration

Microsoft Lync Server 2013 > Migration > Migration from Lync Server 2010 to Lync Server 2013 >

Topic Last Modified: *2012-09-23*

Before you begin, we recommend that you read this document and the following guides to familiarize yourself with deploying the corresponding Lync Server 2013 roles:

- Deploying Lync Server 2013
- Deploying Lync Server 2013 Standard Edition into an Existing Lync Server 2013 Enterprise
- Deploying External User Access
- Deploying Clients and Devices
- Migration Process
- Migration Phases

1.6.1.1.1 Migration Process

Migration Process

Migration > Migration from Lync Server 2010 to Lync Server 2013 > Before You Begin the Migration >

Topic Last Modified: *2012-09-17*

The recommended and supported migration procedure for Lync Server 2013 is side-by-side migration. This topic describes why you should use side-by-side migration and also includes information about coexistence testing.

Side-By-Side Migration

In nearly every migration, you should use the side-by-side migration path. In a side-by-side migration, you deploy a new server with Lync Server 2013 alongside a corresponding server that is running Lync Server 2010, and then transfer operations to the new server. If it becomes necessary to roll back to Lync Server 2010, you have only to shift operations back to the original servers. Be aware that in this situation any new meetings scheduled with upgraded clients will not work, and the clients would also need to be downgraded.

Coexistence Testing

After you have deployed Lync Server 2013 in parallel with Lync Server 2010, the deployment represents a coexistence testing state of Lync Server 2013 and Lync Server 2010. While in this state, it is important to test and ensure that services are started, each site can be administered, and clients can communicate with current and legacy users. Prior to the migration of all users, it is very important that you understand the state of each deployment and ensure that each deployment is functional and working properly. Typically, the coexistence testing phase exists throughout the pilot testing of Lync Server 2013. Legacy users are moved to Lync Server 2013 for a period of time to ensure that application compatibility and features and functions are working properly. After pilot testing, users and applications are moved to the production version of Lync Server 2013, and the legacy pools and applications of Lync Server 2010 are retired.

1.6.1.1.2 Migration Phases

Migration Phases

Migration > Migration from Lync Server 2010 to Lync Server 2013 > Before You Begin the Migration >

Topic Last Modified: *2012-09-17*

In Lync Server 2013, you define sites on your network that contain Lync Server 2013 components. A site is a set of computers that are well-connected by a high-speed, low-latency network, such as a single local area network (LAN) or two networks connected by a high-speed fiber optic network.

A *Front End pool* is a set of Front End Servers that are configured identically and work together to provide services for a common group of users. A pool provides scalability and failover capability to your users. Each server in a pool must run an identical server role or roles. A Standard Edition server, designed for small organizations, also defines a pool and runs on a single server. This enables you to have Lync Server 2013 functionality for a lesser cost, but does not provide a true high-availability solution.

The following phases describe the process of a pool migration from Lync Server 2010 to Lync Server 2013. For multiple sites containing multiple pools, each individual pool should follow this phased approach.

1. Phase 1: Plan Your Migration from Lync Server 2010
2. Phase 2: Prepare for Migration
3. Phase 3: Deploy Lync Server 2013 Pilot Pool
4. Phase 4: Move test users to the Pilot Pool
5. Phase 5: Add Lync Server 2013 Edge Server to Pilot Pool
6. Phase 6: Move from Pilot Deployment into Production
7. Phase 7: Complete Post-Migration Tasks
8. Phase 8: Decommission Legacy Pools

1.6.1.2 Phase 1: Plan Your Migration from Lync Server 2010

Phase 1: Plan Your Migration from Lync Server 2010

Microsoft Lync Server 2013 > Migration > Migration from Lync Server 2010 to Lync Server 2013 >

Topic Last Modified: *2012-09-29*

This section covers planning topics for migrating from Lync Server 2010 to Lync Server 2013.

In This Section

1.6.1.2.1 User Migration

User Migration

Migration > Migration from Lync Server 2010 to Lync Server 2013 > Phase 1: Plan Your Migration from Lync Server 2010 >

Topic Last Modified: *2012-10-19*

A generally accepted best practice for migrations is to create several test users and use them to conduct systems tests. After you have successfully moved and tested those accounts, you should identify a group of pilot production users and move their accounts and conduct validation tests on them. When you get satisfactory results, you can move the rest of your users to the new deployment.

For additional information on enabling users for Lync Server 2013, see the topic Disable or Re-Enable User Account for Lync Server in the Deploying Lync Server 2013 documentation.

1.6.1.2.2 Migrating Archiving and Monitoring Servers

Migrating Archiving and Monitoring Servers

Migration > Migration from Lync Server 2010 to Lync Server 2013 > Phase 1: Plan Your Migration from Lync Server 2010 >

Topic Last Modified: *2012-10-02*

If you deployed Archiving Server and Monitoring Server in your Lync Server 2010 environment, you can deploy these servers in your Lync Server 2013 environment after you migrate your Front End pools. If archiving and monitoring functionality are critical to your organization, however, you should add archiving and monitoring to your Lync Server 2013 pilot pool before you migrate so that the functionality is available during the migration process.

If you want archiving and monitoring functionality during the migration process, keep the following considerations in mind:

- Archiving data and monitoring data are not moved to the Lync Server 2013 deployment. The data you back up prior to decommissioning the legacy environment will be your history of activity in the Lync Server 2010 environment.
- The Lync Server 2010 version of Archiving Server and Monitoring Server can be associated only with a Lync Server 2010 Front End pool. In Lync Server 2013, Archiving and Monitoring are no longer server roles, but services integrated into the Lync Server 2013 Front End pool.
- During the time that your legacy and Lync Server 2013 deployments coexist, the Lync Server 2010 version of Archiving Server and Monitoring Server gather data for users homed on Lync Server 2010 pools. Archiving and Monitoring in

Lync Server 2013 gather data for users homed on Lync Server 2013 pools.

> **Note:**
> During the phase of migration when you are still using your legacy Edge server with the new Lync Server 2013 pilot pool, the Lync Server 2010 version of Archiving Server continues to gather data for users homed on Lync Server 2010 pools and Archiving in Lync Server 2013 gathers data for users homed on Lync Server 2013 pools.

- If you use a third-party archiving and monitoring solution in conjunction with Archiving and Monitoring in Lync Server 2013, consult with your vendor about when and how you need to integrate the third-party solution with Lync Server 2013.

1.6.1.2.3 Migrating Group Chat Servers

Migrating Group Chat Servers

Migration > Migration from Lync Server 2010 to Lync Server 2013 > Phase 1: Plan Your Migration from Lync Server 2010 >

Topic Last Modified: *2012-09-29*

If you deployed Group Chat Server in your legacy Lync Server 2010 environment, you must deploy Lync Server 2013 Persistent Chat Server. Group Chat Server and Persistent Chat Server can coexist, but content (for example, chat rooms, etc.) is not shared across these servers. To access the legacy Group Chat Server content from Persistent Chat Server, you must migrate the Group Chat Server to Persistent Chat Server. For details on migrating to Persistent Chat Server, see Migration from Lync Server 2010, Group Chat or Office Communications Server 2007 R2 Group Chat to Lync Server 2013, Persistent Chat Server in the Migration documentation.

1.6.1.2.4 Administering Servers after Migration

Administering Servers after Migration

Migration > Migration from Lync Server 2010 to Lync Server 2013 > Phase 1: Plan Your Migration from Lync Server 2010 >

Topic Last Modified: *2012-09-29*

In general, you must use the administrative tool that corresponds to the server version that you want to manage. You cannot install the Lync Server 2010 and the Lync Server 2013 administrative tools on the same computer. Also, the Lync Server 2013 Control Panel is not installed automatically on each server. To install the Lync Server 2013 Control Panel, follow the procedure inside the topic Install Lync Server Administrative Tools in the Deployment documentation.

> **Important:**
> After a Lync Server 2013 pilot pool is deployed, you cannot use Lync Server 2010 Topology Builder or Lync Server 2010 Control Panel to manage any Lync Server 2013 resources. You must use Lync Server 2013 tools to manage Lync Server 2013 and Lync Server 2010 resources.

1.6.1.2.5 Migrating Multiple Sites and Pools

Migrating Multiple Sites and Pools

Migration > Migration from Lync Server 2010 to Lync Server 2013 > Phase 1: Plan Your Migration from Lync Server 2010 >

Topic Last Modified: *2012-09-17*

Lync Server 2013 supports multi-site and multi-pool deployments. The process of migrating multiple pools from Lync Server 2010 to Lync Server 2013 requires the following considerations:

1. After deploying a Lync Server 2013 pilot pool, you need to define a subset of pilot users that will be moved to the Lync Server 2013 pool, and a methodology for validating the functionality of the users. For example, after moving a user to the pilot pool, verify the user's conference policy has moved to Lync Server 2013.
2. After deploying an Edge Server in the pilot pool, you need to validate that external users can communicate with the Lync Server 2013 pool.
3. After transitioning the federated routes from Lync Server 2010 Edge Servers to the pilot Lync Server 2013 Edge Servers, you need to validate that federated users can communicate with the Lync Server 2013 pool.
4. After moving all the users and non-user contact objects, you need to validate that the Lync Server 2010 pool is empty.
5. After verifying that the Lync Server 2010 pool is empty, you can then deactivate the pool.
   For details about how to deactivate the legacy Lync Server 2010 pool and servers, see Phase 8: Decommission Legacy Pools.

1.6.1.2.6 Migrating XMPP Federation

Migrating XMPP Federation

Migration > Migration from Lync Server 2010 to Lync Server 2013 > Phase 1: Plan Your Migration from Lync Server 2010 >

Topic Last Modified: *2012-10-19*

Previous versions of Lync Server and Office Communications Server provided an extensible messaging and presence protocol (XMPP) gateway that could be deployed as a separate server role to allow federating with XMPP deployments. In Lync Server 2013, the XMPP functionality can be deployed as a feature. XMPP functionality is installed in two parts: as an XMPP proxy that runs on the Lync Server 2013 Edge Server, and the XMPP Gateway that runs on the Lync Server 2013 Front End Server.

From a migration perspective, a Lync Server user account can be moved to a Lync Server 2013 pool and continue to use the legacy XMPP gateway. This is possible only when the XMPP federated partner is not configured in Lync Server 2013.

In summary, if Lync Server 2010 has been deployed with the Office Communications Server 2007 R2 XMPP Gateway and XMPP federation has been enabled for legacy Lync Server 2010 users, to migrate the XMPP federation to Lync Server 2013:

1. Deploy a Lync Server 2013 pool.
2. Deploy a Lync Server 2013 Edge server.
3. Move all users to the Lync Server 2013 pool
4. Create XMPP access policies and certificates for the Edge Server.
5. Enable XMPP federation in Lync Server 2013.
6. Update the DNS entries to point to the Lync Server 2013 XMPP Gateway.

1.6.1.3 Phase 2: Prepare for Migration

Phase 2: Prepare for Migration

Microsoft Lync Server 2013 > Migration > Migration from Lync Server 2010 to Lync Server 2013 >

Topic Last Modified: *2012-09-17*

Before you begin your migration to Lync Server 2013 from Lync Server 2010, follow the steps described in this section.

In This Section

- Apply Lync Server 2010 Updates
- Configure DNS Records for Pilot Pool Deployment
- Run Best Practices Analyzer
- Back Up Systems and Data
- Configure Clients for Migration
- Verify Lync Server 2010 Environment

1.6.1.3.1 Apply Lync Server 2010 Updates

Apply Lync Server 2010 Updates

Migration > Migration from Lync Server 2010 to Lync Server 2013 > Phase 2: Prepare for Migration >

Topic Last Modified: *2012-10-19*

Before you migrate to Lync Server 2013, updates must be applied to your Lync Server 2010 environment. For the most up-to-date information about Lync Server 2010, see **Updates Resource Center for Lync** at http://go.microsoft.com/fwlink/p/?linkid=232630.

To install updates for Lync Server 2010, we recommend you follow the **Method 1 Cumulative Server Update Installer** procedure described in the Microsoft Knowledge Base article, "Updates for Lync Server 2010," at http://go.microsoft.com/fwlink/p/?linkid=3052&kbid=2493736.

1.6.1.3.2 Configure DNS Records for Pilot Pool Deployment

Configure DNS Records for Pilot Pool Deployment

Migration > Migration from Lync Server 2010 to Lync Server 2013 > Phase 2: Prepare for Migration >

Topic Last Modified: *2012-09-29*

Prior to deploying the Lync Server 2013 pilot pool, you must update the DNS Host A entries for the pilot pool. To successfully complete this procedure, you should be logged on to the server or domain as a member of the Domain Admins group or a member of the DnsAdmins group.

To configure DNS Host A records

1. On the Domain Name System (DNS) server, click **Start**, click **Administrative Tools**, and then click **DNS**.
2. In the console tree for your domain, expand **Forward Lookup Zones**, and

then right-click the domain in which Lync Server 2013 will be installed.
3. Click **New Host (A or AAAA)**.
4. Click **Name**, type the host name for the Lync Server 2013 pool (the domain name is assumed from the zone that the record is defined in and does not need to be entered as part of the A record).
5. Click **IP Address**, type the IP address for the Front End pool.
6. Click **Add Host**, and then click **OK**.
7. When you are finished, click **Done**.

1.6.1.3.3 Run Best Practices Analyzer

Run Best Practices Analyzer

Migration > Migration from Lync Server 2010 to Lync Server 2013 > Phase 2: Prepare for Migration >

Topic Last Modified: *2012-03-21*

The Lync Server 2010 Best Practices Analyzer tool gathers configuration information from an Lync Server 2010 deployment and determines whether the configuration is set according to Microsoft best practices. You can install the tool on a client computer that runs Microsoft .NET Framework 3.5 Service Pack 1, or directly on the server that runs Lync Server 2010. We recommend that you install and run this tool on a client computer. The Lync Server 2010 Administrative Tools should also be installed locally on the client computer so that the Best Practices Analyzer can collect a full set of data.

You can download the Lync Server 2010 Best Practices Analyzer from the Microsoft Download Center at http://go.microsoft.com/fwlink/p/?linkid=246173 .

1.6.1.3.4 Back Up Systems and Data

Back Up Systems and Data

Migration > Migration from Lync Server 2010 to Lync Server 2013 > Phase 2: Prepare for Migration >

Topic Last Modified: *2012-09-18*

Before you begin the migration to Lync Server 2013, we strongly recommend that you perform a full system backup and document your existing system, including an inventory of user accounts that are homed on each pool, so that you can roll back to Lync Server 2010 if it becomes necessary. Multiple tools and programs are available for backing up and restoring data, settings, and systems.

For details and procedures, see Backing Up and Restoring Lync Server 2010 .

1.6.1.3.5 Configure Clients for Migration

Configure Clients for Migration

See Also

Migration > Migration from Lync Server 2010 to Lync Server 2013 > Phase 2: Prepare for Migration >

Topic Last Modified: *2012-09-24*

This topic contains the recommended client deployment steps you should take before migrating to Lync Server 2013. These configuration changes should be made on Lync

Server 2010.

⊟To configure clients before migration

1. Deploy the most recent server, client, and device updates (hotfixes) for Lync Server 2010. For the most up-to-date information about Lync Server 2010, see Updates Resource Center for Lync at http://go.microsoft.com/fwlink/p/?linkid=232630.
2. On Lync Server 2010, use Client Version Filtering to only allow clients with the most current updates installed.

New and Changed Settings for Lync 2013
Client Interoperability in Lync 2013

Other Resources

Planning for Clients and Devices in Lync Server 2013

1.6.1.3.6 Verify Lync Server 2010 Environment

Verify Lync Server 2010 Environment

Migration > Migration from Lync Server 2010 to Lync Server 2013 > Phase 2: Prepare for Migration >

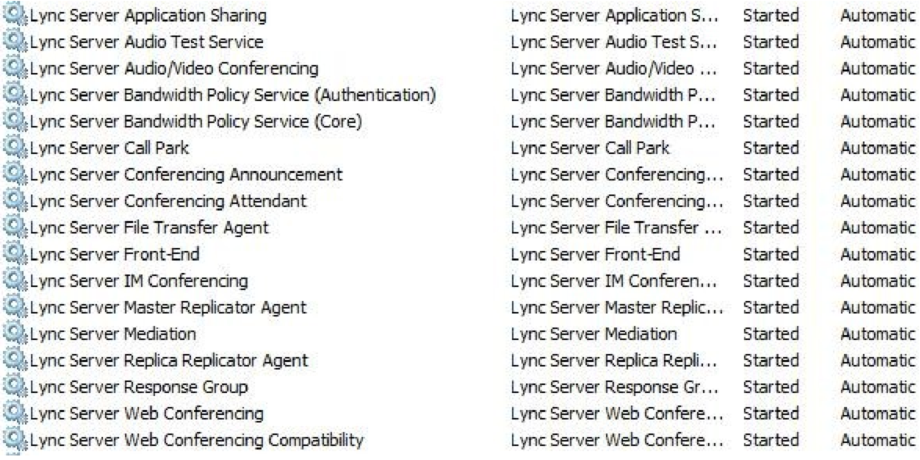
Topic Last Modified: *2012-10-19*

Before deploying Lync Server 2013 in a coexistence state with Lync Server 2010, you need to verify that Lync Server 2010 services have been configured and started. It is important to identify key services and features that exist in your legacy environment, prior to deploying a Lync Server 2013 pilot pool. Before deploying Microsoft Lync Server 2013 XMPP in a coexistence state with a legacy XMPP deployment, you need to verify the legacy XMPP services have been configured and started, and identify which federated partner the legacy XMPP configuration is supporting. Verifying your legacy Lync Server 2010 deployment entails the following:

- Verifying the Lync Server 2010 services are started
- Reviewing the topology and users in Lync Server 2010.
- Verifying the federation and Edge server settings.
- Verifying XMPP services and federated partners.

Verify Lync Server 2010 Services are started

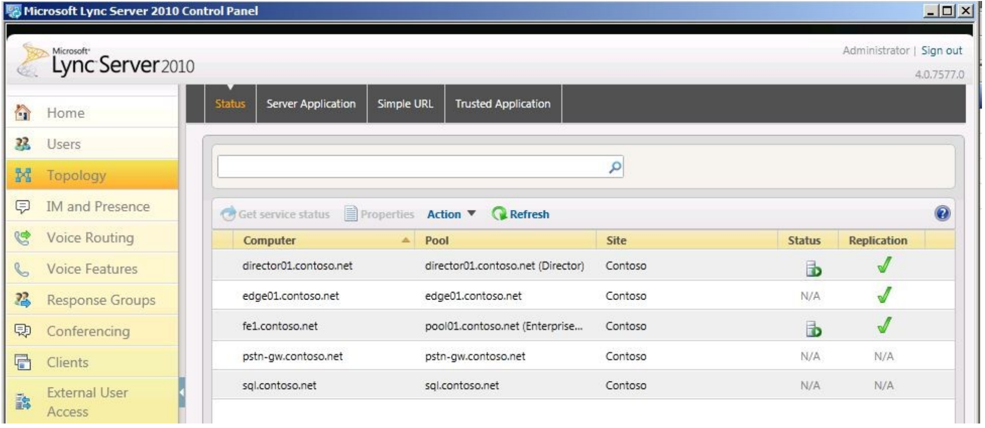
1. From the Lync Server 2010 Front End Server, navigate to the Administrative Tools\Services applet.
2. Verify that the following services are running on the Front End Server:



Lync Server Application Sharing	Lync Server Application S...	Started	Automatic
Lync Server Audio Test Service	Lync Server Audio Test S...	Started	Automatic
Lync Server Audio/Video Conferencing	Lync Server Audio/Video ...	Started	Automatic
Lync Server Bandwidth Policy Service (Authentication)	Lync Server Bandwidth P...	Started	Automatic
Lync Server Bandwidth Policy Service (Core)	Lync Server Bandwidth P...	Started	Automatic
Lync Server Call Park	Lync Server Call Park	Started	Automatic
Lync Server Conferencing Announcement	Lync Server Conferencing...	Started	Automatic
Lync Server Conferencing Attendant	Lync Server Conferencing...	Started	Automatic
Lync Server File Transfer Agent	Lync Server File Transfer ...	Started	Automatic
Lync Server Front-End	Lync Server Front-End	Started	Automatic
Lync Server IM Conferencing	Lync Server IM Conferen...	Started	Automatic
Lync Server Master Replicator Agent	Lync Server Master Replic...	Started	Automatic
Lync Server Mediation	Lync Server Mediation	Started	Automatic
Lync Server Replica Replicator Agent	Lync Server Replica Repli...	Started	Automatic
Lync Server Response Group	Lync Server Response Gr...	Started	Automatic
Lync Server Web Conferencing	Lync Server Web Confere...	Started	Automatic
Lync Server Web Conferencing Compatibility	Lync Server Web Confere...	Started	Automatic

Review the Lync Server 2010 topology in Lync Server Control Panel

1. Log on to the Front End Server with an account that is a member of the RTCUniversalServerAdmins group or a member of the CsAdministrator or CsUserAdministrator administrative role.
2. Open the Lync Server Control Panel.
3. Select **Topology**. Verify that the various servers in your Lync Server 2010 deployment are listed.



Computer	Pool	Site	Status	Replication
director01.contoso.net	director01.contoso.net (Director)	Contoso		✓
edge01.contoso.net	edge01.contoso.net	Contoso	N/A	✓

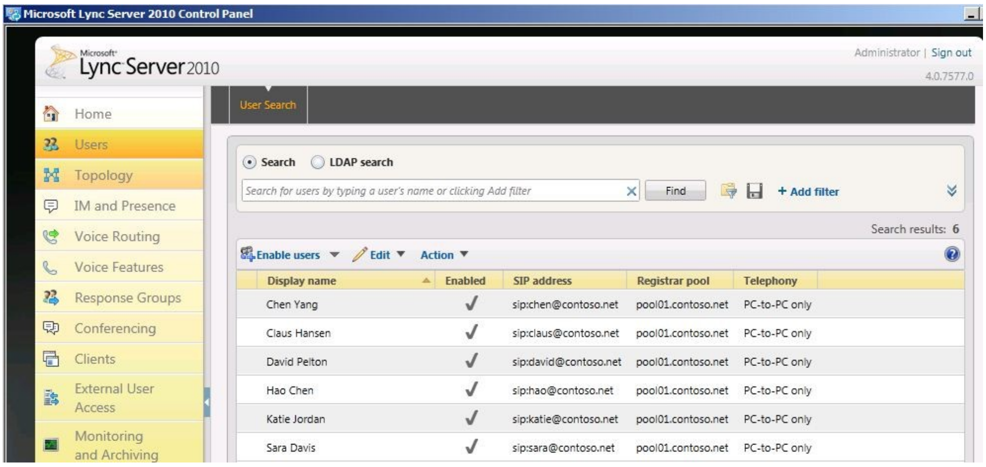
To review Lync Server 2010 users in Lync Server Control Panel

1. Open the Lync Server Control Panel.
2. Select **Users** and then click **Find**.
3. Verify that the **Registrar Pool** column points to the Lync Server 2010 pool for each user listed.



Search results: 6

Display name	Enabled	SIP address	Registrar pool	Telephony
Chen Yang	✓	sip:chen@contoso.net	pool01.contoso.net	PC-to-PC only

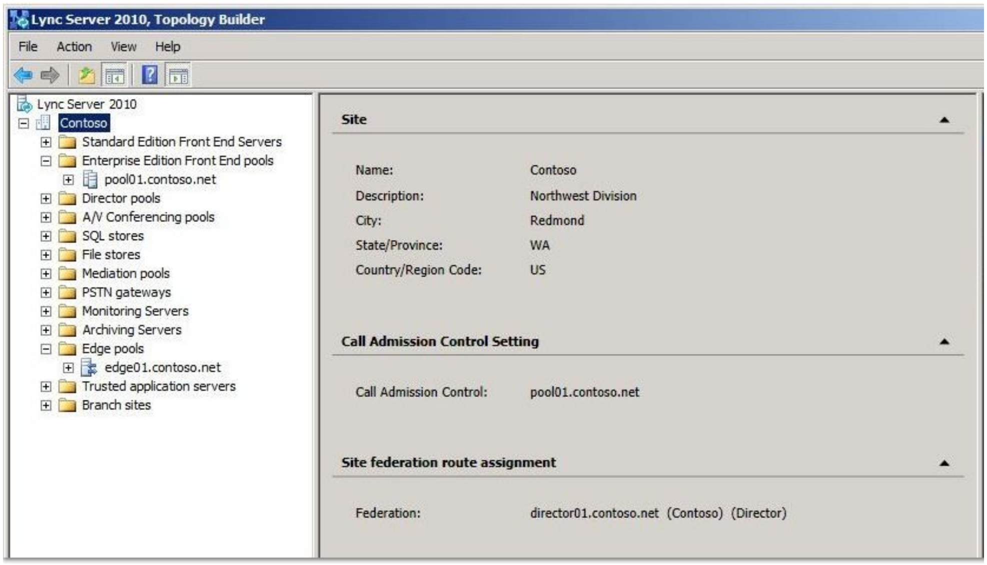
To verify Lync Server 2010 Edge and Federation Settings

1. Start Topology Builder.
2. Select **Download Topology from existing deployment**.
3. Choose a file name and save the topology with the default .tbxml file type.
4. Expand the Lync Server 2010 node to reveal the various server roles in the deployment.
5. Select the site node and verify if a **Site federation route assignment** value is set.



Site

Name: Contoso
Description: Northwest Division
City: Redmond
State/Province: WA
Country/Region Code: US

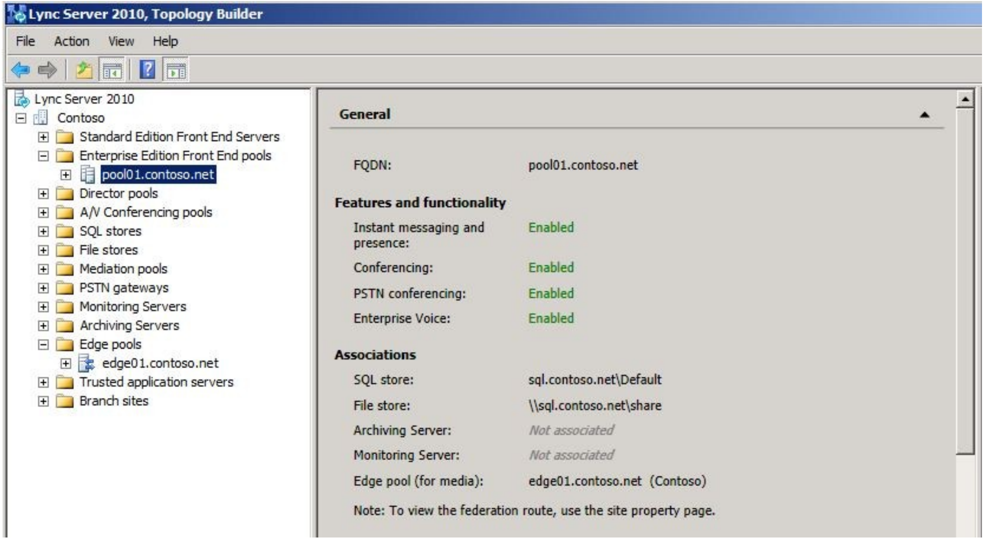
Call Admission Control Setting

Call Admission Control: pool01.contoso.net

Site federation route assignment

Federation: director01.contoso.net (Contoso) (Director)

6. Next, select the Standard Edition Server or Enterprise Edition front end pool. Determine if an Edge pool has been configured for Media below **Associations**.



General

FQDN: pool01.contoso.net

Features and functionality

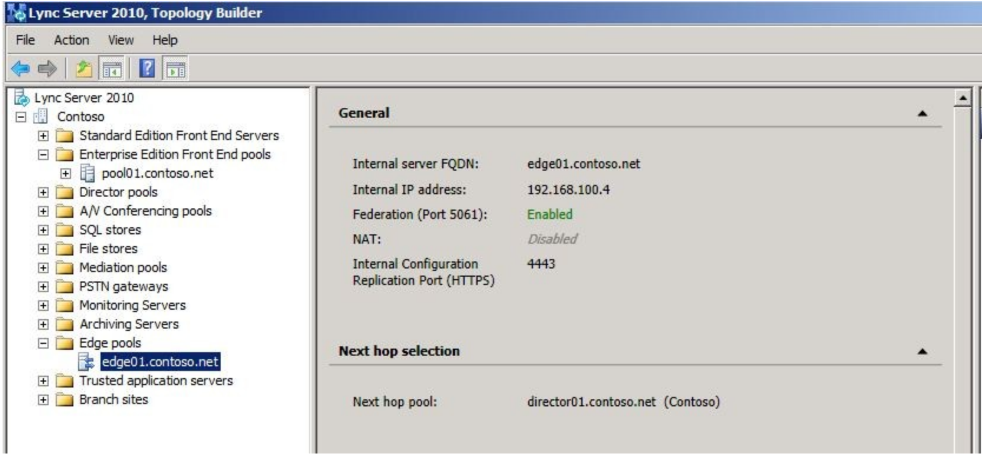
Instant messaging and presence: Enabled
Conferencing: Enabled
PSTN conferencing: Enabled
Enterprise Voice: Enabled

Associations

SQL store: sql.contoso.net\Default
File store: \\sql.contoso.net\share
Archiving Server: *Not associated*
Monitoring Server: *Not associated*
Edge pool (for media): edge01.contoso.net (Contoso)

Note: To view the federation route, use the site property page.

7. Finally, select the Edge pool and identify if a Next hop pool is configured below **Next hop selection**.



General

Internal server FQDN: edge01.contoso.net
Internal IP address: 192.168.100.4
Federation (Port 5061): Enabled
NAT: *Disabled*
Internal Configuration Replication Port (HTTPS) 4443

Next hop selection

Next hop pool: director01.contoso.net (Contoso)

Verify legacy XMPP Federated Partner Configuration

1. From the legacy XMPP server, navigate to the Administrative Tools\Services applet.
2. Verify that the Office Communications Server XMPP Gateway service is started.

1.6.1.4 Phase 3: Deploy Lync Server 2013 Pilot Pool

Phase 3: Deploy Lync Server 2013 Pilot Pool

Microsoft Lync Server 2013 > Migration > Migration from Lync Server 2010 to Lync Server 2013 >

Topic Last Modified: *2012-10-19*

This section covers the steps required to deploy a pilot pool of Lync Server 2013. The deployment of Lync Server 2013 requires using Topology Builder to define your topology and the components you want to deploy, preparing your environment for deployment of the Lync Server 2013 components, publishing your topology design on the first Front End Server, and then installing and configuring Lync Server 2013 software for the components for your deployment. When completed, your Lync Server 2013 pilot pool deployment will coexist with an existing Lync Server 2010 pool.

In This Section

- Prepare Active Directory for Lync Server
- Download Topology From Existing Deployment
- Deploy Lync Server 2013 Pilot Pool
- Verify Pilot Pool Coexistence with Legacy Pool
- Connect Pilot Pool to Legacy Edge Servers
- Configure XMPP Gateway Access Policies and Certificates

1.6.1.4.1 Prepare Active Directory for Lync Server

Prepare Active Directory for Lync Server

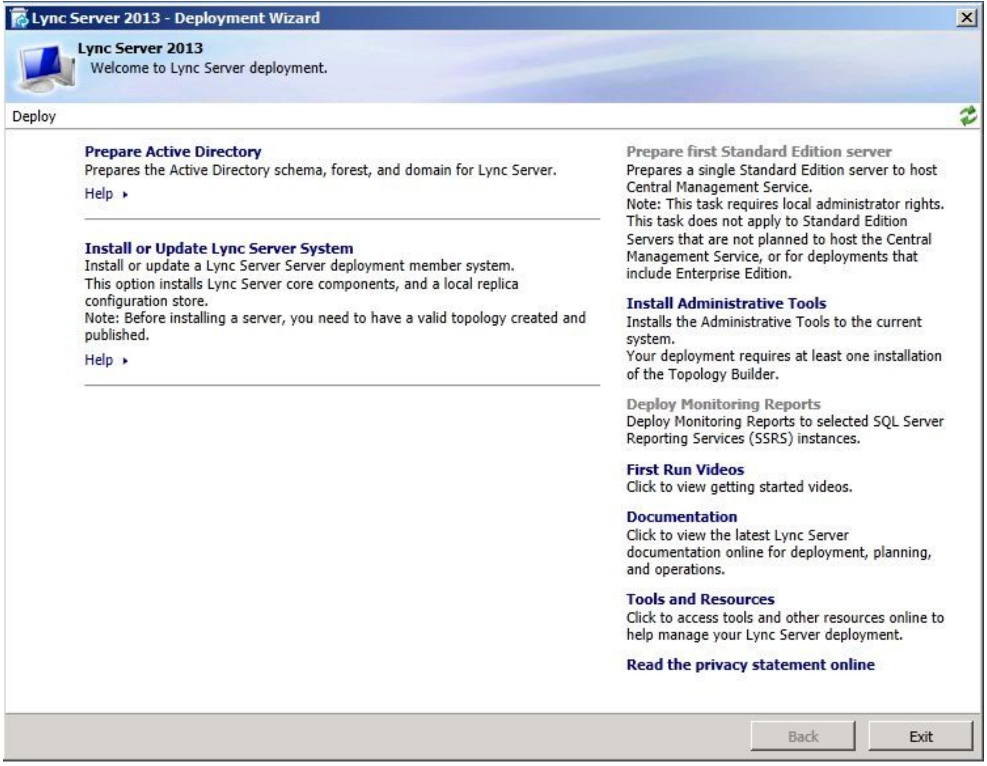
Migration > Migration from Lync Server 2010 to Lync Server 2013 > Phase 3: Deploy Lync Server 2013 Pilot Pool >

Topic Last Modified: *2012-09-17*

Prior to deploying Lync Server 2013 in a coexistence state with Lync Server 2010, you must perform some additional Active Directory tasks to configure the schema, forest, and domain for Lync Server 2013. The schema extensions add the Active Directory classes and attributes that are required by Lync Server 2013. For additional information, see the topic Preparing Active Directory Domain Services for Lync Server 2013.

To prepare Active Directory for Lync Server 2013

1. On the Lync Server 2013 Front End Server, run Lync Server 2013 Setup.
2. Select **Prepare Active Directory**.



Lync Server 2013 - Deployment Wizard

Lync Server 2013

Welcome to Lync Server deployment.

Deploy

Prepare Active Directory
Prepares the Active Directory schema, forest, and domain for Lync Server.
Help ▸

Install or Update Lync Server System
Install or update a Lync Server Server deployment member system.
This option installs Lync Server core components, and a local replica configuration store.
Note: Before installing a server, you need to have a valid topology created and published.
Help ▸

Prepare first Standard Edition server
Prepares a single Standard Edition server to host Central Management Service.
Note: This task requires local administrator rights.
This task does not apply to Standard Edition Servers that are not planned to host the Central Management Service, or for deployments that include Enterprise Edition.

Install Administrative Tools
Installs the Administrative Tools to the current system.
Your deployment requires at least one installation of the Topology Builder.

Deploy Monitoring Reports
Deploy Monitoring Reports to selected SQL Server Reporting Services (SSRS) instances.

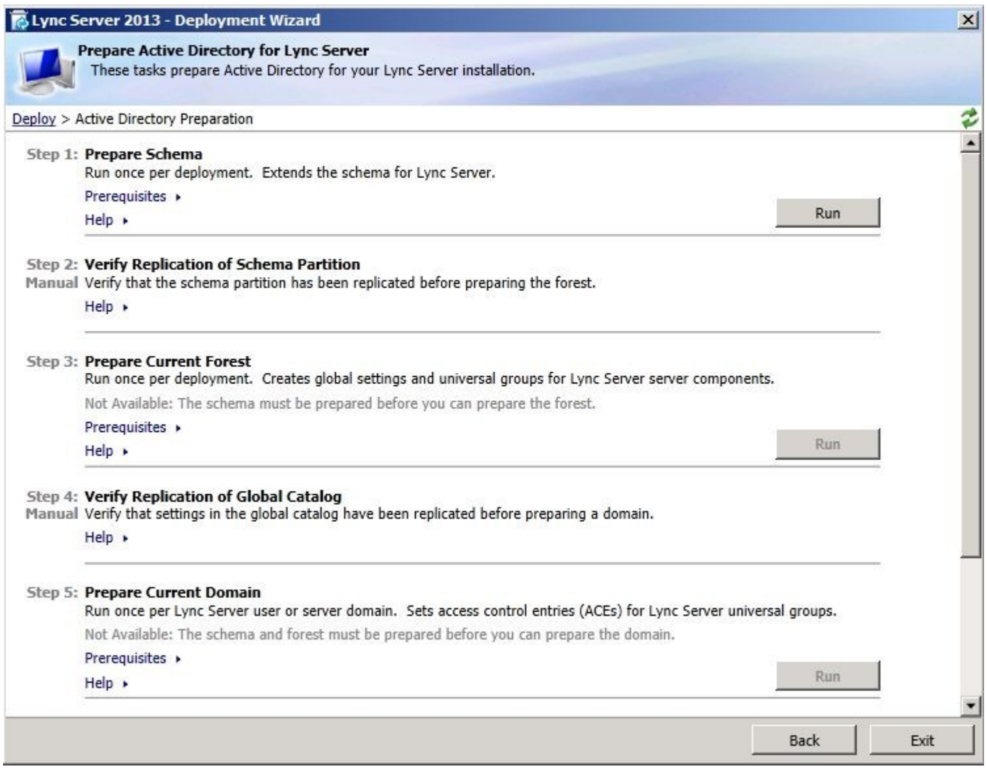
First Run Videos
Click to view getting started videos.

Documentation
Click to view the latest Lync Server documentation online for deployment, planning, and operations.

Tools and Resources
Click to access tools and other resources online to help manage your Lync Server deployment.

Read the privacy statement online

3. Complete steps 1 through 5.



Lync Server 2013 - Deployment Wizard

Prepare Active Directory for Lync Server

These tasks prepare Active Directory for your Lync Server installation.

Deploy > Active Directory Preparation

Step 1: Prepare Schema
Run once per deployment. Extends the schema for Lync Server.

Step 2: Verify Replication of Schema Partition
Manual Verify that the schema partition has been replicated before preparing the forest.

Step 3: Prepare Current Forest
Run once per deployment. Creates global settings and universal groups for Lync Server server components.
Not Available: The schema must be prepared before you can prepare the forest.

Step 4: Verify Replication of Global Catalog
Manual Verify that settings in the global catalog have been replicated before preparing a domain.

Step 5: Prepare Current Domain
Run once per Lync Server user or server domain. Sets access control entries (ACEs) for Lync Server universal groups.
Not Available: The schema and forest must be prepared before you can prepare the domain.

1.6.1.4.2 Download Topology From Existing Deployment

Download Topology From Existing Deployment

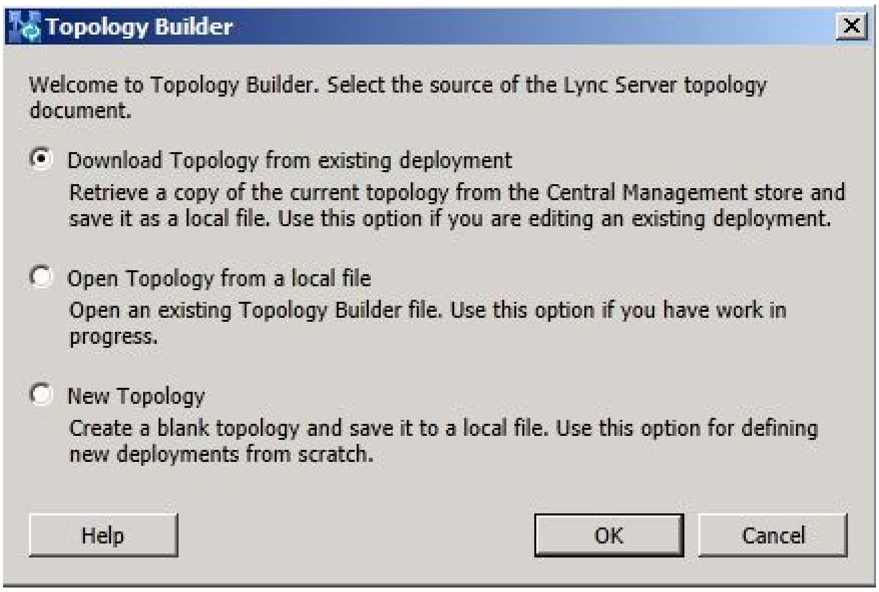
Migration > Migration from Lync Server 2010 to Lync Server 2013 > Phase 3: Deploy Lync Server 2013 Pilot Pool >

Topic Last Modified: *2012-09-29*

When creating a Lync Server 2013 pool, you will use the Central Management Store that is associated with Lync Server 2010. When you start Topology Builder on first use and subsequent edit sessions, you are prompted for the location where you want Topology Builder to load the current configuration document. Because you already have a Lync Server 2010 topology defined and have established the Central Management store, you should choose to download a topology from an existing deployment. Topology Builder will read the database and retrieve the current definition.

To download a topology from an existing deployment

1. Open the **Lync Server Deployment Wizard**.
2. From the **Lync Server 2013 – Deployment Wizard** page, click **Install Administrative Tools**.
3. Start Topology Builder: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013** , and then click **Lync Server Topology Builder**.
4. Select **Download Topology from existing deployment**.



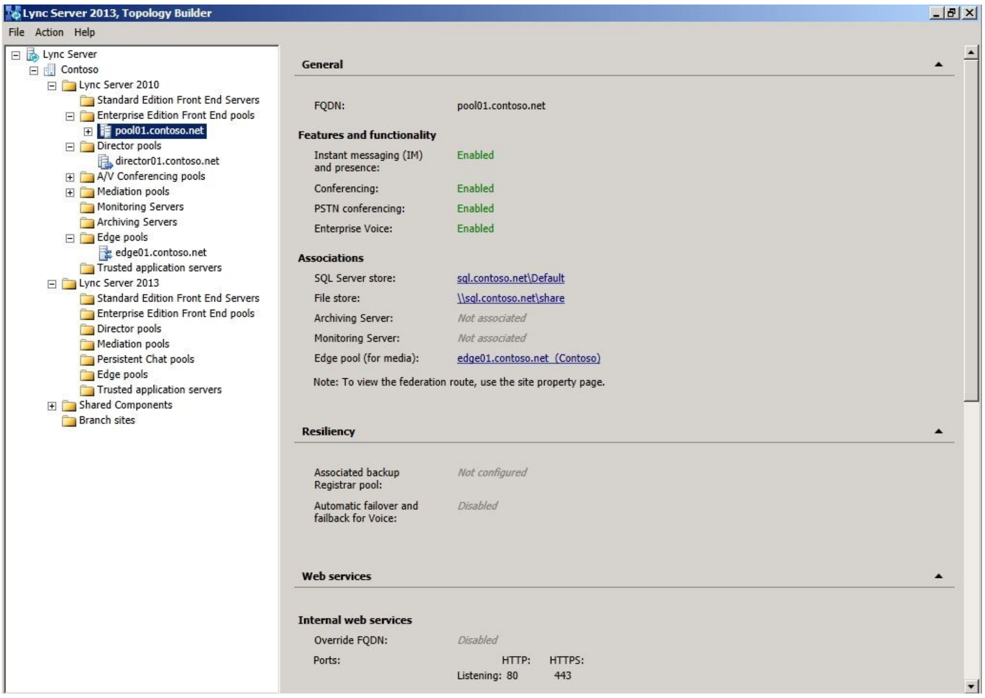
Welcome to Topology Builder. Select the source of the Lync Server topology document.

● Download Topology from existing deployment
Retrieve a copy of the current topology from the Central Management store and save it as a local file. Use this option if you are editing an existing deployment.

○ Open Topology from a local file
Open an existing Topology Builder file. Use this option if you have work in progress.

○ New Topology
Create a blank topology and save it to a local file. Use this option for defining new deployments from scratch.

5. Choose a file name and save the topology with the default .tbxml file type.
6. Expand the Lync Server node, as shown, to reveal the various server roles in the deployment.



General

FQDN: pool01.contoso.net

Features and functionality

Instant messaging (IM) and presence: Enabled
Conferencing: Enabled
PSTN conferencing: Enabled
Enterprise Voice: Enabled

Associations

SQL Server store: sql.contoso.net\Default
File store: \\sql.contoso.net\share
Archiving Server: Not associated
Monitoring Server: Not associated
Edge pool (for media): edge01.contoso.net (Contoso)

Note: To view the federation route, use the site property page.

Resiliency

Associated backup Registrar pool: Not configured
Automatic failover and failback for Voice: Disabled

Web services

Internal web services

Override FQDN: Disabled
Ports: HTTP: HTTPS:
Listening: 80 443

1.6.1.4.3 Deploy Lync Server 2013 Pilot Pool

Deploy Lync Server 2013 Pilot Pool

Migration > Migration from Lync Server 2010 to Lync Server 2013 > Phase 3: Deploy Lync Server 2013 Pilot Pool >

Topic Last Modified: *2012-09-29*

One of the first steps required for migration to Lync Server 2013 is to deploy a pilot pool. The pilot pool is where you test coexistence of Lync Server 2013 with your Lync Server 2010 deployment. Coexistence is a temporary state that lasts until you have moved all users and pools to Lync Server 2013.

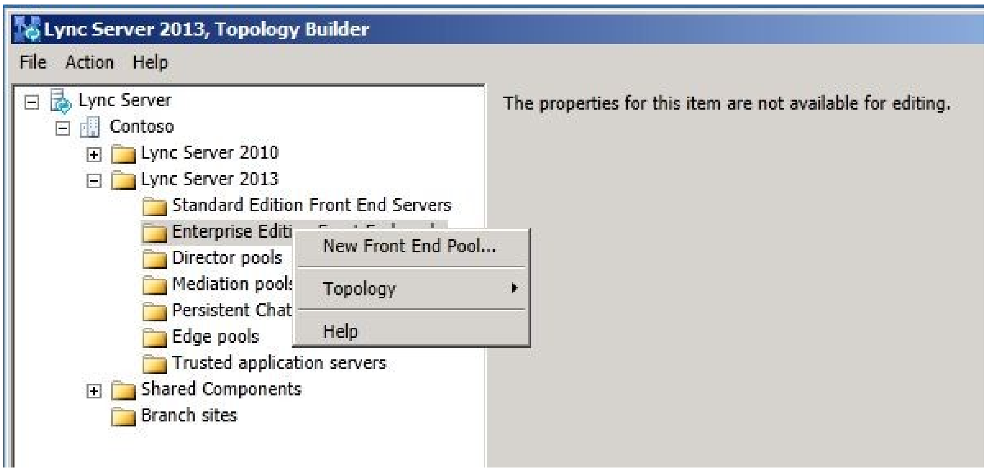
When you deploy a pilot pool, you use the Define New Front End Pool wizard. You should deploy the same features and workloads in your Lync Server 2013 pilot pool that you have in your Lync Server 2010 pool. If you deployed Archiving Server, Monitoring Server, or System Center Operations Manager for archiving or monitoring your Lync Server 2010 environment, and you want to continue archiving or monitoring throughout the migration, you need to also deploy these features in your pilot environment. The version you deployed to archive or monitor your Lync Server 2010 environment will not capture data in your Lync Server 2013 environment.

Note:

The following procedure discusses features and settings you should consider as part of your overall pilot pool deployment process. This section only highlights key points you should consider as part of your pilot pool deployment. For detailed steps, refer to the Deploying Lync Server 2013 deployment guide.

To deploy a Lync Server 2013 pilot pool

1. Log on to the computer where Topology Builder is installed as a member of the Domain Admins group and the RTCUniversalServerAdmins group.
2. Expand the tree until you reach **Lync Server 2013 Enterprise Edition Front End pools**.
3. Right click **Enterprise Edition Front End pools**, and select **New Front End Pool**.

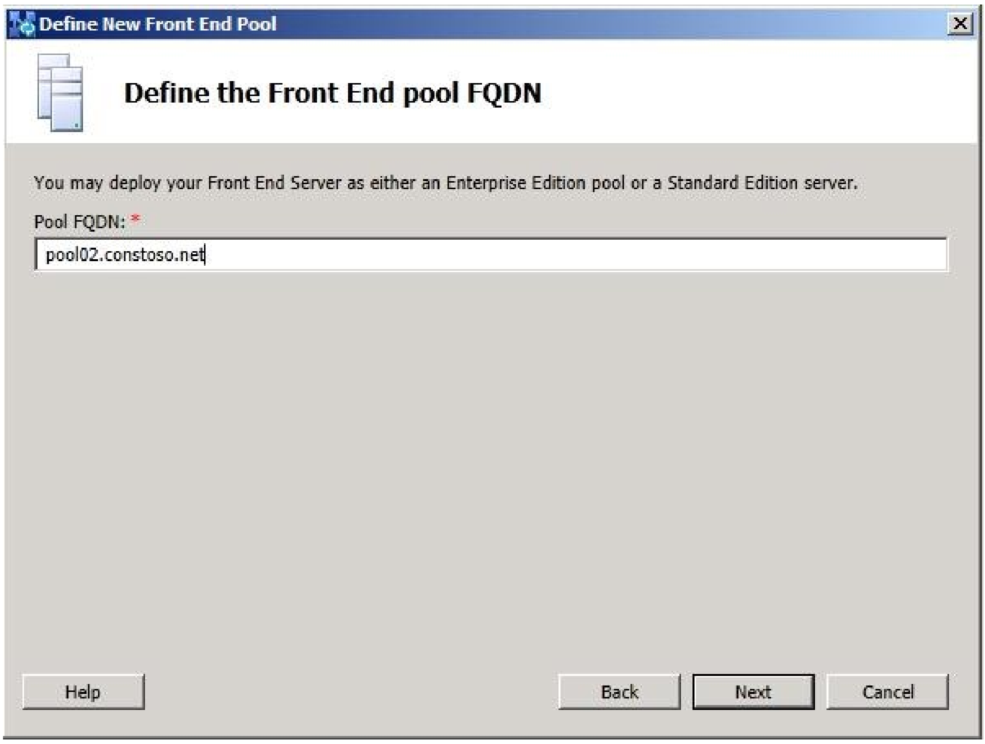


The properties for this item are not available for editing.

4. Enter the pool FQDN. When you define your pilot pool, you can choose to deploy an Enterprise Edition Front End pool or a Standard Edition server. Lync Server 2013 does not require that your pilot pool features match what was deployed in your legacy pool.

Warning:

The pool or server fully qualified domain name (FQDN) that you define for the pilot pool must be unique. It cannot match the name of the currently deployed Lync Server 2010 pool, or any other servers currently deployed.



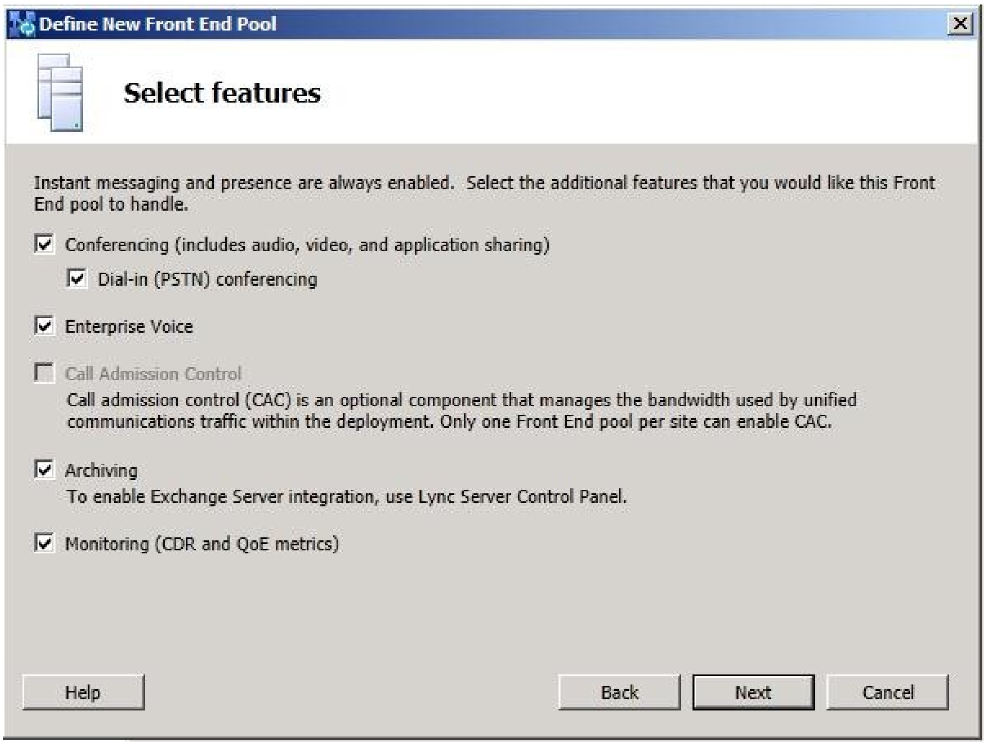
Define the Front End pool FQDN

You may deploy your Front End Server as either an Enterprise Edition pool or a Standard Edition server.

Pool FQDN: *

pool02.constoso.net

5. On the **Select features** page, select the check boxes for the features that you want on this Front End pool. For example, if you are deploying only instant messaging (IM) and presence features, you would select the Conferencing check box to allow multiparty IM, but would not select the Dial-in (PSTN) conferencing, Enterprise Voice, or Call Admission Control check boxes, because they represent voice, video, and collaborative conferencing features. For additional information on selecting features, see Define and Configure a Front End Pool or Standard Edition Server in the Deployment documentation.



Define New Front End Pool

Select features

Instant messaging and presence are always enabled. Select the additional features that you would like this Front End pool to handle.

☑ Conferencing (includes audio, video, and application sharing)

☑ Dial-in (PSTN) conferencing

☑ Enterprise Voice

□ Call Admission Control

Call admission control (CAC) is an optional component that manages the bandwidth used by unified communications traffic within the deployment. Only one Front End pool per site can enable CAC.

☑ Archiving
