1.1 Getting Started

Getting Started

Microsoft Lync Server 2013 >

Topic Last Modified: *2013-02-18*

Lync Server 2013 offers many features to enhance collaboration and communication in your organization. Many of these features are new compared to what was available in previous versions. The topics in this section give a brief overview of the new capabilities.

- Introduction to Lync Server 2013
- New Server Features
- New Client Features
- Release Notes for Lync Server 2013

1.1.1 Introduction to Lync Server 2013

Introduction to Lync Server 2013

Microsoft Lync Server 2013 > Getting Started >

Topic Last Modified: *2013-01-11*

Lync Server 2013 and its client software, such as Lync 2013, enable your users to connect in new ways and to stay connected, regardless of their physical location. Lync and Lync Server bring together the different ways that people communicate in a single client interface, are deployed as a unified platform, and are administered through a single management infrastructure.

This table and the following sections illustrate the major feature sets, or *workloads*, that Lync Server provides for your users.

Workload	Description
IM and presence	Instant messaging (IM) and presence help your users find and communicate with one another efficiently and effectively. IM provides an instant messaging platform with

	conversation history, and supports public IM connectivity with users of public IM networks such as MSN/Windows Live, Yahoo!, AOL, and Google Talk. **Important:** • As of September 1st, 2012, the Microsoft Lync Public IM Connectivity User Subscription License ("PIC USL") is no longer available for purchase for new or renewing agreements. Customers with active licenses will be able to continue to federate with Yahoo! Messenger until the service shut down date (exact date TBD, but no sooner than June 2013). • The PIC USL is a per-user per-month subscription license that is required for Lync Server or Office Communications Server to federate with Yahoo! Messenger. Microsoft's ability to provide this service has been contingent upon support from Yahoo!, the underlying agreement for which is winding down. • More than ever, Lync is a powerful tool for connecting across organizations and with individuals around the world. Federation with Windows Live Messenger requires no additional user/device licenses beyond the Lync Standard CAL. Skype federation will be added to this list, enabling Lync users to reach hundreds of millions of people with IM and voice. Presence establishes and displays a user's personal availability and willingness to communicate through the use of common states such as **Available** or **Busy**, as well as more detailed states such as **Be Right Back** and **Do Not Disturb**. This rich presence information enables other users to immediately make effective communication choices.
Conferencing	Lync Server includes support for IM conferencing, audio conferencing, web conferencing, video conferencing, and application sharing, for both scheduled and impromptu meetings. All these meeting types are supported with a single client. Lync Server also supports dial-in conferencing so that users of public switched telephone network (PSTN) phones can participate in the audio portion of conferences. Conferences can seamlessly change and grow in real time. For example, a single conference can start as just instant messages between a few

	users, and escalate to an audio conference with desktop sharing and a larger audience instantly, easily, and without interrupting the conversation flow.
Enterprise Voice	*Enterprise Voice* is the Voice over Internet Protocol (VoIP) offering in Lync Server. It delivers a voice option to enhance or replace traditional private branch exchange (PBX) systems. In addition to the complete telephony capabilities of an IP PBX, Enterprise Voice is integrated with rich presence, IM, collaboration, and meetings. Features such as call answer, hold, resume, transfer, forward and divert are supported directly, while personalized speed dialing keys are replaced by Contacts lists, and automatic intercom is replaced with IM. Enterprise Voice supports high availability through call admission control (CAC), branch office survivability, and extended options for data resiliency.
Support for remote users	You can provide full Lync Server functionality for users who are currently outside your organization's firewalls by deploying servers called *Edge Servers* to provide a connection for these remote users. These remote users can connect to conferences by using a personal computer with Lync 2013 installed, the phone, or a web interface. Deploying Edge Servers also enables you to *federate* with partner or vendor organizations. A federated relationship enables your users to put federated users on their Contacts lists, exchange presence information and instant messages with these users, and invite them to audio calls, video calls, and conferences.
Mobile client support	Additionally, with Lync Server mobility services, your users can access Lync functionality when using supported Apple iOS, Android, Windows Phone, or Nokia mobile devices and perform such activities as sending and receiving instant messages, viewing contacts, and viewing presence. In addition, mobile devices support some Enterprise Voice features, such as click to join a conference, Call via Work, single number reach, voice mail, and missed calls. Push notifications are also supported for mobile devices that do not support applications running in the background.
Integration with other products	Lync Server integrates with several other products to provide additional benefits to your users and administrators. Meeting tools are integrated into Outlook to enable organizers to schedule a meeting or start an impromptu conference with a single click and make it just as easy for attendees to join.

	Presence information is integrated into Outlook and SharePoint. Exchange Unified Messaging (UM) provides several integration features. Users can see if they have new voice mail within Lync Server. They can click a play button in the Outlook message to hear the audio voice mail, or view a transcription of the voice mail in the notification message. Additionally, running Lync Server 2013 with Exchange 2013 enables several new features such as a unified contact store which can be accessed by clients of both products, as well as high-resolution photos for contacts which are stored in the Exchange 2013 database.
Simple deployment	To help you plan and deploy your servers and clients, Lync Server provides the Topology Builder. Topology Builder is an installation component of Lync Server. You use Topology Builder to create, adjust and publish your planned topology. It also validates your topology before you begin server installations. When you install Lync Server on individual servers, the installation program deploys the server as directed in the topology.
Simple management	After you deploy Lync Server, it offers the following powerful and streamlined management tools: • Central configuration management, which enables you to manage changes centrally and have them replicated quickly to the entire deployment. • Lync Server Control Panel, a web-based graphical user interface for administrators. With this web-based UI, Lync Server administrators can manage their systems from anywhere on the corporate network, without needing specialized management software installed on their computers. • Lync Server Management Shell command-line management tool, which is based on the Windows PowerShell command-line interface. It provides a rich command set for administration of all aspects of the product, and enables Lync Server administrators to automate repetitive tasks using a familiar tool.

While the IM and presence features are automatically installed in every Lync Server deployment, you can choose whether to deploy conferencing, Enterprise Voice, and remote user access, to tailor your deployment to your organization’s needs.

- IM and Presence
- Conferencing
- Enterprise Voice
- Scalability

1.1.1.1 IM and Presence

IM and Presence

Microsoft Lync Server 2013 > Getting Started > Introduction to Lync Server 2013 >

Topic Last Modified: *2013-01-11*

Instant messaging (IM) and presence are automatically installed in any Lync Server deployment.

Presence information enables users to approach colleagues at the right time with the right form of communication, to lead to a more productive work environment. A user's presence is a collection of information that includes availability, willingness to communicate, additional notes (such as location and status), and how the user can be contacted. Presence is enhanced in Lync Server with pictures, location information, and a rich set of presence states that includes "Off Work," "Do Not Disturb," and "Be Right Back," in addition to basic states such as "Available," "Busy," and "In a Conference." Administrators can also define customized, organization-specific presence states.

Contact management and user access options enable users to control what information others can see. Users can set different levels of contacts, each of which can view different levels of presence information.

By simply looking at a Contacts list, users can find everything they need to know at a glance. Simple colored icons indicate other users' presence status, and picture and location are also shown.

With the integration between Lync Server and other products such as Outlook and SharePoint, whenever a contact's name appears, such as in an email message or on a team website, the status and contact information is also displayed. Additionally, if you deploy Exchange 2013, Lync Server and Exchange 2013 can share a unified contact store, which can be accessed by clients of either product.

With instant messaging in Lync Server, users can quickly message each other with timely information. If you prefer, your users can also communicate with users of public IM networks such as MSN/Windows Live, Yahoo!, and AOL. Note that a separate license might be required for public IM connectivity with Windows Live, AOL, and Yahoo! Lync Server also includes Extensible Messaging and Presence Protocol (XMPP) compatibility, so your users can exchange IM messages and presence information with users of XMPP services such as Google Talk.

Important:

- As of September 1st, 2012, the Microsoft Lync Public IM Connectivity User Subscription License ("PIC USL") is no longer available for purchase for new or renewing agreements. Customers with active licenses will be able to continue to federate with Yahoo! Messenger until the service shut down date (exact date TBD, but no sooner than June 2013).
- The PIC USL is a per-user per-month subscription license that is required for Lync Server or Office Communications Server to federate with Yahoo! Messenger. Microsoft's ability to provide this service has been contingent upon support from Yahoo!, the underlying agreement for which is winding down.
- More than ever, Lync is a powerful tool for connecting across organizations and with individuals around the world. Federation with Windows Live Messenger requires no additional user/device licenses beyond the Lync Standard CAL. Skype federation will be added to this list, enabling Lync users to reach hundreds of millions of people with IM and voice.

Conversation history enables users to keep track of old IM conversations, and retrieve information that may have been communicated by IM months ago.

The Persistent Chat feature enables users to participate in multiparty, topic-based conversations that persist over time. Messages posted to chat rooms (discussion forums) can be persistent (that is, available over time), so that people from different locations and departments can participate, even when they are not all online at the same time.

If your organization must follow compliance regulations, you can deploy a message archiving feature to archive the content of instant messages for all users in your organization, or for only certain users you specify. If you also deploy Exchange 2013, your IM archive can be integrated with the In-Place Hold feature of Exchange, to provide a single administration experience for your compliance.

1.1.1.2 Conferencing

Conferencing

Microsoft Lync Server 2013 > Getting Started > Introduction to Lync Server 2013 >

Topic Last Modified: *2012-09-11*

With unified conferencing in Lync Server 2013, users can collaborate, share information, and coordinate their efforts in real time. All your users can use the full breadth of spontaneous collaboration, scheduled meetings, and meeting tools. Voice and video conferencing capabilities can be used from any location with an Internet connection, and users away from a computer can participate in audio conferences by dialing in with a public switched telephone network (PSTN) phone.

Meeting tools integrated into Outlook enable organizers to schedule a meeting or start an impromptu conference with a single click, and also make it just as easy for attendees to join. A web client extends rich conference features to participants who are not running the desktop version of Lync.

Audio and Video Conferencing

Lync Server provides a user experience that is familiar to users of traditional audio bridge services including PSTN dial-in services with touch-tone call control commands. At the same time, it incorporates powerful scheduling, joining, and management features available only with an integrated unified communications platform.

With a single click, users can schedule a meeting from Outlook. Details, such as meeting time, location, and attendees, follow the familiar Outlook template. Additionally, conference call-specific information, such as dial-in number, meeting IDs, and personal identification number (PIN) reminders, are automatically populated.

To help ensure that only the authorized people participate in a call, Lync Server provides multiple levels of authentication for participants. Users who join by using Lync are already authenticated by the Active Directory Domain Services and do not need to enter a PIN, pass code, or meeting ID.

Lync simplifies the video conferencing user experience by incorporating video into the unified client so that scheduling a meeting with video or escalating to video spontaneously is seamless and easy.

Lync Server makes it easy to add video to a standard phone call in just one click. When there are multiple participants in a video call or a conference, each user can see video from up to five other users simultaneously, or a presenter can choose just one video source to be seen exclusively by everyone.

High-definition video (resolution 1270 x 720; aspect ratio 16:9) and VGA video (resolution 640 x 480; aspect ratio 4:3) are supported for peer-to-peer calls between users running Lync on high-end computers. The resolution viewed by each participant in a single conversation may differ, depending on the video capabilities of each user’s respective hardware.

IT administrators can set policies to restrict or disable high-definition or VGA video on clients, depending on computer capability, network bandwidth, and the presence of a camera able to deliver the required resolution. These policies are enforced through in-band provisioning.

Web conferencing

Lync Server integrates conferencing sharing features such as desktop, application, attachment, whiteboard, poll and PowerPoint into the streamlined Lync. Combined with audio or video conferencing, the result is a highly immersive and collaborative session that is simple to facilitate.

To improve the overall experience of users presenting or viewing PowerPoint presentations, Lync Server 2013 employs Office Web Apps to handle PowerPoint presentations. Users can share a picture or copy and paste text using a Whiteboard in the Lync meeting. Presenters can conduct polls in the Lync meeting to solicit feedback from the attendees.

Desktop sharing enables presenters to broadcast any visuals, applications, webpages, documents, software, or part of their desktops to remote participants in real time, right from Lync. Audience members can follow along with mouse movements and keyboard input. Presenters can choose to share the entire screen or only a portion. By sharing their desktops, presenters are able to engage with their audiences in interactive product or software demos from any location.

Application sharing enables presenters to share control of software on their desktops without losing sight of participant feedback or text questions. Presenters can also delegate control of the application to meeting participants.

Dial-in Conferencing

For users that are not using a personal computer, there are several methods available for joining a Lync Server conference call. A PSTN user can dial an access number, access the meeting bridge, and then enter the meeting ID. For more secure meetings, the user can also be required to enter his or her PIN to authenticate against Active Directory. Lync Server also supports Lync Phone Edition devices, which are stand-alone IP phone devices provided by Microsoft partners.

1.1.1.3 Enterprise Voice

Enterprise Voice

Microsoft Lync Server 2013 > Getting Started > Introduction to Lync Server 2013 >

Topic Last Modified: *2013-02-11*

With Enterprise Voice, Lync Server delivers a stand-alone Voice over Internet Protocol (VoIP) offering to enhance or replace traditional private branch exchange (PBX) systems. Enterprise Voice users can call colleagues on your organization’s VoIP network or PBX, and they can call traditional phone numbers outside your organization. The Enterprise Voice solution includes common calling features such as answer, forward, transfer, hold, divert, release and park, and Enhanced 9-1-1 (E9-1-1) calling (E9-1-1 is available only in the United States.) Enterprise Voice also supports a broad range of current and older IP and USB devices.

Placing and Receiving Calls

Using Lync, users can place calls by typing a name or phone number on their keyboard, or using a dial pad displayed on their screen. Users can also initiate calls directly from their Contacts list. You can also deploy Lync Phone Edition devices, which are stand-alone IP phone devices provided by Microsoft partners.

Users can have multiple phone devices registered with Lync Server, and can switch between them easily.

Users are alerted to incoming calls on all their devices simultaneously, with customizable ringtones on IP phone devices and a notification similar to an instant message on their PC.

Users can also set a single telephone number that connects to their desk phone, PC and mobile phone, so they can be reached no matter where they are.

Basic Call Features

While on a call, a user can answer additional incoming calls or initiate outgoing calls, and the existing active call is automatically put on hold. Calls can be transferred from one user to another, either directly or after the first user speaks privately with the second user. Users can also transfer calls to another device; for example, they could transfer an active call to their mobile phone as they walk out the door of their office.

Richer Communications

When talking to another user with Lync, users can easily add text, video, or desktop sharing to the call. The Do-Not-Disturb feature is integrated with the presence settings in Lync.

With Exchange Unified Messaging (UM), Lync and Lync Server integrate with Exchange 2010 and Outlook 2010. Users can see if they have new voice mail both in their Lync window and in email. While in email they can click to play the voice mail audio in an email message, or view a transcript of the voice mail message.

Advanced Calling Features

Enterprise Voice includes several advanced calling features as well, such as delegation, team calling, Group Call Pickup, and Response Groups.

Delegation enables users to delegate call handling to one or more assistants. The delegate can perform multiple calling tasks on behalf of the user, including screening calls, placing calls, and initiating conferences.

Team calling enables a user to have incoming calls simultaneously ring the phones of teammates so that anyone on the team can answer the call.

Group Call Pickup, a new feature in Cumulative Updates for Lync Server 2013: February 2013, lets users answer incoming calls to their colleagues from their own phones. Group Call Pickup differs from team calling primarily in that an incoming call rings only at the intended recipient's phone, but any other user can choose to answer it by dialing a call pickup group number.

Response Groups can be set up for queuing and intelligently routing calls to designated agents. Common uses include IT helpdesks, human resources hotlines, and other internal contact centers.

Enterprise Voice Administration

Lync Server uses standards and published interfaces to interoperate with existing infrastructure. It supports both gateway and SIP options (such as SIP trunking) for interconnection to IP PBX systems and the PSTN networks, so that you can migrate users to Enterprise Voice over time, while minimizing disruption. Lync Server supports traditional codecs such as G.711, G.722, and G.723.1 for interoperability with traditional VoIP solutions.

With call admission control (CAC), administrators can set limits on the amount of Lync Server voice and video traffic carried on constrained network links, and specify the action to be taken if a new call would exceed the limit. The actions could include routing by an alternate path, or refusing the call.

Lync Server works with third-party Survivable Branch Appliances to provide local calling services and connection to PSTN at branch offices, in case of WAN failure at the central site.

1.1.1.4 Scalability

Scalability

Microsoft Lync Server 2013 > Getting Started > Introduction to Lync Server 2013 >

Topic Last Modified: *2012-06-25*

Lync Server is offered in two editions, Enterprise Edition and Standard Edition. The different editions are intended primarily for different sizes of organizations. As shown in the following table, both editions support all functionality in all workloads, except for high availability and disaster recovery.

Feature	**Supported in Enterprise Edition?**	**Supported in Standard Edition?**
Instant messaging (IM) and presence	Yes	Yes
Conferencing	Yes	Yes
A/V conferencing	Yes	Yes
Dial-in conferencing	Yes	Yes
Enterprise Voice	Yes	Yes
Virtualization	Yes	Yes
High availability, failover, and disaster recovery	Yes	No

1.1.2 New Server Features

New Server Features

Microsoft Lync Server 2013 > Getting Started >

Topic Last Modified: *2012-10-04*

Lync Server 2013 introduces many new features, along with significant enhancements to existing functionality. This section provides a high-level introduction to these new features and enhancements.

Discussions of new features in Lync Server 2013 are grouped among the topics in this section.

- New Management and Administration Features
- Topology Changes
- New Disaster Recovery and High Availability Features
- New Virtualization Features
- New IM and Presence Features
- New Conferencing Features
- New Features for External User Access
- New Enterprise Voice Features
- New Monitoring Features
- New Archiving Features
- New Exchange Server Integration Features
- New Persistent Chat Server Features
- New IPv6 Features
- New Unified Contact Store Feature
- New Video Features

1.1.2.1 New Management and Administration Features

New Management and Administration Features

Microsoft Lync Server 2013 > Getting Started > New Server Features >

Topic Last Modified: *2012-09-26*

Lync Server 2013 includes the following new features to simplify the task of managing your deployment.

- Topology Builder Supports SQL Server Mirroring
- New Role Based Access Control (RBAC) Features
- Integration of Persistent Chat Management Tools

1.1.2.1.1 Topology Builder Supports SQL Server Mirroring

Topology Builder Supports SQL Server Mirroring

Getting Started > New Server Features > New Management and Administration Features >

Topic Last Modified: *2012-09-26*

Lync Server 2013 supports mirroring of your Back End Servers for high availability. You can use Topology Builder to set up mirroring, including setting up a witness.

1.1.2.1.2 New Role Based Access Control (RBAC) Features

New Role Based Access Control (RBAC) Features

See Also

Getting Started > New Server Features > New Management and Administration Features >

Topic Last Modified: *2012-09-20*

Lync Server 2013 enhances the role-based access control (RBAC) feature in two major ways. You can now create custom roles, which each have privileges for only a set of cmdlets you specify. These custom roles can also be given privilege to run scripts of cmdlets.

Additionally, Lync Server 2013 includes two new predefined roles.

- Users given the *Response Group Manager* role can manage specific Response Group queues in your organization, but not necessarily have management rights for other queues or the Response Group application as a whole.
- Users given the *Persistent Chat Manager* role can manage specific Persistent Chat rooms in your organization, but not necessarily have management rights for other rooms or the Persistent Chat feature as a whole.

Concepts

Planning for Role-Based Access Control

1.1.2.1.3 Integration of Persistent Chat Management Tools

Integration of Persistent Chat Management Tools

See Also

Getting Started > New Server Features > New Management and Administration Features >

Topic Last Modified: *2012-08-16*

Lync Server 2013 simplifies the administration of Persistent Chat Server by integrating its administration tools with the tools used for the rest of Lync Server.

Persistent Chat Server includes an administrative user interface experience integrated with the Lync Server Control Panel. Also, Persistent Chat Server includes a collection of Windows PowerShell cmdlets to administer and manage Persistent Chat Server categories, rooms (including deleting rooms and purging obsolete content), and add-ins.

Concepts

Overview of Persistent Chat Server

Other Resources

Managing Lync Server 2013, Persistent Chat Server

1.1.2.2 Topology Changes

Topology Changes

Microsoft Lync Server 2013 > Getting Started > New Server Features >

Topic Last Modified: *2012-10-02*

Topology requirements and considerations for Lync Server 2013 are different from those for earlier releases, as described in this section.

New Front End Pools Architecture

In Lync Server 2013, the architecture of Enterprise Edition Front End pools has changed to a distributed systems architecture.

With this new architecture, the Back End database is no longer the real-time data store in a pool. Information about a particular user is kept on three Front End Servers in the pool. For each user, one Front End Server acts as the master for that user's information, and two other Front End Servers serve as replicas. If a Front End Server goes down, another Front End Server which served as a replica is automatically promoted to master.

This happens behind the scenes, and administrators do not need to know which Front End Servers are the masters for which users. This distribution of data storage improves performance and scalability within the pool, and eliminates the single point of failure of a single Back End Server.

The Back End Server serves as backup storage for user and conference data, and is also the primary storage for other databases such as the Response Group database.

These improvements also mean there are changes in how you plan and maintain your pools. We recommend that all your Enterprise Edition Front End pools include at least three Front End Servers, to provide the full number of replicas that the Front End pool architecture is designed for. Additionally, you must follow certain procedures when adding servers to a Front End pool, removing servers from it, or upgrading servers. For more information, see Topologies and Components for Front End Servers, Instant Messaging, and Presence.

Server Role Topology Changes

Some server roles that previously ran on separate servers are now consolidated into the Front End Server role, enabling you to save on hardware costs

- In Lync Server 2013, A/V Conferencing Server is always collocated with Front End Server.
- The front ends for both Monitoring and Archiving are now always collocated with Front End Server. Monitoring and Archiving each still require a separate Back-End Database, which can be collocated on the same server as the Front End Pool's back-end database, or can be hosted on separate Back-End Servers.
- Persistent Chat Server is now a server role. In Microsoft Lync Server 2010, Group Chat Server was a third-party trusted application for Microsoft Lync Server 2010. In Lync Server 2013, Persistent Chat Server functionality is implemented using three new server roles:
  - **PersistentChatService:** Main Persistent Chat Server services implemented as a front end role
  - **PersistentChatStore:** Back End Server role
  - **PersistentChatComplianceStore:** Back End Server role for Persistent Chat Compliance

1.1.2.3 New Disaster Recovery and High Availability Features

New Disaster Recovery and High Availability Features

See Also

Microsoft Lync Server 2013 > Getting Started > New Server Features >

Topic Last Modified: *2012-09-20*

As in Lync Server 2010, the main high availability (HA) scheme for Lync Server 2013 is based on server redundancy via pooling. If a server running a certain server role fails, the other servers in the pool running the same role take the load of that server. This applies to Front End Servers, Edge Servers, Mediation Servers, and Directors.

Lync Server 2013 adds new disaster recovery measures by enabling you to pair Front End pools located in two datacenters. If one of the paired pools goes down, an administrator can fail over the users from that pool to the other pool in the pair, to provide continuation of service. This functionality does not require expensive network or hardware solutions such as storage networks or shared disks.

Lync Server 2013 also adds Back End Server high availability. This is an optional topology in which you deploy two Back End Servers for a Front End pool, and set up synchronous SQL mirroring for all the Lync databases running on the Back End Servers. You may choose whether to deploy a witness for the mirror.

Concepts

Planning for High Availability and Disaster Recovery

1.1.2.4 New Virtualization Features

New Virtualization Features

Microsoft Lync Server 2013 > Getting Started > New Server Features >

Topic Last Modified: *2012-09-20*

Lync Server 2013 supports virtualization on both Windows Server 2012 and Windows Server 2008 R2. Support on Windows Server 2012 includes support for the Single Root I/O Virtualization (SR-IOV) capabilities. With SR-IOV, the virtual function of a physical network adapter is assigned directly to a virtual machine. This increases network throughput and reduces network latency while also reducing the host CPU overhead that is required for processing network traffic. To take advantage of SR-IOV, you must use a host server which has BIOS which supports SR-IOV, as well as use network adapters that support SR-IOV.

1.1.2.5 New IM and Presence Features

New IM and Presence Features

Microsoft Lync Server 2013 > Getting Started > New Server Features >

Topic Last Modified: *2012-10-19*

Microsoft Lync Server 2013 adds the following new instant messaging (IM) and presence features to enrich your users' Lync experience.

- If your organization also runs Exchange 2013, users can take advantage of a unified contact store. Users can manage their contacts in Outlook 2013, Outlook Web App, as well as in Lync 2013.
- Your users can exchange instant messages and presence information with users of public IM providers that use Extensible Messaging and Presence Protocol, such as Google Talk, because of the **XMPP integration** feature of Lync Server 2013. XMPP integration built into Front End Servers and Edge Servers, and you can enable it and configure it to allow this feature.

Tasks

Enable Users for Unified Contact Store

Other Resources

Planning for Extensible Messaging and Presence Protocol (XMPP) Federation

1.1.2.6 New Conferencing Features

New Conferencing Features

See Also

Microsoft Lync Server 2013 > Getting Started > New Server Features >

Topic Last Modified: *2012-11-08*

Lync Server 2013 introduces several new features that enhance conferencing, as described in the following list.

- **Join Launcher**
  Lync Server 2013 updates the Join launcher to validate each meeting before launching a client, and to provide support for opening a meeting in the following clients:
  - Windows Phone 7
  - Android devices
  - Apple iOS devices
  - Windows 8
  - Internet Explorer 10
- **Updated PowerPoint Sharing**
  Lync Server 2013 now uses Office Web Apps and the Office Web Apps Server (formerly known as WAC Server) to handle PowerPoint presentations. The use of Office Web Apps Server allows for higher-resolution displays and better support for PowerPoint capabilities, access to more types of mobile devices (Lync Server 2013 uses standard DHTML and JavaScript to broadcast PowerPoint presentations), and the ability for users with the appropriate privileges to scroll through a PowerPoint presentation independent of the presentation itself.
- **Gallery View and HD Video Conferencing**
  In video conferences, users can see videos of up to five conference participants at the same time.

  > **Note:**
  > Gallery View is experienced in conferences with up to 75 participants. When the conference gets larger than 75 participants, the experience reverts to single view.
- **HD Video**
  Users can experience resolutions up to HD 1080P in two-party calls and multiparty conferences.
- **Presenter Only Video Mode**
  Presenters can configure the conference so that only the video from the presenter is shown. This mode prevents distractions in large conferences when multiple video streams are available and locking to different sources. This mode also applies to video captured and provided by conferencing devices.
- **Video Spotlight**
  Presenters can configure the conference so that only the video from a selected participant who is a video source is seen by everyone in the conference. This mode also applies to video captured and provided by conferencing devices for panoramic video.
- **Dial-out Conferencing for non-Enterprise Voice users**
  Lync Server 2013 now allows participants that are not Enterprise Voice enabled to initiate dial-out calls from a meeting conference. This feature is configurable by the administrator.
- **Archiving**
  Any document that is shared during a conference is archived into Exchange 2013 data storage if Exchange Server integration is enabled with Archiving. This includes PowerPoint presentations, attachments, whiteboards and polls.

- **Meeting Invite Customization**
  Administrators can customize email invitations for online meetings using Lync Server Control Panel or Lync Server Management Shell. Customizations can include URLs for logos, help text, legal text, and footer text. All subsequent invitations will include the customizations.

1.1.2.7 New Features for External User Access

New Features for External User Access

See Also

Microsoft Lync Server 2013 > Getting Started > New Server Features >

Topic Last Modified: *2012-10-17*

Lync Server 2013 introduces new features that extend the features and communications methods for your users. Also, Lync Server 2013 introduces changes to existing services to better integrate and extend the services that are available to your organization. Following is a summary of changes that may affect your planning and deployment of Lync Server 2013 Edge Server services.

- **Support for IPv6 addressing** Lync Server 2013 supports IPv6 addressing for all Edge Server services. If you have provided IPv6 addresses for the interfaces through configuration in Windows Server, you can use IPv6 addresses in your Edge Server configuration through the IP address configuration in Topology Builder.

Important:
Use of IPv6 addresses in Lync Server 2013 depends on support of IPv6 in routers and firewalls that your organization deploys, as well as support through your Internet service provider.

- **Extensible Messaging and Presence Protocol (XMPP)** Lync Server 2013 introduces a fully integrated XMPP proxy (deployed on the Edge Servers) and an XMPP gateway deployed on your Front End Servers. You can deploy XMPP federation as an optional component. Adding and configuring the XMPP proxy and XMPP gateway will allow your Microsoft Lync 2013 users to add contacts from XMPP-based partners for instant messaging (IM) and presence.

Note:
Currently, the XMPP services in Lync Server 2013 only provide instant messaging and presence between Lync clients and XMPP-based contacts.

- **Mobility services for Mobile clients** Introduced in a customer update for Lync Server 2010, Mobility services in Lync Server 2013 allow Microsoft Lync Mobile clients on mobile phones and tablet devices using supported Apple iOS, Android, Windows Phone, or Nokia mobile devices to perform such activities as sending and receiving instant messages, viewing contacts, and viewing presence. In addition, mobile devices support some Enterprise Voice features, such as click to join a conference, Call via Work, single number reach, voice mail, and missed call notification.

Note:
The mobility services use the reverse proxy and published services that are deployed on your Front End Servers. No changes are required to Edge Servers.

- **Directors are an optional role** The role of the Director server in the Lync Server 2013 topology has not changed. It still hosts web services, preauthenticates incoming user requests, and directs external users to their home pool. Changing the Director from a recommended role to an optional role does not diminish the value of the Director, but emphasizes reducing server count and other hardware requirements (for example, hardware load balancers for the Director) requirements without compromising features and functionality. Because the Front End Servers can do the same job as the Director with no impact to services provided, you can optionally deploy Directors if you choose to. You can safely exclude the Director with confidence that the Front End Servers will provide the same services in their place.

1.1.2.8 New Enterprise Voice Features

New Enterprise Voice Features

Microsoft Lync Server 2013 > Getting Started > New Server Features >

Topic Last Modified: *2013-02-22*

Lync Server 2013 introduces several new routing and call management features that enhance Enterprise Voice.

Lync Server 2013 supports multiple trunks between Mediation Servers and gateways. A *trunk* is a logical association between a port number and Mediation Server with a port number and gateway. This means that a Mediation Server can have multiple trunks to different gateways, and a gateway can have multiple trunks to different Mediation Servers. Intertrunk routing makes it possible for Lync Server 2013 to interconnect an IP-PBX to a public switched telephone network (PSTN) gateway or to interconnect multiple IP-PBX systems. Lync Server 2013 serves as the glue (that is, the interconnection) between different telephony systems.

Microsoft Lync Server 2013 makes improvements in the areas of call forwarding, simultaneous ringing, voice mail handling, and caller ID presentation. These features enrich the Enterprise Voice call experience.

Lync Server 2013 introduces the following new enhancements to Enterprise Voice:

- New Call Features
- New Caller ID Feature
- New Voice Mail Feature
- New Trunk Feature
- New Intertrunk Feature
- New Call Management Features
- New Hybrid Voice Features

1.1.2.8.1 New Call Features

New Call Features

See Also

Getting Started > New Server Features > New Enterprise Voice Features >

Topic Last Modified: *2012-10-10*

Lync Server 2013 provides a significantly wider range of configuration options for call forwarding and simultaneous ringing. For example, if an organization does not want incoming calls to be forwarded externally to the public switched telephone network (PSTN), an administrator can apply a special voice policy to deploy this restriction.

Additionally, delegates can now set up simultaneous ringing to their mobile devices for incoming calls to their managers. This provides delegates with more flexibility, enabling them to answer calls on behalf of their manager without being tied to a desk phone.

Concepts

New Enterprise Voice Features

1.1.2.8.2 New Caller ID Feature

New Caller ID Feature

See Also

Getting Started > New Server Features > New Enterprise Voice Features >

Topic Last Modified: *2012-10-05*

Lync Server 2013 provides the administrator the flexibility to modify the format of the calling party's phone number. This Caller ID presentation feature enables the administrator to modify the calling party's phone number to a dialing format that is understood by the trunk peer, if necessary. For example, you can write a translation rule to remove +44 from the beginning of a dial string and replace it with 0144.

Now, with Lync Server 2013, both the caller's phone number and the callee's phone number can be translated into different formats, as needed. This flexibility makes it possible for Lync Server 2013 to serve as a trunk translator between different telephony systems.

Concepts

New Enterprise Voice Features

1.1.2.8.3 New Voice Mail Feature

New Voice Mail Feature

See Also

Getting Started > New Server Features > New Enterprise Voice Features >

Topic Last Modified: *2012-10-05*

Lync Server 2013 introduces Voice mail Escape, an enhancement for managing voice mail. This new feature can detect when a call has been routed to voice mail, and prevent the call from being immediately routed to the user's mobile phone voice mail without giving the user the opportunity to answer the call. This scenario occurs when the user enables simultaneous ringing to their mobile phone, and their mobile phone is turned off, out of battery, or out of range. Voicemail Escape detects that the call was immediately answered by the user's mobile phone voice mail, and disconnects the call to the mobile phone voice mail. The call continues to ring on the user's other endpoints giving the user the opportunity to answer the call. If the user does not answer the call, then the call is routed to the corporate voice mail.

Configuring Voice Mail Escape

Concepts

New Enterprise Voice Features

1.1.2.8.4 New Trunk Feature

New Trunk Feature

See Also

Getting Started > New Server Features > New Enterprise Voice Features >

Topic Last Modified: *2012-09-21*

In Microsoft Lync Server 2013, multiple trunks between a Mediation Server and a gateway can be defined. Microsoft Lync Server 2010 only allowed for a single trunk between a Mediation Server and a PSTN gateway. This feature provides the flexibility to define additional trunks. A trunk is a logical association between a Mediation Server FQDN and listening port and a PSTN gateway FQDN and listening port. This new capability allows for easy trunk definition for resiliency (where multiple Mediation Servers can be used to route calls to the same PSTN Gateway), for PBX interoperability, where multiple trunks with different associated policies can be used between and IP-PBX and a Mediation Server, and for SIP trunk configurations where Mediation Servers at different sites have SIP trunks to the carrier referenced by the same carrier FQDN.

Concepts

New Enterprise Voice Features

1.1.2.8.5 New Intertrunk Feature

New Intertrunk Feature

See Also

Getting Started > New Server Features > New Enterprise Voice Features >

Topic Last Modified: *2012-10-08*

Lync Server 2013 provides basic session management through the support of intertrunk routing. This new capability enables Lync Server to provide call control functionalities to downstream telephony systems. With intertrunk routing, Lync Server can interconnect an IP-PBX to a public switched telephone network (PSTN) gateway so that calls from a private branch exchange (PBX) phone can be routed to the PSTN, and incoming PSTN calls can be routed to a PBX phone. Similarly, Lync Server can interconnect two or more IP-PBX systems so that calls can be placed and received between PBX phones from the different IP-PBX systems.

Concepts

Inter-Trunk Routing
New Enterprise Voice Features

1.1.2.8.6 New Call Management Features

New Call Management Features

See Also

Getting Started > New Server Features > New Enterprise Voice Features >

Topic Last Modified: *2012-12-18*

The following sections describe the changes in call management features in Lync Server 2013.

- New Response Group Application Features
- New Call Park Application Features
- New Group Call Pickup Feature

Concepts

New Enterprise Voice Features

1.1.2.8.6.1 New Response Group Application Features

New Response Group Application Features

See Also

New Server Features > New Enterprise Voice Features > New Call Management Features >

Topic Last Modified: *2012-10-29*

With the Response Group application, you can route and queue incoming calls to designated persons for special purposes, such as customer service, an internal help desk, or general telephone support for a department.

The following Response Group application features are new in Lync Server 2013:

- **Manager role**
  Lync Server 2013 introduces a new Response Group Manager role. Now there are two management roles for response groups: Response Group Manager and Response Group Administrator. While Response Group Administrators can still configure any element for any response group, Managers can configure only certain elements, only for response groups they own.
  This improvement in the administration model benefits Response Group scalability, especially for large deployment scenarios.
- **High availability**
  High availability support for the Response Group application, in the form of SQL Server mirroring, is enabled as part of the overall configuration and deployment of high availability for Lync Server 2013. If you configure for high availability and lose connectivity to the primary back-end server, Response Group functionality is not affected by leveraging the mirrored back-end server. Support for SQL Server mirroring for the Response Group application can’t be individually enabled or configured outside of the overall Lync Server 2013 high availability configuration.
- **Disaster recovery**
  Disaster recovery support for the Response Group application is enabled as part of the configuration and deployment of the paired Front End pools, which are part of the overall Lync Server 2013 disaster recovery configuration. In addition, Response Group import and export cmdlets support the failover process to the backup pool and the failback process to the primary pool or to a new pool. If an outage occurs in the primary pool, response groups can be failed over to the backup pool, and then failed back to the primary pool or to a new pool when the outage is over.

Other Resources

Planning for Response Groups

1.1.2.8.6.2 New Call Park Application Features

New Call Park Application Features

See Also

New Server Features > New Enterprise Voice Features > New Call Management Features >

Topic Last Modified: *2012-10-17*

The Call Park application makes it possible for Enterprise Voice users to put a call on hold and then retrieve it later from any phone. The user who parked the call can either dial the orbit number provided by Call Park to retrieve the parked call or use an external mechanism, such as instant messaging (IM) or a paging system, to ask someone else to retrieve the call.

Lync Server 2013 provides new disaster recovery mechanisms in the form of failover and failback processes. These failover and failback processes support recovery of Call Park functionality by allowing users who are homed in the primary pool to leverage the Call Park application of the backup pool when an outage occurs in the primary pool. Support for disaster recovery of the Call Park application is enabled as part of the configuration and deployment of paired Front End pools.

Planning for Call Park

1.1.2.8.6.3 New Group Call Pickup Feature

New Group Call Pickup Feature

See Also

New Server Features > New Enterprise Voice Features > New Call Management Features >

Topic Last Modified: *2013-02-12*

Cumulative Updates for Lync Server 2013: February 2013 introduces Group Call Pickup as a new Enterprise Voice feature. With Group Call Pickup, you can assign users to groups so that other users can answer incoming calls to users who are in the group from their own phones.

Group Call Pickup is based on the Call Park application. For Group Call Pickup, as with Call Park, you set up a range of virtual numbers to be used as group numbers. A user dials the group number to pick up a call that is ringing for another user who is in the group.

Other Resources

Planning for Group Call Pickup

1.1.2.8.7 New Hybrid Voice Features

New Hybrid Voice Features

See Also

Getting Started > New Server Features > New Enterprise Voice Features >

Topic Last Modified: *2012-10-22*

Hybrid voice enables customers to leverage the on-premises Enterprise Voice environment for Lync Online users as if they were on-premises Enterprise Voice users. The primary feature of a hybrid voice environment is that Lync Online users can place and receive calls from the on-premises gateway. Other important features are:

- Media bypass
- E9-1-1

These features require the tenant administrator to configure on-premises Lync settings onto Office 365.

Media bypass

Media bypass works the same way for Lync Online users as it does for on-premises users. Lync Online PSTN calls are bypassed whenever possible. This is so that the media traffic does not traverse the Lync Online data centers wherever possible.

E9-1-1

Enhanced 9-1-1 works the same way for Lync Online users as it does for on-premises users. The location information and policy of Lync Online users are automatically retrieved and transmitted during an emergency call.

1.1.2.9 New Monitoring Features

New Monitoring Features

Microsoft Lync Server 2013 > Getting Started > New Server Features >

Topic Last Modified: *2012-11-08*

Lync Server 2013 does not have a separate Monitoring Server role. Monitoring is an optional feature available on all Front End Servers in an Enterprise Edition deployment, and on Standard Edition servers, that can be implemented and configured for a pool or a site. New to Lync Server 2013, you can enable SQL Server database mirroring for your Monitoring database.

1.1.2.10 New Archiving Features

New Archiving Features

See Also

Microsoft Lync Server 2013 > Getting Started > New Server Features >

Topic Last Modified: *2012-10-09*

Archiving in Lync Server 2013 can archive the following types of content:

- Peer-to-peer instant messages
- Conferences (meetings) that are multi-party instant messages
- Conference content, including uploaded content (for example, handouts) and event-related content (for example, joining, leaving, uploading sharing, and changes in visibility)

Additionally, Archiving in Lync Server 2013 provides new features that improve deployment and operations efficiency. These new features consist of:

- **Collocation of Archiving on Front End Servers.** Lync Server 2013 does not have a separate Archiving Server role. Archiving is an optional feature available on all Front End Servers in an Enterprise Edition deployment, and on Standard Edition servers, that can be implemented configured for a pool or a site.
- **Microsoft Exchange integration.** When you deploy Archiving, you can integrate data storage for Archiving with your existing Exchange 2013 storage for all users who are homed on Exchange 2013 and have their mailboxes put on In-Place Hold, so you don’t need to deploy separate SQL Server databases to archive Lync data. If you do not have an Exchange 2013 deployment, or if

you prefer not to integrate with it, or if you have any Lync 2013 users who are not homed on Exchange 2013 with their mailboxes put on In-Place Hold, you can deploy separate Archiving databases by using SQL Server to store archived data from Lync communications. You can use both Microsoft Exchange integration and Lync Server 2013 Archiving databases if you want to use Microsoft Exchange integration for some but not all users in your deployment. For details about In-Place Hold, see "In-Place Hold" at http://go.microsoft.com/fwlink/p/?LinkId=267500.

- **SQL Store Mirroring.** When you deploy Archiving, you can enable SQL Server database mirroring for your Archiving database.
- **Archiving of Whiteboards and Polls.** Archived conference content now includes whiteboards and polls that are shared during the meeting.

The following types of content are not archived:

- Peer-to-peer file transfers
- Audio/video for peer-to-peer instant messages and conferences
- Application sharing for peer-to-peer instant messages and conferences

1.1.2.11 New Exchange Server Integration Features

New Exchange Server Integration Features

See Also

Microsoft Lync Server 2013 > Getting Started > New Server Features >

Topic Last Modified: *2012-09-24*

Lync Server 2013 supports new features when it is deployed alongside Microsoft Exchange Server 2013, as described in the following list. For each of these features to work, both Lync Server 2013 and Exchange 2013 must be deployed.

- You can use a **unified contact store**, in which the Lync contact list is stored in Exchange 2013, and you can manage the contact store in Lync 2013, Outlook 2013, and Outlook Web App.
- You can use **high-resolution photos** for contacts. Photos with up to 648x648 pixels are stored in Exchange 2013 and made available to clients including Lync 2013, Outlook 2013, Microsoft Lync Web App, and Outlook Web App.
- You can enable **Lync Archiving integration**, which integrates Lync Server 2013 Archiving into the Exchange 2013 In-Place Hold feature, for users homed on Exchange 2013, which enables one common experience for administrators around compliance and eDiscovery.

Concepts

Planning and Deploying Unified Contact Store
How Archiving Works

1.1.2.12 New Persistent Chat Server Features

New Persistent Chat Server Features

See Also

Microsoft Lync Server 2013 > Getting Started > New Server Features >

Topic Last Modified: *2012-10-29*

Lync Server 2013, Persistent Chat Server enables you to participate in multiparty, topic-based conversations that persist over time. Persistent Chat Server can help your organization do the following:

- Improve communication between geographically dispersed and cross-functional teams
- Broaden information awareness and participation
- Improve communication with your extended organization
- Reduce information overload
- Improve information awareness
- Increase dispersion of important knowledge and information

Lync Server 2013, Persistent Chat Server is not available in Microsoft Office 365. At this time, it is available only to on-premise Lync 2013 customers.

In Lync 2013, Persistent Chat functionality is integrated into the Lync 2013 client. As a result, users have access to Instant Messaging/Presence, Audio/Video, Conferencing, and Persistent Chat all in the Lync 2013 client. For more information about the Lync 2013 client, see http://go.microsoft.com/fwlink/p/?linkid=270877.

This topic describes feature changes between the new version of Lync Server 2013, Persistent Chat Server and the previous version (Microsoft Lync Server 2010, Group Chat), including:

- Provide an administrative experience in Lync Server Control Panel, and eliminate the Group Chat Admin Tool
- Integrate configuration settings for Persistent Chat Server into Topology Builder by eliminating the Group Chat Configuration tool
- Ease migration and upgrade from previous versions of Persistent Chat Server
- Provide high availability and disaster recovery solutions

For additional details about the latest version of Persistent Chat Server, see the following:

- The Persistent Chat Help at http://go.microsoft.com/fwlink/p/?linkid=270945 which provides a detailed list of Persistent Chat features, how they work, and how to use them while running Persistent Chat Server.
- The Planning for Persistent Chat Server in the Planning documentation, Deploying Persistent Chat Server in the Deployment documentation, Migration from Lync Server 2010, Group Chat or Office Communications Server 2007 R2 Group Chat to Lync Server 2013, Persistent Chat Server in the Migration documentation, and Managing Lync Server 2013, Persistent Chat Server in the Operations documentation, all of which provide instructions for setting up Persistent Chat Server.
- The Persistent Chat Server Documentation.msi file (Windows Installer file) lets users access comprehensive offline documentation about Persistent Chat Server.

Key Topology Changes for Persistent Chat Server

The following high-level changes for Persistent Chat Server include:

Persistent Chat Server is now a server role. In Microsoft Lync Server 2010, Group Chat Server was a third-party trusted application for Microsoft Lync Server 2010. Persistent Chat can be added to your Lync Server 2013 topology by using Topology Builder. In Lync Server 2013, Persistent Chat Server functionality is implemented by using three new server roles:

- **PersistentChatService:** This is the front end role for Persistent Chat. In Standard Edition deployments, Persistent Chat Server Service Role is collocated on the Standard Edition server deployed by Bootstrapper, like any other Lync Server role. In Enterprise Edition deployments, Persistent Chat Service Role is deployed on stand-alone computers by Bootstrapper, like any other Lync Server role.

- **PersistentChatStore:** Back End Server that corresponds to the Persistent Chat content database, where all the chat content is stored.
- **PersistentChatComplianceStore:** Back End Server role that corresponds to the Persistent Chat Compliance database, where all compliance events are stored.

These Persistent Chat Server roles are optional, and are installed only by customers who want comprehensive Persistent Chat Server functionality. The **PersistentChatComplianceStore** role is needed only if you choose to deploy Persistent Chat Compliance.

The **PersistentChatService** role runs two services:

- Persistent Chat service
- Persistent Chat Compliance service

Having these services run on each Persistent Chat Server provides high availability for these services in a multiserver Persistent Chat Server pool.

Additionally, to support the file upload and download in Persistent Chat rooms, Persistent Chat Server includes a web service. Previously, this service was collocated on the Persistent Chat Server, Front End Server and required Internet Information Services (IIS) to be installed as a prerequisite. In Lync Server 2013 Persistent Chat Server, the File Upload/Download web service is collocated with the Lync Server 2013 Front End Server. As a side effect, Internet Information Services (IIS) is no longer a prerequisite for Persistent Chat Server. The File Upload/Download web service is identified as **PersistentChat** in the Internet Information Services (IIS) Manager.

Important:

The **PersistentChatService** role can run on the same server as a Lync Server 2013 Front End Server only if that Front End Server is a Standard Edition Front End Server. The **PersistentChatService** role cannot run independently of a Lync Server 2013 Front End Server. It can be installed only in the context of a Lync Server 2013 deployment.

In Persistent Chat Server, Lookup service has been eliminated. In Lync Server 2010, Group Chat, the Lookup service ran on every Group Chat Server Front End Server, and performed routing to one of the Channel Servers. Lync Server 2013 relies on routing by using contact objects, where each Persistent Chat Server pool is represented by a contact object that is used by the Lync Server Front End Servers to identify and route requests to an appropriate Persistent Chat Server pool, and to one of the computers running Persistent Chat Server in the pool.

In Lync Server 2013, there are Compliance service modifications:

- In Lync Server 2010, the Compliance service ran stand-alone (non-collocated), and only on a single server. The Compliance service now runs on all the Persistent Chat Server Front End Servers, alongside the Persistent Chat service, and thereby provides high availability in a multiserver Persistent Chat Server pool. A single compliance adapter can be configured to extract data from the compliance database and into one of the other systems (XML file, Exchange-hosted archives, and so on). Persistent Chat Server includes an XML adapter.
- The Message Queuing (also known as MSMQ) queue that is shared by the Persistent Chat service and the Compliance service on each Persistent Chat Server Front End Server is now a private queue shared only by the two services. All compliance services write to the same Compliance Back End database. They also all read from that database, for the purpose of sending the data to their instance of the adapter. The Compliance Back End Server is

represented as a new Back End Server role.

Important:

As in previous versions, all compliance data is processed only once. The data may be processed by any of the adapter instances invoked by the compliance service running on the various Lync Server 2013, Persistent Chat Server computers. In Persistent Chat Server, any one of the adapter instances could process the data.

Note:

For information about installing Message Queuing, see Install Operating Systems and Prerequisite Software on Servers in the Deployment documentation.

In Lync Server 2013, there are improvements in both high availability and disaster recovery:

- High availability improvements: SQL Server mirroring is used to provide high availability for the Persistent Chat Server content database and Persistent Chat compliance database within a data center (in-site).
- Disaster recovery improvements: Persistent Chat Server supports a stretched pool architecture that enables a single Persistent Chat Server pool to be stretched across two sites (that is, a single logical pool in the topology, with servers in the pool physically located across two sites). SQL Server Log Shipping is used for cross-site disaster recovery.

For more information about high availability and disaster recovery, see Configuring Persistent Chat Server for High Availability and Disaster Recovery in the Deployment documentation.

Key Administration and Management Changes for Persistent Chat Server

Lync Server 2013 has made it easier to administer and manage Persistent Chat Server by providing:

- Unified administration and management. Lync Server 2013 makes it easier to manage and administer Persistent Chat Server by using tools that are already familiar to Lync administrators. Persistent Chat Server includes an administrative user interface experience that is integrated with the Lync Server Control Panel, which addresses performance issues with the previous versions of the Group Chat Server user interface. Also, Persistent Chat Server includes a collection of Windows PowerShell cmdlets to administer and manage Persistent Chat Server categories, Persistent Chat Server rooms (including deleting rooms and purging obsolete content), and add-ins.
- Simplified administration model. Lync Server 2013 has changed and simplified the Persistent Chat Server model by addressing the following key customer requirements:
  - Remove the complex nested hierarchies of scopes and categories.
  - Support to define deny lists as well as allowed lists (scopes) for current MindAlign customers who are planning to migrate to Persistent Chat Server.

What’s Different about User Roles from Previous Group Chat Server Versions?

Lync Server 2010, Group Chat had a user administrator role, a chat room administrator role and a Lync Server administrator role that could manage add-ins. Persistent Chat Server simply provides a Persistent Chat Administrator role (which is similar to other Lync

Server role-based access control (RBAC) roles). Anyone who is a member of this RBAC role can manage chat rooms, add-ins, and categories (and therefore gain user access for these categories), and configuration of the Persistent Chat Server pool.

What's Different about Chat Room Categories from Previous Group Chat Server Versions?

Chat room categories can no longer be nested, and the root category can no longer be modified. AllowedMembers/DeniedMembers comprise what a scope used to be in legacy Group Chat Server versions (except that it didn't support specifying a Denied list). Scopes can no longer be overridden, because there are no nested categories. A Persistent Chat Administrator in Lync Server 2013 can create and manage chat room categories. As part of creating and managing chat room categories, a Persistent Chat Administrator can configure principals (Active Directory groups/containers/users) that have access to be members/creators of chat rooms of a particular category. A Persistent Chat Administrator can also add DeniedMembers to a category, and these become explicit exclusions to the allowed list. DeniedMembers override what's in AllowedMembers.

What's Different about Chat Room Properties from Previous Group Chat Server Versions?

A new concept of open chat rooms exists in Lync Server 2013, Persistent Chat Server. All allowed members can join the chat room, without exclusive membership.

The following chat room properties that were included in previous versions of Persistent Chat Server have been eliminated:

- Topic: A Room now only has a Description.
- Create New Member list: In Persistent Chat Server, all chat rooms start with empty membership (and can maximize to a membership equaling the Allowed Members).
- File Upload: Used to be a setting per chat room to control whether file upload/ downloads were allowed. This is now set only the category level and applies to all rooms in that category.
- Chat History: Used to be a setting per chat room to control if Chat History was enabled, but is now set only at the category level and applies to all rooms in that category.
- Invites: A room always inherits the Invites setting for the category; or it can be turned off on the room. A room cannot turn on Invites if the category was previously set to Invites off.

What's Different about Policies from Previous Group Chat Server Versions?

Persistent Chat Server has a new Lync policy enabled with Persistent Chat, per user/pool/ site/global settings. In the Lync 2013 client, the Persistent Chat environment is available only for users who are enabled by policy for Persistent Chat (either directly or through the pool/site/global setting).

Previous versions of Group Chat Server did not have any policies integrated into the Lync

Server policies. On a per user and per category/room basis, by using the **Can Upload Files** per user feature, you could make the user a User administrator, a chat room administrator, or configure the user's ability to upload files. The Persistent Chat Server **File Upload** feature is just per category.

Logging

Logging for Persistent Chat Server and System Center Operations Manager is integrated into the Lync Server 2013 trace logging.

Planning for Persistent Chat Server

1.1.2.13 New IPv6 Features

New IPv6 Features

See Also

Microsoft Lync Server 2013 > Getting Started > New Server Features >

Topic Last Modified: *2012-08-16*

Lync Server 2013 includes support for IPv6 addresses. Due to an increasing number of devices requiring IP addresses, the number of available IPv4 addresses, which are 32-bit addresses, is running out. IPv6 provides a much larger number of available addresses, because it uses 128-bit addresses. Use of IPv6 addresses in your environment depends on support for IPv6 in the devices you use.

Because many existing devices do not yet support IPv6, a complete transition from IPv4 to IPv6 is likely to take several years. Therefore, Lync Server 2013 includes support for network environments with only IPv4 addresses, only IPv6 addresses, and dual-stack (both IPv4 and IPv6) addresses.

Concepts

Planning for and Configuring IPv6

1.1.2.14 New Unified Contact Store Feature

New Unified Contact Store Feature

See Also

Microsoft Lync Server 2013 > Getting Started > New Server Features >

Topic Last Modified: *2012-09-13*

Lync Server 2013 introduces unified contact store. Unified contact store allows users to keep all their contact information in Microsoft Exchange Server 2013. After users' Lync contacts are migrated to Exchange 2013, the users can access and manage their contacts from Lync 2013, Outlook, or Outlook Web App, and their Favorites stay synchronized. For example, if a user adds a contact to Favorites in Outlook, the contact appears in the Favorites group in Lync 2013. Users do not need to be logged in to Lync to manage their contacts from Outlook or Outlook Web App.

Unified contact store is enabled by default. You can enable or disable users for unified contact store globally, by site, by tenant, or by individuals or groups of individuals.

1.1.2.15 New Video Features

New Video Features

See Also

Microsoft Lync Server 2013 > Getting Started > New Server Features >

Topic Last Modified: *2012-08-16*

Lync Server 2013 introduces the following new video features:

- **HD video** Users can experience resolutions up to HD 1080P in two-party calls and multiparty conferences.
- **Gallery View** In video conferences that have more than two people, users can see videos of participants in the conference. If the conference has more than five participants, video of only the most active participants appear in the top row, and a photo appears for the other participants.
- **H.264 video** The H.264 video codec is now the default for encoding video on Lync 2013 clients. H.264 video supports a greater range of resolutions and frame rates, and improves video scalability.

1.1.3 New Client Features

New Client Features

Microsoft Lync Server 2013 > Getting Started >

Topic Last Modified: *2012-06-04*

The following sections describe new features and deployment updates for Lync Server 2013 clients.

- What's New for Clients
- What's New for Devices

1.1.3.1 What's New for Clients

What's New for Clients

See Also

Microsoft Lync Server 2013 > Getting Started > New Client Features >

Topic Last Modified: *2013-02-19*

Microsoft Lync 2013 has a redesigned user interface and important new features. For administrators, the client is now included with the Office setup program, providing a more streamlined approach to deploying Office and customizing clients in your organization.

Note:
For an illustrated view of Lync 2013 user interface updates, see "What's New in Lync 2013" at http://go.microsoft.com/fwlink/?LinkId=273885.

Integration with Office Setup

The Lync 2013 client and the Online Meeting Add-in for Lync 2013—which supports meeting management from within the Outlook messaging and collaboration client—are now both included with the Office 2013 Setup program.

In previous versions of Lync and Office Communicator, you could use Windows Installer properties to customize and control the Office installation. Because Lync 2013 is integrated with Office setup, you can use the following methods to customize Lync 2013 setup:

- Use the Office Customization Tool (OCT)
- Use the Config.xml to perform installation tasks
- Use Setup Command-Line Options

Note:

The Lync 2013 setup program does not uninstall previous versions of Lync or Office Communicator. The Lync 2013 client installs side-by-side with other Lync or Office Communicator clients

For details, see Deploying Lync Clients.

Group Policy Deployment

Because Lync 2013 is now included in Office setup, the method for deploying Lync Group Policy settings has changed. In previous versions of Lync and Office Communicator, you could use the Communicator.adm to define Group Policy settings, whereas in Lync 2013 you can now use the Lync ADMX and ADML administrative templates that are provided along with the Office Group Policy Administrative Templates.

For details, see Group Policy Settings for Lync 2013.

Outlook Scheduling Add-in Updates

The Online Meeting Add-in for Lync 2013 includes meeting invite customization and new meeting options.

- Administrators can customize the organization’s meeting invitations by adding a custom logo, a support URL, a legal disclaimer URL, or custom footer text. For details, see Customizing the Online Meeting Add-in.
- New attendee mute controls allow meeting organizers to schedule conferences that have attendee audio and video muted by default.

Virtual Desktop Infrastructure Plug-in

The Lync 2013 client now supports audio and video in a Virtual Desktop Infrastructure (VDI) environment. A user can connect an audio or video device (for example, a headset or a camera) to the local computer (for example, a thin client or repurposed computer). The user can connect to the virtual machine, sign in to the Lync 2013 client that is running on the virtual machine, and participate in real-time audio and video communication as though the client is running locally. The following features are supported in a virtual desktop environment:

- Device integration for audio and video, including the following:
  - Call controls from the device
  - Presence integration on the device
  - Multiple HID (human interface device) support
- Location and emergency services support.
- Support for all Lync modalities, including IM, audio, video, application sharing, desktop sharing, PowerPoint sharing, whiteboard, and file transfer.
- Audio and video support in person-to-person calls and conference calls.

For information about deploying the VDI plug-in, see Deploying the Lync VDI Plug-in.

Video Enhancements

Several new features significantly enhance the video experience for conference participants.

- Video is enhanced with face detection and smart framing, so that a participant's video moves to help keep them centered in the frame.
- High-definition video is now supported in two-party calls and multiparty conferences. Users can experience resolutions up to HD 1080P.
- Participants can select from different meeting layouts: Gallery View shows all participants' pictures or videos; Speaker View shows the meeting content and only the current speaker's video or picture; Presentation View shows meeting content only; Compact View shows just the meeting controls.
- With the new Gallery feature, participants can see multiple video feeds at the same time. If the conference has more than five participants, video feeds of only the most active participants appear in the top row, and pictures appear for the other participants.
- Participants can use video pinning to select one or more of the available video feeds to be visible at all times.
- Presenters can use the Video Spotlight feature to select one person's video feed so that every participant in the meeting sees that participant only.

Chat Room Integration

Lync 2013 now integrates the features previously provided by Lync 2010 Group Chat. A separate group chat client is no longer required.

- From within Lync 2013, users can search for chat rooms, add chat rooms to their contacts, monitor chat room activity, and read and post messages.
- Users can create topic feeds so that they'll be notified if someone in one of their chat rooms adds a post containing specific keywords.
- With the new **Persistent Chat** options page, users can set notification alerts and sounds that apply when people post messages to their chat rooms.

Lync Web App Updates

Lync Web App is the web-based conferencing client for Lync Server 2013 meetings. In this release, the addition of computer audio and video to Lync Web App provides a complete in-meeting experience for anyone who doesn't have a Lync client installed locally. Meeting participants have access to all collaboration and sharing features and presenter meeting controls.

When a user tries to join a meeting but doesn't have a locally installed client, Lync Web App opens. If you want to allow additional options for joining the meeting, you can configure the Meeting Join page; see Configuring the Meeting Join Page in the Deployment documentation.

Because of the enhancements to Lync Web App, an updated version of Attendee isn't available for Lync Server 2013. Lync Web App is the client of choice for participants outside your organization. No local client installation is required, although audio, video, and sharing features require a plug-in to be installed at first use.

Lync 2013 for Mobile Clients Updates

In addition to enhanced presence, contacts, and IM capabilities, Lync 2013 mobile clients now provide voice and video calling over the Internet and cellular data connections. With a single tap of the meeting link in a calendar item, mobile users can join Lync voice and video meetings. For more information about Lync 2013 mobile clients, see Planning for Mobile Clients.

Lync 2013 User Interface Updates

Accessibility Updates

Lync 2013 incorporates several new accessibility features.

- Lync 2013 supports high DPI resolution, enabling users to scale text and graphics for 125% and 150% dots per inch.
- Lync provides high-contrast support so that the user interface remains fully functional when used with high contrast themes in Windows.
- Lync offers more than 100 keyboard shortcuts so that users can access important functions without a mouse. For example, users can press Alt+C to accept a call, or Alt + I to ignore it, without having to tab or set the focus. Pressing (Alt+Q) ends a call, (Ctrl+N) starts OneNote, and (Alt+T) opens the Tools menu.
- Extensive screen reader support in Lync 2013 ensures that all notifications, incoming requests, and instant messages are read aloud when a screen reader is enabled.

Presence While Sharing

When Lync detects that a user is sharing, Lync automatically assigns the user a Presenting presence status. This status blocks all incoming communications unless the sender is assigned the Workgroup privacy relationship. If the user is using the sharing feature entirely on a secondary monitor, Lync does not assign a Presenting presence status.

Conversation Window Updates

The redesigned Conversation window provides quicker access to important features.

- With the new tabbed conversations feature, users can now keep all their IMs and chat rooms in one Conversation window. The tabs along the left side of the Conversation window let users navigate easily among all active conversations.
- Users can pop out an individual conversation into a separate window, and then resize the window. They can also pop the window back into the main Conversation window.
- Lync 2013 reopens a user’s conversations when the user signs out and signs back in to Lync.
- Users can quickly add IM, video, program sharing, desktop sharing, or web conferencing tools (whiteboard, meeting notes, shared notebooks, and attachments) to any conversation.
- In a meeting where video or content is being shared, users can pop out the meeting video or shared content, and then resize the window.

Lync Main Window Updates

The new streamlined look retains familiar features such as the **What’s happening today?** note field, the status selector, and the **Set Your Location** selector.

- When chat rooms are enabled, users see a new **Chat Rooms** icon on the main Lync page. With the **Chat Rooms** icon, users can quickly access their chat rooms and filters.
- Users can click the view icons to switch to the **Contacts** view, **Chat Rooms** view, **Conversations** view, or **Phone** view.
- If users have been migrated to Exchange 2013, they can upload a high resolution picture.

Contacts View and Contact Card Updates

Lync 2013 gives users different ways to view contacts and groups in their **Contacts** view.

- With the new unified contact store, after users' Lync contacts are migrated to Exchange 2013, the users can access and manage their contacts from Lync 2013, Outlook, or Outlook Web App, and their Favorites stay synchronized. For example, if a user adds a contact to Favorites in Outlook, the contact appears in the Favorites group in Lync 2013.
- If you have added and configured the XMPP proxy and XMPP gateway, users can add contacts from XMPP-based partners for instant messaging and presence.
- A new **Add a Contact That's Not in My Organization** feature gives users an easy way to add people who are external to the organization.
- A new **Favorites** group lets users build a list of people users contact most often for quicker access.
- Users can use the new **Contacts List** options page to choose how users want to sort and display contacts. Users can select an expanded, two-line view that shows contacts' pictures, or a condensed one-line view. Users can also sort contacts alphabetically or by availability.

Conferencing Updates

Lync 2013 offers several enhancements to conferencing features.

- Depending on the type of meeting, users can now mute the audience and allow or block video sharing when scheduling the meeting. These options are available on the **Meeting Options** page and are recommended for large meetings with more than 20 participants.
- Easy to use audio controls in the meeting room allow the user to control audio options, such as mute, unmute, change device, and so on.
- When sharing programs, users can select multiple programs to share if they need to work with more than one program.
- Users can now upload presentations that contain video clips by uploading the PowerPoint file, and pointing the mouse over the slide to display video controls, such as play, pause, and audio controls.
- While in a meeting, users can merge another open conversation into the meeting by using **Merge This Call Into** on the **More Options** (**...**) menu.
- To see the participants' names, users can hover the mouse over the **View Participants** button, or click **Show Participant List** to dock the panel in the meeting.
- Depending on the meeting type, users can select from several different content and participant views.
- Meeting recordings are automatically saved in a format that plays in Windows Media Player (MP4). Users can easily share the file with anyone, or use the **Publish** feature in recording manager to post the recording on a shared location.
- OneNote enables new ways to collaborate in a meeting. During a meeting, users can take notes with OneNote for personal use after the meeting, or use shared notebooks and co-edit with meeting participants in real time. All team members can access the shared notes to contribute information, brainstorm ideas, or use the notebook pages as a virtual whiteboard. People and content shared in the meeting are automatically added to the Notes.
- Users can switch between content types using **Share content and lead meeting activities** at the bottom of the meeting room. Users can also use the **Manage Presentable Content** menu to choose which content they want to share.

1.1.3.2 What's New for Devices

What's New for Devices

See Also

Microsoft Lync Server 2013 > Getting Started > New Client Features >

Topic Last Modified: *2012-06-22*

Lync Server 2013 includes Lync Phone Edition, software that runs on qualified devices and provides traditional and advanced telephony features, integrated security, manageability, and more. Lync Phone Edition works the same way with Lync Server 2013 as it does with Lync Server 2010. For details about the newest features related to devices, see What's New for Devices in the Lync Server 2010 TechNet Library.

1.1.4 Release Notes for Lync Server 2013

Release Notes for Lync Server 2013

Microsoft Lync Server 2013 > Getting Started >

Topic Last Modified: *2013-03-12*

Welcome to the Lync Server 2013 Release Notes. Refer to this file for information regarding known issues about Lync Server 2013.

About this document

This document contains important information that you should know before you deploy and use Lync Server 2013. For details about Lync Server 2013, refer to the Microsoft Lync Server 2013 documentation.

This document contains the following sections:

Lync Server

If Lync Server Storage Service data replication fails, administrators will need to check performance counters for stale Storage Service queue items (3225121)

Issue:

The Lync Server Storage Service uses Windows Fabric for replication. If data is deleted on a primary Front End Server, but the deletion on a secondary Front End Server fails—for example, if there is an unexpected shutdown or error on the Front End Server—data can be left behind and "orphaned." The orphaned data can cause performance to degrade and waste drive space.

Workaround:

To work around this issue, if the events LYSS_DB_SPACE_USED_ERROR (Id=32058) and LYSS_DB_SPACE_USED_CRITICAL (Id=32059) are generated in the event log, administrators should check the performance counter on the Front End Server under **LS:LYSS - Storage Service API** with a name of **LYSS - Current number of Storage Service stale queue items**. If this performance counter has a high value—for example, greater than 50,000—then the administrator should run the CleanuUpStorageServiceData.exe tool in the Lync Server 2013 Resource Kit, which will delete all orphaned data from the pool. For details about the tool, see the Lync Server 2013 Resource Kit documentation.

Whenever the IP Address configuration is changed for a server or pool, Lync Server services need to be restarted (3212447)

Issue:

When the IP Address configuration is changed for a Lync Server 2013 deployment, such as changing from IPv4 to Dual Stack, or from Dual Stack to Ipv6, not all server components pick up the configuration change until the services are restarted.

Workaround:

To work around this issue, restart Lync Server services after changing the IP Address configuration for the deployment. To do so, run the following cmdlets in the Lync Server Management Shell:

```
Stop-CsWindowsService -graceful
```

```
Start-CsWindowsService
```

The dial-in conferencing synthetic transaction cmdlet is no longer available in the Lync Server 2013 Management Pack (3212342)

Issue:

The dial-in conferencing synthetic transaction cmdlet **Test-CsDialInConferencing** is no longer available in the Lync Server 2013 Management Pack.

Workaround:

Use of the Dial-In Conferencing Synthetic Transaction cmdlet **Test-CsDialInConferencing** is supported only internally to an enterprise.

Administrators may continue to use the cmdlet in Lync Server Management Shell for troubleshooting purposes. If required, an enterprise can also develop a private management pack to run the cmdlet internally.

The Centralized Logging Service stops if network traffic is disrupted when log files are being copied to network share (3212464)

Issue:

When the Centralized Logging Service is configured to use a network path (the value of the CacheFileNetworkFolder parameter of the **Get-CsClsConfiguration** cmdlet is a valid UNC path), cached log files are copied to the network share. If there is a disruption in network traffic while the files are being copied, an exception will occur that will cause the centralized logging service to stop.

The service is configured to automatically restart up to three times, so the service will recover from the first three exceptions.

Workaround:

There is no workaround for this issue. To identify the issue, monitor the event log for Event ID 7031 from the "Service Control Manager" that logs when the "Lync Server Centralized Logging Service Agent" service has terminated unexpectedly. If this happens more than three times, manually restart the service by using the **Start-CsWindowService** cmdlet.

Storage Service Queue Items need to be imported manually (3211368)

Issue:

Lync Server 2013 stores data about conferencing and instant messaging, such as archived messages and call detail recording (CDR), on a database on each Front End Server. The data is stored in the database while it is being processed before being delivered to the intended destination. To improve performance, Lync Server 2013 periodically exports the queue items from the local database that are not processed for an extended period of time, and saves them on the file store. If the file store is unavailable, the items are stored on each Front End Server. The same operation occurs to prevent data loss during pool failover.

During the export operation, the Lync Server Storage Service records every stage in the event log with event IDs of 32075 (full flush operation is started), 32076 (full flush is completed), 32082 (maintenance level flush is started), 32083 (maintenance level flush is completed), 32089 (flush occurred due to filling up of database). This data will not automatically be imported back to the system to be processed and delivered to its final destination (SQL Server or Exchange Server).

Workaround:

To import the data to the system, administrators will need to use the ImportStorageServiceData tool in the Lync Server Resource Kit, which will add the data back into the system to be processed and delivered to its final destination.

Address Book Web Query searches will fail if the default value for UseNormalizationRules is changed to False (3175514)

Issue:

If the default value for UseNormalizationRules is changed to False, Address Book Web Query searches will fail. After the default value is changed, Lync Client users will not be able to use Lync Address Book web query to search for users.

Workaround:

If the default value for UseNormalizationRules is set to False so that users can use phone numbers as defined in Active Directory Domain Services (AD DS) without Lync Server 2013 applying normalization rules, work around this issue by doing the following:

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Do one of the following:
    - If your deployment includes only Lync Server 2013 servers, run the following cmdlet at the global level to change the values for

UseNormalizationRules and IgnoreGenericRules to True:

```
Set-CsAddressBookConfiguration -identity <XdsIdentity> -UseN
```

- If your deployment includes a combination of Lync Server 2013 and Lync Server 2010 or Office Communications Server 2007 R2, run the following cmdlet and assign it to each Lync Server 2013 pool in the topology:

```
new-csAddressBookConfiguration -identity <XdsIdentity> -UseN
```

3. Wait for CMS replication to occur on all pools.
4. Modify the phone normalization rules file for your deployment to clear the content. The file is on the file share of each Lync Server 2013 pool. If the file is not present, then create an empty file named "Company_Phone_Number_Normalization_Rules.txt."
5. Wait several minutes for all Front End pools to read the new files.
6. Run the following cmdlet on each Lync Server 2013 pool in your deployment.

```
Update-csAddressBook
```

Address Book Server error event 20154 is generated once daily for each Lync 2013 pool (3195918)

Issue:

Lync Server 2013 Address Book Server will generate error event 20154 once every day when performing daily maintenance. The error is also generated every time an administrator runs the **Update-csAddressBook** cmdlet, even when the update is successful. However, this error event can safely be ignored when the update is successful.

Workaround:

When you encounter this error event, run the following cmdlet:

```
Debug-csAddressBookReplication -Poolfqdn <Pool FQDN for which the event was gener
```

If the cmdlet reports that there are no unindexed or abandoned objects, the error event 20154 can be safely ignored.

Additionally, the Key Health Indicator (KHI) "Address Book Users Correctly Indexed" should be turned off in System Center Operations Manager.

Requests may fail when IPv6 is configured on an Edge pool (3205810)

Issue:

When IPv6 is configured on an Edge pool, some requests to the Edge pool may fail.

Workaround:

To work around this issue, do not configure an Edge pool with IPv6.

The invoke-csPoolFailback cmdlet may fail during pool failback (3206153)

Issue:

When attempting to fail back a pool, the **invoke-csPoolFailback** cmdlet may fail with the error, "Failed to complete hydration process after repeated attempts."

Workaround:

To work around this issue, run the cmdlet again, and wait until the cmdlet succeeds. Note that the failback process can take several minutes to complete. It may take up to 60 minutes for a pool with 20,000 users.

Data loss may occur when you add a Front End Server to an already established pool (3015990) – Hybrid, Lync Online

Issue:

You may encounter this issue in an environment where a pool has more than one Front End Server, and you either restart one of the Front End Servers, or add a new Front End Server that was not previously part of the pool.

Users whose data is being archived may experience data loss until a stable distribution of data archiving is established for the pool. This period of potential data loss is limited to 15 minutes for person-to-person conversations, and 30 minutes for conferences.

Workaround:

When you perform maintenance, instead of starting Front End Servers in the pool one by one, you should fail over the pool to another pool, and then perform maintenance tasks on the servers. You can also make the service unavailable before performing maintenance tasks, and then restore availability when maintenance is complete.

Administrators cannot get licensee count by using the Get-CsClientAccessLicense cmdlet (3012255)

Issue:

Administrators cannot get accurate client license usage by using the **Get-CsClientAccessLicense** cmdlet.

Workaround:

To check the server license type, you can run the **Get-CsService** cmdlet to retrieve the fully qualified domain names (FDQNs) of all databases. If the FQDN of the Front End Server is the same as the FQDN of the back-end database, the license is a Standard edition license. Otherwise, the license is an Enterprise edition license.

Client licensee count is not accurately reported (3010175)

Issue:

When determining client license counts, you may experience the following conditions:

1. **Inaccurate license count for mobile users**
   The license count is based on the number of unique IP addresses for device-based users. The license count will be limited in the following ways:
   - Licenses will be overcounted if the IP address for the user changes during Lync sessions. This can occur when a user connects to Lync Server from more than one location with a desktop client.
   - Licenses will be undercounted if a user connects with a mobile client, because the IP address for the device cannot be determined.
2. **Licenses are counted twice for public switched telephone network (PSTN) calls to Lync client, Lync client calls to PSTN lines, and Lync calls forwarded to PSTN lines**
   In the following scenarios, two additional licenses will be counted instead of one because both the phone number and the Lync user are counted to determine the number of licenses used. To obtain accurate licensing data, manually remove the licenses generated by a phone number.
   - A PSTN phone call to Lync
   - A Lync call to a PSTN line
   - A PSTN call to Lync, and then Lync forwards the call to a PSTN line. One of

the PSTN lines will be counted.

3. **A license will not be counted for a logged-on Lync phone**
   When a user uses a Lync-certified phone, if the phone logs in and stays connected, which retains its logon status, the phone will not be counted as using a license if the query for licenses occurs after the phone logged in.
4. **Licenses counted for PSTN phones joining conferences**
   When a user joins a conference with a PSTN phone, a license will inaccurately be counted for joining the conference. However, no license is needed to join a conference with a PSTN phone.

Workaround:

1. **Inaccurate license count for mobile users**
   - You can manually identify the IP addresses that belong to the same device and then remove one of them in the license count.
   - There is no workaround for this issue with mobile devices connecting with Lync client.
2. **Licenses are counted twice for PSTN calls to Lync client, Lync client calls to PSTN lines, and Lync calls forwarded to PSTN lines**
   You will need to manually identify the PSTN phone number and remove the license count generated for it.
3. **A license will not be counted for a logged-in Lync phone**
   You can configure the Lync phone to log off, and then log on again, at a regular interval, such as every 3 months.
4. **Licenses counted for PSTN phones joining conferences**
   You can manually identify the PSTN phone number that is used to join the conference and remove the license generated by the phone number.

The Lync Server Control Panel stops working in a VMware environment after upgrading to Silverlight 5 (3010077)

Issue:

If you use the Lync Server Control Panel in a VMware environment, the Lync Server Control Panel may stop working after you upgrade Microsoft Silverlight to version 5.

Workaround:

To work around this issue, do one of the following:

- Uninstall Silverlight 5, and install Silverlight 4 from http://go.microsoft.com/fwlink/p/?LinkID=149156&v=4.0.
- Access the Lync Server Control Panel from a computer that is not a VMware virtual computer.
  To do so, you can start the Lync Server Control Panel from the Windows **Start** menu on the server, if the Lync Server Administration tools are installed on the computer.
  You can also access the Lync Server Control Panel by using a web browser. The URL will be similar to https://<frontend_pool_fqdn>/cscp.

User information in the Address Book Service is not updated after the distinguished name for the user is modified in Active Directory (3211549)

Issue:

If a user’s distinguished name (also known as DN) is changed in Active Directory Domain Services (AD DS), any additional changes will not be updated in the Address Book Service (ABS). This does not affect sign-in or presence for the user, but it will prevent communication for the user if the SIP address is also changed, because searches will return an outdated SIP address.

Workaround:

To work around this issue, do not change a user’s DN. If you revert the DN for the user to the previous value, updates will be reflected in the Address Book Service.

Installation

The hotfix for "Heap corruption occurs when a module calls the InsertEntityBody method in IIS 7.5" must be installed prior to installing Lync Server 2013.

Issue:

The hotfix for "Heap corruption occurs when a module calls the InsertEntityBody method in IIS 7.5" (http://go.microsoft.com/fwlink/p/?LinkId=268602), described in Microsoft Knowledge Base article 264886 (http://go.microsoft.com/fwlink/p/?LinkId=268603), must be installed prior to installing Lync Server 2013.

Workaround:

Download and install the hotfix from the Microsoft Download Center at http://go.microsoft.com/fwlink/p/?LinkId=268602.

Lync Server 2013 fails to install on ITA Windows Server 2012 OS RTM version (3179467)

Issue:

Lync Server 2013 installation fails on ITA Windows Server 2012 due to Windows Fabric installation failing.

Windows Fabric installation fails because fabric traces are created with the time format of HH:MM:SS. However, in ITA Windows Server, the time format is HH.MM.SS.

Workaround:

To work around this issue, update the system registry before installing Lync Server 2013. The registry key that needs to be updated is: HKEY_USERS\.DEFAULT\Control Panel \International\sTimeFormat. Change the value of sTimeFormat to HH:mm:ss by using the Windows PowerShell command-line interface as follows:

1. Start Windows PowerShell and run the following cmdlets:

   ```
   New-PSDrive -Name HKU -PSProvider Registry -Root HKEY_USERS
   ```

   ```
   $a="HKU:\.Default\Control Panel\International"
   ```

2. To view the current value, run the following cmdlet:

   ```
   Get-itemproperty $a -Name sTimeFormat
   ```

   Make note of the current value for sTimeFormat so it can be restored after the installation is complete.

3. To set to new value, run the following cmdlet:

   ```
   Set-ItemProperty $a -Name sTimeFormat -Value "HH:mm:ss"
   ```

4. After Lync Server 2013 has been successfully installed, restore the original value for the sTimeFormat by running the following cmdlet:

   ```
   - Set-ItemProperty $a -Name sTimeFormat -Value "<Value noted down in S
   ```

Mobility

Issues for mobile clients during the server failover process (3345992)

Issue:

When a Lync Server fails and the failover process begins, the following issues may affect mobile client users:

- No incoming Lync call or signal for up to 10 minutes after failover begins.
- Cannot accept incoming Chat requests
- Cannot join meetings if the failed server is the home server for the user

Workaround:

There is no workaround for this issue. Normal functionality will be restored once the failover process is complete.

If a mobile user declines an incoming call from another Lync endpoint, the call is displayed as a missed conversion on Lync Mobile clients (3346251)

Issue:

If a mobile user declines an incoming call, and the call originated from another Lync endpoint, the call is displayed as a missed conversation in the Lync Mobile client instead of a call in the device call list.

Workaround:

There is no workaround for this issue.

The mobile client may not display a federated contact’s display name when searching for contacts (3346256)

Issue:

The display name for federated contacts may not be displayed in some scenarios, such as when searching for a federated contact in the contact list. This can occur when the there is no active presence subscription for the contact from the Lync mobile client.

Workaround:

There is no workaround for this issue.

In the mobile client, invitee and timestamp information are missing from a missed conversation that is an invitation to a conference (3346265)

Issue:

In the mobile client, when a missed conversation is an invitation to a conference, the invitee and timestamp information is missing from the missed conversation message.

Workaround:

There is no workaround for this issue.

Mobile client users making calls using VoIP are not be able to leave voice mail for users whose voice mail is configured in Exchange 2010 or earlier versions (3346260)

Issue:

If a mobile client user is using VoIP to place calls, the user will not be able to leave voice mail messages for users configured to use voice mail in Microsoft Exchange Server 2007 or Microsoft Exchange Server 2010.

Workaround:

To work around this issue, use Exchange 2010 with SP1 or later version of Microsoft Exchange Server.

When using Block with URL for Client Version Configuration on mobile clients, an incorrect error message may be displayed (3346258)

Issue:

When using **Block with URL** for Client Version Configuration on mobile clients, an incorrect error message may be displayed when the client version is not supported.

Workaround:

To work around this issue, configure Client Version Configuration to use **Block** instead of **Block with URL**.

Conferencing

Antivirus software running on Lync Server 2013 Front End Servers can cause Application Domain recycling, which temporarily interrupts service for Lync Web App 2013, Lync Mobile 2010, and Lync Mobile 2013 clients (3212531)

Issue:

Antivirus software can trigger application domain restarts, which can result in Lync Mobility Service 2013 and unified communications (UC) Web API client applications (Lync Web App 2013, Lync Mobile 2010, and Lync Mobile 2013) to lose their state.

Workaround:

To work around this issue, exclude the folders containing Web components and .NET framework from antivirus scanning. For details, see Microsoft Knowledge Base article 312592, "PRB: Random application restarts with 'Application is restarting' error in ASP.NET," at http://go.microsoft.com/fwlink/p/?linkid=3052&kbid=312592.

The following folders should be excluded:

- %ProgramFiles%\Microsoft Lync Server 2013\Web Components\Mcx\Ext
- %ProgramFiles%\Microsoft Lync Server 2013\Web Components\Mcx\Int
- %ProgramFiles%\Microsoft Lync Server 2013\Web Components\Ucwa\Int
- %ProgramFiles%\Microsoft Lync Server 2013\Web Components\Ucwa\Ext
- %Windows%\Microsoft.NET\Framework64\v4.0.30319\Config

ActiveX Controls or native XMLHTTP support must be enabled in Windows Internet Explorer to successfully join conferences (2798163)

Issue:

If a user has disabled both ActiveX Controls and native XMLHTTP support in Windows Internet Explorer Internet browser settings, the user will not be able to join a meeting if

Internet Explorer is selected as the default browser.

Workaround:

Enable either ActiveX Controls or "native XMLHTTP support" in Internet Explorer.

Lync Server Web Conferencing service cannot recover from critical mode (2788663)

Issue:

If critical mode is turned for archiving, in case of system failures, critical mode will start and the conferences will no longer work for the participants. After the administrator fixes the system failures (such as fixing a database issue), the data conferencing service doesn't automatically recover, and the administrator must manually restart the conferencing service for conferencing to resume.

Workaround:

An administrator needs to manually restart the conferencing service after the system failure is fixed.

Web Conferencing service ignores the HTTP proxy for external Office Web App Servers (2602182)

Issue:

If you have deployed an Office Web Apps Server external to the Web Conferencing service (that is, a server that is not in the internal corporate network) in the Internet, perimeter network, and the Web Conferencing service requires an HTTP proxy to connect to this, the Office Web Apps Server discovery will fail. The Web Conferencing service ignores the HTTP proxy setting, as defined in Topology Builder for Office Web Apps Server setup. As a result, the Lync client will not be able to do Microsoft PowerPoint 2010 sharing with other participants in the conference. If you are installing Lync Server on-premises and also configure Office Web Apps Server on-premises in the internal network, a proxy configuration is not required.

Workaround:

The only workaround is to not have a deployment configuration that requires the use of HTTP proxy to communicate with an external Office Web Apps Server.

Adding video to an audio conferencing provider conference is not supported (2603861)

Issue:

Adding a video is not supported if the user is joined to an audio conferencing provider conference for audio.

Workaround:

There is no workaround for this issue.

Topologies with IPv6 enabled force the Lync Web App Silverlight plug-in auto-update to ensure screen sharing functionality can work from Lync Web App (2604634)

Issue:

When a topology is configured with IPv6 enabled, users cannot share their screen from the Lync Web App client if an earlier version of the screen-sharing plug-in is already installed.

Workaround:

To force an update to the most recent version of the screen-sharing plug-in when joining meeting via Lync Web App, modify the value of **MinSupportedBuildVersion** from "4.0.7457.0" to "4.0.7577.380" in both of the following files:

- %ProgramFiles%\Microsoft Lync Server 15\Web Components\Reach\Int\Client \Plugins\ReachAppShPluginProperties.xml
- %ProgramFiles%\Microsoft Lync Server 15\Web Components\Reach\Ext\Client \Plugins\ReachAppShPluginProperties.xml

Enterprise Voice

In some cases, a Lync client running on a computer configured to use IPv4 and IPv6 dual stack might not support capabilities that rely in the IP subnet of the computer such as E911, Media Bypass, Call Admission Control and Location Based Routing (3335508)

Note:

The information in this section pertains to Cumulative Updates for Lync Server 2013: February 2013.

Issue:

When a Lync client is running on a computer that is enabled for IPv4 and IPv6 dual stack and based on the DNS resolution of the proxy server, the client may use the IPv6 address of the computer to sign in. After doing so, the Lync Client will support only the capabilities supported for IPv6, which excludes E911, Media Bypass, Call Admission Control and Location Based Routing.

Workaround:

To work around this issue, disable IPv6 support on the client computer.

If Enterprise Voice is not configured for a user, the user will need to use E164 format to dial out from a conference (3215342)

Issue:

If Enterprise Voice is not configured for a user, that user will need to use the E164 format to successfully dial out from a conference. If the E164 format is not used, the user will not be able to dial out from the conference.

Workaround:

To work around this issue, users who are not enabled for Enterprise Voice should dial out from a conference by using numbers in the E164 format.

Presence

If a user has selected "Block all invites and communications" while the unified contact store is turned on for the user,

Presence status is not rejected when it should be (3204526)

Issue:

If a user has selected "Block all invites and communications" while the unified contact store is turned on for the user, Presence status is not rejected when it should be.

Workaround:

To work around this issue, you can turn off the unified contact store for the user. To do so, run the following cmdlets:

```
Set-CsUserServicesPolicy -Identity "<user display name>" -UcsAllowed $False
```

For example:

```
Set-CsUserServicesPolicy -Identity "Ken Myer" -UcsAllowed $False
```

Office Communications Server 2007 R2 users homed on-premises are not able to see the Presence status of Lync Online users in hybrid deployments (3014624) - Hybrid

Issue:

The issue may occur in a hybrid deployment when you are using a Lync Server 2013 Director.

Presence status for users homed to Lync Online is displayed as Presence Unknown for on-premises users. Also, users homed to Lync Online are not able to see presence status for Office Communications Server R2 on-premises users.

Workaround:

To partially work around this issue, change the Home Server (msrtcsip-presencehomeserver) of the Lync Online users to point to a Lync Server 2013 on-premises pool instead of the Lync Server 2013 Director. You can modify this setting on the on-premises Front End Server.

This workaround will correctly display the Presence status of users homed to Office Communications Server 2007 R2 to Lync Online users.

Response Group application, Call Park application, and Group Call Pickup

A caller might hear one second of music-on-hold during the establishment of a call with the retrieving party (3334097)

> **Note:**
>
> The information in this section pertains to Cumulative Updates for Lync Server 2013: February 2013.

Issue:

When a call is retrieved via Group Call Pickup, the caller might hear one second of music-on-hold during the establishment of the call with the retriever party.

Workaround:

There is no workaround for this issue.

A Response Group agent can sign in and sign out through a Lync Server 2010 Agent Console to Lync Server 2010 formal Agent Groups only (2773455)

Issue:

A Lync Server 2013 Response Group agent can sign in and sign out through a Lync Server 2010 Agent Console to Lync Server 2010 formal Agent Groups only. In the Lync Server 2010 Agent Console, users can see only the Lync Server 2010 Response Group that they belong to. They cannot see any of the Lync Server 2013 Response Groups that they belong to.

Workaround:

If the Response Group agent is a Lync Server 2013 user, and part of a Lync Server 2013 formal Agent Group, the user must access the Lync Server 2013 Agent Console directly via a web link in a browser to sign in to and sign out from Lync Server 2013 Agent Groups.

A Lync Server 2010 Response Group agent cannot place calls on behalf of a Lync Server 2013 Response Group (2773471)

Issue:

A Lync Server 2010 user who is an Agent of a Lync Server 2013 Response Group is not able to place a call on behalf of the Response Group. The Lync Server 2013 Response Group will not be available in the Lync Client to place a call.

Workaround:

To work around this issue, you must move the Lync Server 2010 user to Lync Server 2013.

Removing a Response Group from Lync Server 2010 after it has been migrated to Lync Server 2013 will prevent the Response Group from accepting any incoming calls (3016227)

Issue:

If a Response Group that has been migrated from Lync Server 2010 to Lync Server 2013 is removed from Lync Server 2010 through the Lync Server Control Panel or the Lync Server Management Shell, the Response Group in Lync Server 2013 will stop receiving any incoming calls.

Workaround:

To work around this issue, do not remove any Response Groups from Lync Server 2010 that have been migrated from Lync Server 2010 to Lync Server 2013.

If the Response Group has already been removed, you should redeploy it in Lync Server 2013.

When a new managed workflow is set to inactive when created, deployment of the workflow will fail (3207527)

Issue:

When a new managed workflow is set to inactive when created, deployment of the workflow will fail. This issue is encountered when the workflow is set to inactive when created, but does not affect a workflow that is edited to set it to inactive after is has been deployed.

Workaround:

When creating and deploying a workflow, set the workflow as active and then deploy it. After the workflow is successfully deployed, the workflow can be edited and set to inactive.

Removing a Response Group from the Owner pool will prevent the Response Group of the Backup pool from accepting any incoming calls during failover if the Response Group has been imported to the Backup pool (3016214)

Issue:

If a Response Group that is owned by the primary pool has been imported to the backup pool without overwriting the owner, and the Response Group is removed from the owner pool, the Response Group in the Backup pool will not accept any incoming calls during failover.

Workaround:

You will need to redeploy the Response Group in the Primary pool. You will then need to export the Response Group configuration from the Primary pool and import it to the Backup pool again.

You can also recreate the Response Group in the Backup pool. In this case, the Backup pool will be the owner pool of the Response Group.

A parked call can't be retrieved from the Call Park application if the retrieve request is done on behalf of a Response Group (3211798)

Issue:

When the following conditions are true, a retrieve request for a parked call will fail:

- An agent is part of an anonymous Response Group
- The agent attempts to retrieve a parked call from the Call Park application through the anonymous Response Group
- The agent attempts to retrieve the call by dialing the orbit number through the Call On Behalf option or through the same option in the Lync attendant client

Workaround:

There are no workarounds for this issue. The parked call should be retrieved without doing so on behalf of a Response Group.

Lync Server Control Panel, Topology Builder, and Planning Tool

Planning Tool Limitations (3331056 and 3331059)

Note:

The information in this section pertains to Cumulative Updates for Lync Server 2013: February 2013.

Issue:

The Planning Tool has the following limitations when planning for your deployment:

- There is a maximum of 10 central sites supported
- Each central site can have a maximum of 14 branch sites
- Each central site can have a maximum of 240,000 users

In addition, the Planning Tool does not include values for the following when calculating the recommended topology:

- The number of users that are homed online
- The percentage of users that are enabled for XMPP federation
- Percentage of users that are using Lync Web App
- The percentage of users that are configured for Hybrid Voice

Workaround:

There is no workaround for these issues. For more information about the Planning Tool, see Designing the Topology by Using the Planning Tool.

Planning Tool may not use previously defined IP addresses for the Edge network when updating options

Issue:

After you complete your design using the Planning Tool, if you make changes to the Edge Network options, additional IP addresses may be added to the design instead of updating the existing IP addresses. This can occur when you are viewing the details of the Edge Network Diagram, select **Click here to update your options**, and then, on the Configuration Options dialog, you select Edge Network select **I want to use the same FQDNs and IP addresses, but different ports for the edge services on my Edge Server**. Applying any changes may result in new IP addresses and Edge servers being added to the design.

Workaround:

There is no workaround for this issue at this time.

In Lync Server Control Panel, "Move all users to pool" may not work as expected (3199270)

Issue:

When using the Lync Server Control Panel to move all users from one pool to another pool in a complex Active Directory environment, such as one with multiple Domain Controllers and parent/child domains, an error message may be returned that states, “Specified user is not a legacy user, use Move-CsUser cmdlet instead.” This is a result of longer replication times in complex Active Directory environments.

Workaround:

To work around this issue, do one of the following:

- Use filters in the Lync Server Control Panel to search for legacy users, select those users, and then use the **Move selected users to pool command** instead of **Move all users to pool**.
- Use the Lync Server Management Shell to move legacy users in batches by using Lync Server cmdlets.

The Lync Server Control Panel stops working in a VMware environment after the Microsoft Silverlight browser plug-in is

updated to version 5 (3199270)

Issue:

If you use the Lync Server Control Panel in a VMware environment, the Lync Server Control Panel may stop working after you upgrade Silverlight to version 5.

Workaround:

To work around this issue, do one of the following:

- Uninstall Silverlight 5, and then install Silverlight 4 from http://go.microsoft.com/fwlink/p/?LinkID=149156&v=4.0.
- Open the Lync Server Control Panel from a computer that is not a VMware virtual computer.
  To open the Lync Server Control Panel from a remote computer, install Lync Server Administration tools on the computer, and then start the Lync Server Control Panel from the Windows **Start** menu.
  You can also open the Lync Server Control Panel by entering the URL in a web browser. The URL will be similar to https://<frontend_pool_fqdn>/cscp.

An administrator cannot run the Uninstall-csMirrorDB cmdlet after removing the mirroring database in Topology Builder (3199266)

Issue:

When an administrator disables a mirroring database in Topology Builder, and then deletes the mirroring database in Topology Builder, a message is displayed in the To do list for the administrator to run the **Uninstall-csMirrorDatabase** cmdlet to remove mirroring from SQL Server. When the administrator attempts to run the cmdlet, it fails.

Workaround:

To remove SQL mirroring of a pool in Topology Builder, you must first use a cmdlet to remove the mirror in SQL Server. You can then use Topology Builder to remove the mirror from the topology. To remove the mirror in SQL Server, use the following cmdlet:

```
Uninstall-CsMirrorDatabase -SqlServerFqdn <SQLServer FQDN> [-SqlInstanceName <SQL
```

For example, to remove mirroring and drop the databases for the user databases, type the following:

```
Uninstall-CsMirrorDatabase -SqlServerFqdn primaryBE.contoso.com -SqlInstanceName
```

The *DropExistingDatabasesOnMirror* parameter causes the affected databases to be deleted from the mirror. Then, to remove the mirror from the topology, do the following:

1. In Topology Builder, right-click the pool and click **Edit Properties**.
2. Clear **Enable SQL Store Mirroring** and click **OK**.
3. Publish the topology.

◆**Important:**
Whenever you make a change to a back-end database mirroring relationship, you must restart all the Front End Servers in the pool.

Validation errors are returned in Topology Builder when an administrator attempts to remove a deployment with a Front End pool that has an associated witness store (3199266)

Issue:

If an administrator attempts to use the **Remove Deployment** command in Topology Builder to remove a deployment that includes a Front End pool with an associated witness store, a validation error is displayed in Topology Builder and the action will not proceed.

Workaround:

To work around this issue, do one of the following:

- Remove the witness store before attempting to remove the deployment.
- Add a witness store for the Front End pool and then remove it.

Persistent Chat Server deployment information is inconsistent between the Planning Tool and Topology Builder (3012228)

Issue:

When the Lync Server 2013, Planning Tool outputs the site topology diagram for a Persistent Chat Server deployment with disaster recovery enabled, the site topology diagram includes multiple (physical) sites, with evenly assigned Persistent Chat Servers at each site. In Topology Builder, all Persistent Chat Servers are represented as belonging to a single (logical) site, and are listed under the same Persistent Chat Server pool node.

Workaround:

Currently, we do not have a workaround for this issue. The user should analyze the output of the Planning Tool for the Persistent Chat Server deployment, and modify the plan to meet their specific needs.

Localization

Monitoring

The Deploy Monitoring Reports wizard displays incorrect characters under certain circumstances when using the East Asian version of Lync Server (3113565)

Issue:

When using an East Asian version of Lync Server 2013—for example, Chinese (Simplified), Chinese (Traditional), Japanese, or Korean—on an operating system that has the system locale not set to an East Asian language, the Deploy Monitoring Reports wizard will display question marks or other characters instead of localized messages.

Workaround:

To correct this issue, set the locale for the operating system and Lync Server 2013 to the same language, which will display all messages correctly.

Lync Server Control Panel

In certain cases, the first item in the top navigation bar on a page of Lync Server Control Panel disappears when the last item in the top navigation bar is clicked (3158118)

Issue:

There are three known cases where clicking the last item in the top navigation bar on a page of the Lync Server Control Panel will cause the first item in the top navigation bar to disappear:

- In the French of version, on the page "Féderation et accès externe," the item "Stratégie d'accès externe" will disappear when "Partenaires fédérés XMPP" is clicked.

- In the German version, on the "Clients" page, the item "Clientversionskonfiguration" disappears when "Pushbenachrichtigungskonfiguration" is clicked.
- In the Russian version, on "Конфигурация сети" page, the item "Глобально" disappears when "Маршрут региона" is clicked.

Workaround:

To work around this issue, refresh the page of the Lync Server Control Panel in your browser. The page will load in the browser with all of the items in the top navigation bar displayed.

Address Book

Indexing in the Address Book does not work as expected in some languages (3336047)

> **Note:**
> The information in this section pertains to Cumulative Updates for Lync Server 2013: February 2013.

If a user’s properties contain an indexed field, and that field contains only characters that cannot be indexed, then the user will not appear in searches performed in the Address Book.

The following characters and locales cannot be indexed:

- Upper-case Cyrillic, Greek, and Armenian characters
- Upper-case accented characters
- Thai
- Lao
- Myanmar
- Devanagari
- Ethiopic
- Tibetan
- Bengali
- Gujarati
- Telugu
- All other Indic scripts

Lync Web App, Web Scheduler, and Web components

Language fallback for certain languages in Lync Web Scheduler, Dial-In, Join Launcher, Persistent Chat Room Management, and OCTab might not work as expected (3079700)

Issue:

When selecting a neutral locale in a web browser (in Internet Explorer, for example, the language name without further specification, like "Norwegian [no]") instead of a locale specifying language, script and locale (such as "Norwegian, Bokmål (Norway) [nb-NO]") might lead to unexpected display behavior for certain languages in Lync Web Scheduler, Dial-In, Join Launcher, Persistent Chat Room Management, and OCTab. For example, users might see the English page when one of the following languages is selected:

- Norwegian
- Portuguese
- Serbian

Workaround:

If you want to select a language with a neutral locale, always make sure that you also add the language with a specific locale (with script and/or country code) as an additional language in your browser's language preference list.

There is limited support for Azeri and Uzbek locales when using Lync Web Scheduler, Dial-In, Join Launcher, Persistent Chat Room Management, and OCTab in some web browsers (3336748)

Note:
The information in this section pertains to Cumulative Updates for Lync Server 2013: February 2013.

Issue:

When you use Internet Explorer 8 or Internet Explorer 9, and set the browser language to Azeri (Latin) or Uzbek (Latin), the Dial-in and Join Launcher pages will be displayed in English or the preferred language set in the browser.

When you use Firefox or Chrome browsers, and you set the browser language to Azeri (Latin) or Uzbek (Latin), the Lync Web App, Lync Web Scheduler, and RGS OCTab will be shown in English or the preferred language set for the browser.

The Uzbek (Latin) locale is not supported in the Safari browser.

Workaround:

There is not workaround for these issues.

The drop-down arrow is missing for "Join meeting from" list in the Romanian version of Lync Web App (3154899)

Issue:

When a user who is using the Romanian version of Lync Web App performs the following steps, the drop-down arrow is not displayed for **Join meeting** in drop-down list:

1. Select **Remember me on this computer** on the **General** tab.
2. Select the **Phone** tab.
3. Click the drop-down list for **Join meeting from**.
   Users will not see an arrow that indicates that there are more options than the default **Lync Web App**, which include: **Don't join audio** (in Romanian, "Nu se asociaža la componenta audio") and **New number**" (in Romanian, "Numar nou").

Workaround:

Even though the arrow for this drop-down list is not displayed, users can still select the additional settings in the list by clicking on the default value.

When using the Turkish version of Lync Web Scheduler, a meeting cannot be saved when using the "People I choose" option under "Who is a presenter" (3169483)

Issue:

When creating or editing a meeting in the Turkish version of the Lync Web Scheduler, the option "People I choose" under "Who is a presenter" is not supported. When this option is selected, the meeting can't be saved. Instead, an error message appears, indicating that one or more people cannot be made presenters.

Workaround:

To work around this issue, users can use the default option of "People from my company," or any other choice, such as "Only Organizer" or "Everyone including people outside of my company." The organizer can demote or promote people to their correct roles later, after they have joined the meeting.

Alternatively, users who understand another language can change the language selection in their browser to one of the other 43 supported languages and attempt to use the “People I choose” option.

1.2 Supportability

Supportability

Microsoft Lync Server 2013 >

Topic Last Modified: *2012-04-23*

Microsoft Lync Server 2013 communications software supports topologies that are designed to meet the needs of organizations that are small, medium, or large and that have varying requirements for performance, high availability, and scalability.

- Active Directory Support
- Supported Lync Server 2013 Topologies
- Supported Server Collocation
- Supported Migration Paths and Coexistence Scenarios
- Supported Hardware
- Server Software and Infrastructure Support
- Additional Server Support and Requirements
- Client and Device Software and Infrastructure Support

1.2.1 Active Directory Support

Active Directory Support

Microsoft Lync Server 2013 > Supportability >

Topic Last Modified: *2012-12-04*

The Active Directory Domain Services (AD DS) on-premises topologies that are supported by Lync Server 2013 are as follows:

- Single forest with single domain
- Single forest with a single tree and multiple domains
- Single forest with multiple trees and disjoint namespaces
- Multiple forests in a central forest topology
- Multiple forests in a resource forest topology

Note:

Lync Server 2013 does not support single-label domains. For example, a forest with a root domain named **contoso.local** is supported, but a single-label root domain named **local** is not supported. For details, see Microsoft Knowledge Base article 300684, "Information about configuring Windows for domains with single-label DNS names," at http://go.microsoft.com/fwlink/p/?linkId=143752.

Note:

Lync Server 2013 does not support renaming domains. If you need to rename a domain where Lync Server is deployed, you need to first uninstall Lync Server, then rename the domain, and then reinstall Lync Server.

For details about supported topologies and requirements for on-premises deployments, see Active Directory Domain Services Requirements, Support, and Topologies in the Planning documentation.

1.2.2 Supported Lync Server 2013 Topologies

Supported Lync Server 2013 Topologies

Microsoft Lync Server 2013 > Supportability >

Topic Last Modified: *2012-11-08*

Lync Server 2013 supports deployment of sites on premises in an organization and integration of on-premises deployments with Lync Online deployments, which is known as a hybrid deployment. In a hybrid deployment, some users are homed on-premises and some users are homed online.

For on-premises deployments, Lync Server 2013 supports deployment of one or more sites that can be scaled to meet high availability and location requirements. You can structure these sites and their components to meet the access and resiliency requirements of your organization.

A Lync Server 2013 on-premises deployment consists of the following:

- Your deployment must include at least one central site (also known as a data center). Each central site must contain at least one Enterprise Edition Front End pool or one Standard Edition server. These consist of the following:
    - Enterprise Edition Front End pool, which consists of one or more Front End Servers (typically, at least two Front End Servers for scalability) and a separate Back End Server. A Front End pool can contain a maximum of twelve Front End Servers. Load balancing is required for multiple Front End Servers. For SIP traffic, we recommend DNS load balancing, but hardware load balancing is also supported. If you use DNS load balancing for SIP traffic, you still need a hardware load balancer for HTTP traffic. We recommend SQL Server mirroring for high availability of databases. The back-end database requires a separate instance, but you can collocate the archiving database, monitoring database, persistent chat database, and persistent chat compliance database with it. Lync Server 2013 supports the use of a shared cluster for the file shares in your deployment. For details about database storage requirements, see Database Software Support. For details about file storage requirements, see File Storage Support.

        > **Important:**
        > If you collocate Lync Server databases, we highly recommend assessing all factors that might affect availability and performance. To verify failover capabilities, we recommend testing all failover scenarios.

    - Standard Edition server, which includes a collocated SQL Server Express database.
- Your deployment can also have one or more branch sites associated with a central site.

This section describes the sites and components of a Lync Server 2013 deployment. For details about Lync Server 2013 site, topology, and component planning, see Topology Basics You Must Know Before Planning and Reference Topologies in the Planning documentation. For details about integration of components of previous releases, see Supported Migration Paths and Coexistence Scenarios.

Central Site Topologies and Components (On-Premises)

Although a central site topology must include one Front End pool or one Standard Edition server, each central site can also contain the following:

- Multiple Front End pools, which can be in the same domain or different domains. However, all Front End Servers in a Front End pool, and the Back End Server for that pool, must be in the same domain.
- Multiple Standard Edition servers.
- Office Web Apps Server, which is used with Office Web Applications in Lync Server 2013 to handle the sharing and rendering of Microsoft PowerPoint 2010 presentations.
- Edge Server or Edge pool in your perimeter network, if you want your deployment to support federated partners, public IM connectivity, an extensible messaging and presence protocol (XMPP) gateway, remote user access, participation of anonymous users in meetings, or Exchange Unified Messaging (UM). You cannot collocate any other server role with an Edge Server. We recommend DNS load balancing, where appropriate, but hardware load balancing is also supported. The internal Edge interface and external

Edge interface must use the same type of load balancing. You cannot use DNS load balancing on one Edge interface and hardware load balancing on the other Edge interface. For details about load balancing requirements and support, see Planning for External User Access in the Planning documentation and Deploying External User Access in the Deployment documentation.

- Mediation Server or pool, if you want to support Enterprise Voice or dial-in conferencing in a Front End pool at the central site. Depending on how you deploy Enterprise Voice support, you can collocate the Mediation Server in a Front End pool (the default) or deploy a stand-alone Mediation Server or pool. You can use DNS, hardware, or application load balancing (when appropriate) to distribute traffic from a Mediation Server pool's gateway peer, including a PSTN gateway, IP-PBX, or SIP trunk Session Border Control (SBC).For details about planning the appropriate Mediation Server topology, see Deployment Guidelines for Mediation Server in the Planning documentation.
- Persistent Chat Server, if you want to users to be able to participate in multiparty, topic-based conversations that persist over time. To provide more capacity and increased reliability, your topology can include multiple computers running Persistent Chat Server. You cannot collocate Persistent Chat Server with other server roles in an Enterprise pool. However, you can collocate Persistent Chat Server on a Standard Edition server. Persistent chat requires a database and, if you implement persistent chat compliance, a persistent chat compliance database, but the databases can be collocated with the Archiving database, Monitoring database, or on the Back End Server of an Enterprise Edition Front End pool. For details about planning the appropriate Persistent Chat Server topology, see Planning for Persistent Chat Server in the Planning documentation.
- Monitoring, if you want to support data collection for audio/video Quality of Experience (QoE) and call detail recording (CDR) for Enterprise Voice and A/V conferences in your deployment. Optionally, you can install the Microsoft System Center Operations Manager (formerly Microsoft Operations Manager), which uses Monitoring CDR and QoE data to generate near real-time alerts that show the health of call reliability and media quality. Monitoring, when deployed, is collocated on Front End Servers or a Standard Edition server. Monitoring requires a database, but the database can be collocated with the Archiving database, persistent chat database, persistent chat compliance database, or on the Back End Server of an Enterprise Edition Front End pool.
- Archiving, if you want to archive IM communications and meeting content (for compliance reasons) in your deployment. Archiving, when deployed, is collocated on Front End Servers or a Standard Edition server. Archiving storage requires either deployment of an Archiving database or integration with Exchange 2013 storage. If you use both, which is known as *mixed mode*, Exchange 2013 storage is used to store archive data for users who are homed on Exchange 2013, and the Archiving database is used to archive data for all other users in your deployment. If you require an Archiving database, the database can be collocated on the Monitoring database, persistent chat database, persistent chat compliance database, or on the Back End Server of a Front End pool. For details about planning the appropriate Archiving topology, see Planning for Archiving in the Planning documentation.
- Director or Director pool, if you want to facilitate resiliency and redirection of Lync Server 2013 user requests to the user's home pool, which can be either an Enterprise Edition Front End pool or a Standard Edition server. We recommend that you deploy a Director or Director pool in each central site that supports external user access and in each central site in which you deploy one or more Front End pools. Each Director pool can contain a maximum of ten Directors. A Director cannot be collocated with any other server role. For details about planning the appropriate Director topology, see Scenarios for the Director in the Planning documentation.
- Reverse proxy, which is not a Lync Server 2013 component, but is required if you want to support sharing of web content for federated users or to support Mobility traffic. You cannot collocate a reverse proxy server with any Lync

Server 2013 server role, but you can implement reverse proxy support for a Lync Server 2013 deployment by configuring the support on an existing reverse proxy server in your organization that is used for other applications. For details about reverse proxy servers, see Setting Up Reverse Proxy Servers in the Deployment documentation.

Note:
In Lync Server 2013, A/V Conferencing, Monitoring, and Archiving run on Front End Servers and are no longer separate server roles.

All Front End pools and Standard Edition servers that you deploy at a central site share any of the following that you deploy for the central site:

- Director or Director pool
- Stand-alone Mediation Server or pool
- Office Web Apps Server
- Edge Server or Edge pool
- Persistent Chat Server or pool
- Monitoring
- Archiving

Note:
An Exchange UM Server can be implemented with your Lync Server 2013 deployment if you want to support integration of Exchange 2013 Unified Messaging, but it is not a component of the Lync Server 2013 site.

Multiple central sites can also share any of the following that you deploy in one central site:

- Stand-alone Mediation Server or pool
- Edge Server or Edge pool
- Persistent Chat Server or pool
- Archiving
- Monitoring

Note:
An Exchange UM Server can be implemented with your Lync Server 2013 deployment and shared by multiple central sites, but it is not a component of the Lync Server 2013 site.

For details about Lync Server 2013 server roles and functionality, see Server Roles in the Planning documentation.

For a summary of Lync Server 2013 server collocation support, see Supported Server Collocation.

In addition to the server roles and functionality covered previously in this section, Lync Server 2013 has additional components and options, which can include some or all of the following:

- Firewalls
- PSTN gateways (if deploying Enterprise Voice)
- Exchange UM Server
- DNS load balancing
- Hardware load balancers
- SQL Server databases
- File shares

For details about all of the Lync Server 2013 features, components, and options, see the Planning documentation.

Branch Site Topologies and Components (On-Premises)

A branch site is associated with a central site, and each Survivable Branch Appliance in a branch site is associated with an Enterprise Edition Front End pool or a Standard Edition server in the associated central site. Branch sites depend on the central site for most of their functionality, so components at a branch site contain only the following:

- A Survivable Branch Appliance, which combines a public switched telephone network (PSTN) gateway with some Lync Server functionality. A Mediation Server can be collocated with the instance of the Registrar on the Survivable Branch Appliance, and you can deploy a stand-alone Mediation Server or pool of Mediation Servers.
- A Survivable Branch Server, which is a server running Windows Server that has Lync Server 2013 Registrar and Mediation Server software installed.
- A stand-alone PSTN gateway (not part of the Survivable Branch Appliance) and a stand-alone Mediation Server.

The requirements for Survivable Branch Servers are the same as the requirements for any Lync Server 2013 server role.

1.2.3 Supported Server Collocation

Supported Server Collocation

Microsoft Lync Server 2013 > Supportability >

Topic Last Modified: *2012-06-29*

Lync Server 2013 supports collocation of some server roles and features. Which server roles and features you can collocate depends, in part, on whether you are deploying a Front End pool or a Standard Edition server.

- Server Collocation in an Enterprise Edition Front End Pool Deployment
- Server Collocation in a Standard Edition Server Deployment

1.2.3.1 Server Collocation in an Enterprise Edition Front End Pool Deployment

Server Collocation in an Enterprise Edition Front End Pool Deployment

Microsoft Lync Server 2013 > Supportability > Supported Server Collocation >

Topic Last Modified: *2012-10-29*

This section describes the server roles, databases, and file shares that you can collocate in a Lync Server 2013 Front End pool deployment.

Server Roles

In Lync Server 2013, A/V Conferencing service, Mediation service, Monitoring, and Archiving are collocated on the Front End Server, but additional configuration is required to enable them. If you do not want to collocate the Mediation Server with the Front End Server, you can deploy it as a stand-alone Mediation Server on a separate computer.

You can collocate a trusted application server with the Front End Server.

The following server roles must each be deployed on a separate computer:

- Director
- Edge Server
- Mediation Server (if not collocated with the Front End Server)
- Office Web Apps Server

Databases

You can collocate each of the following databases on the same database server:

- Back-end database
- Monitoring database
- Archiving database
- Persistent Chat database
- Persistent Chat compliance database

You can collocate any or any or all of these databases in a single instance of SQL Server or use a separate instance of SQL Server for each, with the following limitations:

- Each instance of SQL Server can contain only a single back-end database, a single Monitoring database, a single Archiving database, a single Persistent Chat database, and a single Persistent Chat compliance database.
- The database server cannot support more than one Front End pool, one Archiving deployment, and one Monitoring deployment, but it can support one of each, regardless of whether the databases use the same instance of SQL Server or separate instances of SQL Server.

You can collocate a file share with the databases, as described later in this section.

Note:

In Lync Server 2013, you have the option of integrating Monitoring and Archiving storage with Exchange 2013 storage for some or all users in your deployment. You cannot deploy any servers running Lync Server or components on the same servers as the Exchange storage.

Important:

Although collocation of databases is supported, the size of the databases can grow quickly. For example, when you consider collocating the Archiving database with other databases, be aware that if you are archiving the messages of more than a few users, the disk space needed by the Archiving database can grow very large. For this reason, we do not recommend collocating multiple databases, especially the Archiving database, the Persistent Chat database, or the Persistent Chat compliance database with the back-end database.

File Share

The file share can be a separate server or can be collocated on the same server as any or all of the following:

- Database server, including the Back End Server of an Enterprise Edition Front End pool
- Archiving database
- Monitoring database
- Persistent Chat database
- Persistent Chat compliance database

A single file share can be used for multiple Front End pools, Standard Edition servers (all in the same site).

Note:

In Lync Server 2013, Monitoring and Archiving use the Lync Server file share as the Front End Server.

Other Components

You cannot collocate a reverse proxy server, which is not a Lync Server 2013 component, but is required in your deployment if you want to support sharing of web content for federated users with any Lync Server 2013 server role. You can, however, implement reverse proxy support for a Lync Server 2013 deployment by configuring the support on an existing reverse proxy server in your organization that is used for other applications.

You cannot collocate any Exchange Unified Messaging (UM) component or SharePoint component with any SharePoint Server role.

1.2.3.2 Server Collocation in a Standard Edition Server Deployment

Server Collocation in a Standard Edition Server Deployment

Microsoft Lync Server 2013 > Supportability > Supported Server Collocation >

Topic Last Modified: *2013-01-20*

This section describes the server roles, databases, and file shares that you can collocate in a Lync Server 2013 Standard Edition server deployment.

Server Roles

In Lync Server 2013, A/V Conferencing service, Mediation service, Monitoring, and Archiving are collocated on the Standard Edition Server, but additional configuration is required to enable them. You can choose to deploy Mediation service on separate servers.

You can collocate a trusted application server with a Standard Edition server.

The following server roles must each be deployed on a separate computer:

- Director
- Edge Server
- Mediation Server (if not collocated with the Standard Edition server)
- Office Web Apps Server

Databases

By default, the SQL Server Express back-end database is collocated on the Standard Edition server. You cannot move it to a separate computer. With one exception, you cannot collocate other databases on the Standard Edition server. If you choose to deploy Persistent Chat Server on a Standard Edition server, you can collocate the Persistent chat database and the Persistent Chat Compliance database on the same Standard Edition server.

You can collocate each of the following databases on a single database server:

- Monitoring database
- Archiving database
- A back-end database for an Enterprise Edition Front End pool

You can collocate any or any or all of these databases in a single SQL instance or use a separate SQL instances for each, with the following limitations:

- Each SQL instance can contain only a single back-end database (for an Enterprise Edition Front End pool), single Monitoring database, single Archiving database, single persistent chat database, and single persistent chat compliance database.
- The database server cannot support more than one Enterprise Edition Front End pool, one server running Archiving, one server running Monitoring, single Persistent Chat database, and single Persistent Chat compliance database, but it can support one of each, regardless of whether the databases use the same instance of SQL Server or separate instances of SQL Server.

You can collocate a file share with the databases, as described later in this section.

Note:

In Lync Server 2013, you have the option of integrating Monitoring and Archiving storage with Exchange 2013 storage for some or all users in your deployment. You cannot deploy any servers running Lync Server or components on the same servers as the Exchange storage.

Important:

Although collocation of databases is supported, the size of the databases can grow quickly. For example, when you consider collocating the Archiving database with other databases, be aware that if you are archiving the messages of more than a few users, the disk space needed by the Archiving database can grow very large. For this reason, we do not recommend collocating multiple databases, especially the Archiving database, Persistent Chat database, and Persistent Chat compliance database with the back-end database of an Enterprise pool.

File Shares

The file share can be a separate server or can be collocated on the same server as any or all of the following:

- Database server, including the Back End Server of an Enterprise Edition Front End pool
- Archiving database
- Monitoring database
- Persistent Chat database
- Persistent Chat compliance database

A single file share can be used for multiple Front End pools, Standard Edition servers (all in the same site).

Note:

In Lync Server 2013, Monitoring and Archiving use the Lync Server file share as the Standard Edition server.

Other Components

You cannot collocate a reverse proxy server, which is not a Lync Server 2013 component, but is required in your deployment if you want to support sharing of web content for federated users with any Lync Server 2013 server role. You can, however, implement reverse proxy support for a Lync Server 2013 deployment by configuring the support on an existing reverse proxy server in your organization that is used for other applications.

You cannot collocate any Exchange UM component or SharePoint component with any Lync Server 2013 role.

1.2.4 Supported Migration Paths and Coexistence Scenarios

Supported Migration Paths and Coexistence Scenarios

Microsoft Lync Server 2013 > Supportability >

Topic Last Modified: *2012-04-30*

Lync Server 2013 supports migration from Microsoft Lync Server 2010 and Microsoft Office Communications Server 2007 R2, including coexistence with specific client and server components of those previous deployments.

- Supported Server Migration Paths and Coexistence Scenarios
- Supported Clients from Previous Deployments

1.2.4.1 Supported Server Migration Paths and Coexistence Scenarios

Supported Server Migration Paths and Coexistence Scenarios

Microsoft Lync Server 2013 > Supportability > Supported Migration Paths and Coexistence Scenarios >

Topic Last Modified: *2012-10-16*

Lync Server 2013 supports migration from either of the following:

- Microsoft Lync Server 2010
- Microsoft Office Communications Server 2007 R2

Migration from an environment running both of these previous versions is not supported. Migration from earlier versions, such as Microsoft Office Communications Server 2007 or Live Communications Server 2005, is not supported. If your previous deployment included Group Chat, you must migrate it separately.

Migration Methods

Migration of all Lync Server topologies and server roles is supported. You can migrate from one topology to a different topology, including from Standard Edition server to Enterprise Edition server.

Lync Server 2013 supports only the following migration method:

- **Side-by-side migration.** In side-by-side migration, Lync Server 2013 is deployed alongside an existing Microsoft Lync Server 2010 or Office Communications Server 2007 R2 deployment, and then you transfer operations to the new servers and move users to Lync Server 2013. This method requires additional server platforms, including hardware and software, during migration, and system names and pool names are different in the new configuration. If it becomes necessary to roll back to the previous version, you can shift operations back to the previous servers.

Migration across Active Directory Domain Services (AD DS) forests is not supported.

The recommended migration path is a phased approach. For details about migrating from a previous release, including the appropriate phasing of component deployment, see the following topics in the Migration documentation:

- Migration from Lync Server 2010 to Lync Server 2013
- Migration from Office Communications Server 2007 R2 to Lync Server 2013

- Migration from Lync Server 2010, Group Chat or Office Communications Server 2007 R2 Group Chat to Lync Server 2013, Persistent Chat Server

Coexistence Scenarios

Lync Server 2013 can coexist with components of either a Lync Server 2010 deployment or an Office Communications Server 2007 R2 deployment. Concurrent deployment of Lync Server 2013 with both Lync Server 2010 and Office Communications Server 2007 R2 (concurrent deployment of all three versions) is not supported.

During a phased migration in which a previous Lync Server 2010 or Office Communications Server 2007 R2 deployment coexists temporarily with the new Lync Server 2013 deployment, support for mixed version routing is limited. For details, see the Migration documentation.

You must use separate and distinct computers running Microsoft SQL Server 2008 R2 or Microsoft SQL Server 2012 for your Lync Server 2013 database instances. You cannot use the same instance of SQL Server for a Lync Server 2013 Front End pool that you use for a Lync Server 2010 or Office Communications Server 2007 R2 Front End pool. If you define and configure Lync Server 2013 in Topology Builder for a deployment that already has Lync Server 2010 or Office Communications Server 2007 R2 deployed, Topology Builder will not allow you to define an instance of a Lync Server 2013 that is already in use in the topology.

Topology Builder will display the following message to inform you of this issue: "The SQL server [FQDN of the server] already contains a SQL instance hosting role 'User Store'."

Note:
If you intend to deploy server roles that are new to your Lync Server 2013 deployment, you should first upgrade your existing deployment as described in the Migration documentation and the Deployment documentation, and then deploy the new server roles as described in the Planning documentation and Deployment documentation. If you are migrating a previous version of Group Chat, migrate it last, after completing the process for migrating all other components from Lync Server 2010 or Office Communications Server 2007 R2.

For specific coexistence requirements and other details about coexistence and migration of Lync Server 2010 or Office Communications Server 2007 R2 and Lync Server 2013 components, see Migration from Lync Server 2010 to Lync Server 2013 and Migration from Office Communications Server 2007 R2 to Lync Server 2013 in the Migration documentation. For details about mixed version support for clients, see Supported Clients from Previous Deployments.

1.2.4.2 Supported Clients from Previous Deployments

Supported Clients from Previous Deployments

Microsoft Lync Server 2013 > Supportability > Supported Migration Paths and Coexistence Scenarios >

Topic Last Modified: *2012-12-14*

In a coexistence scenario, Lync Server 2013 clients can interact with clients from earlier versions of Lync Server and Office Communications Server. Unlike previous releases, Lync Server 2010 supports the new Lync 2013 clients. This allows organizations who are upgrading from Lync Server 2010 to roll out new clients independent of Lync Server upgrades.

Supported Server and Client Combinations

The following table shows the supported combinations of client versions and server versions. Lync Server 2013 supports two previous client versions, and Lync Server 2010 supports the new Lync 2013 client.

Client	Lync Server 2013	Lync Server 2010	Office Communications Server 2007 R2
Lync 2013	Supported	Supported	Not Supported
Lync Web App 2013	Supported	Not Supported	Not Supported
Lync 2010	Supported	Supported	Not Supported
Lync 2010 Attendant	Supported	Supported	Not Supported
Lync 2010 Group Chat	Not Applicable	Supported[1]	Not Applicable
Lync Web App 2010	Not Supported	Supported	Not Supported
Lync 2010 Attendee	Not Supported[2]	Supported	Not Supported
Office Communicator 2007 R2	Interoperable[3]	Supported	Supported
Microsoft Office Communications Server 2007 R2 Attendant	Not Supported	Supported	Supported
Office Communicator 2007	Not Supported	Supported	Supported
Office Live Meeting 2007	Not Supported	Supported	Supported

[1] In Microsoft Lync Server 2010, group chat functionality was available with Group Chat Server, a third-party trusted application for Lync Server 2010. Lync 2013 clients are not compatible with Lync Server 2010, Group Chat.

[2] Lync Web App 2013 now provides a full in-meeting experience, including computer audio and video, and is considered the replacement for Lync 2010 Attendee.

[3] The presence and IM features in Office Communicator 2007 R2 are compatible with Lync Server 2013, but conferencing features are not. During migration from Office Communications Server 2007 R2, Office Communicator 2007 R2 is suitable for presence and IM interoperability, but users should use Lync Web App 2013 to join Lync Server 2013 meetings.

Note:

For details about the ability of Lync Server 2013 clients to coexist and interact with clients from earlier versions of Lync Server and Office Communications Server, see Client Interoperability in Lync 2013 in the Planning documentation.

1.2.5 Supported Hardware

Supported Hardware

Microsoft Lync Server 2013 > Supportability >

Topic Last Modified: *2012-09-21*

Lync Server 2013 hardware requirements vary according to server role, topology, storage requirements, and the specific deployment scenario.

- Server Hardware Platforms
- Client and Device Hardware Support
- File Storage Support

1.2.5.1 Server Hardware Platforms

Server Hardware Platforms

Microsoft Lync Server 2013 > Supportability > Supported Hardware >

Topic Last Modified: *2013-01-07*

Lync Server 2013 server roles and computers running Lync Server administrative tools require 64-bit hardware.

The specific hardware used for Lync Server 2013 deployment can vary, depending on size and usage requirements. This section describes the recommended hardware. Although these are recommendations, not requirements, using hardware that does not meet these recommendations may result in significant performance issues and other issues.

Recommended Hardware Platform

For best performance, we recommend that you run Lync Server on servers with hardware that meets the requirements in the following table. If you use less powerful hardware, you may experience functionality problems or poor performance. Note that these hardware requirements are higher than those of previous versions of Lync Server, primarily because in Lync Server 2013, all Front End Servers run SQL Server.

Recommended Hardware for Front End Servers, Back End Servers, Standard Edition Servers, and Persistent Chat Store and Persistent Chat Compliance Store (Back End Server Roles for Persistent Chat Server)

Hardware component	Recommended
CPU	64-bit dual processor, hex-core, 2.26 gigahertz (GHz) or higher Intel Itanium processors are not supported for Lync Server server roles.
Memory	32 gigabytes (GB)
Disk	• 8 or more 10,000 RPM hard disk drives with at least 72 GB free disk space. Two of the disks should use RAID 1, and six should use RAID 10. - OR - • Solid state drives (SSDs) which provide performance similar to 8 10,000-RPM

	mechanical disk drives.
Network	• 1 dual-port network adapter, 1 Gbps or higher (2 recommended, which requires teaming with a single MAC address and single IP address)

Recommended Hardware for Edge Servers, Standalone Mediation Servers, and Directors

Hardware component	Recommended
CPU	• 64-bit dual processor, quad-core, 2.0 gigahertz (GHz) or higher - OR - • 64-bit 4-way processor, dual-core, 2.0 GHz or higher Intel Itanium processors are not supported for Lync Server server roles.
Memory	16 gigabytes (GB)
Disk	• 4 or more 10,000 RPM hard disk drives with at least 72 GB free disk space - OR - • Solid state drives (SSDs) which provide performance similar to 4 10,000-RPM mechanical disk drives.
Network	• 1 dual-port network adapter, 1 Gbps or higher (2 recommended, which requires teaming with a single MAC address and single IP address)

1.2.5.2 Client and Device Hardware Support

Client and Device Hardware Support

Microsoft Lync Server 2013 > Supportability > Supported Hardware >

Topic Last Modified: *2012-10-01*

Client computers must meet certain hardware requirements to support clients in your Lync Server 2013 deployment. Additional hardware configurations must be in place before you deploy IP phones and analog devices.

- Lync Client Hardware Support
- Device Hardware Support
- Mobility Support

1.2.5.2.1 Lync Client Hardware Support

Lync Client Hardware Support

Supportability > Supported Hardware > Client and Device Hardware Support >

Topic Last Modified: *2012-12-14*

This section describes the recommended hardware for Lync 2013 and the Online Meeting Add-in for Lync 2013.

Recommended Hardware for Lync 2013 and the Online Meeting Add-in for Lync 2013

System component	Minimum requirement
Computer/processor	Intel Pentium 4, AMD Athlon 64, or equivalent
Memory	2 gigabytes (GB) of RAM
Data and Voice	Minimum 1.6 gigahertz (GHz) or faster processor. We recommend 2.0 gigahertz (32-bit or 64- bit).
Video	See Lync Client Video Requirements
Display resolution	1024x768 required
Graphics hardware	• Support for Microsoft DirectX 9 application programming interface • 128 megabytes (MB) of graphics memory (minimum). We recommend 256 MB of graphics memory. • Windows Display Driver Model driver • Pixel Shader 2.0 in hardware • 32 bits per pixel
Telephony	Microphone and speakers, headset with microphone, or equivalent device(s). Recommended devices: • Phones with the "Optimized for Microsoft Lync" logo (see Phones and Devices Qualified for Microsoft Lync at http://go.microsoft.com/fwlink/p/?LinkID=208938 for a list) • Phones that run Lync Phone Edition
Video source	USB 2.0 video camera or Polycom CX5000 HD device (RoundTable device)
Bandwidth Requirements	See Network Bandwidth Requirements for Media Traffic

1.2.5.2.2 Device Hardware Support

Device Hardware Support

Supportability > Supported Hardware > Client and Device Hardware Support >

Topic Last Modified: *2012-12-14*

Specific hardware configurations must be in place before you deploy IP phones and analog devices.

IP phones running Lync Phone Edition support Link Layer Discovery Protocol-Media Endpoint Discovery (LLDP-MED) and Power over Ethernet (PoE). To take advantage of LLDP-MED, the switch must support IEEE802.1AB and ANSI/TIA-1057. To take advantage of PoE, the switch must support PoE802.3AF or 802.3at.

To enable LLDP-MED, the administrator must enable LLDP by using the switch console window and set the LLDP-MED network policy with the correct voice VLAN ID.

In addition, if your deployment includes analog devices, you must configure the analog gateway to use Lync Server, and the gateway must be one of the following:

- An analog telephone adapter (ATA)
- A PSTN analog gateway
- A Survivable Branch Appliance that includes a PSTN analog gateway
- A Survivable Branch Appliance that includes a PSTN gateway that communicates with an ATA

To learn how to configure an analog gateway, see "Planning to Deploy Analog Devices" at http://go.microsoft.com/fwlink/p/?LinkId=268537 in the Lync Server 2010 TechNet Library. (Analog devices work the same way in Lync Server 2013 as they do in Lync Server 2010.)

◆**Important:**
You can configure the switch for Enhanced 9-1-1 (E9-1-1), if the switch supports this.

1.2.5.2.3 Mobility Support

Mobility Support

Supportability > Supported Hardware > Client and Device Hardware Support >

Topic Last Modified: *2012-06-29*

With Lync Server 2013 mobility, users have access to Lync 2013 functionality on their mobile devices. Supported mobile devices include the following:

- Supported Apple iOS devices
- Windows Phone
- Android
- Nokia

For details about mobility features and requirements, see Planning for Mobility in the Planning documentation.

1.2.5.3 File Storage Support

File Storage Support

Microsoft Lync Server 2013 > Supportability > Supported Hardware >

Topic Last Modified: *2012-10-16*

Lync Server 2013 uses the same file store for all file storage. File storage support includes the following:

- A file share on either direct attached storage (DAS) or a storage area network (SAN), including Distributed File System (DFS), and on a redundant array of independent disks (RAID) for file stores. For details about storage requirements, see Technical Requirements for Front End Servers, Instant Messaging, and Presence and Hardware and Software Requirements for the Director in the Planning documentation. For details about DFS for Windows Server 2008 operating system, see the DFS Step-by-Step Guide for Windows Server 2008 at http://go.microsoft.com/fwlink/p/?linkId=202835.
- A shared cluster for the file share. If you use a shared cluster, you should use cluster servers running Windows Server 2008 or Windows Server 2008 R2. Using cluster servers running an older version of Windows may result in permission issues that prevent some features from being available. Use the Cluster Administrator to create the file shares. For details about using the Cluster Administrator, see Microsoft Knowledge Base article 284838, "How to

Create a Server Cluster File Share with Cluster.exe" at http://go.microsoft.com/fwlink/p/?linkId=140899.

1.2.6 Server Software and Infrastructure Support

Server Software and Infrastructure Support

Microsoft Lync Server 2013 > Supportability >

Topic Last Modified: *2012-06-29*

Software support for server components, including all Lync Server 2013 server roles and storage, includes supported operating systems, database software, infrastructure software, and other software required to support specific functionality. It also includes virtualization of server components.

- Server and Tools Operating System Support
- Database Software Support
- Exchange Server and SharePoint Integration Support
- Certificate Infrastructure Support
- Wildcard Certificate Support
- Domain Name System (DNS) Infrastructure Support
- Internet Information Services (IIS) Support
- IP and Networking Protocol Support
- Public Instant Messaging Support
- Browser Support for Lync Server 2013 Control Panel
- Voice Support
- Virtualization Support

1.2.6.1 Server and Tools Operating System Support

Server and Tools Operating System Support

Microsoft Lync Server 2013 > Supportability > Server Software and Infrastructure Support >

Topic Last Modified: *2012-10-22*

All server roles support the same Windows Server operating systems. The required operating system support for other server roles, such as database servers, depends on what software you install on those servers.

Lync Server 2013 administrative tools are installed by default on the server running Lync Server 2013, but you can install administrative tools separately on other computers running Windows operating systems. For example, you can use a client computer running Windows 7 with Service Pack 1 (SP1) as an administrative console for planning purposes.

◆**Important:**
Lync Server 2013 is available only in 64-bit, which requires 64-bit hardware and 64-bit editions of Windows Server. This means that all server roles and computers running Lync Server 2013 administrative tools run a 64-bit edition operating system.

Operating Systems for Server Roles

Lync Server 2013 supports the 64-bit editions of the following operating systems:

- The Windows Server 2008 R2 with Service Pack 1 (SP1) Standard operating system (required) or latest service pack (recommended)
- The Windows Server 2008 R2 with SP1 Enterprise operating system (required)

or latest service pack (recommended)
- The Windows Server 2008 R2 with SP1 Datacenter operating system (required) or latest service pack (recommended)
- The Windows Server 2012 Standard operating system
- The Windows Server 2012 Datacenter operating system

Lync Server 2013 is not supported on the following:
- The Server Core installation option of Windows Server 2008 R2 or Windows Server 2012
- The Windows Web Server 2008 R2 operating system or the Windows Web Server 2012 operating system
- Windows Server 2008 R2 HPC Edition or Windows Server 2012 HPC Edition

Operating Systems for Other Servers

Operating system support for servers other than those on which you deploy Lync Server 2013 server roles depends on the software that you plan to install on those servers. For details about requirements for Back End Servers and other database servers, see Database Software Support in the Supportability documentation. For details about requirements for reverse proxy servers (for Edge deployment), see Internet Information Services (IIS) Support in the Supportability documentation. For details about other software requirements, including infrastructure and virtualization support, see the other topics in the Server Software and Infrastructure Support section of the Supportability documentation.

Additional Operating Systems for Administrative Tools

Lync Server 2013 supports installation of the administrative tools, which includes the Topology Builder, on computers running any of the 64-bit editions of the operating systems supported for deployment of server roles (as described in the previous section). Additionally, you can install administrative tools on the 64-bit editions of the following operating systems:
- The Windows 7 operating system with SP1 operating system (required) or latest service pack (recommended)
- The Windows 8 operating or latest service pack (recommended)

1.2.6.2 Database Software Support

Database Software Support

Microsoft Lync Server 2013 > Supportability > Server Software and Infrastructure Support >

Topic Last Modified: *2013-03-12*

The following list contains the database management systems for the back-end database, the Archiving database, the Monitoring database, the Persistent Chat database, and the Persistent Chat compliance database that are supported by Lync Server 2013:
- **Back-end database of a Front End pool, Archiving database, Monitoring database, persistent chat database, and persistent chat compliance database**
  - Microsoft SQL Server 2008 R2 Enterprise database software (64-bit edition). Additionally running the latest service pack is recommended.
  - Microsoft SQL Server 2008 R2 Standard (64-bit edition). Additionally running the latest service pack is recommended.
  - Microsoft SQL Server 2012 Enterprise (64-bit edition). Additionally running the latest service pack is recommended.

  - Microsoft SQL Server 2012 Standard (64-bit edition). Additionally running the latest service pack is recommended.
- **Standard Edition server database and local configuration store databases**
  - Microsoft SQL Server 2012 Express (64-bit edition)

Note:
Microsoft SQL Server 2012 Express (64-bit edition) is automatically installed by Lync Server 2013 on each Standard Edition server and each Lync Server 2013 server on which the local configuration store is deployed.

Important:
- Lync Server 2013 does not support the 32-bit edition of SQL Server. You must use the 64-bit edition.
- SQL Server Web edition and SQL Server Workgroup edition are not supported. You cannot use them with Lync Server 2013.
- Lync Server 2013 does support native database mirroring.
- To use the Monitoring Server role, you should install SQL Server Reporting Services.

In a Front End pool, the back-end database can be a single SQL Server computer.

Important:
If you collocate Lync Server databases with other databases, we highly recommend assessing all factors that might affect availability and performance, as well as ensuring that, if one node fails, the remaining node can handle the load. To verify failover capabilities, we recommend testing all failover scenarios.

SQL Clustering Topologies

SQL clustering topologies are not supported for new Lync Server 2013 deployments. For Back End Server high availability, SQL mirroring is the recommended and supported option.

If you are upgrading from a previous version of Lync Server and you have deployed an Enterprise Edition Front End pool that uses SQL clustering in that existing Lync Server topology, we recommend that you implement SQL Mirroring as a replacement for the existing SQL clustering deployment. However, continuing to use the existing SQL cluster with Lync Server 2013 is supported, but not recommended.

1.2.6.3 Exchange Server and SharePoint Integration Support

Exchange Server and SharePoint Integration Support

Microsoft Lync Server 2013 > Supportability > Server Software and Infrastructure Support >

Topic Last Modified: *2012-09-30*

Lync Server 2013 and Lync 2013 can securely and seamlessly communicate with other applications and server products, including Office 2013, Exchange 2013, and SharePoint, if you integrate these products. Integrating Lync Server 2013 and Office provides users with in-context access to the instant messaging (IM), enhanced presence, telephony, and conferencing capabilities of Lync. Office users can access Lync features from within the Outlook 2013 messaging and collaboration client and other Office programs or from a Microsoft SharePoint Server 2010 page. Users can also view a record of Lync conversations in the Outlook Conversation History folder. When integrated with Exchange 2013, Lync Server 2013 also supports the following the following:

- Unified contact store, which enables users to store all contact information in

Exchange 2013 so that the information is available globally across Lync 2013, Exchange 2013, Outlook, and Outlook Web App.

- Conversation history and Web conferencing history, which is stored in Exchange 2013 user folders.
- Archive data for users who are homed on Exchange 2013, if their mailboxes have been put on In-Place Hold.

Note:

Lync Server 2013 supports integration with previous versions of Microsoft Exchange Server and SharePoint, but not all functionality is supported with these previous versions, such as integration of Archiving storage with Microsoft Exchange.
If you are migrating your users to Exchange 2013, you can use both Exchange storage and Lync Server storage on an interim basis, while you complete the migration. Permanent use of both Exchange and Lync Server storage is not supported.

Integration of Lync Server 2013 with Exchange 2013 and SharePoint Server requires server-to-server authentication between servers running Lync Server 2013, Microsoft Exchange Server, and SharePoint Server. Lync Server 2013 supports OAuth (Open Authorization) protocol for server-to-server authentication and authorization. For on-premises server-to-server authentication between two Microsoft servers, there is no need to use a third-party token server. Lync Server 2013, Exchange 2013, and SharePoint have a built-in token server that can be used for authentication purposes with each other. For example, Lync Server 2013 can issue and sign a security token by itself, and use that token when communicating with Exchange 2013. In this case, there is no need to use a third-party token server.

Lync Server 2013 supports the two server-to-server authentication scenarios. These include configuration of server-to-server authentication between the following:

- An on-premise installation of Lync Server 2013 and an on-premises installation of Exchange 2013 and/or SharePoint Server.
- A pair of Office components (for example, between Microsoft Exchange 365 and Microsoft Lync Server 365, or between Microsoft Lync Server 365 and Microsoft SharePoint 365).

Note:

Server-to-server authentication between an on-premises server and an Office 365 component is not supported in this Lync Server 2013 release. Among other things, this means that you cannot set up server-to-server authentication between an on-premises installation of Lync Server 2013 and Microsoft Exchange 365.

For details about server-to-server authentication, see Managing Server-to-Server Authentication (Oauth) and Partner Applications in the Deployment documentation or Operations documentation.

1.2.6.4 Certificate Infrastructure Support

Certificate Infrastructure Support

Microsoft Lync Server 2013 > Supportability > Server Software and Infrastructure Support >

Topic Last Modified: *2012-11-16*

Lync Server 2013 requires a public key infrastructure (PKI) to support Transport Layer Security (TLS) and mutual TLS (MTLS) connections. By default, Lync Server 2013 is configured to use TLS for client-to-server connections. MTLS is used for connections between servers.

MTLS certificates must be issued by trusted certification authorities (CAs) for Lync Server

2013. Lync Server supports certificates that are issued from the following CAs:

- Certificates issued from an internal CA:
  - The Windows Server 2003 operating system CA
  - The Windows Server 2008 operating system CA
  - The Windows Server 2008 R2 operating system CA
  - The Windows Server 2012 operating system CA
- Certificates issued from a public CA

Communication with other applications and servers, such as Exchange 2013, requires a certificate that is supported by the other applications and products. For the 2013 release, Lync Server 2013 and other Microsoft server products, including Exchange 2013 and SharePoint Server, support the Open Authorization (OAuth) protocol for server-to-server authentication and authorization. For details, see Managing Server-to-Server Authentication (Oauth) and Partner Applications in the Deployment documentation or the Operations documentation.

For connections from clients running Windows 7 operating system, Windows Server 2008 R2 operating system, and Microsoft Office Communicator 2007 Phone Edition, Lync Server 2013 includes support for (but does not require) certificates signed using the SHA-256 cryptographic hash function. To support external access using SHA-256, the external certificate is issued by a public CA using SHA-256.

For details about certificate requirements, see Certificate Infrastructure Requirements in the Planning documentation. For details about use of wildcards with certificates, see Wildcard Certificate Support in the Supportability documentation.

1.2.6.5 Wildcard Certificate Support

Wildcard Certificate Support

Microsoft Lync Server 2013 > Supportability > Server Software and Infrastructure Support >

Topic Last Modified: *2012-09-21*

Lync Server 2013 uses certificates to provide communications encryption and server identity authentication. In some cases, such as web publishing through the reverse proxy, strong subject alternative name (SAN) entry matching to the fully qualified domain name (FQDN) of the server presenting the service is not required. In these cases, you can use certificates with wildcard SAN entries (commonly known as “wildcard certificates”) to reduce the cost of a certificate requested from a public certification authority and to reduce the complexity of the planning process for certificates.

⚠**Warning:**
To retain the functionality of unified communications (UC) devices (for example, desk phones), you should test the deployed certificate carefully to ensure that devices function properly after you implement a wildcard certificate.

There is no support for a wildcard entry as the subject name (also referred to as the common name or CN) for any role. The following server roles are supported when using wildcard entries in the SAN:

- **Reverse proxy.** Wildcard SAN entry is supported for simple URL publishing certificate.
- **Director.** Wildcard SAN entry is supported for simple URLs in Director web components.
- **Front End Server (Standard Edition) and Front End pool (Enterprise Edition).** Wildcard SAN entry is supported for simple URLs in Front End web components.

- **Exchange Unified Messaging (UM).** The server does not use SAN entries when deployed as a stand-alone server.
- **Microsoft Exchange Server Client Access server.** Wildcard entries in the SAN are supported for internal and external clients.
- **Exchange Unified Messaging (UM) and Microsoft Exchange Server Client Access server on same server.** Wildcard SAN entries are supported.

Server roles that are not addressed in this topic:

- Internal server roles (including, but not limited to the Mediation Server, Archiving and Monitoring Server, Survivable Branch Appliance, or Survivable Branch Server)
- External Edge Server interfaces
- Internal Edge Server

> **Note:**
> For the internal Edge Server interface, a wildcard entry can be assigned to the SAN, and is supported. The SAN on the internal Edge Server is not queried, and a wildcard SAN entry is of limited value.

For details about certificate configurations, including the use of wildcards in certificates, see the following topics:

- Certificate Requirements for Internal Servers
- Certificate Requirements for External User Access
- Certificate Summary - DNS and HLB Load Balanced
- Certificate Summary - Single Director
- Certificate Summary - Scaled Director Pool, Hardware Load Balancer
- Certificate Summary - Reverse Proxy
- Guidelines for Integrating On-Premises Unified Messaging and Lync Server 2013

For details about configuring certificates for Exchange, including the use of wildcards, see the Exchange 2013 product documentation.

1.2.6.6 Domain Name System (DNS) Infrastructure Support

Domain Name System (DNS) Infrastructure Support

Microsoft Lync Server 2013 > Supportability > Server Software and Infrastructure Support >

Topic Last Modified: *2013-03-08*

Lync Server 2013 requires Domain Name System (DNS) and uses it in the following ways:

- To discover internal servers or pools for server-to-server communications.
- To enable clients to discover the Front End pool or Standard Edition server used for various SIP transactions.
- To associate the simple URLs for conferences with the servers hosting those conferences.
- To enable external servers and clients to connect to Edge Servers or the HTTP reverse proxy for instant messaging (IM) or conferencing.
- To enable unified communications (UC) devices that are not logged in to discover the Front End pool or Standard Edition server running Device Update Web service, obtain updates, and send logs.
- To enable mobile clients to automatically discover Web Services resources without requiring users to manually enter URLs in device settings.
- For DNS load balancing.

Note:
Lync Server 2013 does not support internationalized domain names (IDNs).

Important:
The name you specify must be identical to the computer name configured on the server. By default, the computer name of a computer that is not joined to a domain is a short name, not a fully qualified domain name (FQDN). Topology Builder uses FQDNs, not short names. So, you must configure a DNS suffix on the name of the computer to be deployed as an Edge Server that is not joined to a domain. **Use only standard characters** (including A–Z, a–z, 0–9, and hyphens) when assigning FQDNs of your Lync Servers, Edge Servers, and pools. Do not use Unicode characters or underscores. Nonstandard characters in an FQDN are often not supported by external DNS and public CAs (that is, when the FQDN must be assigned to the SN in the certificate).

1.2.6.7 Internet Information Services (IIS) Support

Internet Information Services (IIS) Support

Microsoft Lync Server 2013 > Supportability > Server Software and Infrastructure Support >

Topic Last Modified: *2012-06-29*

Several Lync Server 2013 components require Internet Information Services (IIS). Supported versions of IIS included the following:

- IIS 8.0
- IIS 7.5

For details about the IIS requirements for Lync Server 2013 components, see Internet Information Services (IIS) Requirements in the Planning documentation.

1.2.6.8 IP and Networking Protocol Support

IP and Networking Protocol Support

Microsoft Lync Server 2013 > Supportability > Server Software and Infrastructure Support >

Topic Last Modified: *2012-09-21*

Lync Server 2013 supports the following IP and networking protocols:

- **IP Protocols.** Lync Server 2013 supports either IP version 4 (IPv4) or IP version 6 (IPv6) for the server network.

  Note:
  Lync Server 2013 can function in a network with dual IP stack enabled.

- **SIP Transport Protocols.** Generically, SIP can use at least three transport types: User Datagram Protocol (UDP), Transmission Control Protocol (TCP), and Transport Layer Security (TLS). In the default SIP transport configuration, TLS runs over TCP. TLS is used within the Lync Server 2013 network. At the edge of the network, Lync Server 2013 can interoperate over TCP. Lync Server 2013 does not support UDP for SIP transport because it doesn’t meet the minimum standards for enterprise communications security, reliability, and scalability. For details, see the NextHop blog article, "To UDP, or not to UDP, that is the question," at http://go.microsoft.com/fwlink/p/?linkId=185369.

  Note:

The content of each blog and its URL are subject to change without notice.

1.2.6.9 Public Instant Messaging Support

Public Instant Messaging Support

Microsoft Lync Server 2013 > Supportability > Server Software and Infrastructure Support >

Topic Last Modified: *2013-01-11*

Lync Server 2013 supports the use of licensed public instant messaging (IM) connectivity providers, as well as the use of eXtensible Messaging and Presence Protocol (XMPP) to implement a special type of federation that enables a Lync Server to access configured XMPP domain partners by using the Lync 2013 client.

Public IM Connectivity Provider Support

The currently supported public instant messaging connectivity partners are:

- America Online
- Windows Live
- Yahoo!

For communications with Windows Live users, Lync Server 2013 supports peer-to-peer IM and audio and video calls. For communications with AOL and Yahoo!, Lync Server 2013 supports peer-to-peer IM. A separate license may be required.

Important:

- As of September 1st, 2012, the Microsoft Lync Public IM Connectivity User Subscription License ("PIC USL") is no longer available for purchase for new or renewing agreements. Customers with active licenses will be able to continue to federate with Yahoo! Messenger until the service shut down date (exact date TBD, but no sooner than June 2013).
- The PIC USL is a per-user per-month subscription license that is required for Lync Server or Office Communications Server to federate with Yahoo! Messenger. Microsoft's ability to provide this service has been contingent upon support from Yahoo!, the underlying agreement for which is winding down.
- More than ever, Lync is a powerful tool for connecting across organizations and with individuals around the world. Federation with Windows Live Messenger requires no additional user/device licenses beyond the Lync Standard CAL. Skype federation will be added to this list, enabling Lync users to reach hundreds of millions of people with IM and voice.

XMPP Federation Support

XMPP federation supports Lync users communication with configured XMPP domain users who use a public provider, such as GTalk. Communications with these users can include the following:

- Peer-to-peer IM and presence
- Creation of XMPP federated contacts in the Lync client

1.2.6.10 Browser Support for Lync Server 2013 Control Panel

Browser Support for Lync Server 2013 Control Panel

Microsoft Lync Server 2013 > Supportability > Server Software and Infrastructure Support >

Topic Last Modified: *2012-09-28*

Lync Server 2013 supports the use of Topology Builder and Lync Server 2013 Control Panel is supported when using the following browsers:

- Internet Explorer 10, 32-bit
- Internet Explorer 9, 32-bit
- Internet Explorer 8, 32 bit

1.2.6.11 Voice Support

Voice Support

Microsoft Lync Server 2013 > Supportability > Server Software and Infrastructure Support >

Topic Last Modified: *2012-06-29*

If your deployment includes a Front End pool, you can deploy support for Enterprise Voice, the Voice over IP (VoIP) solution offered by Microsoft. Voice over IP (VoIP) is a software-based alternative to traditional PBX-based telephony. Although the VoIP call experience is similar to the traditional telephony experience, Enterprise Voice includes features that enable richer communication and collaboration. For example, your Enterprise Voice deployment can be configured to make it possible for Lync 2013 and Lync Phone Edition users to view enhanced presence information or location information for contacts in your organization's address book. Some Lync Server 2013 features are enabled through integration with other Lync Server 2013 workloads and with Exchange Unified Messaging (UM). For details about the features and functionality available with Enterprise Voice and how to plan for deployment, see Planning for Enterprise Voice in the Planning documentation.

- SIP Trunking Support
- Direct SIP Connections Support
- Exchange Unified Messaging (UM) Support
- E9-1-1 Support

1.2.6.11.1 SIP Trunking Support

SIP Trunking Support

Supportability > Server Software and Infrastructure Support > Voice Support >

Topic Last Modified: *2012-10-03*

If you plan to use Enterprise Voice with SIP trunking, you must deploy a Mediation Server and make sure that other infrastructure and components meet the support requirements appropriate to your deployment model. For details about determining whether to implement SIP trunking, see Overview of SIP Trunking in the Planning documentation.

You can use the Microsoft Unified Communications Open Interoperability Program for enterprise telephony infrastructure to find qualified public switched telephone network (PSTN) gateways, IP-PBXs, and SIP trunking services, including qualified IP telephony service providers. For details, see the Microsoft Unified Communications Open Interoperability Program website at http://go.microsoft.com/fwlink/p/?LinkId=203309.

Mediation Server Support

To implement SIP trunking, you must route the connection through a Mediation Server, which acts as a proxy for communications sessions between Lync Server 2013 clients and the service provider. The Mediation Server decodes the media traffic from clients and servers and re-encodes it before sending it to the service provider. The re-encoding is needed because SIP trunks do not support some codecs used, such as Real Time Audio (RTA) or Interactive Connectivity Establishment (ICE) protocol negotiation for firewall traversal.

Each Mediation Server can have two network adapters, which provide an internal and an external network interface. The external interface is commonly called the gateway interface because, traditionally, it has been used to connect to a PSTN gateway or an IP-PBX. To implement a SIP trunk, you connect the external interface to a Session Border Controller (SBC) at a service provider.

Centralized vs. Distributed SIP Trunking

Centralized SIP trunking routes all Voice over Internet Protocol (VoIP) traffic, including branch site traffic, through your data center. The centralized deployment model is simple, cost-effective, and is generally the preferred approach for implementing SIP trunks with Lync Server 2013.

Depending on usage patterns within your enterprise, you may not want to route all users through the centralized SIP trunk. To analyze your needs, answer the following questions:

- How big is each site? How many users?
- Which Direct Inward Dialing (DID) numbers at each site get the most phone calls?

Distributed SIP trunking is a deployment model in which you implement a local SIP trunk at one or more branch sites. VoIP traffic is then routed from the branch site directly to their service provider, without going through your data center.

Distributed SIP trunking is required only in the following cases:

- The branch site requires survivable phone connectivity (for example, if the WAN goes down). If the branch does need redundancy and failover, the service provider will charge more and the configuration will take longer. This should be analyzed for each branch site. Some of your branches may require redundancy and failover, while others may not.
- The branch site and data center are in different countries/regions. For compatibility and legal reasons, you need at least one SIP trunk per country/region.

Deciding whether to deploy centralized or distributed SIP trunking requires a cost-benefit analysis. In some cases, it may be advantageous to opt for the distributed deployment mode, even if it is not required. In a completely centralized deployment, all branch site traffic is routed over WAN links. Instead of paying for the bandwidth required for WAN linking, you may want to use distributed SIP trunking.

Note:
For details about why and how you might use distributed SIP trunking, see Branch Site SIP Trunking in the Planning documentation.

Supported SIP Trunking Connection Types

Lync Server 2013 supports the following connection types for SIP trunking:

- Multiprotocol Label Switching (MPLS) is a private network that directs and carries data from one network node to the next. The bandwidth in an MPLS network is shared with other subscribers, and each data packet is assigned a label to distinguish one subscriber's data from another's. This connection type does not require VPN. A potential drawback is that excessive IP traffic can interfere with VoIP operation unless VoIP traffic is given priority.
- A private connection with no other traffic is typically the most reliable and secure connection type (for example, a leased fiber-optic connection or T1 line). This connection type provides the highest call-carrying capacity, but is typically the most expensive. VPN is not required. Private connections are appropriate for organizations with high call volumes or stringent security and availability requirements.
- The public Internet is the least expensive connection type, but also the least reliable, and the one with the lowest call-carrying capacity. Your Internet Telephony Service Provider (ITSP) can help secure this SIP trunk connection type if it supports Transport Layer Security (TLS) and Secure Real-Time Transport Protocol (SRTP) to encrypt signaling and media traffic. If you cannot configure a SIP trunk connection through the Internet to use TLS and SRTP, we strongly recommend that you use a VPN tunnel to provide a more secure connection. Contact your ITSP to determine whether it provides support for TLS with SRTP.

Selecting a Connection Type

The most appropriate SIP trunking connection type for your enterprise depends on your needs and your budget.

- For a mid-size or larger enterprise, an MPLS network generally provides the most value. It can provide the necessary bandwidth at a cheaper rate than a specialized private network.
- Large enterprises may require a private fiber-optic or T1 connection.
- For a small enterprise or branch site with low call volume, SIP trunking through the Internet may be the best choice. However, this connection type is not recommended for mid-size or larger sites.

Codec Support

The service provider proxy must support the following codecs:

- G.711 a-law (used primarily outside North America)
- G.711 µ-law (used in North America)

1.2.6.11.2 Direct SIP Connections Support

Direct SIP Connections Support

Supportability > Server Software and Infrastructure Support > Voice Support >

Topic Last Modified: *2012-06-29*

Lync Server 2013 supports the use of direct SIP connections to connect Lync Server 2013 to either of the following:

- An IP-PBX
- A PSTN gateway

The Mediation Servers in a Lync Server 2013 pool can control multiple gateways, Session Border Controllers (SBCs) provided by telephony service providers, or some combination thereof. Additionally, multiple Mediation Servers in the pool can interact with a single gateway.

You can use the Microsoft Unified Communications Open Interoperability Program for enterprise telephony infrastructure to find qualified PSTN gateways, IP-PBXs, and SIP trunking services. For details, see the Microsoft Unified Communications Open Interoperability Program website at http://go.microsoft.com/fwlink/p/?linkId=203309.

For details about the topology and deployment options for direct SIP connections, see Direct SIP Connections in the Planning documentation.

1.2.6.11.3 Exchange Unified Messaging (UM) Support

Exchange Unified Messaging (UM) Support

Supportability > Server Software and Infrastructure Support > Voice Support >

Topic Last Modified: *2012-09-21*

Lync Server 2013 supports integration with Exchange Unified Messaging (UM) for combining voice messaging and email messaging into a single messaging infrastructure. In Exchange 2013, Exchange UM consists of the Exchange UM service, which is installed and runs on the Mailbox server, and the UM Call Router, which is installed and runs on the Client Access server. For Lync Server 2013 Enterprise Voice deployments, Exchange UM combines voice messaging and email messaging into a single store that is accessible from a telephone (that is, Outlook Voice Access) or a computer. Exchange UM and Lync Server 2013 work together to provide call answering, Outlook Voice Access, and auto attendant services to users of Enterprise Voice.

In addition to the support for integration with on-premises deployments of Exchange UM, Lync Server 2013 supports integration with hosted Exchange UM. This enables you to provide voice messaging to your users if you migrate some or all of them to a hosted Exchange service provider such as Microsoft Exchange Online.

Lync Server 2013 supports the following versions:

- Microsoft Exchange 2013
- Microsoft Exchange Server 2010 (required) or with latest service pack (recommended)
- Microsoft Exchange Server 2007 with Service Pack 1 (SP1) (required) or latest service pack (recommended)

You cannot collocate Exchange UM with Lync Server 2013 or a Lync Server 2013 database. You can install Exchange UM and Lync Server 2013 in separate forests.

Note:

Exchange UM may not be required for Enterprise Voice deployments that have a PBX deployed, because the PBX can continue to provide voice mail and related services to all users. If you eventually retire the PBX (for example, if you deploy SIP trunking for public switched telephone network (PSTN) connectivity), you must reconfigure Exchange UM to provide voice mail to users who previously used the PBX voice mail system.

- Components and Topologies for On-Premises Unified Messaging
- Support for Hosted Exchange UM Integration

1.2.6.11.3.1 Components and Topologies for On-Premises Unified Messaging

Components and Topologies for On-Premises Unified Messaging

Server Software and Infrastructure Support > Voice Support > Exchange Unified Messaging (UM) Support >

Topic Last Modified: *2012-09-25*

This topic describes the Microsoft Exchange Server 2013 components required to provide Exchange Unified Messaging (UM) features to Lync Server 2013 deployment. It also describes the supported topologies for on-premises Exchange UM integration.

Exchange Server Components

To provide the Exchange UM features and services described in Features of Integrated Unified Messaging and Lync Server 2013 to Enterprise Voice users in your organization, you must deploy an Microsoft Exchange Mailbox server and Client Access server, which hosts user mailboxes and provides a single storage location for email and voice mail. Exchange UM runs as a service on Exchange Mailbox and Client Access servers.

For details about Exchange UM components in Microsoft Exchange Server 2007 and Microsoft Exchange Server 2010, see Deploying On-Premises Exchange UM to Provide Lync Server 2013 Voice Mail in the Deployment documentation.

Supported Topologies

You can deploy Lync Server 2013 and Exchange Unified Messaging (UM) in the same forest or multiple forests. If the deployment spans multiple forests, you must perform the Exchange integration steps for each Exchange UM forest. Furthermore, you must configure each Microsoft Exchange forest to trust the Lync Server 2013 forest and the Lync Server 2013 forest to trust each Exchange UM forest. In addition to this forest trust, the Exchange UM settings for all users must be set on the user objects in the Lync Server 2013 forest.

Lync Server 2013 supports the following topologies for Exchange UM integration:

- Single forest
- Single domain (that is, a single forest with a single domain). Lync Server 2013, Microsoft Exchange, and users all reside in the same domain.
- Multiple domain (that is, a root domain with one or more child domains). Lync Server 2013, and Microsoft Exchange servers are deployed in different domains from the domain where you create users. Exchange UM servers can be deployed in different domains from the Lync Server 2013 pool they support.
- Multiple forest (that is, resource forest). Lync Server 2013 is deployed in a single forest, and then users are distributed across multiple forests. The users' Exchange UM attributes must be replicated over to the Lync Server 2013 forest.

Note:
Exchange can be deployed in multiple forests. Each Exchange organization can provide Exchange UM to its users, or Exchange UM can be deployed in the same forest as Lync Server 2013.

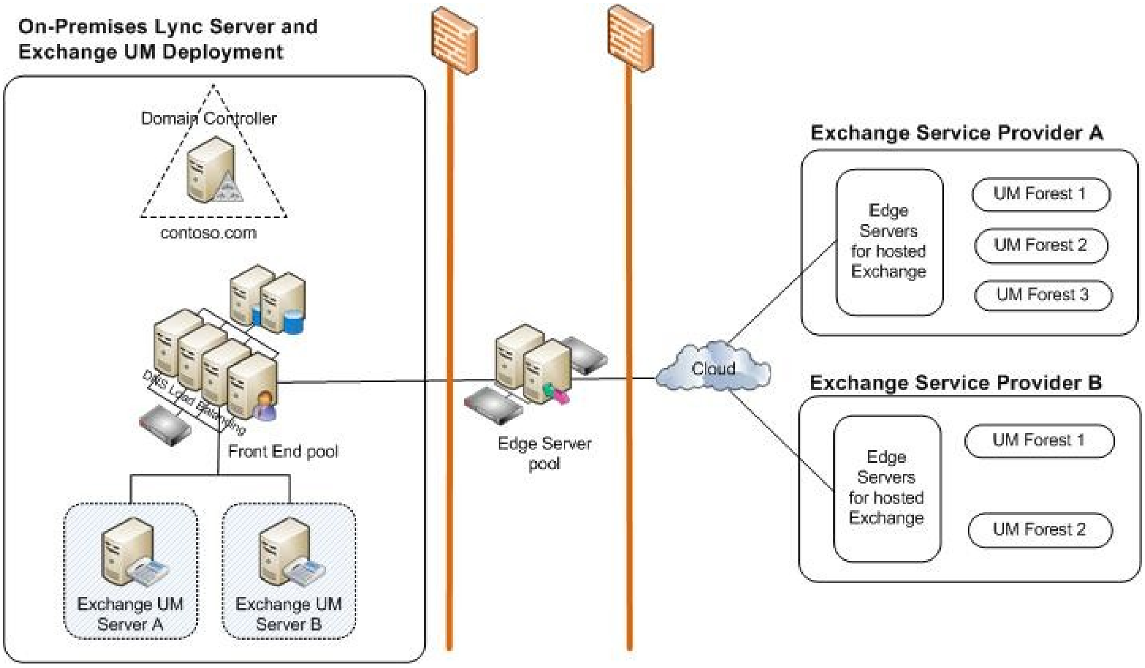
1.2.6.11.3.2 Support for Hosted Exchange UM Integration

Support for Hosted Exchange UM Integration

Server Software and Infrastructure Support > Voice Support > Exchange Unified Messaging (UM) Support >

Topic Last Modified: *2012-09-21*

The Lync Server 2013 ExUM Routing application supports integration with Exchange Unified Messaging (UM) in an on-premises environment, where Lync Server 2013 and Exchange UM are both installed locally within your enterprise, or in with Exchange UM hosted by a service provider, as shown in the following diagram.



The following modes are supported:

- **On-premises Mode** Lync Server 2013 and Exchange UM are both deployed on local servers within your enterprise.
- **Cross-premises Mode** Lync Server 2013 is deployed on local servers within your enterprise and Exchange UM is hosted in an online service provider's facility, such as a Microsoft Exchange Online data center.
- **Mixed Mode** Your Lync Server 2013 deployment has some user mailboxes homed on local servers running Microsoft Exchange Server within your enterprise and some mailboxes homed in a hosted Exchange service data center.

Note:

Mixed mode can be used as a transitional solution during evaluation and stepwise migration of users to hosted Exchange UM, or as a permanent solution if you opt to keep some users' Exchange UM services on-premises after migrating others.

To integrate Lync Server 2013 with hosted Exchange UM, you must configure a *shared SIP address space* (also called a *split domain*). In this configuration, both Lync Server 2013 and the third-party hosted Exchange UM service provider can access the same SIP domain address space. For details, see Hosted Exchange UM Integration Architecture in the Planning documentation.

1.2.6.11.4 E9-1-1 Support

E9-1-1 Support

Supportability > Server Software and Infrastructure Support > Voice Support >

Topic Last Modified: *2012-09-21*

Lync Server 2013 supports Enhanced 9-1-1 (E9-1-1) as part of an enterprise deployment. E9-1-1 is an emergency notification feature that associates the calling party's telephone number with a civic (that is, a street) address. E9-1-1 support is available only in the United States.

To support E9-1-1 as part of a Lync Server 2013 deployment, you must obtain E9-1-1 routing service from a certified emergency services provider or use an Emergency Location Identification Number (ELIN) gateway. The emergency services provider or carrier routes emergency calls that originate from Lync Server 2013 to the correct Public Safety Answering Point (PSAP), based on the location information contained within the call. For details about E9-1-1 support, see Planning for Emergency Services (E9-1-1) in the Planning documentation.

1.2.6.12 Virtualization Support

Virtualization Support

Microsoft Lync Server 2013 > Supportability > Server Software and Infrastructure Support >

Topic Last Modified: *2012-09-21*

Lync Server 2013 supports virtualization topologies that support all major workloads, including instant messaging (IM) and presence, conferencing, and Enterprise Voice. Virtualization is supported only on the Windows Server 2008 R2 operating system and Windows Server 2012 for all host and guest operating systems.

Lync Server 2013 supports virtualization of the following:

- **Servers in Front End pools.** If you virtualize a Front End Server, you can also virtualize some or all of the other server roles in the pool.
- **Standard Edition servers.** When deploying a virtualized Standard Edition server, the only server roles that can be deployed with it are Director and Edge Server, as well as Monitoring and Archiving, both of which run on the Standard Edition server.
- **Edge Servers for Front End pools and Standard Edition servers.**

Support includes both of the following:

- Microsoft Hyper-V technology
- VMWare

1.2.7 Additional Server Support and Requirements

Additional Server Support and Requirements

Microsoft Lync Server 2013 > Supportability >

Topic Last Modified: *2012-10-18*

In addition to the software support described in the other sections of this Supportability documentation, Lync Server 2013 has the following support limitations:

- Lync Server 2013 supports Domain Name System (DNS) and hardware load balancing for specific server roles. It also supports application load balancing for Mediation Servers, where appropriate. For details about when to use each, see the Planning documentation.
- Lync Server 2013 uses the Distribution List Expansion Protocol (DLX) to expand distribution lists. This protocol also specifies the web service method that is used to get the membership of a distribution list. Microsoft Exchange Server supports dynamic groups that do not have members statically assigned to them. Instead, they store queries that are evaluated when the group is expanded. DLX does not support dynamic distribution lists.
- The Enable User Wizard does not support automatic conversion of non-English characters to a SIP-compliant URI, so you must modify the SIP address manually.
- For servers running antivirus software, include all servers running Lync Server 2013 in the exception list in order to provide optimal performance and audio quality.
- If you use IPsec, we recommend disabling IPsec over the port ranges used for audio and video traffic. For details, see IPsec Exceptions in the Planning documentation.
- If your organization uses a Quality of Service (QoS) infrastructure, the media subsystem is designed to work within this existing infrastructure. For details about implementing QoS, see Managing Quality of Service (QoS) in the Operations documentation.
- Use of the operating system firewall is supported. Lync Server 2013 manages the firewall exceptions for the operating system firewall, except for Microsoft SQL Server database software. For details about SQL Server firewall requirements, see the SQL Server documentation.
- The external interfaces used to implement support for external user access must be on a separate subnet, *not* on the same network as the internal interfaces.
- The XMPP capability of Lync Server 2013 is tested and supported by Microsoft for instant messaging federation with Google Talk. For any other XMPP systems contact the third-party vendor to verify that they support federation with Lync Server 2013, and for any deployment or troubleshooting recommendations.
- Lync Server 2013 does not support two-factor authentication. However, if you deploy Lync Server 2013 in a network environment that already provides two-factor authentication (for example, a VPN with two-factor authentication), Lync Server 2013 works in that environment.
- Most internal servers require a certificate type defined as **Open Authentication** (OAuth). You are required to request and assign an OAuth certificate during the **Request, Install and Assign Certificates** phase of the Lync Server Deployment Wizard. The minimum size for an OAuth certificate key is 1024 bits. A warning may be displayed if you request a certificate with a key length less than 2048 bits in length. To avoid potential problems in the event that a key length of 2048 is enforced instead of warned, it is strongly recommended to always use a key length of 2048 for OAuth certificates.
- Lync Server 2013 and Microsoft Exchange Server 2010 Service Pack 1 (SP1) operate with support for Federal Information Processing Standard (FIPS) 140-2 algorithms if the Windows Server 2008 R2 operating systems are configured to use the FIPS 140-2 algorithms for system cryptography. To implement FIPS support, you must configure each server running Lync Server 2013 to support it. For details about FIPS-compliant algorithms and how to implement FIPS support, see Microsoft Knowledge Base article 811833, "System cryptography: Use FIPS compliant algorithms for encryption, hashing, and signing security setting in Windows XP and in later versions of Windows at http://go.microsoft.com/fwlink/p/?linkid=3052&kbid=811833. For details about FIPS 140-2 support and limitations in Exchange 2010, see "Exchange 2010 SP1 and Support for FIPS Compliant Algorithms" at http://go.microsoft.com/fwlink/p/?linkId=205335.

Lync Server 2013 requires the installation of other software on specific components prior to or during deployment. This includes software that is available with the operating system, downloadable software, and software that is automatically installed during installation of Lync Server 2013. Following is a list of additional software that can be required:

- Windows Update
- Windows Identity Foundation
- Microsoft .NET 4.5 Framework
- Microsoft Visual C++ 2012 Redistributable

> **Note:**
> Microsoft Visual C++ 2012 Redistributable is automatically installed when you install Lync Server 2013. You should not install and use any other version.

- URL Rewrite Module version 2.0 Redistributable
- Windows Media Format Runtime
- Windows PowerShell version 3.0
- Microsoft Silverlight 4 browser plug-in (Silverlight 4.0.50524.0 or the latest version for Lync Server Control Panel)
- Active Directory Domain Services (AD DS) tools

Some of these software requirements only apply to specific server roles or components. For details about these software requirements, see Additional Software Requirements in the Planning documentation.

1.2.8 Client and Device Software and Infrastructure Support

Client and Device Software and Infrastructure Support

Microsoft Lync Server 2013 > Supportability >

Topic Last Modified: *2012-10-01*

Software support for clients and devices of a Lync Server 2013 deployment includes the supported operating systems, infrastructure software, and other additional software required to support client and device features.

- Lync Client Software Support

> **Note:**
> Lync Phone Edition works the same way with Lync Server 2013 as it does with Lync Server 2010. For details about software support for devices, see the following topics in the Lync Server 2010 TechNet Library:
> - Required Lync Server 2010 Components for Devices at http://go.microsoft.com/fwlink/p/?linkid=256488
> - Device System and Infrastructure Support at http://go.microsoft.com/fwlink/p/?linkid=256489

1.2.8.1 Lync Client Software Support

Lync Client Software Support

See Also

Microsoft Lync Server 2013 > Supportability > Client and Device Software and Infrastructure Support >

Topic Last Modified: *2013-03-07*

This section summarizes software support for Lync 2013 and the Online Meeting Add-in for Lync 2013.

Note:

The Online Meeting Add-in for Lync 2013, which supports meeting management from within the Outlook messaging and collaboration client, installs automatically with Lync 2013.

Software Requirements for Lync 2013 and the Online Meeting Add-in for Lync 2013

System component	Minimum requirement
Windows Operating system	Windows 8 Windows 7 operating system Windows Server 2008 R2 with latest service pack
Installation and updates	Administrator rights and permissions
Browser	Windows Internet Explorer 10 Internet browser Windows Internet Explorer 9 Internet browser Windows Internet Explorer 8 Internet browser Windows Internet Explorer 7 Internet browser Mozilla Firefox web browser **Note:** If you are using Lync with Microsoft Exchange Online and your organization has deployed an authenticating HTTP proxy, Internet Explorer 9 or Internet Explorer 8 is required.
Microsoft Office Integration	For the full set of integration features: • Outlook 2013 messaging and collaboration client • Outlook 2010 messaging and collaboration client
Microsoft Exchange Integration	For the full set of integration features: • Microsoft Exchange Server 2013 • Microsoft Exchange Server 2010

Macintosh Operating Systems

Lync 2013 is available only for Windows. However, Lync Server 2013 supports the following clients on computers that are running Mac OS 10.5.8 or latest service pack or release (Intel-based) operating systems. For details about supported features, see Client Comparison Tables.

- Microsoft Lync for Mac 2011 (see “Lync for Mac 2011 Deployment Guide” at http://go.microsoft.com/fwlink/p/?LinkId=268786)
- Microsoft Communicator for Mac 2011 (see “Communicator for Mac 2011 Deployment Guide” at http://go.microsoft.com/fwlink/p/?LinkId=268787)

Lync Web App Browsers

Lync Web App supports specific combinations of operating systems and browsers. For details, see Lync Web App Supported Platforms in the Planning documentation.

Microsoft Office Supportability

Lync Server 2013 clients support integration with various versions of Microsoft Office, as summarized in this section.

- Lync 2013 integration features are supported on Outlook 2013 and Microsoft Outlook 2010.
- Lync 2013 integration features are supported on Microsoft Exchange Server 2013 and Microsoft Exchange Server 2010.
- Certain Lync 2013 integration features are supported on Microsoft Office 2007 and Microsoft Office 2003 Service Pack 3 (SP3). For integration with Microsoft Office 2007 to work correctly, you may have to install an update to Microsoft Office 2007. For details about the Outlook update, see Microsoft Knowledge Base article 936864, "Description of the 2007 Office hotfix package" at http://go.microsoft.com/fwlink/p/?linkid=3052&kbid=936864.
- The Online Meeting Add-in for Lync 2013 is supported with Office 2013, Microsoft Office 2010, Microsoft Office 2007, and the Microsoft Office 2003 suites.

Using Mandatory Profiles

If users are planning to use Lync 2013 conferencing features, they should not use Active Directory Domain Services (AD DS) mandatory profiles to sign in to the Lync 2013 client. Because mandatory profiles are read-only user profiles, the public key infrastructure (PKI) keys that are required for Lync 2013 conferencing cannot be saved to the profile. For details, see Microsoft Knowledge Base article 2552221, “Lync 2010 conferencing feature fails when the user is signed in using a mandatory user profile,” at http://go.microsoft.com/fwlink/p/?linkid=3052&kbid=2552221.

1.3 Planning

Planning

Microsoft Lync Server 2013 >

Topic Last Modified: *2012-10-16*

The planning phase is the time in which you decide what Lync Server 2013 features to deploy, and how to deploy them. The topics in this section describe how to plan for a successful Lync Server deployment.

- Planning Primer: Planning for Your Organization
- Determining Your Infrastructure Requirements
- Network Planning for Lync Server
- Capacity Planning
- Planning for High Availability and Disaster Recovery
- Planning for Manageability and Virtualization
- Planning for Front End Servers, Instant Messaging, and Presence
- Planning for Conferencing
- Planning for External User Access

- Planning for Enterprise Voice
- Planning for Monitoring
- Planning for Archiving
- Planning for Persistent Chat Server
- Planning for Exchange Server Integration
- Planning for Clients and Devices in Lync Server 2013
- Planning for Remote Call Control
- Planning for Mobility

1.3.1 Planning Primer: Planning for Your Organization

Planning Primer: Planning for Your Organization

Microsoft Lync Server 2013 > Planning >

Topic Last Modified: *2012-09-24*

The topics in this section help you get started with planning your Lync Server deployment.

- Deciding How to Deploy Microsoft Lync provides guidelines for choosing between these basic deployment scenarios for Lync Server 2013.
- Beginning the Planning Process helps you understand how to get started planning an on-premises deployment and how the planning documentation works with Topology Builder.
- Topology Basics You Must Know Before Planning describes the basics of Lync Server topologies, including sites, server pools, and topologies that support high availability and disaster recovery.
- Initial Planning Decisions takes you through the questions you must answer to decide what workloads and features of Lync Server to deploy.
- Clients for Lync Server 2013 describes the different types of client software that you can deploy to your organization’s users, including computer-installed client software, web-based clients, and mobile devices.
- Reference Topologies shows three sample topologies that illustrate good topology design in three typical organization types, and explains the reasoning behind many of the decisions in designing those topologies.

1.3.1.1 Deciding How to Deploy Microsoft Lync

Deciding How to Deploy Microsoft Lync

Microsoft Lync Server 2013 > Planning > Planning Primer: Planning for Your Organization >

Topic Last Modified: *2012-10-03*

When planning for Lync, the first major decision is how to deploy Microsoft Lync: as Lync Server 2013 on premises, or Lync Online with Microsoft Office 365 in the cloud.

- **Lync Server 2013 on-premises** : This choice provides the complete Lync feature set and provides ultimate flexibility in configuring, customizing, and operating your deployment. All servers are installed onsite and maintained by your organization. An on-premises deployment provides the full range of Lync Server features.
- **Lync Online in the cloud** Lync Online is designed for organizations that want the cost and agility benefits of cloud-based instant messaging, presence, and meetings without sacrificing the business-class capabilities of Lync Server. With Lync Online, Microsoft deploys and maintains the required server infrastructure, and handles ongoing maintenance, patches, and upgrades. Some features available in an on-premises deployment are not available in

Lync Online.

Which type of deployment would be best for you depends on the workloads you want to deploy, and your organization’s geographical and business status.

Lync Server

An on-premises Lync Server deployment is best for the following scenarios:

- **Full Enterprise Voice Capabilities** If you plan to deploy a full Enterprise Voice solution to replace your PBX or which uses advanced calling features, an on-premises Lync Server deployment is required. On-premises supports direct connectivity with PBX systems and trunks, and advanced phone features such as response groups and call park. Lync Online does not currently support these features.
- **Media Quality Controls** If you want the full range of media quality assurance features, such as Call Admission Control (CAC) and Quality of Service (QoS) features, you will want an on-premises deployment .
- **Persistent Chat** If you need to deploy Persistent chat for your organization, you must choose an on-premises deployment.
- **3rd-Party Server Applications** Only on-premises deployments can work with trusted 3rd-party applications that use the Microsoft Unified Communications Managed API (UCMA).
- **Multi-National/Multi-Regional Companies Needing Regional Support** If you have datacenters in multiple countries or regions and need servers to be deployed and managed on a regional basis, an on-premises deployment is best, as it provides this type of regional management capabilities.
- **Complete control over policies, reports, and upgrades** With an on premises Lync Server deployment, you have access to the full set of server and client policies, Monitoring and other reports, and timing of upgrades. Lync Online provides a subset of policy setting and reports, and provides a limited, though significant, window for accepting upgrades.

Lync Online

If none of the factors in the preceding list are critical for you, you may want to choose Lync Online, for simpler deployment and manageability. Lync Online provides a robust IM, presence and conferencing feature set, and also enables voice and video calls over IP between users in your organization.

1.3.1.2 Beginning the Planning Process

Beginning the Planning Process

Microsoft Lync Server 2013 > Planning > Planning Primer: Planning for Your Organization >

Topic Last Modified: *2012-09-24*

While planning an on-premises unified communications deployment may seem intimidating, Lync Server provides two valuable tools to help you:

- **The Planning Tool** is a wizard that presents a series of questions about your organization, the Lync Server features that you want to enable, and your capacity planning needs. It then creates a recommended deployment topology based on your answers, and produces a Microsoft Visio diagram of this deployment.
- **Topology Builder** is an installation component of Lync Server. You use Topology Builder to create, adjust, and publish your planned topology. It also validates your topology before you begin server installations. When you install Lync Server on individual servers, the servers read the published topology as

part of the installation process, and the installation program deploys the server as directed in the topology.

Lync Server Planning Tool

The Planning Tool takes your answers to the questions in the tool and generates a topology based on Lync Server guidelines and best practices. It also provides several views of a deployment based on your answers. It shows both a global view of all your sites (that is, including both central sites and branch sites), and detailed views showing the servers and other components at each site.

Running the Planning Tool does not commit you to any specific deployment or initiate any processes. In fact, running the Planning Tool even before you have a firm plan in mind can be a very instructive way to understand the kinds of questions you need to think about in your planning process.

You can run the Planning Tool multiple times, answering questions differently, and compare the outcomes. If you have a design you are mostly satisfied with but that you need to make changes to, you can return to the Planning Tool, load the design, and make the changes. It takes about 15 minutes to complete the Planning Tool once.

After you are satisfied, you can use the Planning Tool to create a diagram of your planned deployment. You can use this diagram while creating the deployment in Topology Builder.

Note:

The Planning Tool included with this release of Lync Server 2013 is a prerelease version. Note that the capacity planning numbers in the Planning Tool are preliminary and are not supported for the final release.

Lync Server Topology Builder

Once you have decided on your deployment plan, you use Topology Builder to begin deploying. When finished, you use Topology Builder to validate the topology, and then, if it passes, you can publish the topology. When you publish the topology, Lync Server puts the topology into the Central Management store, which is created at this time if it does not already exist. When you install Lync Server on each server in your deployment, the server reads the topology from the Central Management store and installs itself to fit into its role in your deployment.

Alternatively, if you are very familiar with Lync Server and need less prescriptive guidance, you can skip the Planning Tool and use the wizards in Topology Builder for the initial design of your deployment and also for the validation and publishing steps.

Using Topology Builder to plan and publish a topology is a required step. You cannot bypass Topology Builder and install Lync Server individually on the servers in your deployment. Each server must read the topology from a validated, published topology in the Central Management store.

High-Level Planning Process

We recommend the following general process for using both the documentation and the Planning Tool to plan your Lync Server deployment.

1. If you are familiar with previous versions of Lync Server, read New Server Features to familiarize yourself with the new features and requirements in Lync Server 2013.
2. Read the other topics in this section of the documentation: Topology Basics You Must Know Before Planning, Reference Topologies, Initial Planning Decisions, and Clients for Lync Server 2013. Note the planning decisions

represented in Reference Topologies.

3. Now that you are more familiar with Lync Server features and the kinds of questions that must be answered, run the Planning Tool and view the resulting topology and its details. Make sure that the topology fits the unique requirements for your organization.
4. If there are particular workloads or features you are interested in or need to learn about, read the appropriate sections of Planning.
5. Run the Planning Tool again. You can start with the deployment you created in step 3 and modify the results, or start over from the beginning. If needed, run the Planning Tool a third time and repeat until you are satisfied with the output.
6. When you have finalized the topology plan, use Planning Tool to create and print a Visio diagram of your topology. You can use this printout while working with Topology Builder to input your topology.
7. Before you begin deployment, read Determining Your System Requirements and Determining Your Infrastructure Requirements to familiarize yourself with the prerequisites and necessary infrastructure for Lync Server. Additionally, be sure you have read all the sections of Planning that apply to the workloads and features that you plan to deploy.

Migrating from Previous Versions

If you are migrating to Lync Server from a previous version, see the Migration documentation for specific instructions for your migration and deployment.

1.3.1.3 Topology Basics You Must Know Before Planning

Topology Basics You Must Know Before Planning

Microsoft Lync Server 2013 > Planning > Planning Primer: Planning for Your Organization >

Topic Last Modified: *2012-09-25*

You do not have to be an expert on Lync Server to run the Planning Tool. In fact, running the Planning Tool multiple times, answering questions differently, and comparing the output is a good way to learn about Lync Server.

Before you learn about the various components in more depth, you should understand the following basic aspects of Lync Server 2013 topologies.

- Sites
- Server Roles
- High Availability and Disaster Recovery Support

1.3.1.3.1 Sites

Sites

Planning > Planning Primer: Planning for Your Organization > Topology Basics You Must Know Before Planning >

Topic Last Modified: *2012-10-16*

In Lync Server, you define *sites* on your network that contain Lync Server components. A site is a set of computers that is well-connected by a high-speed, low-latency network, such as a single local area network (LAN) or two networks connected by a high-speed fiber optic network. Note that Lync Server sites are a separate concept from Active

Directory Domain Services (AD DS) sites and Microsoft Exchange Server sites. Your Lync Server sites do not need to correspond to your Active Directory sites.

Site Types

Each site is either a *central site*, which contains at least one Front End pool or a Standard Edition server, or a *branch site*. Each branch site is associated with exactly one central site, and the users at the branch site get most of their Lync Server functionality from the servers at the associated central site.

Each branch site contains one of the following:

- A *Survivable Branch Appliance (SBA)*, which is an industry-standard blade server with a Lync Server Registrar and a Mediation Server running on Windows Server. The Survivable Branch Appliance also contains a public switched telephone network (PSTN) gateway. The Survivable Branch Appliance is designed for branch sites with between 25 and 1000 users.
- A *Survivable Branch Server (SBS)*, which is a server running Windows Server that meets specified hardware requirements, and that has Lync Server Registrar and Mediation Server software installed on it. It must connect to either a PSTN gateway or a SIP trunk to a telephone service provider. The Survivable Branch Server is designed for branch sites with between 1000 and 5000 users.
- A PSTN gateway, and, optionally, a *Mediation Server*. For details on this and other server roles, see Server Roles.

A branch office with a resilient wide area network (WAN) link to a central site can use the third option—a PSTN gateway, and, optionally, a Mediation Server. Branch office sites with less-resilient links should use a Survivable Branch Appliance or Survivable Branch Server, which provide resiliency in times of wide-area network failures. For example, in a site with a Survivable Branch Appliance or Survivable Branch Server deployed, users can still make and receive Enterprise Voice calls if the WAN connecting the branch site to the central site is down. For details about the Survivable Branch Appliance, Survivable Branch Server, and resiliency, see Planning for Enterprise Voice Resiliency in the Planning documentation.

Site Topologies

Your deployment must include at least one central site, and can include zero to many branch sites. Each branch site is affiliated with one central site. The central site provides the Lync Server services to the branch site that are not hosted locally at the branch site, such as presence and conferencing.

If you have multiple sites, you can pair together the Front End pools at different sites to enable disaster recovery abilities. For details, see High Availability and Disaster Recovery Support.

Planning for Enterprise Voice Resiliency

Server Roles

Planning > Planning Primer: Planning for Your Organization > Topology Basics You Must Know Before Planning >

Topic Last Modified: *2013-01-11*

Each server running Lync Server runs one or more *server roles*. A server role is a defined set of Lync Server functionalities provided by that server. You do not need to deploy all available server roles in your network. Install only the server roles that contain the functionality that you want.

Even if you are not familiar with server roles in Lync Server, the Planning Tool can guide you to the best solution for the servers that you need to deploy, based on the features that you want. This section provides a brief overview of the server roles and the general features that they provide:

- Standard Edition Server
- Front End Server and Back End Server
- Edge Server
- Mediation Server
- Director
- Persistent Chat Front End Server
- Persistent Chat Store (Persistent Chat Back End Server)
- Persistent Chat Compliance Store (Persistent Chat Compliance Back End Server)

For most server roles, for scalability and high availability you can deploy *pools* of multiple servers all running the same server role. Each server in a pool must run an identical server role or roles. For most types of pools in Lync Server, you must deploy a load balancer to spread traffic between the various servers in the pool. Lync Server supports both Domain Name System (DNS) load balancing and hardware load balancers.

Standard Edition Server

The Standard Edition server is designed for small organizations, and for pilot projects of large organizations. It enables many of the features of Lync Server, including the necessary databases, to run on a single server. This enables you to have Lync Server functionality for a lower cost, but does not provide a true high-availability solution.

Standard Edition server enables you to use instant messaging (IM), presence, conferencing, and Enterprise Voice, all running on one server.

For a high-availability solution, use Lync Server Enterprise Edition.

Front End Server and Back End Server

In Lync Server Enterprise Edition, the Front End Server is the core server role, and runs many basic Lync Server functions. The Front End Server, along with the Back End Servers, are the only server roles required to be in any Lync Server Enterprise Edition deployment.

A *Front End pool* is a set of Front End Servers, configured identically, that work together to provide services for a common group of users. A pool of multiple servers running the same role provides scalability and failover capability.

The Front End Server includes the following:

- User authentication and registration
- Presence information and contact card exchange
- Address book services and distribution list expansion
- IM functionality, including multiparty IM conferences
- Web conferencing, PSTN Dial-in conferencing and A/V conferencing (if deployed)
- Application hosting, for both applications included with Lync Server (for example, Conferencing Attendant and Response Group application), and third-party applications
- Optionally, Monitoring, to collect usage information in the form of call detail records (CDRs) and call error records (CERs). This information provides metrics about the quality of the media (audio and video) traversing your network for both Enterprise Voice calls and A/V conferences.
- Web components to supported web-based tasks such as web scheduler and join launcher.
- Optionally, Archiving, to archive IM communications and meeting content for compliance reasons. For details, see Planning for Archiving in the Planning documentation.
  In Lync Server 2010 and prior versions, Monitoring and Archiving were separate server roles, not collocated on Front End Server.
- Optionally, if Persistent chat is enabled, Persistent Chat Web Services for Chat Room Management and Persistent Chat Web Services for File Upload/Download.

Front End Pools are also the primary store for user and conference data. Information about each user is replicated among three Front End Servers in the pool, and backed up on the Back End Servers.

Additionally, one Front End pool in the deployment also runs the *Central Management Server*, which manages and deploys basic configuration data to all servers running Lync Server. The Central Management Server also provides Lync Server Management Shell and file transfer capabilities.

The Back End Servers are database servers running Microsoft SQL Server that provide the database services for the Front End pool. The Back End Servers serve as backup stores for the pool’s user and conference data, and are the primary stores for other databases such as the Response Group database. You can have a single Back End Server, but a solution that uses SQL Server mirroring is recommended for failover. Back End Servers do not run any Lync Server software.

Important:

We do not recommend collocating Lync Server databases with other databases. If you do so, availability and performance may be affected.

Information stored in the Back End Server databases includes presence information, users' Contacts lists, conferencing data, including persistent data about the state of all current conferences, and conference scheduling data.

Edge Server

Edge Server enables your users to communicate and collaborate with users outside the organization’s firewalls. These external users can include the organization’s own users who are currently working offsite, users from federated partner organizations, and outside users who have been invited to join conferences hosted on your Lync Server deployment. Edge Server also enables connectivity to public IM connectivity services, including Windows Live, AOL, Yahoo!, and Google Talk.

Important:

- As of September 1st, 2012, the Microsoft Lync Public IM Connectivity User

Subscription License (“PIC USL”) is no longer available for purchase for new or renewing agreements. Customers with active licenses will be able to continue to federate with Yahoo! Messenger until the service shut down date (exact date TBD, but no sooner than June 2013).

- The PIC USL is a per-user per-month subscription license that is required for Lync Server or Office Communications Server to federate with Yahoo! Messenger. Microsoft’s ability to provide this service has been contingent upon support from Yahoo!, the underlying agreement for which is winding down.
- More than ever, Lync is a powerful tool for connecting across organizations and with individuals around the world. Federation with Windows Live Messenger requires no additional user/device licenses beyond the Lync Standard CAL. Skype federation will be added to this list, enabling Lync users to reach hundreds of millions of people with IM and voice.

Deploying Edge Server also enables mobility services, which supports Lync functionality on mobile devices. Users can use supported Apple iOS, Android, Windows Phone, or Nokia mobile devices to perform activities such as sending and receiving instant messages, viewing contacts, and viewing presence. In addition, mobile devices support some Enterprise Voice features, such as click to join a conference, Call via Work, single number reach, voice mail, and missed calls. The mobility feature also supports *push notifications* for mobile devices that do not support applications running in the background. A push notification is a notification that is sent to a mobile device about an event that occurs while a mobile application is inactive.

Edge Servers also include a fully-integrated Extensible Messaging and Presence Protocol (XMPP) proxy, with an XMPP gateway included on Front End Servers. You can configure these XMPP components to enable your Lync Server 2013 users to add contacts from XMPP-based partners (such as Google Talk) for instant messaging and presence.

For details, see Planning for External User Access in the Planning documentation.

Mediation Server

Mediation Server is a necessary component for implementing Enterprise Voice and dial-in conferencing. Mediation Server translates signaling, and, in some configurations, media between your internal Lync Server infrastructure and a public switched telephone network (PSTN) gateway, IP-PBX, or a Session Initiation Protocol (SIP) trunk. You can run Mediation Server collocated on the same server as Front End Server, or separated into a stand-alone Mediation Server pool.

For details, see Mediation Server Component in the Planning documentation.

Director

Directors can authenticate Lync Server user requests, but they do not home user accounts or provide presence or conferencing services. Directors are most useful to enhance security in deployments that enable external user access. The Director can authenticate requests before sending them on to internal servers. In the case of a denial-of-service attack, the attack ends with the Director and does not reach the Front End servers. For details, see Scenarios for the Director in the Planning documentation.

Persistent Chat Server Roles

Persistent chat enables users to participate in multiparty, topic-based conversations that persist over time. The Persistent Chat Front End Server runs the persistent chat service.

The Persistent Chat Back End Server stores the chat history data, and information about categories and chat rooms. The optional Persistent Chat Compliance Back End Server can store the chat content and compliance events for the purpose of compliance.

Servers running Lync Server Standard Edition can also run Persistent chat collocated on the same server. You cannot collocate the Persistent Chat Front End Server with Enterprise Edition Front End Server.

For details, see Planning for Persistent Chat Server.

1.3.1.3.3 High Availability and Disaster Recovery Support

High Availability and Disaster Recovery Support

See Also

Planning > Planning Primer: Planning for Your Organization > Topology Basics You Must Know Before Planning >

Topic Last Modified: *2012-09-25*

Lync Server 2013 provides high availability by server redundancy via pooling. If a server running a certain server role fails, the other servers in the pool running the same role take the load of that server. This applies to Front End Servers, Edge Servers, Mediation Servers, and Directors. For details about server roles, see Server Roles.

Lync Server 2013 also provides disaster recovery measures by enabling pool pairing. If you deploy this topology, you will designate pairs of Front End pools, with each pool in a pair located in a separate data center, and in a separate geographical area. If one pool or site goes down, you can redirect the users of that pool to use the other pool in the pair, with minimal interruption of service.

Lync Server 2013 also supports Back End Server high availability. This is an optional topology in which you deploy two Back End Servers for a Front End pool, and set up synchronous SQL Server mirroring for all the Lync databases running on the Back End Servers.

For details about pool pairing and Back End Server mirroring, see Planning for High Availability and Disaster Recovery.

Server Roles
Planning for High Availability and Disaster Recovery

1.3.1.4 Initial Planning Decisions

Initial Planning Decisions

Microsoft Lync Server 2013 > Planning > Planning Primer: Planning for Your Organization >

Topic Last Modified: *2012-10-01*

The first part of the planning process is deciding which Lync Server workloads and major features you want for your organization.

1. **Do you want an on-premises or online deployment?** Lync Server supports both deployment scenarios. For more information on making this decision, see Deciding How to Deploy Microsoft Lync, earlier in this section
2. **Do you want a physical or virtualized topology?** Lync Server supports all workloads and server roles in both physical and virtualized topologies. User capacity and scalability can differ between physical and virtual topologies. For more information, see Running Lync Server on Virtual Servers.
3. **Instant messaging *(IM)* and *presence* are always enabled.** In any Lync Server deployment, the instant messaging (IM) and presence workload is installed and enabled by default. IM enables your users to communicate with real-time text messages, and presence enables them to see the status of other users on the network. A user’s presence status provides information to help others decide whether they should try to contact the user, and by what means. For details, see Planning for Front End Servers, Instant Messaging, and Presence in the Planning documentation.
4. **Do you want to deploy any modes of conferencing?** Conferencing is another core feature of Lync Server. Several modes of conferencing are supported. You can choose to deploy all supported types of conferencing, or just some of them. *Web conferencing* enables users to see a file, such as a slide deck created with Microsoft PowerPoint presentation graphics program, that is being presented. *Application sharing* enables users to share all or part of their desktop with each other in real time. With *A/V conferencing*, users can add audio (and possibly video) to their conferences and peer-to-peer communications. *Dial-in conferencing* enables users to use standard PSTN phones to join the audio portion of conferences hosted at your organization. For details, see Planning for Conferencing in the Planning documentation.
   In Lync Server 2013, if you deploy Web conferencing, you must also plan for integration with Office Web Apps Server to enable Powerpoint sharing and viewing in meetings. For more information, see Configuring Integration with Office Web Apps Server and Lync Server 2013.
5. **If you deploy A/V conferencing, you should also monitor the audio quality of these conferences.** Many factors affect the audio and video quality of Lync Server A/V conferences. By using Monitoring, you can monitor the A/V quality of your calls and conferences. You can detect issues that affect media quality, and ensure that your users have the best possible media experience. For more information, see Planning for Monitoring.
6. **Do you want high availability for your IM, presence, and conferencing servers?** If you have only one server at a site providing IM, presence and conferencing features, your users’ productivity will be greatly affected if that server goes down. By deploying an Enterprise Edition *pool* of at least three servers for these functions, you make it possible for Lync Server to continue functioning with all of these features intact even if a server is unavailable. Another option for organizations with 5000 or fewer users who want high availability is to deploy two servers running Lync Server Standard Edition and pair these servers together. For more information, see Planning for High Availability and Disaster Recovery.
7. **Do you want disaster recovery options?** If you have two datacenters and want disaster recovery options to enable your users to continue to work if all or many servers at one datacenter go down, you can deploy your servers with disaster recovery in mind. For this deployment, you pair a pool of servers at one datacenter with a corresponding pool at another datacenter. If one

datacenter goes down, the other pool in the pair can service users in both pools with minimum interruption of services. For more information, see Planning for High Availability and Disaster Recovery.

8. **Do you want to enable your users to communicate and collaborate with external users?** Enabling communication and collaboration with external users can increase your return on investment in Lync Server. This enables your organization’s own users to benefit from Lync Server features even when they are working outside your organization’s firewalls. You can also federate with your partner or customer organizations that run Lync Server. By doing so, your users and federated partner users can easily send and receive IM messages, invite each other to meetings, and see each other’s presence. Additionally, your users can use an email message to invite specific outside users to conferences that they organize. For more information, see Planning for External User Access.
9. **Do you want to deploy Enterprise Voice?** *Enterprise Voice* is the voice over IP (VoIP) solution provided by Lync Server. It provides an attractive alternative to traditional PBX-based telephony. Enterprise Voice enables users to place calls from their computers or VoIP phones by clicking a contact in Outlook or Lync Server. They can place calls over the IP network from computer to computer, computer to telephone, or telephone to computer. Users benefit from having all of their communications options-voice, email, IM, and conferencing-available and integrated on their computers. For details, see Planning for Enterprise Voice in the Planning documentation.
10. **If you deploy Enterprise Voice, you should also monitor the audio quality of these calls.** We recommend you use Monitoring to ensure the audio quality of your Enterprise Voice calls, if you deploy Enterprise Voice. For more information, see Planning for Monitoring.
11. **Do you need to archive IM content or meeting content for compliance purposes?** If your organization has to archive IM content or meeting content for compliance purposes, you can deploy Archiving. For more information, see Planning for Archiving.
12. **Do you want to deploy Persistent chat?** If you want to enable your users to have real-time conversations that can persist over time, you can deploy Persistent chat. For more information, see Planning for Persistent Chat Server.
13. **Do you have Microsoft Exchange deployed?** If your organization uses Microsoft Exchange Server for its email services, you can enable several features which enhance the usefulness of both Lync Server and Microsoft Exchange Server. Some of these features, called Exchange Unified Messaging (UM), include enabling users to receive voice mail notices and listen to voice mail from Outlook or Outlook Web Access, to access their Microsoft Exchange mailboxes using a telephone, and to receive faxes in their Microsoft Exchange mailboxes. Additionally, if you have Exchange 2013 deployed, you can integrate the contact stores for users between the two systems, use Exchange to store higher-resolution contact photos, and integrate the archiving of emails and instant messages. For more information, see Planning for Exchange Server Integration.
14. **Do you have branch offices in your organization?** If your organization has branch offices, Lync Server supports a variety of ways to support them and ensure their resiliency for voice and other features. In particular, at a branch office that does not have a resilient WAN link to a data center, you can install a Survivable Branch Appliance or Survivable Branch Server to maintain Enterprise Voice support should the wide area network (WAN) link go down. For more information, see Planning for Branch-Site Voice Resiliency.

1.3.1.5 Clients for Lync Server 2013

Clients for Lync Server 2013

See Also

Microsoft Lync Server 2013 > Planning > Planning Primer: Planning for Your Organization >

Topic Last Modified: *2013-02-19*

Lync Server 2013 supports several types of client software that you can deploy to your organization's users, including computer-installed client software, web-based clients, and mobile devices. This topic outlines the clients that you can use. For a detailed comparison of the features provided by Lync Server 2013 clients, see Client Comparison Tables.

Lync 2013

Lync 2013 is the full-featured client for Lync Server. The Lync 2013 user interface has been fully redesigned and includes newly integrated features, such as Persistent Chat (Lync 2010 had a separate client for chat functionality), tabbed conversations, video preview, and multiparty video. For a summary of changes, see What's New for Clients.

Lync 2013 client setup is part of the Office setup program on the installation media.

Online Meeting Add-in for Lync 2013

The Online Meeting Add-in for Lync 2013 supports meeting management from within Microsoft Outlook messaging and collaboration client. The Online Meeting Add-in for Lync 2013 software installs automatically with Lync 2013.

Lync Web Scheduler

Lync Web Scheduler is a web-based meeting scheduling and management tool for users who don't have access to Microsoft Outlook, or who are on an operating system not based on Windows. With Lync Web Scheduler, users can create new meetings, modify existing meetings, and send invitations using their preferred email program.

Lync Web App

Lync Web App is the web-based conferencing client for Lync Server 2013 meetings. In this release, the addition of computer audio and video to Lync Web App provides a complete in-meeting experience for anyone who does not have a Lync client installed locally. Meeting participants have access to all collaboration and sharing features and presenter meeting controls.

If Lync 2013 is not installed on a user's computer and the user clicks a meeting link in a meeting request, Lync Web App opens. You can also configure the Meeting Join page to allow users to join meetings by using previous versions of clients; see Configuring the Meeting Join Page in the Deployment documentation.

Because of the enhancements to Lync Web App, an updated version of Microsoft Lync 2010 Attendee is not available for Lync Server 2013. Lync Web App is the client of choice for participants outside your organization. With Lync Web App, no local client installation is required, although audio, video, and sharing features require installation of a plug-in during first use.

Lync 2013 Basic

Lync 2013 Basic is a downloadable client for customers who have a licensed, on-premises Lync Server 2013 deployment and customers who subscribe to a Microsoft Office 365 plan that does not include the full Lync 2013 client. The Lync Basic client includes enhanced presence, contacts, instant messaging (IM), Lync meetings, and basic voice functionality. Features not supported in Lync Basic include multiparty video, OneNote integration, virtual desktop infrastructure (VDI) support, skill search, recording, Enterprise Voice features, and advanced call handling (for example, call forwarding and Team Call). For details, see Client Comparison Tables.

Lync Windows Store App

The Lync Windows Store app is a touch-optimized Lync app designed specifically for Windows 8 and Windows RT. Users can download the app through the Windows Store by searching for "Lync." For more information, see Client Comparison Tables, Lync Windows Store App Requirements, and Deploying Lync Windows Store App.

Lync 2013 for Mobile Devices

Lync 2013 mobile apps now include voice over IP (VoIP) and video over IP capabilities, in addition to contacts, presence, and IM features. Mobile users can choose to communicate with others through IM, voice calls, or video calls by using either Wi-Fi or their cellular data connection. With a single click of the meeting link in a calendar item, mobile users can join voice and video meetings. For more information about Lync 2013 mobile apps, see Planning for Mobile Clients.

Supported Clients from Previous Releases

Lync Server 2013 supports the following clients from previous server releases. You can make certain previous clients available to users when they join meetings. For details, see Configuring the Meeting Join Page in the Deployment documentation.

- **Lync 2010** Lync 2010 provides a full desktop experience, including IM, enhanced presence, voice, video, sharing, and telephony. However, none of the new features introduced in Lync Server 2013 will be available until the user’s client is upgraded to Lync 2013.
- **Lync 2010 Mobile** Lync Server 2013 supports all of the Microsoft Lync 2010 Mobile mobile apps. Microsoft Lync 2010 Mobile provides IM, enhanced presence, and telephony for users in your organization who are connecting from a smartphone or a phone running a Professional edition of Windows Mobile. You can instruct your users to install Microsoft Lync 2010 Mobile by directing them to the app marketplace for their mobile phone. For details, see “Planning for Mobile Clients” in the Lync Server 2010 documentation at http://go.microsoft.com/fwlink/p/?LinkID=235955.
- **Lync Phone Edition** Lync Phone Edition software for intelligent IP phones (for example, USB-attached phones) has not been updated for Lync Server 2013. Lync Phone Edition continues to be supported in for placing and receiving calls, enhanced presence, and client audio capabilities for conferences.
- **Lync 2010 Attendant** The Microsoft Lync 2010 Attendant integrated call-management program enables a receptionist to manage multiple conversations at the same time through rapid call handling, IM, and onscreen routing.

1.3.1.6 Reference Topologies

Reference Topologies

Microsoft Lync Server 2013 > Planning > Planning Primer: Planning for Your Organization >

Topic Last Modified: *2012-05-21*

The ideal Lync Server topology depends on your organization's size, the workloads you want to deploy, and your preferences for high availability versus cost of investment.

The following topics outline three reference topologies, including the reasoning behind many of the decisions that drive the requirements for each topology.

- Reference Topology For Small Organizations
- Reference Topology For Medium Organizations
- Reference Topology for Large Organizations With Multiple Data Centers

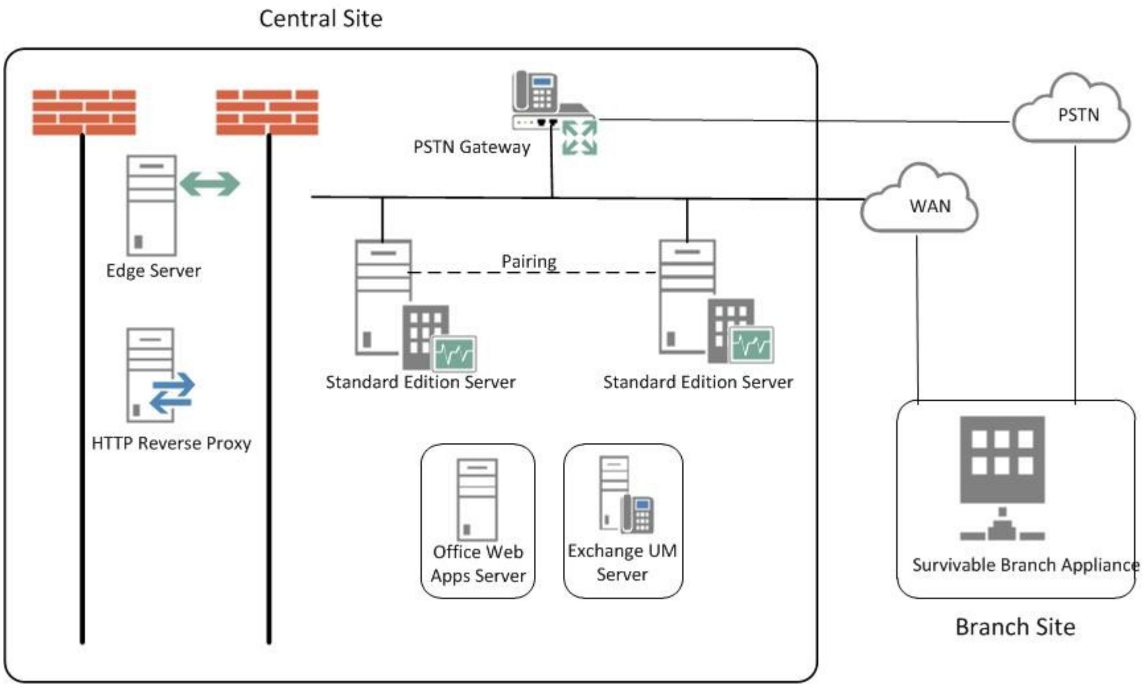
1.3.1.6.1 Reference Topology For Small Organizations

Reference Topology For Small Organizations

Planning > Planning Primer: Planning for Your Organization > Reference Topologies >

Topic Last Modified: *2013-03-12*

The reference topology for small organizations shows how you can deploy a robust, highly available solution by deploying only three servers running Lync Server.



- **Pair of Standard Edition Servers Deployed** This organization has 4,000 users at their central site. The organization has deployed two Standard Edition servers and paired them together to enable high availability and disaster recovery. Each server homes 2,000 users, but information about all users is synchronized between the two servers. If one goes down, an administrator can fail over those users to be served by the other server, with a minimum of disruption to users. For more information about high availability and disaster recovery features in Lync Server 2013, see Planning for High Availability and Disaster Recovery.

- **Edge Server deployment is recommended.** Although deploying an Edge Server is not required for internal IM, presence and conferencing, we recommend it even for small deployments. You can maximize your Lync Server investment by deploying an Edge Server to provide service to users currently outside your organization's firewalls. The benefits include the following:
  - Your organization's own users can use Lync Server functionality, if they are working from home or are out on the road.
  - Your users can invite outside users to participate in meetings.
  - If you have a partner, vendor or customer organization that also uses Lync Server, you can form a *federated relationship* with that organization. Your Lync Server deployment would then recognize users from that federated organization, leading to better collaboration.
  - Your users can exchange instant messages with users of public IM services, including any or all of the following: Windows Live, AOL, Yahoo!, and Google Talk. A separate license might be required for public IM connectivity with these services.

Important:

- As of September 1st, 2012, the Microsoft Lync Public IM Connectivity User Subscription License ("PIC USL") is no longer available for purchase for new or renewing agreements. Customers with active licenses will be able to continue to federate with Yahoo! Messenger until the service shut down date (exact date TBD, but no sooner than June 2013).
- The PIC USL is a per-user per-month subscription license that is required for Lync Server or Office Communications Server to federate with Yahoo! Messenger. Microsoft's ability to provide this service has been contingent upon support from Yahoo!, the underlying agreement for which is winding down.
- More than ever, Lync is a powerful tool for connecting across organizations and with individuals around the world. Federation with Windows Live Messenger requires no additional user/device licenses beyond the Lync Standard CAL. Skype federation will be added to this list, enabling Lync users to reach hundreds of millions of people with IM and voice.

- **Branch site survivability.** This organization is running a pilot program of the Enterprise Voice feature of Lync Server. Some users are using Lync Server as their sole voice solution. Some of these Voice pilot users are located at the branch site. The branch site does not have a reliable wide area network (WAN) link to the central site, so a Survivable Branch Appliance is deployed there. With this deployed, if the WAN link goes down, users at the branch site can still make and receive calls (both calls within the organization and PSTN calls), have voice mail functionality, and communicate with two-party instant messaging (IM). Users can also be authenticated when the WAN link is unavailable as well.
- **Exchange UM deployment.** This reference topology includes an Exchange Unified Messaging (UM) Server, which runs Microsoft Exchange Server, not Lync Server.
  For details about Exchange UM, see Planning for Exchange Unified Messaging

Integration and Hosted Exchange Unified Messaging Integration in the Planning documentation.
- **Office Web Apps Server.** We recommend deploying an Office Web Apps Server or Office Web Apps Server farm in every organization that uses web conferencing. Office Web Apps Server makes it possible for PowerPoint slides to be presented in web conferences. For more information, see Configuring Integration with Office Web Apps Server and Lync Server 2013.

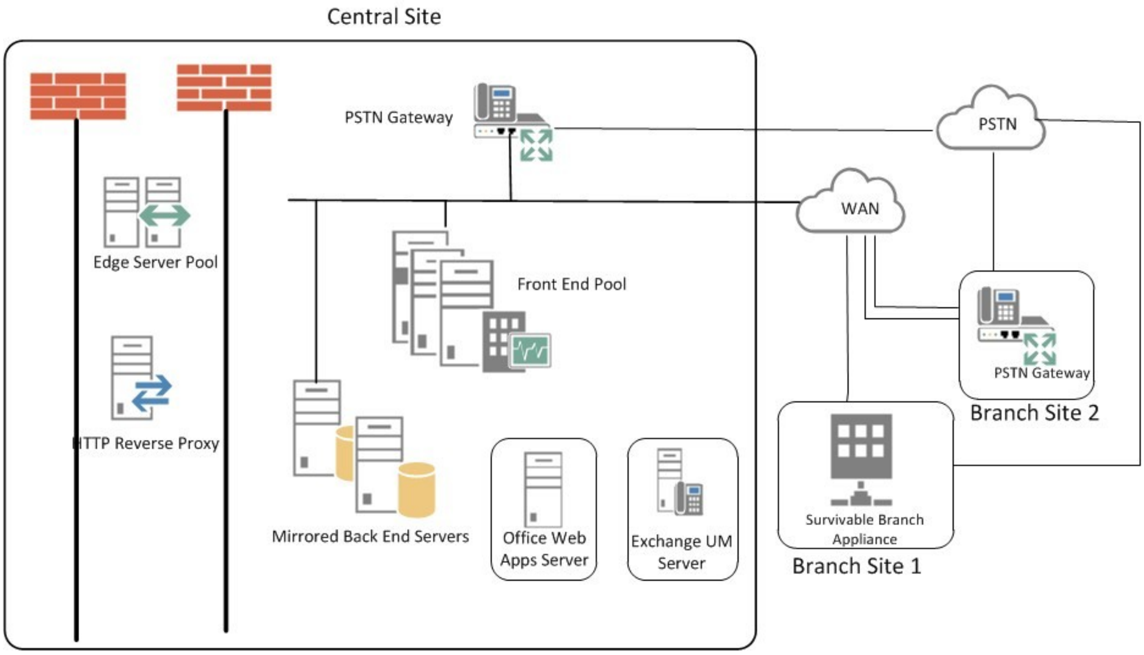
1.3.1.6.2 Reference Topology For Medium Organizations

Reference Topology For Medium Organizations

Planning > Planning Primer: Planning for Your Organization > Reference Topologies >

Topic Last Modified: *2013-01-11*

The reference topology with high availability and a single data center is designed for a small-to-medium size organization with one central site. The exact topology in the following diagram is for an organization of 20,000 users.



- **Accommodate more users by adding more Front End Servers.** The exact topology in this diagram has three Front End Servers to provide support for 20,000 users. If you have a single central site and more users, you can simply add more Front End Servers to the pool. The maximum number of users per pool is 80,000, with twelve Front End Servers.
However, the single site topology can support even more users by adding another Front End pool to the site.
- **Disaster Recovery could be added.** For this organization, high availability for their Lync Server services is a necessary feature, but disaster recovery is not. The pool of Front End Servers they have deployed provides high availability. If they wanted to add disaster recovery ability, they could consider establishing another datacenter and adding another Front End pool there, and pairing it with the Front End pool in their current datacenter. Then, if there was a disaster affecting their primary pool, the administrators could fail over users to the backup pool.

- **Back End Servers are mirrored** To provide more high availability for basic user features, the organization has deployed a mirrored pair of Back End Servers for each Front End pool. This is a new topology option for Lync Server 2013, and is optional. You could choose to deploy a single Back End Server instead.
- **Monitoring Server database options.** This organization has deployed Monitoring to ensure the quality of Enterprise Voice calls and A/V conferences. Monitoring is deployed on every Front End Server, and the Monitoring database is collocated with the Back End Servers. We also support topologies in which the Monitoring database is located on a separate server.
- **Edge Server high availability** In this example organization with 20,000 users, just one Edge Server would be sufficient for performance. However, there is a pool of two Edge Servers deployed to provide high availability.
- **Branch site deployment options.** The organization in this topology has Enterprise Voice deployed as their voice solution. Branch Site 1 does not have a resilient wide area network (WAN) link to the central site, so it has a Survivable Branch Appliance deployed to maintain many Lync Server features in case the WAN link to the central site goes down. Branch Site 2 however has a resilient WAN link, so only a public switched telephone network (PSTN) gateway is needed. The PSTN gateway deployed there supports media bypass, so no Mediation Server is needed at Branch Site 2. For details about deciding what to deploy at a branch site, see Planning for Branch-Site Voice Resiliency in the Planning documentation.
- **DNS load balancing.** The Front End pool andEdge Server pool, have DNS load balancing for SIP traffic deployed. This eliminates the need for hardware load balancers for the Edge Servers, and significantly lessens the setup and maintenance of the hardware load balancers for the other pools, as the hardware load balancers are needed only for HTTP traffic. For details about DNS load balancing, see DNS Load Balancing in the Planning documentation.
- **Exchange UM deployment.** This reference topology includes an Exchange Unified Messaging (UM) Server, which runs Microsoft Exchange Server, not Lync Server.
  For details about Exchange UM, see Planning for Exchange Unified Messaging Integration and Hosted Exchange Unified Messaging Integration in the Planning documentation.
- **Office Web Apps Server.** We recommend deploying an Office Web Apps Server or Office Web Apps Server farm in every organization that uses web conferencing. Office Web Apps Server makes it possible for Powerpoint slides to be presented in web conferences. For more information, see Configuring Integration with Office Web Apps Server and Lync Server 2013.
- **Edge Servers are recommended.** Although deploying an Edge Server is not required, we recommend it for any size of deployment. You can maximize your Lync Server investment by deploying an Edge Server to provide service to users currently outside your organization's firewalls. The benefits include the following:
  - Your organization's own users can use Lync Server functionality, if they are working from home or are out on the road.
  - Your users can invite outside users to participate in meetings.
  - If you have a partner, vendor or customer organization that also uses Lync Server, you can form a *federated relationship* with that organization. Your Lync Server deployment would then recognize users from that federated organization, leading to better collaboration.
  - Your users can exchange instant messages with users of public IM services, including any or all of the following: Windows Live, AOL, Yahoo!, and Google Talk. A separate license might be required for public IM connectivity with these services.

◆**Important:**
- As of September 1st, 2012, the Microsoft Lync Public IM Connectivity User Subscription License

> ("PIC USL") is no longer available for purchase for new or renewing agreements. Customers with active licenses will be able to continue to federate with Yahoo! Messenger until the service shut down date (exact date TBD, but no sooner than June 2013).
>
> - The PIC USL is a per-user per-month subscription license that is required for Lync Server or Office Communications Server to federate with Yahoo! Messenger. Microsoft's ability to provide this service has been contingent upon support from Yahoo!, the underlying agreement for which is winding down.
> - More than ever, Lync is a powerful tool for connecting across organizations and with individuals around the world. Federation with Windows Live Messenger requires no additional user/device licenses beyond the Lync Standard CAL. Skype federation will be added to this list, enabling Lync users to reach hundreds of millions of people with IM and voice.

- **Directors could be added.** If this organization wanted to help to increase security against denial of service attacks, it could also deploy a pool of Directors. A Director is a separate, optional server role in Lync Server that does not home user accounts, or provide presence or conferencing services. It serves as an internal next hop server to which an Edge Server routes inbound SIP traffic destined for internal servers. The Director pre-authenticates inbound requests and redirects them to the user's home pool or server. Pre-authentication at the Director allows for dropping of requests from user accounts unknown to the deployment. A Director helps insulate Front End Servers from malicious traffic such as denial-of-service (DoS) attacks. If the network is flooded with invalid external traffic in such an attack, the traffic ends at the Director.
- **System Center Operations Manager is recommended.** We recommend that you monitor the health of your Lync Server deployment to help ensure service availability for end-users. You can monitor Lync with the System Center Operations Manager Management Pack for Lync that is available as a free download from Microsoft. With the Lync Management Pack, you can proactively get real-time alerts when issues occur, run synthetic transactions to test end-to-end Lync functionality, get reports for service availability, and so on. This helps you to proactively respond to issues with your deployment before end-users experience them.

1.3.1.6.3 Reference Topology for Large Organizations With Multiple Data Centers

Reference Topology for Large Organizations With Multiple Data Centers

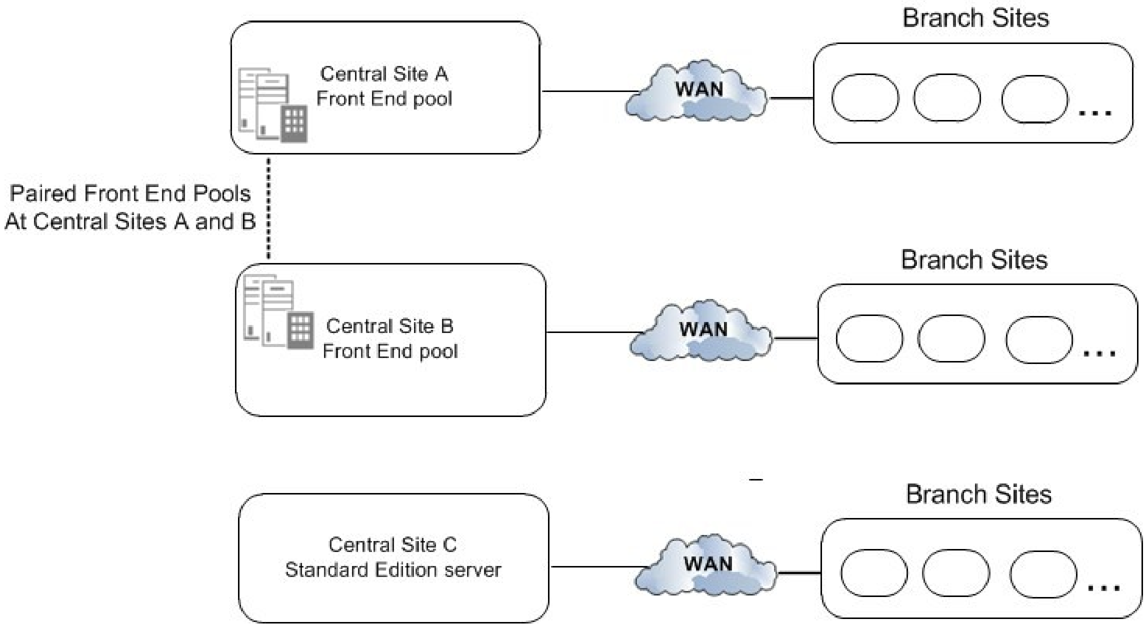
Planning > Planning Primer: Planning for Your Organization > Reference Topologies >

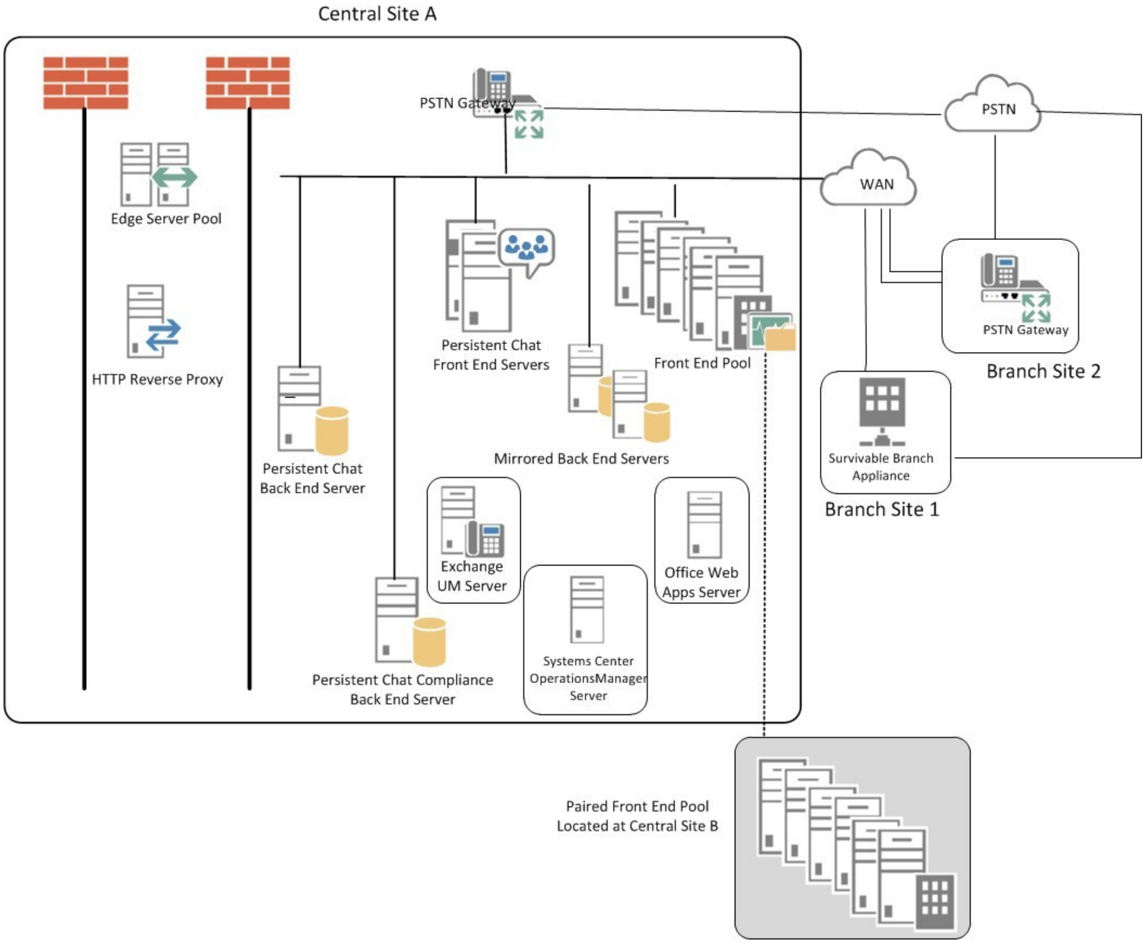
Topic Last Modified: *2012-10-22*

The reference topology for a large organization with multiple data centers support is for any size of organization with more than one central site. The exact topology in the following diagram is for an organization of 50,000 users, with 20,000 users at Central Site A, 20,000 at Central Site B. and a total of 10,000 at Central Site C and branch sites. The type of topology shown in this diagram can accommodate organizations with any number of users.

In addition to the high availability provided by pools of Front End Servers, this topology adds disaster recovery support. The Front End pools at Central Sites A and B are paired together. If one of these pools goes down, the administrator can shift the services for the affected users to the paired pool at the unaffected site.

This topology is shown in multiple diagrams, with an overview first followed by detailed views of the central sites.





Central Site A

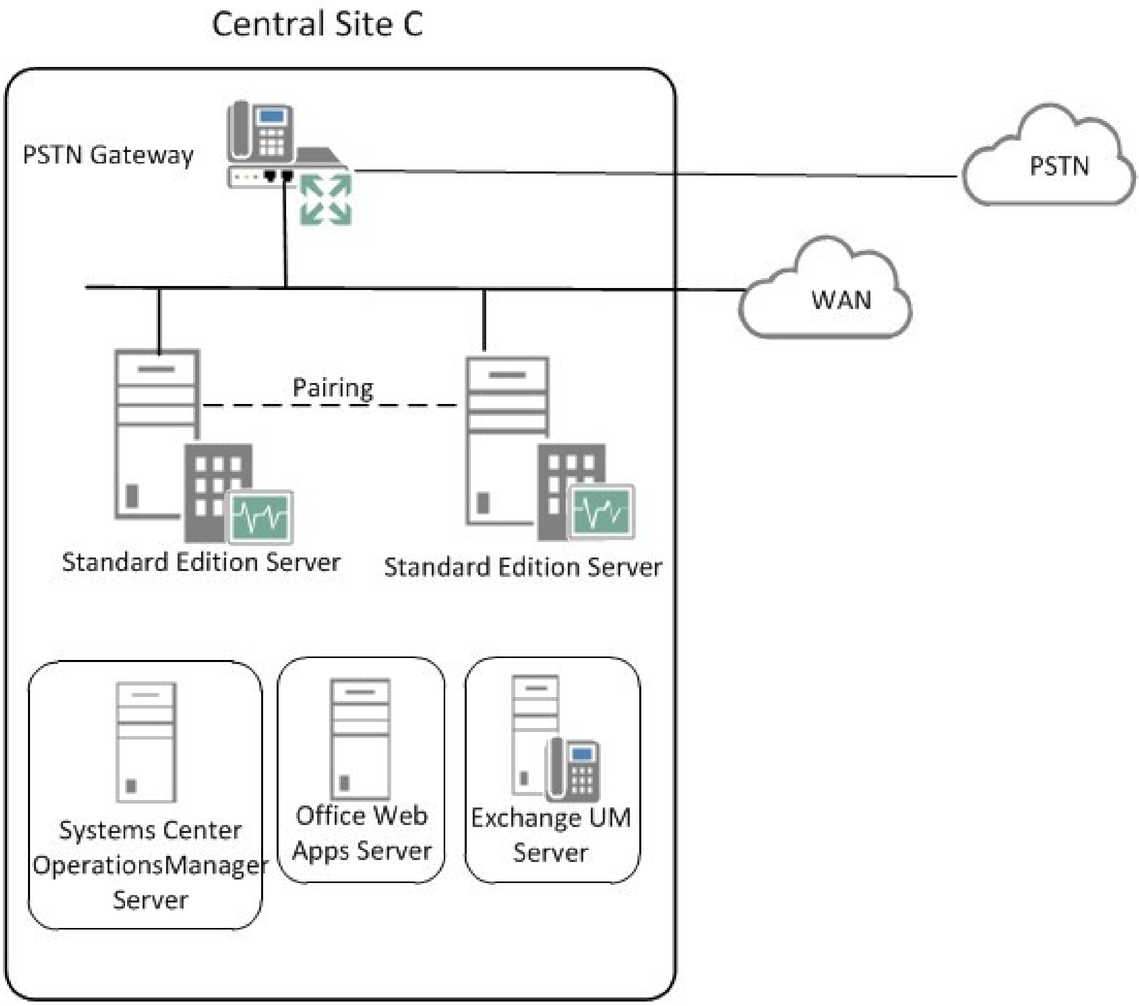
Apps Server
Survivable Branch
Appliance
Branch Site 1
Paired Front End Pool
Located at Central Site A



- **Front End pools Are Paired to Enable Disaster Recovery.** The Front End pools at Site A and Site B are paired with each other, to provide disaster recovery support. If the pool at one site fails, the administrator can fail over the users from that site to the paired Front End pool at the other site, with a minimum of service interruption for users. Each of these two Front End pools has six servers, which is enough for all 40,000 users in both pools in case of failover. For more information, see Planning for High Availability and Disaster Recovery.
- **Back End Servers are mirrored** To provide more high availability for basic user features, the organization has deployed a mirrored pair of Back End Servers for each Front End pool. This is an optional topology, and you could choose to deploy a single Back End Server instead.
- **Using Standard Edition server at a branch site.** This organization considers Site C as a branch site because it has only 600 employees. However, the users there have many A/V conferences among themselves. If it was deployed in Lync Server as a branch site, the media for these conferences would run across the wide area network (WAN) to and from a central site that has a Front End Server deployed. To avoid this potential bandwidth load, they have installed a pair of Standard Edition servers at this site, which will host these conferences. And because Standard Edition servers are installed there, Lync Server by definition considers it a central site, and it is treated as such in Topology Builder and the Planning Tool.
  Just one Standard Edition server would be enough for performance here, but

the organization has deployed two and paired them together to provide high availability in case one server goes down.
Although Site C is considered a central site, you do not have to deploy Edge Servers there. In this example, Site C will use the Edge Servers deployed at Site A.

- **Monitoring and Archiving** This organization has deployed both Monitoring and Archiving. When you deploy Monitoring or Archiving, it runs on every Front End Server. The databases for these features can be collocated with the Back End Database, or located on a separate server. This organization has located these databases on a server separate from the Back End Servers, in Central Site B. The databases here receive Monitoring and Archiving data from the Front End Servers in all sites.
- **Branch site deployment options.** This organization actually has over 50 branch sites, only three of which are shown in the detailed diagrams. Branch Sites 1 and 3 do not have a resilient WAN link to the central site, so they have Survivable Branch Appliances deployed to provide telephone service in case the WAN link to the central site goes down. Branch Site 2 however has a resilient WAN link, so you need only a public switched telephone network (PSTN) gateway. The PSTN gateway deployed there supports media bypass, so no Mediation Server is needed at Branch Site B. For details about deciding what to install at a branch site, see Planning for Enterprise Voice Resiliency in the Planning documentation.
- **SIP trunking and Mediation Server.** Notice that at Central Site B, Mediation Server is not collocated with the Front End Servers. This is because stand-alone Mediation Server is recommended for sites that use SIP trunking. In most other instances, we recommend you collocate Mediation Server with Front End Server. For details about Mediation Server topologies, see Components and Topologies for Mediation Server in the Planning documentation.
- **Persistent Chat is Deployed.** This organization has deployed the servers necessary to enable Persistent Chat. It has deployed multiple Persistent Chat Front End Servers to both handle the load for the number of users in the pool, and to provide high availability. It has also deployed Compliance for Persistent Chat, and located the Persistent Chat Store and the Persistent Chat Compliance Store on separate servers. These stores could be collocated, and can even be collocated with the Back End Server, but this organization has chosen to separate them to provide better performance.
- **DNS load balancing.** The Front End pool and Edge Server pool,. This eliminates the need for hardware load balancers for the internal interface of the Edge Servers, and significantly decreases the amount of time you have to spend on the setup and maintenance of the hardware load balancers for the other pools, as the hardware load balancers are needed only for HTTP traffic. For details about DNS load balancing, see DNS Load Balancing in the Planning documentation.
- **Exchange UM deployment.** Lync Server works with both *on-premises* deployments of Exchange Unified Messaging (UM) and *hosted* Exchange UM. Central Site A includes an Exchange Unified Messaging (UM) Server, which runs Microsoft Exchange Server, not Lync Server. The Exchange UM functionality for Lync Server runs on the Front End pool.
Central Site B uses hosted Exchange, so the Exchange UM Server functionality is also hosted.
For details about Exchange UM, see Planning for Exchange Unified Messaging Integration and Hosted Exchange Unified Messaging Integration in the Planning documentation.
- **Office Web Apps Server.** We recommend deploying an Office Web Apps Server or Office Web Apps Server farm in every organization that uses web conferencing. You could deploy a single Office Web Apps Server farm in one site which serves traffic from all sites, or deploy it in each site. Office Web Apps Server makes it possible for Powerpoint slides to be presented in web conferences. For more information, see Configuring Integration with Office

Web Apps Server and Lync Server 2013.

- **Directors could be added.** If this organization wanted to increase security against denial of service attacks, it could also deploy a pool of Directors. A Director is a separate, optional server role in Lync Server that does not home user accounts, or provide presence or conferencing services. It serves as an internal next hop server to which an Edge Server routes inbound SIP traffic destined for internal servers. The Director pre-authenticates inbound requests and redirects them to the user's home pool or server. Pre-authentication at the Director allows for dropping of requests from user accounts unknown to the deployment. A Director helps insulate Front End Servers from malicious traffic such as denial-of-service (DoS) attacks. If the network is flooded with invalid external traffic in such an attack, the traffic ends at the Director.
- **System Center Operations Manager is deployed.** We recommend that you monitor the health of your Lync Server deployment to ensure service availability for end-users. You can monitor Lync with the System Center Operations Manager Management Pack for Lync that is available as a free download from Microsoft. With the Lync Management Pack, you can proactively get real-time alerts when issues occur, run synthetic transactions to test end-to-end Lync functionality, get reports for service availability, and so on. This helps you to proactively respond to issues with your deployment before end-users experience them.
  This organization has deployed a System Center Operations Manager server in each central site.

1.3.2 Determining Your Infrastructure Requirements

Determining Your Infrastructure Requirements

Microsoft Lync Server 2013 > Planning >

Topic Last Modified: *2012-09-10*

You need to identify and understand the infrastructure requirements for your deployment, so you can plan how to meet those requirements before you deploy Lync Server.

- Determining Your System Requirements
- Active Directory Infrastructure Requirements
- Certificate Infrastructure Requirements
- Internet Information Services (IIS) Requirements

1.3.2.1 Determining Your System Requirements

Determining Your System Requirements

See Also

Microsoft Lync Server 2013 > Planning > Determining Your Infrastructure Requirements >

Topic Last Modified: *2012-09-14*

All servers running Lync Server must meet certain minimum system requirements. System requirements for Lync Server include the server hardware, the operating system to be installed on each server, and related software requirements, such as the Windows updates and other software that must be installed on the servers.

◆**Important:**
Lync Server is available only in a 64-bit edition, which requires 64-bit hardware and a 64-bit edition of Windows Server. The exception is the Microsoft Lync Server 2013, Planning Tool, which is available in a 32-bit edition.

- Server Hardware Platforms
- Server and Tools Operating System Support
- Database Software Support
- Additional Software Requirements

Supportability

1.3.2.1.1 Server Hardware Platforms

Server Hardware Platforms

Microsoft Lync Server 2013 > Supportability > Supported Hardware >

Topic Last Modified: *2013-01-07*

Lync Server 2013 server roles and computers running Lync Server administrative tools require 64-bit hardware.

The specific hardware used for Lync Server 2013 deployment can vary, depending on size and usage requirements. This section describes the recommended hardware. Although these are recommendations, not requirements, using hardware that does not meet these recommendations may result in significant performance issues and other issues.

Recommended Hardware Platform

For best performance, we recommend that you run Lync Server on servers with hardware that meets the requirements in the following table. If you use less powerful hardware, you may experience functionality problems or poor performance. Note that these hardware requirements are higher than those of previous versions of Lync Server, primarily because in Lync Server 2013, all Front End Servers run SQL Server.

Recommended Hardware for Front End Servers, Back End Servers, Standard Edition Servers, and Persistent Chat Store and Persistent Chat Compliance Store (Back End Server Roles for Persistent Chat Server)

Hardware component	Recommended
CPU	64-bit dual processor, hex-core, 2.26 gigahertz (GHz) or higher Intel Itanium processors are not supported for Lync Server server roles.
Memory	32 gigabytes (GB)
Disk	• 8 or more 10,000 RPM hard disk drives with at least 72 GB free disk space. Two of the disks should use RAID 1, and six should use RAID 10. - OR - • Solid state drives (SSDs) which provide performance similar to 8 10,000-RPM mechanical disk drives.
Network	• 1 dual-port network adapter, 1 Gbps or higher (2 recommended, which requires teaming with a single MAC address and

	single IP address)

Recommended Hardware for Edge Servers, Standalone Mediation Servers, and Directors

Hardware component	Recommended
CPU	• 64-bit dual processor, quad-core, 2.0 gigahertz (GHz) or higher - OR - • 64-bit 4-way processor, dual-core, 2.0 GHz or higher Intel Itanium processors are not supported for Lync Server server roles.
Memory	16 gigabytes (GB)
Disk	• 4 or more 10,000 RPM hard disk drives with at least 72 GB free disk space - OR - • Solid state drives (SSDs) which provide performance similar to 4 10,000-RPM mechanical disk drives.
Network	• 1 dual-port network adapter, 1 Gbps or higher (2 recommended, which requires teaming with a single MAC address and single IP address)

1.3.2.1.2 Server and Tools Operating System Support

Server and Tools Operating System Support

Microsoft Lync Server 2013 > Supportability > Server Software and Infrastructure Support >

Topic Last Modified: *2012-10-22*

All server roles support the same Windows Server operating systems. The required operating system support for other server roles, such as database servers, depends on what software you install on those servers.

Lync Server 2013 administrative tools are installed by default on the server running Lync Server 2013, but you can install administrative tools separately on other computers running Windows operating systems. For example, you can use a client computer running Windows 7 with Service Pack 1 (SP1) as an administrative console for planning purposes.

◆**Important:**
Lync Server 2013 is available only in 64-bit, which requires 64-bit hardware and 64-bit editions of Windows Server. This means that all server roles and computers running Lync Server 2013 administrative tools run a 64-bit edition operating system.

Operating Systems for Server Roles

Lync Server 2013 supports the 64-bit editions of the following operating systems:

- The Windows Server 2008 R2 with Service Pack 1 (SP1) Standard operating system (required) or latest service pack (recommended)
- The Windows Server 2008 R2 with SP1 Enterprise operating system (required) or latest service pack (recommended)

- The Windows Server 2008 R2 with SP1 Datacenter operating system (required) or latest service pack (recommended)
- The Windows Server 2012 Standard operating system
- The Windows Server 2012 Datacenter operating system

Lync Server 2013 is not supported on the following:

- The Server Core installation option of Windows Server 2008 R2 or Windows Server 2012
- The Windows Web Server 2008 R2 operating system or the Windows Web Server 2012 operating system
- Windows Server 2008 R2 HPC Edition or Windows Server 2012 HPC Edition

Operating Systems for Other Servers

Operating system support for servers other than those on which you deploy Lync Server 2013 server roles depends on the software that you plan to install on those servers. For details about requirements for Back End Servers and other database servers, see Database Software Support in the Supportability documentation. For details about requirements for reverse proxy servers (for Edge deployment), see Internet Information Services (IIS) Support in the Supportability documentation. For details about other software requirements, including infrastructure and virtualization support, see the other topics in the Server Software and Infrastructure Support section of the Supportability documentation.

Additional Operating Systems for Administrative Tools

Lync Server 2013 supports installation of the administrative tools, which includes the Topology Builder, on computers running any of the 64-bit editions of the operating systems supported for deployment of server roles (as described in the previous section). Additionally, you can install administrative tools on the 64-bit editions of the following operating systems:

- The Windows 7 operating system with SP1 operating system (required) or latest service pack (recommended)
- The Windows 8 operating or latest service pack (recommended)

1.3.2.1.3 Database Software Support

Database Software Support

Microsoft Lync Server 2013 > Supportability > Server Software and Infrastructure Support >

Topic Last Modified: *2013-03-12*

The following list contains the database management systems for the back-end database, the Archiving database, the Monitoring database, the Persistent Chat database, and the Persistent Chat compliance database that are supported by Lync Server 2013:

- **Back-end database of a Front End pool, Archiving database, Monitoring database, persistent chat database, and persistent chat compliance database**
  - Microsoft SQL Server 2008 R2 Enterprise database software (64-bit edition). Additionally running the latest service pack is recommended.
  - Microsoft SQL Server 2008 R2 Standard (64-bit edition). Additionally running the latest service pack is recommended.
  - Microsoft SQL Server 2012 Enterprise (64-bit edition). Additionally running the latest service pack is recommended.
  - Microsoft SQL Server 2012 Standard (64-bit edition). Additionally running the

latest service pack is recommended.

- **Standard Edition server database and local configuration store databases**
  - Microsoft SQL Server 2012 Express (64-bit edition)

Note:
Microsoft SQL Server 2012 Express (64-bit edition) is automatically installed by Lync Server 2013 on each Standard Edition server and each Lync Server 2013 server on which the local configuration store is deployed.

Important:

- Lync Server 2013 does not support the 32-bit edition of SQL Server. You must use the 64-bit edition.
- SQL Server Web edition and SQL Server Workgroup edition are not supported. You cannot use them with Lync Server 2013.
- Lync Server 2013 does support native database mirroring.
- To use the Monitoring Server role, you should install SQL Server Reporting Services.

In a Front End pool, the back-end database can be a single SQL Server computer.

Important:
If you collocate Lync Server databases with other databases, we highly recommend assessing all factors that might affect availability and performance, as well as ensuring that, if one node fails, the remaining node can handle the load. To verify failover capabilities, we recommend testing all failover scenarios.

SQL Clustering Topologies

SQL clustering topologies are not supported for new Lync Server 2013 deployments. For Back End Server high availability, SQL mirroring is the recommended and supported option.

If you are upgrading from a previous version of Lync Server and you have deployed an Enterprise Edition Front End pool that uses SQL clustering in that existing Lync Server topology, we recommend that you implement SQL Mirroring as a replacement for the existing SQL clustering deployment. However, continuing to use the existing SQL cluster with Lync Server 2013 is supported, but not recommended.

1.3.2.1.4 Additional Software Requirements

Additional Software Requirements

See Also

Planning > Determining Your Infrastructure Requirements > Determining Your System Requirements >

Topic Last Modified: *2012-12-08*

In addition to the hardware and operating system requirements for server platforms, Lync Server 2013 requires the installation of additional software on the servers that you deploy.

Note:
For details about the platform requirements for servers running Lync Server, see Server Hardware Platforms and Server and Tools Operating System Support. For details about system requirements for client computers and devices, see Planning for Clients and Devices in Lync Server 2013 in the Planning documentation. For details about software

requirements for administrative tools, see Administrative Tools Software Requirements.

Additional Software Necessary for All Internal Server Roles

On all internal server roles, you must also make sure that Windows PowerShell command-line interface 3.0 and Microsoft .NET Framework 4.5, are installed.

Important:

Edge Servers and Edge pools have different requirements from servers deployed on the internal network. The requirements for the Edge Servers and Edge pools are listed later in this topic under **Additional Software for Edge Servers**.

Additionally, Microsoft .NET Framework 4.5 is required on any computer where you will run the Lync Server administrative tools or Microsoft Lync Server 2013, Planning Tool.

Windows PowerShell 3.0

Each server running Lync Server 2013 must have the correct release of Windows PowerShell 3.0 installed. For details, see Installing Windows PowerShell 3.0.

Microsoft .NET Framework 4.5

Lync Server requires Microsoft .NET Framework 4.5. For Lync Server 2013, you must manually install the 64-bit edition of Microsoft .NET Framework 4.5 on the server prior to installing Lync Server 2013. To manually install it, download the Microsoft .NET 4.5 Framework from the Microsoft Download Center at http://go.microsoft.com/fwlink/p/?LinkId=268529

Installing Microsoft .NET Framework 4.5 on Servers Running Windows Server 2012

When you install Microsoft .NET Framework 4.5 on servers that will run Lync Server 2013 and Windows Server 2012, you must perform one additional step. After .NET Framework 4.5 is installed, use Server Manager to install HTTP Activation.

To Install .NET 4.5 HTTP Activation on Windows Server 2012

1. From the **Start** menu, click **Programs**, then click **Administrative Tools**, then click **Server Manager**.
2. In Server Manager, under **Features Summary**, choose **Add Features**.
3. Expand **.NET Framework 4.5**.
4. Select **WCF Activation** if it isn't already selected. Then select **HTTP Activation**.
5. Click **Next** and follow the prompts to finish the installation.

Windows Identity Foundation

Windows Identity Foundation in Lync Server 2013 requires the installation of Windows Identity Foundation in order to support server to server authentication scenarios. Windows Server 2008 R2 and Windows Server 2012 require different procedures to install the Windows Identify Foundation. Select your server operating system from the following list:

- Windows Server 2008 R2   For Windows Server 2008 R2, you check to see if it has already been installed on your computer. To do this, go to **Add/Remove Programs**, **View Installed Updates**, and look under **Windows** for the entry **Windows Identity Foundation (KB974405)**. For details about installing Windows Identity Foundation, see http://go.microsoft.com/fwlink/p/?linkId=204657.
- Windows Server 2012   For Windows Server 2012, you use **Server Manager** to install the Windows Identity Foundation. In the Server Manager **Add Roles and Features Wizard**, select **Features**. Select **Windows Identity Foundation**

3.5 from the list. Click **Next**, then click **Install**.

Additional Software for All Front End Servers and Standard Edition Servers

All Front End Servers and Standard Edition servers must also run Internet Information Services (IIS) with certain modules. Additionally, all Front End Servers and Standard Edition servers where conferencing, Call Park application, Announcement, or Response Groups are deployed must run Windows Media Format Runtime.

Internet Information Services (IIS)

Front End Servers and Standard Edition servers must run Internet Information Services (IIS), with the following modules:

- Static Content
- Default Document
- HTTP Errors
- ASP.NET
- .NET Extensibility
- Internet Server API (ISAPI) Extensions
- ISAPI Filters
- HTTP Logging
- Logging Tools
- Tracing
- Windows Authentication
- Request Filtering
- Static Content Compression
- Dynamic Content Compression
- IIS Management Console
- IIS Management Scripts and Tools
- Anonymous Authentication (this is installed by default when IIS is installed.)
- Client Certificate Mapping Authentication

Windows Desktop Experience

Windows Desktop Experience All Front End Servers and Standard Edition servers where conferencing will be deployed must have the Windows Media Format Runtime installed, which, except for Windows Server 2012 is installed as part of the Windows desktop experience. Windows Server 2012 requires Microsoft Media Foundation. The Windows Media Format Runtime is required to run the Windows Media Audio (.wma) files that the Call Park, Announcement, and Response Group applications play for announcements and music.

We recommend that you install Windows desktop experience before you install Lync Server 2013. If Lync Server 2013 does not find this software on the server, it will prompt you to install it, and then you must restart the server to complete installation.

Additional Software for Front End Servers and Standard Edition Servers Running on Windows Server 2012

Front End Servers require .NET 3.5, which is not installed by default on Windows Server 2012. To install it, put your Windows Server 2012 installation media in Drive D and type the following:

```
Add-WindowsFeature RSAT-ADDS, Web-Server, Web-Static-Content, Web-Default-Doc, We
```

For details about installing .NET 3.5 on servers running Windows Server 2012, see "Microsoft .NET Framework 3.5 Deployment Considerations" at http://go.microsoft.com/fwlink/p/?linkid=275032.

Additional Software for Directors

Directors must run Internet Information Services (IIS), with the following modules:

- Static Content
- Default Document
- HTTP Errors
- ASP.NET
- .NET Extensibility
- Internet Server API (ISAPI) Extensions
- ISAPI Filters
- HTTP Logging
- Logging Tools
- Tracing
- Windows Authentication
- Request Filtering
- Static Content Compression
- IIS Management Console
- IIS Management Scripts and Tools
- Anonymous Authentication (This is installed by default when IIS is installed.)
- Client Certificate Mapping Authentication

Additional Software for Persistent Chat Front End Servers

Persistent Chat Front End Servers must run Message Queuing (also known as MSMQ), which is a component of Windows Server.

Additional Software for Edge Servers

Edge Servers require the following software:

- Each server running Lync Server 2013 must have the correct release of Windows PowerShell 3.0 installed. For details, see Installing Windows PowerShell 3.0.
- Lync Server requires Microsoft .NET Framework 4.5. For Lync Server 2013 installed on Windows Server 2008 R2, you must manually install the 64-bit edition of Microsoft .NET Framework 4.5 on the server prior to installing Lync Server 2013. To manually install it, download the Microsoft .NET 4.5 Framework from the Microsoft Download Center at http://go.microsoft.com/fwlink/p/?LinkId=268529
- **Windows Identity Foundation** in Lync Server 2013 requires the installation of Windows Identity Foundation in order to support server to server authentication scenarios. Windows Server 2008 R2 and Windows Server 2012 require different procedures to install the Windows Identify Foundation. Select your server operating system from the following list:
  - Windows Server 2008 R2   For Windows Server 2008 R2, you check to see if it has already been installed on your computer. To do this, go to **Add/Remove Programs**, **View Installed Updates**, and look under **Windows** for the entry **Windows Identity Foundation (KB974405)**. For details about installing Windows Identity Foundation, see http://go.microsoft.com/fwlink/p/?linkId=204657.

- Windows Server 2012   For Windows Server 2012, you use **Server Manager** to install the Windows Identity Foundation. In the Server Manager **Add Roles and Features Wizard**, select **Features**. Select **Windows Identity Foundation 3.5** from the list. Click **Next**, then click **Install**.

Do Not Install Layered Socket Providers on Media Servers

Do not install any Microsoft Internet Security and Acceleration (ISA) Server client software, or any other Winsock Layered Service Providers (LSP) software, on any Front End Servers or stand-alone Mediation Servers. Installing this software could cause poor media traffic performance.

Administrative Tools Software Requirements

1.3.2.2 Active Directory Domain Services Requirements, Support, and Topologies

Active Directory Domain Services Requirements, Support, and Topologies

Microsoft Lync Server 2013 > Planning > Determining Your Infrastructure Requirements >

Topic Last Modified: *2012-10-05*

Prior to Lync Server 2010, Lync Server relied on Active Directory Domain Services (AD DS) to store all the global settings and groups necessary to deploy and manage Lync Server. Now much of this information is stored in the Central Management store instead of AD DS. However, user object schema extensions, including Lync Server 2013, Lync Server 2010, and Office Communications Server 2007 R2 schema extensions, are still stored in AD DS.

- Active Directory Domain Services Support
- Supported Active Directory Topologies
- Active Directory Infrastructure Requirements

1.3.2.2.1 Active Directory Domain Services Support

Active Directory Domain Services Support

Planning > Determining Your Infrastructure Requirements > Active Directory Domain Services Requirements, Support, and Topologies >

Topic Last Modified: *2012-12-04*

Lync Server 2013 uses the Central Management store to store configuration data for servers and services, instead of relying on Active Directory Domain Services (AD DS) for this information, as in the past. Lync Server 2013 still stores the following in AD DS:

- **Schema extensions**
  - User object extensions
  - Extensions for Lync Server 2010 and Office Communications Server 2007 R2 classes to maintain backward compatibility with previous supported versions
- **Data** (stored in Lync Server 2013 extended schema and in existing classes)
  - User SIP URI and other user settings
  - Contact objects for applications (for example, the Response Group

application and the Conferencing Attendant application)
- Data published for backward compatibility
- A service control point (SCP) for the Central Management store
- Kerberos Authentication Account (an optional computer object)

This section describes the AD DS support requirements for Lync Server 2013. For details about topology support, see Supported Active Directory Topologies in the Supportability documentation.

Supported Domain Controller Operating Systems

Lync Server 2013 supports domain controllers running the following operating systems:

- Windows Server 2012 operating system
- Windows Server 2008 R2 operating system
- Windows Server 2008 operating system
- Windows Server 2008 Enterprise 32-Bit
- The 32-bit or 64-bit versions of the Window Server 2003 R2 operating system
- The 32-bit or 64-bit versions of the Windows Server 2003 operating system

Forest and Domain Functional Level

You must raise all domains in which you deploy Lync Server 2013 to a domain functional level of Windows Server 2012, Windows Server 2008 R2, Windows Server 2008, or at least Windows Server 2003.

All forests in which you deploy Lync Server 2013 must be raised to a forest functional level of Windows Server 2012, Windows Server 2008 R2, Windows Server 2008, or at least Windows Server 2003.

Support for Read-Only Domain Controllers

Lync Server 2013 supports Active Directory Domain Services (AD DS) deployments that include read-only domain controllers or read-only global catalog servers, as long as there are writable domain controllers available.

Domain Names

Lync Server does not support single-labeled domains. For example, a forest with a root domain named **contoso.local** is supported, but a root domain named **local** is not supported. For details, see Microsoft Knowledge Base article 300684, "Information about configuring Windows for domains with single-label DNS names," at http://go.microsoft.com/fwlink/p/?linkId=143752.

Note:

Lync Server does not support renaming domains. If you need to rename a domain where Lync Server is deployed, you need to first uninstall Lync Server, then rename the domain, and then reinstall Lync Server.

Locked Down AD DS Environments

In a locked-down AD DS environment, Users and Computer objects are often placed in specific organizational units (OUs) with permissions inheritance disabled to help secure administrative delegation and to enable use of Group Policy objects (GPOs) to enforce security policies. Lync Server 2013 can be deployed in a locked-down Active Directory environment. For details about what is required to deploy Lync Server in a locked-down environment, see Preparing a Locked-Down Active Directory Domain Services in the Deployment documentation.

1.3.2.2.2 Supported Active Directory Topologies

Supported Active Directory Topologies

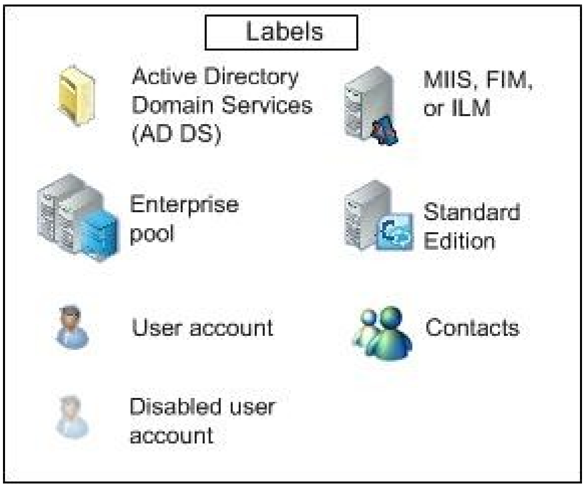
Planning > Determining Your Infrastructure Requirements > Active Directory Domain Services Requirements, Support, and Topologies >

Topic Last Modified: *2012-06-14*

Lync Server 2013 supports the same Active Directory Domain Services (AD DS) topologies as Microsoft Lync Server 2010 and Microsoft Office Communications Server 2007 R2. The following topologies are supported:

- Single forest with single domain
- Single forest with a single tree and multiple domains
- Single forest with multiple trees and disjoint namespaces
- Multiple forests in a central forest topology
- Multiple forests in a resource forest topology

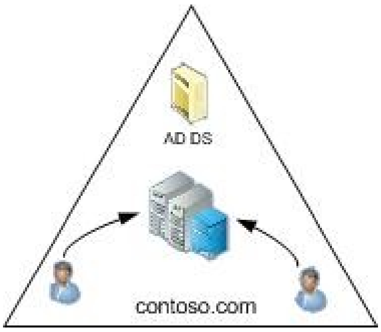
The following figure identifies the icons used in the illustrations in this section.



Single Forest, Single Domain

The simplest Active Directory topology supported by Lync Server, a single domain forest, is a common topology.

The following figure illustrates a Lync Server deployment in a single domain Active Directory topology.

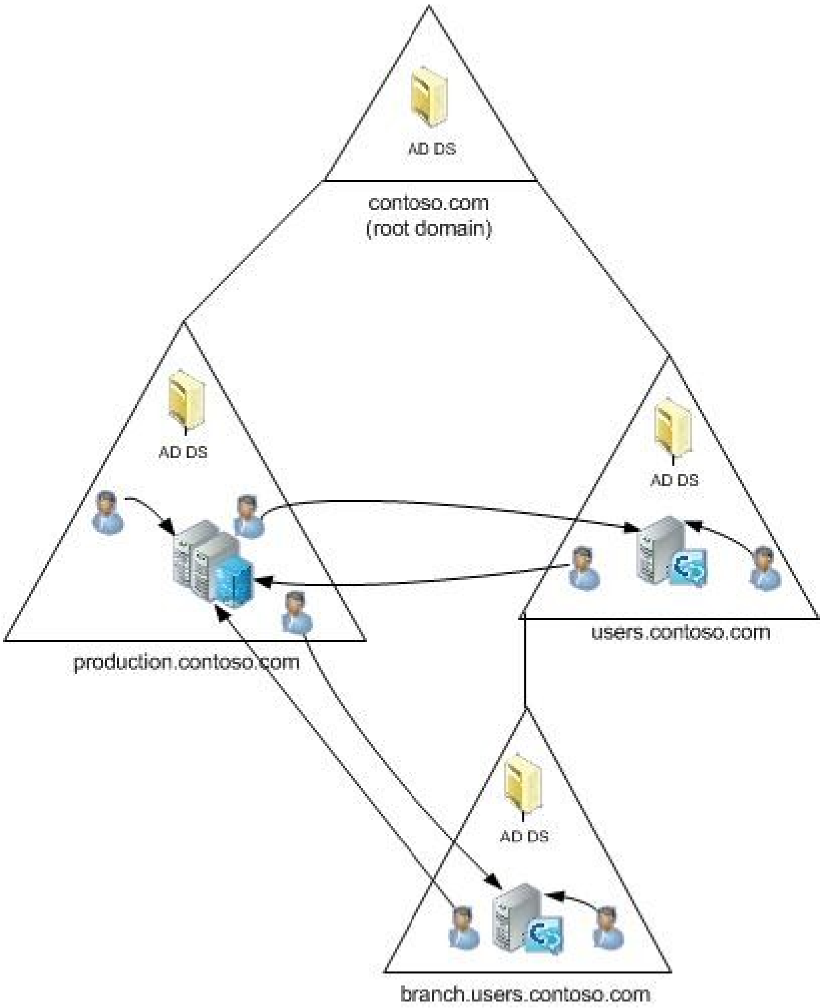


Single Forest, Multiple Domains

Another Active Directory topology supported by Lync Server is a single forest that consists of a root domain and one or more child domains. In this type of Active Directory topology, the domain where you create users can be different from the domain where you deploy Lync Server. However, if you deploy a Front End pool, you must deploy all the Front End Servers in the pool within a single domain. Lync Server support for Windows universal administrator groups enables cross-domain administration.

The following figure illustrates a deployment in a single forest with multiple domains. In this figure, a user icon shows the domain where the user account is homed, and the arrow points to the domain where the Lync Server pool resides. User accounts include the following:

- User accounts within the same domain as the Lync Server pool
- User accounts in a different domain from the Lync Server pool
- User accounts in a child domain of the domain with the Lync Server pool

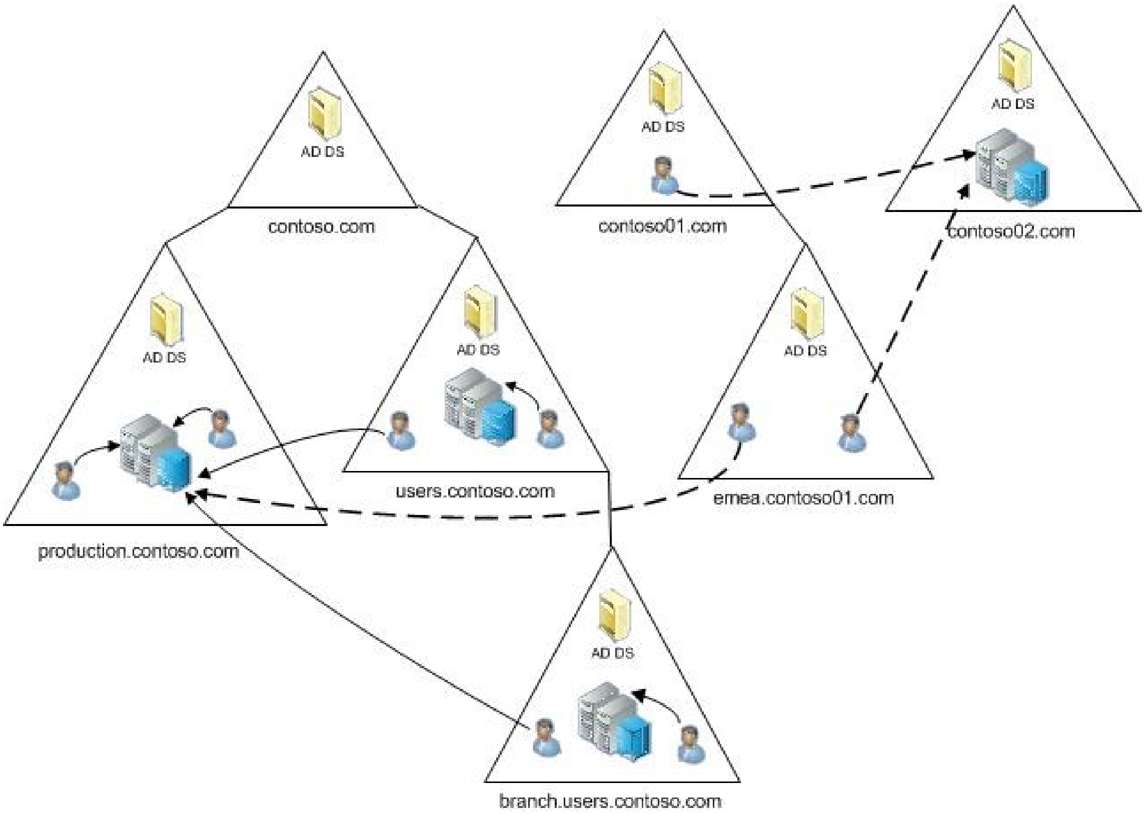


Single Forest, Multiple Trees

A multiple-tree forest topology consists of two or more domains that define independent tree structures and separate Active Directory namespaces.

The following figure illustrates a single forest with multiple trees. In this figure, a user icon shows the domain where the user account is homed, a solid line points to a Lync Server pool that resides in the same or a different domain, and a dashed line points to Lync Server pool that resides in a different tree. User accounts include the following:

- User accounts within the same domain as the Lync Server pool
- User accounts in a different domain from (but the same tree as) the Lync Server pool
- User accounts in a different tree from the Lync Server pool



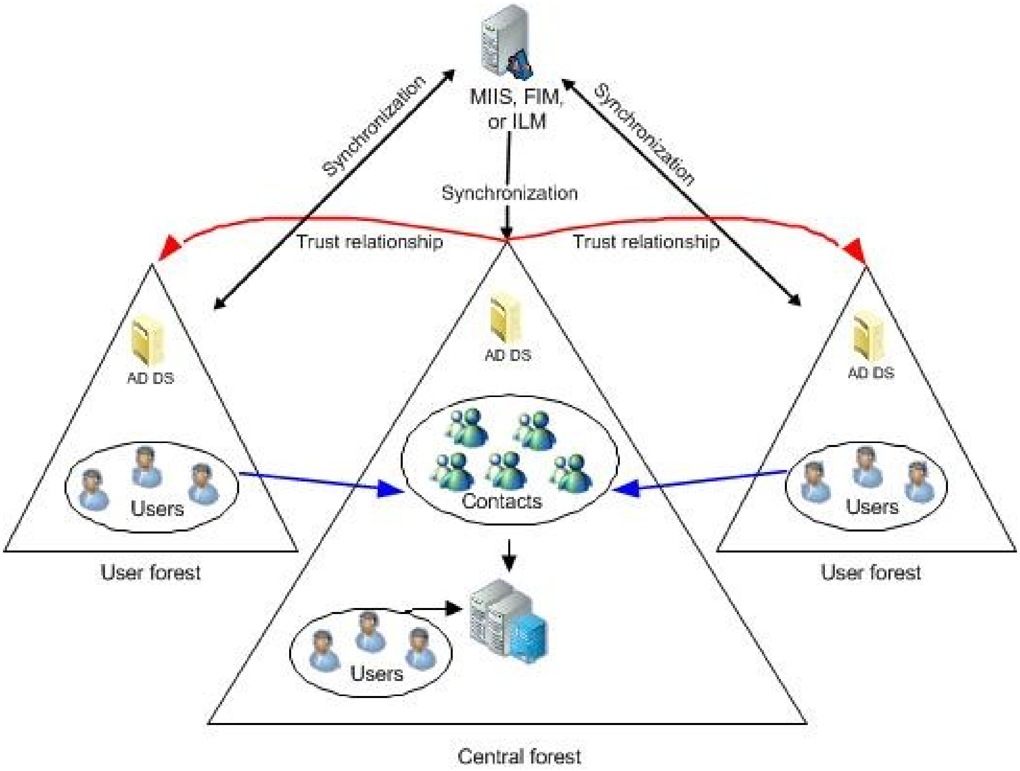
Multiple Forests, Central Forest

Lync Server supports multiple forests that are configured in a central forest topology. Central forest topologies use contact objects in the central forest to represent users in the other forests. The central forest also hosts user accounts for any users in this forest. A directory synchronization product, such as Microsoft Identity Integration Server (MIIS), Microsoft Forefront Identity Manager (FIM) 2010, or Microsoft Identity Lifecycle Manager (ILM) 2007 Feature Pack 1 (FP1), manages the life cycle of user accounts within the organization: When a new user account is created in one of the forests or a user account is deleted from a forest, the directory synchronization product synchronizes the corresponding contact in the central forest.

A central forest has the following advantages:

- Servers running Lync Server are centralized within a single forest.
- Users can search for and communicate with other users in any forest.
- Users can view presence of other users in any forest.
- The directory synchronization product automates the addition and deletion of contact objects in the central forest as user accounts are created or removed.

The following figure illustrates a central forest topology. In this figure, there are two-way trust relationships between the domain that hosts Lync Server, which is in the central forest, and each user-only domain, which is in a separate forest. The schema in the separate user forests does not need to be extended.



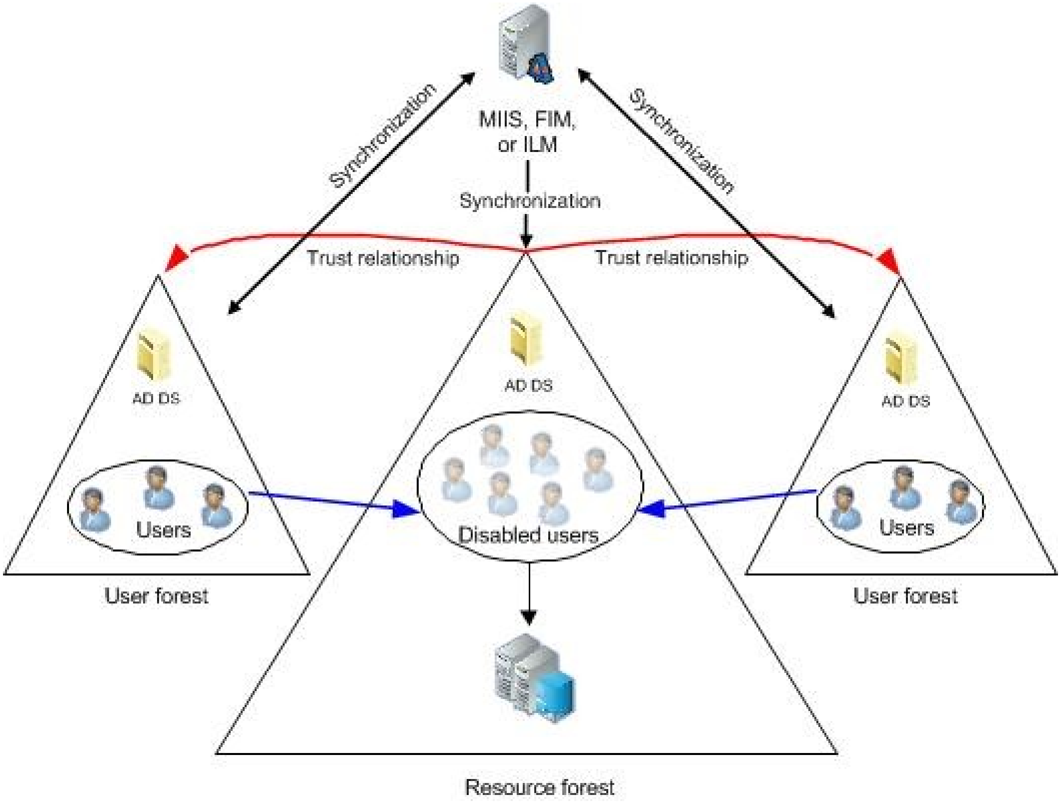
Multiple Forests, Resource Forest

In a resource forest topology, one forest is dedicated to running server applications, such as Microsoft Exchange Server and Lync Server. The resource forest hosts the server applications and a synchronized representation of the active user object, but it does not contain logon-enabled user accounts. The resource forest acts as a shared services environment for the other forests where user objects reside. The user forests have a forest-level trust relationship with the resource forest. When you deploy Lync Server in this type of topology, you create one disabled user object in the resource forest for every user account in the user forests. If Microsoft Exchange is already deployed in the resource forest, the disabled user accounts might already exist. A directory synchronization product, such as MIIS, Microsoft Forefront Identity Manager (FIM) 2010, or Microsoft Identity Lifecycle Manager (ILM) 2007 Feature Pack 1 (FP1), manages the life cycle of user accounts. When a new user account is created in one of the user forests or a user account is deleted from a forest, the directory synchronization product synchronizes the corresponding user representation in the resource forest.

This topology can be used to provide a shared infrastructure for services in organizations that manage multiple forests or to separate the administration of Active Directory objects from other administration. Companies that need to isolate Active Directory administration for security reasons often choose this topology.

This topology provides the benefit of limiting the need to extend the Active Directory schema to a single forest (that is, the resource forest).

The following diagram illustrates a resource forest topology.



1.3.2.2.3 Active Directory Infrastructure Requirements

Active Directory Infrastructure Requirements

[Planning](#) > [Determining Your Infrastructure Requirements](#) > [Active Directory Domain Services Requirements, Support, and Topologies](#) >

Topic Last Modified: *2012-11-27*

Before you start the process of preparing Active Directory Domain Services (AD DS) for Lync Server 2013, make sure that your Active Directory infrastructure meets the following prerequisites:

- All domain controllers (which include all global catalog servers) in the forest where you deploy Lync Server run one of the following operating systems:
  - Windows Server 2012 operating system
  - Windows Server 2008 R2 operating system
  - Windows Server 2008 operating system
  - Windows Server 2008 Enterprise 32-Bit
  - 32-bit or 64-bit versions of the Windows Server 2003 R2 operating system
  - 32-bit or 64-bit versions of the Windows Server 2003 operating system
- All domains in which you deploy Lync Server are raised to a domain functional level of Windows Server 2012, Windows Server 2008 R2, Windows Server 2008, or at least Windows Server 2003.
- The forest in which you deploy Lync Server is raised to a forest functional level of Windows Server 2012, Windows Server 2008 R2, Windows Server 2008, or at least Windows Server 2003.

Note:

To change your domain or forest functional level, see "Raising domain and forest functional levels" in the TechNet Library at http://go.microsoft.com/fwlink/p/?LinkId=263775.

- A global catalog is deployed in every domain where you deploy Lync Server computers or users.

Lync Server 2013 supports the universal groups in the Windows Server 2012, Windows Server 2008 R2, Windows Server 2008, and Windows Server 2003 operating systems. Members of universal groups can include other groups and accounts from any domain in the domain tree or forest and can be assigned permissions in any domain in the domain tree or forest. Universal group support, combined with administrator delegation, simplifies the management of a Lync Server deployment. For example, it is not necessary to add one domain to another to enable an administrator to manage both.

1.3.2.3 Certificate Infrastructure Requirements

Certificate Infrastructure Requirements

Microsoft Lync Server 2013 > Planning > Determining Your Infrastructure Requirements >

Topic Last Modified: *2013-01-11*

Lync Server 2013 requires a public key infrastructure (PKI) to support TLS and mutual TLS (MTLS) connections.

Lync Server uses certificates for the following purposes:

- TLS connections between client and server
- MTLS connections between servers
- Federation using automatic DNS discovery of partners
- Remote user access for instant messaging (IM)
- External user access to audio/video (A/V) sessions, application sharing, and conferencing
- Mobile requests using automatic discovery of Web Services

For Lync Server, the following common requirements apply:

- All server certificates must support server authorization (Server EKU).
- All server certificates must contain a CRL Distribution Point (CDP).
- All certificates must be signed using the RSA Sha1 signing algorithm

Important:
The RSA Sha1 signing algorithm is currently the only signing method recognized by Lync Server. Configuring your PKI to use a different signing algorithm may cause difficult to troubleshoot certificate failures in certificates on Lync Server role servers.

- Auto-enrollment is supported for internal servers running Lync Server.
- Auto-enrollment is not supported for Lync Server Edge Servers.
- When you submit a web-based certificate request to a Windows Server 2003 CA, you must submit it from a computer running either Windows Server 2003 with SP2 or Windows XP.
  Note that although KB922706 provides support for resolving issues with enrolling web certificates against a Windows Server 2003 Certificate Services web enrollment, it does not make it possible to use Windows Server 2008, Windows Vista, or Windows 7 to request a certificate from a Windows Server 2003 CA.
- Key lengths of 1024, 2048, and 4096 are supported. Key lengths of 2048 and greater are recommended.
- The default hash algorithm is RSA. The ECDH_P256, ECDH_P384, and

ECDH_P521 hash algorithms are also supported.

1.3.2.3.1 Certificate Requirements for Internal Servers

Certificate Requirements for Internal Servers

See Also

Planning > Determining Your Infrastructure Requirements > Certificate Infrastructure Requirements >

Topic Last Modified: *2012-09-19*

Internal servers that are running Lync Server and that require certificates include Standard Edition server, Enterprise Edition Front End Server, Mediation Server, and Director. The following table shows the certificate requirements for these servers. You can use the Lync Server certificate wizard to request these certificates.

Tip:

Wildcard certificates are supported for the subject alternative names associated with the simple URLs on the Front End pool, Front End Server, or Director. For details about wildcard certificate support, see Wildcard Certificate Support.

Although an internal enterprise certification authority (CA) is recommended for internal servers, you can also use a public CA. For a list of public CAs that provide certificates that comply with specific requirements for unified communications (UC) certificates and have partnered with Microsoft to ensure they work with the Lync Server Certificate Wizard, see article Microsoft Knowledge Base 929395, "Unified Communications Certificate Partners for Exchange Server and for Communications Server," at http://go.microsoft.com/fwlink/p/?linkId=202834.

Communication with other applications and servers, such as Exchange 2013, requires a certificate that is supported by the other applications and products. For the 2013 release, Lync Server 2013 and other Microsoft server products, including Exchange 2013 and SharePoint Server, support the Open Authorization (OAuth) protocol for server-to-server authentication and authorization. For details, see Managing Server-to-Server Authentication (Oauth) and Partner Applications in the Deployment documentation or the Operations documentation.

For connections from clients running Windows 7 operating system, Windows Server 2008 operating system, Windows Server 2008 R2 operating system, Windows Vista operating system, and Microsoft Office Communicator 2007 Phone Edition, Lync Server 2013 includes support for (but does not require) certificates signed using the SHA-256 cryptographic hash function. To support external access using SHA-256, the external certificate is issued by a public CA using SHA-256.

The following tables show certificate requirements by server role for Front End pools and Standard Edition servers. All these are standard web server certificates, private key, non-exportable.

Note that server enhanced key usage (EKU) is automatically configured when you use the certificate wizard to request certificates.

Certificates for Standard Edition Server

Certificate	Subject	Subject alternative name	Example	Comments

	name/ Common name			
Default	Fully qualified domain name (FQDN) of the pool	FQDN of the pool and the FQDN of the server If you have multiple SIP domains and have enabled automatic client configuration, the certificate wizard detects and adds each supported SIP domain FQDNs. If this pool is the auto-logon server for clients and strict Domain Name System (DNS) matching is required in group policy, you also need entries for sip.sipdomain (for each SIP domain you have).	SN=se01.contoso.com; SAN=se01.contoso.com If this pool is the auto-logon server for clients and strict DNS matching is required in group policy, you also need SAN=sip.contoso.com; SAN=sip.fabrikam.com	On Standard Edition server, the server FQDN is the same as the pool FQDN. The wizard detects any SIP domains you specified during setup and automatically adds them to the subject alternative name. You can also use this certificate for Server-to-Server Authentication.

Web internal	FQDN of the server	Each of the following:
		• Internal web FQDN (which is the same as the FQDN of the server)
		• Meet simple URLs
		• Dial-in simple URL
		• Admin simple URL
		• Or, a wildcard entry for the simple URLs
			SN=se01.contoso.com; SAN=se01.contoso.com; SAN=meet.contoso.com; SAN=meet.fabrikam.com; SAN=dialin.contoso.com; SAN=admin.contoso.com
			Using a wildcard certificate:
			SN=se01.contoso.com; SAN=se01.contoso.com; SAN=*.contoso.com
				Internal web FQDN cannot be overwritten in Topology Builder.
				If you have multiple Meet simple URLs, you must include all of them as subject alternative names.
				Wildcard entries are supported for the simple URL entries.

Web external	FQDN of the server	Each of the following: • External web FQDN • Dial-in simple URL • Admin simple URL	SN=se01.contoso.com; SAN=webcon01.contoso.com ; SAN=meet.contoso.com;	If you have multiple Meet simple URLs, you must include all of them as subject

		- Or, a wildcard entry for the simple URLs	SAN=meet.fabrikam.com;
			SAN=dialin.contoso.com
			Using a wildcard certificate:
			SN=se01.contoso.com;
			SAN=webcon01.contoso.com;
			SAN=*.contoso.com
				alternative names.
				Wildcard entries are supported for the simple URL entries.

Certificates for Front End Server in a Front End Pool

Certificate	Subject name/ Common name	Subject alternative name	Example	Comments

Default	FQDN of the pool	FQDN of the pool and FQDN of the server.
		If you have multiple SIP domains and have enabled automatic client configuration, the certificate wizard detects and adds each supported SIP domain FQDNs.
		If this pool is the auto-logon server for clients and strict DNS matching is required in group policy, you also need entries for sip.sipdomain (for each SIP domain you have).
			SN=eepool.contoso.com;
			SAN=eepool.contoso.com;
			SAN=ee01.contoso.com
			If this pool is the auto-logon server for clients and strict DNS matching is required in group policy, you also need SAN=sip.contoso.com;
			SAN=sip.fabrikam.com
				The wizard detects any SIP domains you specified during setup and automatically adds them to the subject alternative name.
				You can also use this certificate for Server-to-Server Authentication.

Web Internal	FQDN of the server	Each of the following:
		- Internal web FQDN (which is the same as the FQDN of the server)
		- Meet simple URLs
		- Dial-in simple URL
		- Admin simple URL
		- Or, a wildcard entry for the simple URLs
			SN=ee01.contoso.com;
			SAN=ee01.contoso.com;
			SAN=meet.contoso.com;
			SAN=meet.fabrikam.com;
			SAN=dialin.contoso.com;
			SAN=admin.contoso.com
			Using a wildcard certificate:
				Internal web FQDN cannot be overwritten in Topology Builder.
				If you have multiple Meet simple URLs, you must include all of them as subject alternative names.

			SN=ee01.contoso.com;
			SAN=ee01.contoso.com;
			SAN=*.contoso.com
				Wildcard entries are supported for the simple URL entries.

Web external	FQDN of the server	Each of the following:
		• External web FQDN
		• Dial-in simple URL
		• Admin simple URL
		• Or, a wildcard entry for the simple URLs
			SN=ee01.contoso.com;
			SAN=webcon01.contoso.com;
			SAN=meet.contoso.com;
			SAN=meet.fabrikam.com;
			SAN=dialin.contoso.com
			Using a wildcard certificate:
			SN=ee01.contoso.com;
			SAN=webcon01.contoso.com;
			SAN=*.contoso.com
				If you have multiple Meet simple URLs, you must include all of them as subject alternative names.
				Wildcard entries are supported for the simple URL entries.

Certificates for Director

Certificate	Subject name/ Common name	Subject alternative name	Example

Default	FQDN of the Director pool	FQDN of the Director, FQDN of the Director pool
		If this pool is the auto-logon server for clients and strict DNS matching is required in group policy, you also need entries for sip.sipdomain (for each SIP domain you have).
			SN=dir-pool.contoso.com;
			SAN=dir-pool.contoso.com;
			SAN=dir01.contoso.com
			If this Director pool is the auto-logon server for clients and strict DNS matching is required in group policy, you also need SAN=sip.contoso.com;
			SAN=sip.fabrikam.com

Web Internal	FQDN of the server	Each of the following:
		• Internal web FQDN (which is the same as the FQDN of the
			SN=dir01.contoso.com;
			SAN=dir01.contoso.com;

		server)
		- Meet simple URLs
		- Dial-in simple URL
		- Admin simple URL
		- Or, a wildcard entry for the simple URLs
			SAN=meet.contoso.com;
			SAN=meet.fabrikam.com;
			SAN=dialin.contoso.com;
			SAN=admin.contoso.com
			
			SN=dir01.contoso.com;
			SAN=dir01.contoso.com
			SAN=*.contoso.com

Web external	FQDN of the server	Each of the following:
		- External web FQDN
		- Dial-in simple URL
		- Admin simple URL
		- Or, a wildcard entry for the simple URLs
			The Director external web FQDN must be different from the Front End pool or Front End Server.
			
			SN=dir01.contoso.com;
			SAN=directorwebcon01.contoso.com
			SAN=meet.contoso.com;
			SAN=meet.fabrikam.com;
			SAN=dialin.contoso.com
			
			SN=dir01.contoso.com;
			SAN=directorwebcon01.contoso.com
			SAN=*.contoso.com

If you have a stand-alone Mediation Server pool, the Mediation Servers in it each need the certificates listed in the following table. If you collocate Mediation Server with the Front End Servers, the certificates listed in the "Certificates for Front End Server in Front End Pool" table earlier in this topic are sufficient.

Certificates for Stand-alone Mediation Server

Certificate	Subject name/ Common name	Subject alternative name	Example

Default	FQDN of the pool	FQDN of the pool
		
		FQDN of pool member server
			SN=medsvr-pool.contoso.net;
			SAN=medsvr-pool.contoso.net;
			SAN=medsvr01.contoso.net

Certificates for Survivable Branch Appliance

Certificate	Subject name/	Subject alternative	Example

	Common name	name	

Default	FQDN of the appliance	SIP.<sipdomain> (need one entry per SIP domain)	SN=sba01.contoso.net;
			SAN=sip.contoso.com;
			SAN=sip.fabrikam.com

1.3.2.3.2 Certificate Requirements for External User Access

Certificate Requirements for External User Access

See Also

Planning > Determining Your Infrastructure Requirements > Certificate Infrastructure Requirements >

Topic Last Modified: *2012-09-08*

Microsoft Lync Server 2013 communications software supports the use of a single public certificate for access and web conferencing Edge external interfaces, plus the A/V Authentication service. The Edge internal interface typically uses a private certificate issued by an internal certification authority (CA), but can also use a public certificate, provided that it is from a trusted public CA. The reverse proxy in your deployment uses a public certificate and encrypts the communication from the reverse proxy to clients and the reverse proxy to internal servers by using HTTP (that is, Transport Layer Security over HTTP).

Following are the requirements for the public certificate used for access and web conferencing Edge external interfaces, and the A/V authentication service:

- The certificate must be issued by an approved public CA that supports subject alternative name. For details, see Microsoft Knowledge Base article 929395, "Unified Communications Certificate Partners for Exchange Server and for Communications Server," at http://go.microsoft.com/fwlink/p/?linkId=202834.
- If the certificate will be used on an Edge pool, it must be created as exportable, with the same certificate used on each Edge Server in the Edge pool. The exportable private key requirement is for the purposes of the A/V Authentication service, which must use the same private key across all Edge Servers in the pool.
- If you want to maximize the uptime for your Audio/Video services, review the certificate requirements for implementing a decoupled A/V Edge service certificate (that is, a separate A/V Edge service certificate from the other External Edge certificate purposes). For details, see Changes in Lync Server 2013 That Affect Edge Server Planning, Plan for Edge Server Certificates and Staging AV and OAuth Certificates Using -Roll in Set-CsCertificate.
- The subject name of the certificate is the Access Edge service external interface fully qualified domain name (FQDN) or hardware load balancer VIP (for example, access.contoso.com).

  Note:

  For Lync Server 2013, this is no longer a requirement, but it is still recommended for compatibility with Office Communications Server.

- The subject alternative name list contains the FQDNs of the following:
  - The Access Edge service external interface or hardware load balancer VIP (for example, sip.contoso.com).

    Note:

Even though the certificate subject name is equal to the access Edge FQDN, the subject alternative name must also contain the access Edge FQDN because Transport Layer Security (TLS) ignores the subject name and uses the subject alternative name entries for validation.

- The web conferencing Edge external interface or hardware load balancer VIP (for example, webcon.contoso.com).
- If you are using client auto-configuration or federation, also include any SIP domain FQDNs used within your company (for example, sip.contoso.com, sip.fabrikam.com).
- The A/V Edge service does not use the subject name or the subject alternative names entries.

Note:

The order of the FQDNs in the subject alternative names list does not matter.

If you are deploying multiple, load-balanced Edge Servers at a site, the A/V authentication service certificate that is installed on each Edge Server must be from the same CA and must use the same private key. Note that the certificate's private key must be exportable, regardless of whether it is used on one Edge Server or many Edge Servers. It must also be exportable if you request the certificate from any computer other than the Edge Server. Because the A/V authentication service does not use the subject name or subject alternative name, you can reuse the access Edge certificate as long as the subject name and subject alternative name requirements are met for the access Edge and the web conferencing Edge and the certificate’s private key is exportable.

Requirements for the private (or public) certificate used for the Edge internal interface are as follows:

- The certificate can be issued by an internal CA or an approved public certificate CA.
- The subject name of the certificate is typically the Edge internal interface FQDN or hardware load balancer VIP (for example, lsedge.contoso.com). However, you can use a wildcard certificate on the Edge internal.
- No subject alternative name list is required.

The reverse proxy in your deployment services requests for:

- External user access to meeting content for meetings
- External user access to expand and display members of distribution groups
- External user access to downloadable files from the Address Book Service
- External user access to the Lync Web App client
- External user access to the Dial-in Conferencing Settings web page
- External user access to the Location Information Service
- External device access to the Device Update Service and obtain updates

The reverse proxy publishes the internal server Web Components URLs. The Web Components URLs are defined on the Director, Front End Server or Front End pool as the **External web services** in Topology Builder.

Wildcard entries are supported in the subject alternative name field of the certificate assigned to the reverse proxy. For details about how to configure the certificate request for the reverse proxy, see Request and Configure a Certificate for Your Reverse HTTP Proxy.

Concepts

Wildcard Certificate Support

1.3.2.3.3 Certificate Requirements for Persistent Chat Server

Certificate Requirements for Persistent Chat Server

Planning > Determining Your Infrastructure Requirements > Certificate Infrastructure Requirements >

Topic Last Modified: *2012-10-03*

To install Persistent Chat Server, you must have a certificate issued by the same CA as the one used by Lync Server 2013 internal servers for each server running the Persistent Chat Web Services for File Upload/Download. Make sure that you have the required certificate(s) before you start the Persistent Chat installation, especially if you are using an external CA.

1.3.2.3.4 Certificate Requirements for Mobility

Certificate Requirements for Mobility

Planning > Determining Your Infrastructure Requirements > Certificate Infrastructure Requirements >

Topic Last Modified: *2012-06-24*

If you deploy the mobility feature and support automatic discovery for mobile clients, you need to include certain subject alternative name entries on certificates to support secure connections from the mobile clients.

You need to include subject alternative name entries for automatic discovery on the following certificates:

- Director pool
- Front End pool
- Reverse proxy

This section describes the subject alternative name entries that are required on your certificates for automatic discovery.

Note:

Reissuing certificates by using an internal certificate authority is typically a simple process, but adding multiple subject alternative name entries to public certificates used by the reverse proxy can be expensive. If you have many SIP domains, making the addition of subject alternative names very expensive, you can configure the reverse proxy to use HTTP for the initial Autodiscover Service request, instead of using HTTPS (the default configuration). For details, see Technical Requirements for Mobility.

Director Pool Certificate Requirements

Description	Subject alternative name entry
Internal Autodiscover Service URL	SAN=lyncdiscoverinternal.<sipdomain>
External Autodiscover Service URL	SAN=lyncdiscover.<sipdomain>

Note:

Alternatively, you can use SAN=*.<sipdomain>

Front End Pool Certificate Requirements

Description	Subject alternative name entry

Internal Autodiscover Service URL	SAN=lyncdiscoverinternal.<sipdomain>
External Autodiscover Service URL	SAN=lyncdiscover.<sipdomain>

Note:

Alternatively, you can use SAN=*.<sipdomain>

Reverse Proxy (Public CA) Certificate Requirements

Description	Subject alternative name entry
External Autodiscover Service URL	SAN=lyncdiscover.<sipdomain>

Note:

You assign this SAN to the certificate assigned to the SSL Listener on the reverse proxy.

Note:

Your reverse proxy listener will have subject alternative names for your external Web Services URL(s) (for example, SAN=lyncwebextpool01.contoso.com, and dirwebexternal.contoso.com if you have deployed the optional Director).

1.3.2.4 Internet Information Services (IIS) Requirements

Internet Information Services (IIS) Requirements

Microsoft Lync Server 2013 > Planning > Determining Your Infrastructure Requirements >

Topic Last Modified: *2012-06-19*

Several Lync Server 2013 components require Internet Information Services (IIS). This topic describes the specific IIS features required to support Lync Server. The topics in this section describe the requirements of specific components for IIS.

When the Web Server (IIS) role is enabled on Windows Server 2008, various role services are installed by default. The following table describes the additional role services that must be installed when the Web Server (IIS) role is enabled on Windows Server 2008.

Role service	Feature
Common HTTP Features	HTTP Redirection
Application Development	ASP.NET
Application Development	.NET Extensibility
Application Development	ISAPI Extensions
Application Development	ISAPI Filters
Health and Diagnostics	Logging Tools
Health and Diagnostics	Tracing
Security	Basic Authentication
Security	Windows Authentication
Management Tools	IIS Management Scripts and Tools
Management Tools	IIS 6 Management Compatibility

Security Note:

If you are using IIS 7.0 on a Windows Server 2008 operating system, Lync Server Setup disables kernel mode authentication in IIS.

- IIS Requirements for Front End Pools and Standard Edition Servers

1.3.2.4.1 IIS Requirements for Front End Pools and Standard Edition Servers

IIS Requirements for Front End Pools and Standard Edition Servers

Planning > Determining Your Infrastructure Requirements > Internet Information Services (IIS) Requirements >

Topic Last Modified: *2012-06-19*

For Standard Edition servers and Front End Servers, and Directors, the Lync Server 2013 installer creates virtual directories in Internet Information Services (IIS) for the following purposes:

- To enable users to download files from the Address Book Service
- To enable clients to obtain updates
- To enable conferencing
- To enable users to download meeting content
- To enable users to expand distribution groups
- To enable phone conferencing
- To enable response group features

In addition, the cumulative update for Lync Server 2010: November 2011 installer creates virtual directories in IIS for the following purposes:

- On Front End Servers or Standard Edition servers to support mobility functionality, such as instant messaging (IM) and presence, on mobile devices
- On Front End Servers or Standard Edition servers and on Directors to enable mobile devices to automatically discover mobility resources

Note:

If you are deploying mobility, we recommend that you use IIS 7.5. The Lync Server Mobility Service installer sets some ASP.NET flags to improve performance. IIS 7.5 is installed by default on Windows Server 2008 R2, and the Mobility Service installer automatically changes the ASP.NET settings. If you use IIS 7.0 on Windows Server 2008, you need to manually change these settings.

Lync Server requires the following IIS modules to be installed:

Important:

If your organization requires that you locate IIS and all Web Services on a drive other than the system drive, you can change the installation location path for the Lync Server files in the Setup dialog box. If you install the Setup files to this path, including OCSCore.msi, the rest of the Lync Server files will be deployed to this drive as well. For details about how to relocate the INETPUB deployed by Windows Server Manager when installing IIS, see http://go.microsoft.com/fwlink/p/?linkId=216888.

- Static Content
- Default Document
- HTTP Errors
- ASP.NET
- .NET Extensibility
- Internet Server API (ISAPI) Extensions
- ISAPI Filters

- HTTP Logging
- Logging Tools
- Tracing
- Windows Authentication
- Request Filtering
- Static Content Compression
- Dynamic Content Compression
- IIS Management Console
- IIS Management Scripts and Tools
- Anonymous Authentication (installed by default when IIS is installed)
- Client Certificate Mapping Authentication

The following table lists the URIs for the virtual directories for internal access and the file system resources to which they refer.

Virtual Directories for Internal Access

Feature	**Virtual directory URI**	**Refers to**
Address Book Server	https://*<Internal FQDN>*/ABS/int/Handler	Location of Address Book Server download files for internal users.
Autodiscover Service	https://*<Internal FQDN>*/Autodiscover	Location of the Lync Server Autodiscover Service that locates mobility resources for internal mobile device users.
Client updates	http://*<Internal FQDN>*/AutoUpdate/Int	Location of update files for internal computer-based clients.
Conf	http://*<Internal FQDN>*/Conf/Int	Location of conferencing resources for internal users.
Device updates	http://*<Internal FQDN>*/DeviceUpdateFiles_Int	Location of unified communications (UC) device update files for internal UC devices.
Meeting	http://*<Internal FQDN>*/etc/place/null	Location of meeting content for internal users.
Mobility Service	https://*<Internal FQDN>*/Mcx	Location of Mobility Service resources for internal mobile device users.
Group Expansion and Address Book Web Query service	http://*<Internal FQDN>*/GroupExpansion/int/service.asmx	Location of the Web service that enables group expansion for internal users. Also, the location of the Address Book Web Query service that provides global address list information to internal Lync Mobile Microsoft Lync 2010 Mobile clients.
Phone Conferencing	http://*<Internal FQDN>*/PhoneConferencing/Int	Location of phone conferencing data for internal users.
Device updates	http://*<Internal FQDN>*/	Location of the Device

	RequestHandler	Update Web service Request Handler that enables internal UC devices to upload logs and check for updates.
Response Group application	http://*<Internal FQDN>*/RgsConfig http://*<Internal FQDN>*/RgsClients	Location of Response Group Configuration Tool.

Note:
For Front End pools in a consolidated configuration, you must deploy IIS before you can add servers to the pool.

Security Note:
You must use the IIS administrative snap-in to assign the certificate used by the IIS web component server.

1.3.3 Network Planning for Lync Server

Determining Your Infrastructure Requirements

1.3.3.1 Network Infrastructure Requirements

Network Infrastructure Requirements

Microsoft Lync Server 2013 > Planning > Network Planning for Lync Server >

Topic Last Modified: *2012-10-18*

The network adapter card of each server in the Lync Server 2013 topology must support at least 1 gigabit per second (Gbps). In general, you should connect all server roles within the Lync Server topology using a low latency and high bandwidth local area network (LAN). The size of the LAN is dependent on the size of the topology:

- In Standard Edition topologies, servers should be in a network that supports 1

Gbps Ethernet or equivalent.
- In Front End pool topologies, most servers should be in a network that supports more than 1 Gbps, especially when supporting audio/video (A/V) conferencing and application sharing.

For public switched telephone network (PSTN) integration, you can integrate by using either T1/E1 lines or SIP trunking.

Audio/Video Network Requirements

Network requirements for audio/video (A/V) in a Lync Server deployment include the following:

- If you are deploying a single Edge Server or an Edge pool using DNS load balancing, you can configure the external firewall as a NAT. You cannot configure the internal firewall as a NAT. For details about these requirements, see Determine External A/V Firewall and Port Requirements in the Planning documentation.

Important:

If you have an Edge pool and are using a hardware load balancer, you must use public IP addresses on each of the Edge Servers and you cannot use NAT for the servers or the pool at your NAT device (for example, the firewall, or other infrastructure device that would NAT inbound or outbound traffic). For details, see Port Summary - Scaled Consolidated Edge with Hardware Load Balancers in the Planning for External User Access documentation.

- If your organization uses a Quality of Service (QoS) infrastructure, the media subsystem is designed to work within this existing infrastructure.
- If you use Internet Protocol security (IPsec), we recommend disabling IPsec over the port ranges used for A/V traffic. For details, see IPsec Exceptions in the Planning documentation.

To ensure optimal media quality, do the following:

- Provision your network links to support throughput of 65 kilobits per second (Kbps) per audio stream and 500 Kbps per video stream, if enabled, during peak usage periods. A bidirectional audio or video session consists of two streams.
- To cope with unexpected spikes in traffic above this level and increased usage over time, Lync Server media endpoints can adapt to varying network conditions and support loads of three times the throughput (see previous paragraph) for audio and video while still retaining acceptable quality. However, do not assume that this adaptability will support an under-provisioned network. In an under-provisioned network, the ability of the Lync Server media endpoints to dynamically deal with varying network conditions (for example, temporary high packet loss) is reduced.
- For network links where provisioning is extremely costly and difficult, you may need to consider provisioning for a lower volume of traffic. In this scenario, let the elasticity of the Lync Server media endpoints absorb the difference between the traffic volume and the peak traffic level, at the cost of some reduction in the voice quality. Also, there is a decrease in the headroom otherwise available to absorb sudden peaks in traffic.
- For links that cannot be correctly provisioned in the short term (for example, a site with very poor WAN links), consider disabling video for certain users.
- Provision your network to ensure a maximum end-to-end delay (latency) of 150 milliseconds (ms) under peak load. Latency is the one network impairment that Lync Server media components cannot reduce, and it is important to find and eliminate the weak points.
- For servers running antivirus software, include all servers running Lync Server in the exception list in order to provide optimal performance and audio quality.

Conferencing Network Requirements

The bandwidth that is used to download conference content from the Internet Information Services (IIS) server depends on the size of the content that is uploaded.

1.3.3.2 Planning for and Configuring IPv6

Planning for and Configuring IPv6

[Microsoft Lync Server 2013](#) > [Planning](#) > [Network Planning for Lync Server](#) >

Topic Last Modified: *2012-06-14*

Lync Server 2013 includes support for IP version 6 (IPv6) addresses, along with continued support of IP version 4 (IPv4) addresses. IPv4 addresses are 32-bit addresses that allow a computer to communicate over the Internet. Due to the increasing number of devices worldwide, the available IPv4 addresses have run out. Because of this, many new devices are moving to using IPv6 addresses. IPv6 addresses perform the same function as IPv4 addresses (with some additional features), but instead of using only 32-bits, IPv6 addresses use 128-bits. This provides not only a new set of addresses, but also a much larger number of them. A typical IPv4 address looks something like this: 192.0.2.235, whereas an IPv6 address looks like this: 2001:0db8:85a3:0000:0000:8a2e:0370:7334. The change in formatting and functionality for devices that use IPv6 addresses requires several deployment and configuration considerations in your Lync Server 2013 installation.

In This Section

- [Overview of IP Address Types for Lync Server 2013](#)
- [Technical Requirements for IPv6](#)
- [Migration and Coexistence Considerations for IPv6](#)
- [Configure IP Address Types](#)

1.3.3.2.1 Overview of IP Address Types for Lync Server 2013

Overview of IP Address Types for Lync Server 2013

[Planning](#) > [Network Planning for Lync Server](#) > [Planning for and Configuring IPv6](#) >

Topic Last Modified: *2013-01-29*

You have three options when configuring IP addresses in Lync Server 2013. You can configure Lync Server 2013 to support only IP version 4 (IPv4), only IP version 6 (IPv6), or a combination of both (known as a *dual stack*). There are several issues to consider with each type of configuration:

- **IPv4 only** IPv6 was created because the world is running out of IPv4 addresses. Ultimately, IPv6 will be fully supported worldwide, but at this time, many companies and devices that your enterprise might need to communicate with do not yet support IPv6, and may not for some time. An IPv4-only configuration will help to ensure that your Lync Server implementation can communicate with most existing devices.
- **IPv6 only** Conversely, a full IPv6 implementation, at this time, will exclude communication with many existing devices.
- **Dual Stack** Dual stack is a network where both IPv4 and IPv6 addresses are

enabled. This configuration is supported in Lync Server 2013 because in most cases the transition from full-IPv4 to full-IPv6 will take several years.

The following sections outline the compatibility among these three configurations for various Lync Server features.

Note:

Client or server configuration with IPv6 only is supported only for lab or validation purposes. IPv6 only configuration is not supported in the production deployment.

Client Registration

Client endpoint network	Server network
IPv4	IPv4
IPv4	Dual stack
Dual stack	IPv4
Dual stack	Dual stack
Dual stack	IPv6
IPv6	Dual stack
IPv6	IPv6

Peer-to-Peer Client

Peer-to-peer communications include audio, audio/video, application sharing, and file transfer. After both clients have successfully registered, the following combinations are supported.

Client endpoint 1	Client endpoint 2
IPv4	IPv4
IPv4	Dual stack
Dual stack	Dual stack
IPv6	Dual stack
IPv6	IPv6

Conferencing

Conferencing includes audio/video, application sharing, and data collaboration (whiteboarding and file sharing).

Client endpoint network	Server network
IPv4	IPv4
IPv4	Dual stack
Dual stack	IPv4
Dual stack	Dual stack

Dual stack	IPv6
IPv6	Dual stack
IPv6	IPv6

Mediation Server/PSTN

Lync Server 2013 does not support media bypass for public switched telephone network (PSTN) calls if the traffic is through an IPv6 interface. If media bypass is required, we recommend that the PSTN gateway is configured to IPv4.

Primary interface*	PSTN interface (on Mediation Server)	PSTN gateway setting
IPv4	Dual stack	IPv4
Dual stack	Dual stack	IPv4
Dual stack	Dual stack	IPv6

* The primary interface is the interface that communicates with the Lync Server components.

Remote User Peer-to-Peer Communications

Peer-to-peer communications with remote users include instant messaging, audio/video, application sharing, and file transfer.

Remote user network	Edge server (External edge)
IPv4	IPv4
Dual stack	IPv4
Dual stack	Dual stack
IPv6	Dual stack
IPv6	IPv6

Front End Pool and Edge Pool Configuration

The following table shows the support matrix between the Front End Server pool and the internal Edge Server pool.

Front End Pool and Edge Pool (Internal Edge) Matrix

	Edge Pool: IPv4	Edge Pool: Dual Stack	Edge Pool: IPv6
Front End Pool: IPv4	Yes	Yes	No
Front End Pool: Dual Stack	Yes	Yes	No

Front End Pool: IPv6	No	No	Yes*

* Use this combination only in a lab environment.

The following table is a matrix of the supported combinations of internal and external edge interfaces.

Edge Pool (Internal Edge) and Edge pool (External Edge) Matrix

	Edge Pool (External Edge) : IPv4	**Edge Pool (External Edge): Dual Stack**	**Edge Pool (External Edge): IPv6**
Edge Pool (Internal Edge): IPv4	Yes	Yes	No
Edge Pool (Internal Edge): Dual Stack	No	Yes	No
Edge Pool (Internal Edge): IPv6	No	No	Yes*

* Use this combination only in a lab environment.

Advanced Enterprise Voice Support for IPv6

Deployments that include call admission control (CAC), Enhanced 9-1-1 (E9-1-1), or media bypass must be configured as IPv4 only or as a dual-stacked implementation.

Note:
In a dual-stacked deployment, even if a Lync client connects to a Lync Server by using IPv6, Lync will make a best effort to map an appropriate IPv4 address to support E9-1-1.

Location Information service with IPv6 addresses is not supported.

Exchange Unified Messaging (UM) does not support IPv6. For Exchange UM, be sure that DNS resolution does not return an IPv6 address. Using IPv6 may cause failure when calls are sent to voice mail.

Other Lync Server 2013 Feature Support for IPv6

In addition to the features and components mentioned previously, Lync Server 2013 supports IPv6 for the following features:

- **Persistent Chat**
  You configure IPv6 for Persistent Chat by using Topology Builder. For details about configuring Persistent Chat, see the Deploying Persistent Chat Server documentation.
- **Quality of Experience (QoE) and call detail recording (CDR) reports**
  Monitoring reports include the IP address as it is stored in the Monitoring Server database, whether of type IPv4 or IPv6.

1.3.3.2.2 Technical Requirements for IPv6

Technical Requirements for IPv6

See Also

Planning > Network Planning for Lync Server > Planning for and Configuring IPv6 >

Topic Last Modified: *2012-10-30*

If you plan to configure Lync Server 2013 for IPv6, keep the following requirements in mind:

- To use IPv6 addresses with Lync Server, you need to create domain name system (DNS) records for records that must be discovered and resolved to an IPv6 address. IPv6 DNS uses host AAAA (quad-A) records. If you use both IPv4 and IPv6 in your deployment, it is best to configure and maintain both host A records for IPv4 and host AAAA records for IPv6. Even when you fully transition your deployment to IPv6, you may still require IPv4 DNS host records for external users who still use IPv4.
  You can deploy IPv6 DNS host records before you start using IPv6. If the client or server doesn't use IPv6, the record will not be referenced. Transitional technologies will make the decision about which record to use, based on transition technology configuration and policies.
- Each IPv6 address has a scope. The three scopes that you can use for IPv6 addressing are IPv6 global addresses (similar to public IPv4 addresses), IPv6 unique local addresses (similar to the private IPv4 address ranges), and IPv6 link-local addresses (similar to automatic private IP addresses in Windows Server for IPv4). All the servers within a pool should have IPv6 addresses with the same scope.

◆**Important:**
IPv6 is a complex topic and requires careful planning with your networking team and your Internet provider to help ensure that the addresses that you assign at the Windows Server level and at the Lync Server 2013 level work as expected. See the links at the end of this topic for additional resources on IPv6 addressing and planning.

1.3.3.2.3 Migration and Coexistence Considerations for IPv6

Migration and Coexistence Considerations for IPv6

Planning > Network Planning for Lync Server > Planning for and Configuring IPv6 >

Topic Last Modified: *2012-06-14*

IP version 6 (IPv6) is not supported on Lync Server 2010 or Office Communications Server. For piloting purposes, you can test Lync Server 2010 and Lync Server 2013 dual-stack coexistence. We recommend that all pools for a given central site are upgraded to Lync Server 2013 before you enable IPv6 (dual-stack network) for any of the pools. If you need to configure a pool for IPv6 only, we recommend that you set up an IPv6-only pool in your lab environment for testing.

The following scenarios are supported during migration and coexistence:

- Lync Server 2013, Lync Server 2010, and Office Communications Server 2007 R2 pools in IPv4 mode, coexisting with Lync Server 2013 in dual-stack mode.

- Lync Server 2013 pool in IPv6-only mode, if the IPv6-only pool is siloed.

1.3.3.2.4 Configure IP Address Types

Configure IP Address Types

Planning > Network Planning for Lync Server > Planning for and Configuring IPv6 >

Topic Last Modified: *2012-06-13*

You deploy IP address types by using topology settings that you configure in Topology Builder. This section describes how to deploy IP address types on Front End Servers, Mediation Servers, and Edge Servers.

In This Section

- Deploy IP Address Types on a Front End Server
- Deploy IP Address Types on a Mediation Server
- Deploy IP Address Types on an Edge Server

1.3.3.2.4.1 Deploy IP Address Types on a Front End Server

Deploy IP Address Types on a Front End Server

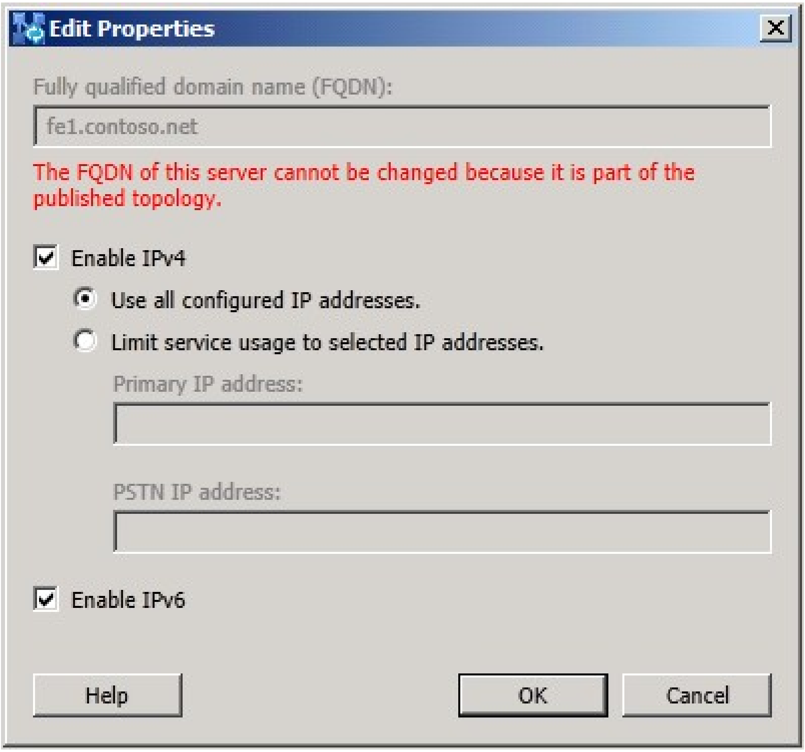
Network Planning for Lync Server > Planning for and Configuring IPv6 > Configure IP Address Types >

Topic Last Modified: *2012-06-14*

Using Topology Builder, perform the steps in the following procedure to deploy IP address types on a Front End Server.

⊟To deploy IP address types on a Front End Server

1. Under **Enterprise Edition Front End pools**, right-click the server within a pool, and then select **Edit Properties**. (Alternatively, select the server, and then click **Edit Properties** from the **Action** menu.)
2. In the **Edit Properties** dialog box, select the IP address type that you want to configure. For a dual-stack configuration, select **Enable IPv4** and **Enable IPv6**, as shown in the following figure.



Edit Properties

Fully qualified domain name (FQDN):

fe1.contoso.net

The FQDN of this server cannot be changed because it is part of the published topology.

☑ Enable IPv4

● Use all configured IP addresses.

○ Limit service usage to selected IP addresses.

Primary IP address:

PSTN IP address:

☑ Enable IPv6

- **Use all configured IP addresses**. Select this option if you want to allow any IP address defined on the computer to be used.

> **Note:**
> This is the recommended option for IP version 6 (IPv6) configurations.

- **Limit service usage to selected IP addresses**. Select this option to specify a specific address to use on the new server. If you select this option, you must enter a value for **Primary IP address**.
- **Primary IP address**. Enter an IP address that the server will use for all communications except public switched telephone network (PSTN). The IP address entered must match the format of the select address type.
- **PSTN IP address**. Define a PSTN IP address when a Mediation Server is collocated on the Front End Server. This address must match the format of the selected address type.

1.3.3.2.4.2 Deploy IP Address Types on a Mediation Server

Deploy IP Address Types on a Mediation Server

Network Planning for Lync Server > Planning for and Configuring IPv6 > Configure IP Address Types >

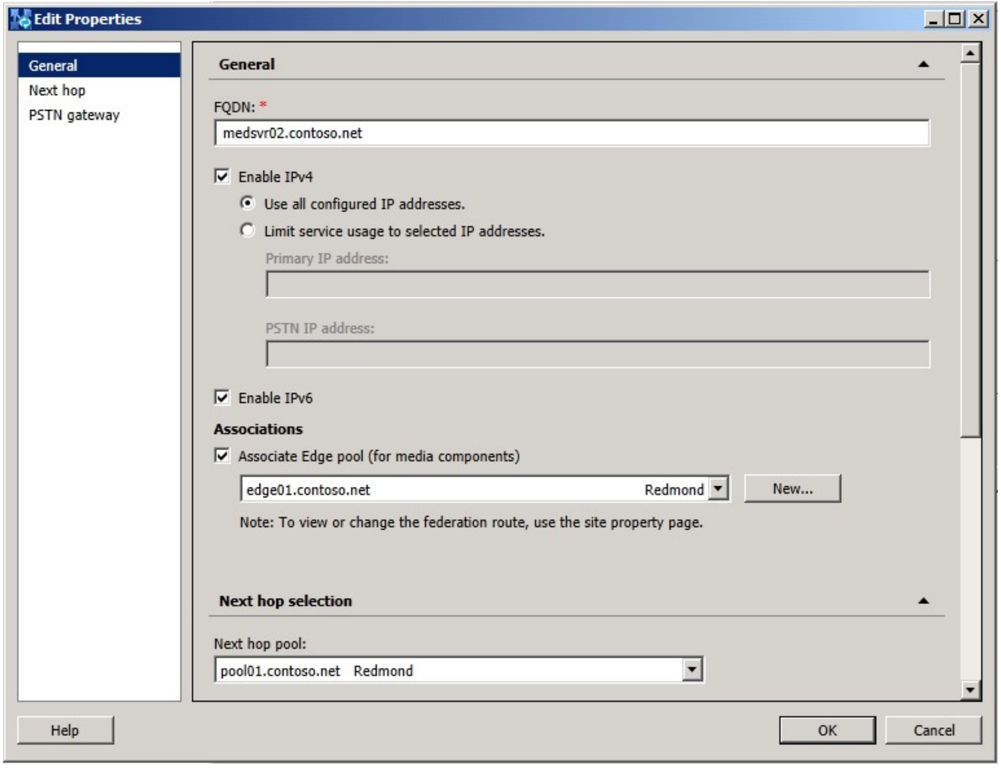
Topic Last Modified: *2012-06-14*

Using Topology Builder, perform the steps in the following procedure to deploy IP address types on a Mediation Server.

⊟To deploy IP address types on a Mediation Server

- In Topology Builder, under **Mediation pools**, right-click the server within a pool, and then select **Edit Properties**. (Alternatively, select the server, and then click **Edit Properties** from the **Action** menu.)

- In the **Edit Properties** dialog box, select the IP address type that you want to configure. For a dual-stack configuration, select **Enable IPv4** and **Enable IPv6**, as shown in the following figure.



General

FQDN: * medsvr02.contoso.net

☑ Enable IPv4

● Use all configured IP addresses.

○ Limit service usage to selected IP addresses.

Primary IP address:

PSTN IP address:

☑ Enable IPv6

Associations

☑ Associate Edge pool (for media components)

edge01.contoso.net Redmond

Note: To view or change the federation route, use the site property page.

Next hop selection

Next hop pool: pool01.contoso.net Redmond

- **Use all configured IP addresses**. Select this option if you want to allow any IP address defined on the computer to be used.

Note:
This is the recommended option for IP version 6 (IPv6) configurations.

- **Limit service usage to selected IP addresses**. Select this option to specify a specific address to use on the new server. If you select this option, you must enter a value for Primary IP address.
- **Primary IP address**. Enter an IP address that the server will use for all communications except public switched telephone network (PSTN). The IP address entered must match the format of the select address type.
- **PSTN IP address**. Define a PSTN IP address when a Mediation Server is collocated on the Front End Server. This address must match the format of the selected address type.

1.3.3.2.4.3 Deploy IP Address Types on an Edge Server

Deploy IP Address Types on an Edge Server

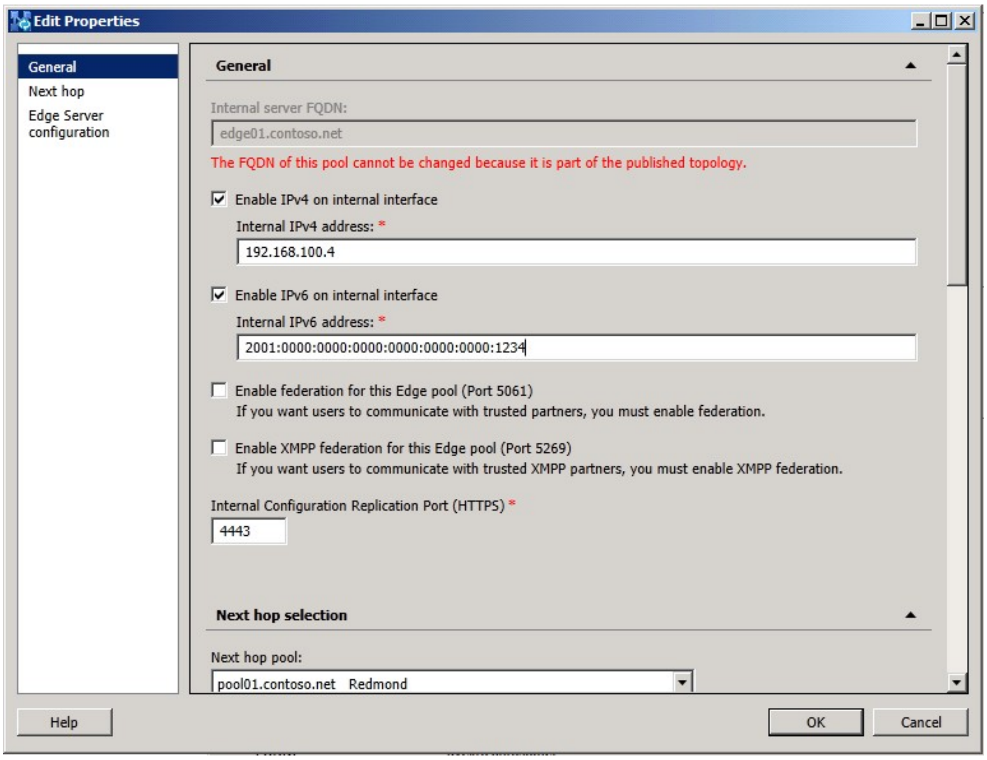
Network Planning for Lync Server > Planning for and Configuring IPv6 > Configure IP Address Types >

Topic Last Modified: *2012-06-14*

Using Topology Builder, perform the steps in the following procedure to deploy IP address types on an Edge Server.

⊟To deploy IP address types on an Edge Server

1. In Topology Builder, under **Edge pools**, right-click the server within a pool, and then select **Edit Properties**. (Alternatively, select the server, and then click **Edit Properties** from the **Action** menu.)
2. In the **Edit Properties** window, select the IP address configuration that you want to support. The following figures show a dual stack configuration for the internal interface and the external interface.



General

Internal server FQDN:

edge01.contoso.net

The FQDN of this pool cannot be changed because it is part of the published topology.

☑ Enable IPv4 on internal interface

Internal IPv4 address: *

192.168.100.4

☑ Enable IPv6 on internal interface

Internal IPv6 address: *

2001:0000:0000:0000:0000:0000:0000:1234

☐ Enable federation for this Edge pool (Port 5061)
If you want users to communicate with trusted partners, you must enable federation.

☐ Enable XMPP federation for this Edge pool (Port 5269)
If you want users to communicate with trusted XMPP partners, you must enable XMPP federation.

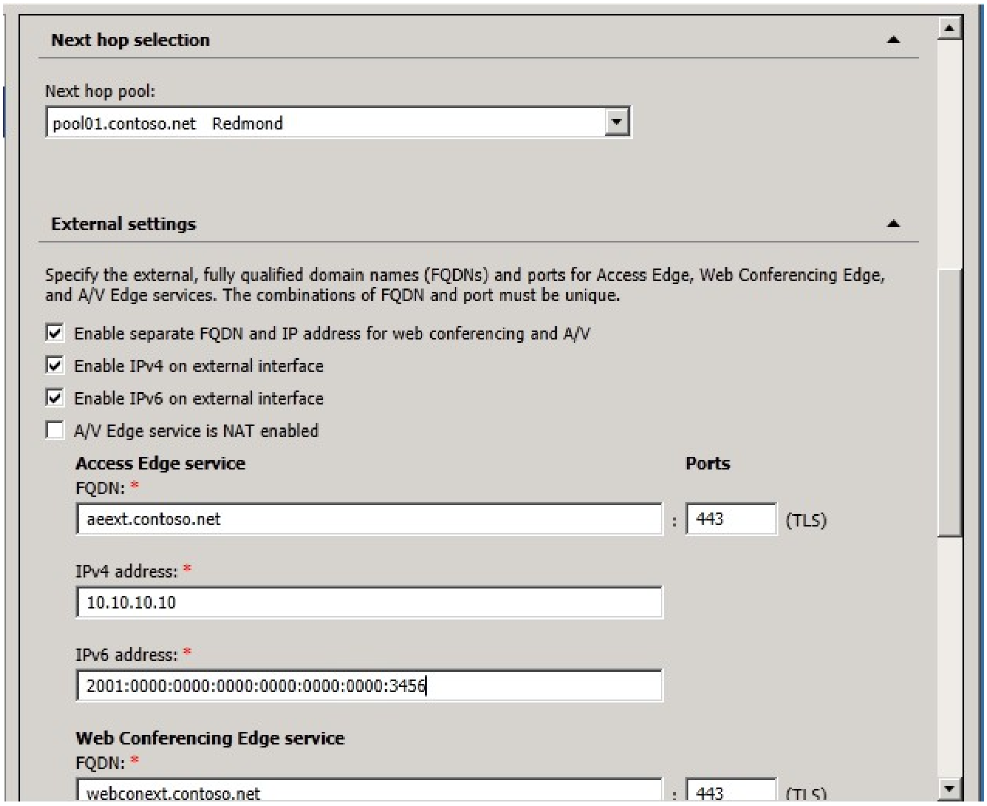
Internal Configuration Replication Port (HTTPS) *

4443

Next hop selection

Next hop pool:

pool01.contoso.net Redmond



Next hop selection

Next hop pool:
pool01.contoso.net Redmond

External settings

Specify the external, fully qualified domain names (FQDNs) and ports for Access Edge, Web Conferencing Edge, and A/V Edge services. The combinations of FQDN and port must be unique.

☑ Enable separate FQDN and IP address for web conferencing and A/V
☑ Enable IPv4 on external interface
☑ Enable IPv6 on external interface
☐ A/V Edge service is NAT enabled

Access Edge service — Ports
FQDN: *
aeext.contoso.net : 443 (TLS)

IPv4 address: *
10.10.10.10

IPv6 address: *
2001:0000:0000:0000:0000:0000:0000:3456

Web Conferencing Edge service
FQDN: *
webconext.contoso.net : 443 (TLS)

3. For each address type that you select, you must supply appropriate internal and external addresses.

1.3.3.3 Load Balancing Requirements

Load Balancing Requirements

Microsoft Lync Server 2013 > Planning > Network Planning for Lync Server >

Topic Last Modified: *2012-10-05*

If you have Front End pools, Director pools, or Edge Server pools, you need to deploy load balancing for these pools. Load balancing distributes the traffic among the servers in a pool.

Lync Server 2013 supports two types of load balancing solutions for client-to-server traffic: Domain Name System (DNS) load balancing and hardware load balancing. DNS load balancing offers several advantages including simpler administration, more efficient troubleshooting, and the ability to isolate much of your Lync Server traffic from any potential hardware load balancer problems.

Decide which load balancing solution is appropriate for each pool in your deployment, keeping in mind the following restrictions:

- The internal Edge interface and external Edge interface must use the same type of load balancing. You cannot use DNS load balancing on one interface and hardware load balancing on the other.
- Some types of traffic require a hardware load balancer. For example, HTTP traffic requires a hardware load balancer instead of DNS load balancing. DNS load balancing does not work with client-to-server web traffic.

For more details about choosing a hardware load balancer solution, see Hardware Load

Balancer Requirements.

If you choose to use DNS load balancing for a pool but still need to implement hardware load balancers for traffic such as HTTP traffic, the administration of the hardware load balancers is greatly simplified. For example, configuring the hardware load balancer will be simpler as it will only manage the HTTP and HTTPS traffic, while all other protocols will be managed by DNS load balancing. For details, see DNS Load Balancing.

For server-to-server traffic, Lync Server 2013 uses topology-aware load balancing. Servers read the published topology in the Central Management store to obtain the FQDNs of servers in the topology, and automatically distribute the traffic among the servers. Administrators do not need to set up or manage this type of load balancing.

If you use DNS load balancing and you need to block traffic to a specific computer, it is not sufficient to just remove the IP address entries from the Pool FQDN. You must remove the DNS entry for the computer as well.

1.3.3.3.1 Hardware Load Balancer Requirements

Hardware Load Balancer Requirements

Planning > Network Planning for Lync Server > Load Balancing Requirements >

Topic Last Modified: *2012-10-22*

The Lync Server 2013 scaled consolidated Edge topology is optimized for DNS load balancing for new deployments federating primarily with other organizations using Lync Server. If high availability is required for any of the following scenarios, a hardware load balancer must be used on Edge Server pools for the following:

- Federation with organizations using Office Communications Server 2007 R2 or Office Communications Server 2007
- Exchange UM for remote users using Exchange UM prior to Exchange 2010 with SP1
- Connectivity to public IM users

> **Important:**
>
> Using DNS load balancing on one interface and hardware load balancing on the other is not supported. You must use hardware load balancing for both interfaces or DNS load balancing for both.

> **Note:**
>
> If you are using a hardware load balancer, the load balancer deployed for connections with the internal network must be configured to load balance only the traffic to servers running the Access Edge service and the A/V Edge service. It cannot load balance the traffic to the internal Web Conferencing Edge service or the internal XMPP Proxy service.

> **Note:**
>
> The direct server return (DSR) NAT is not supported with Lync Server 2013.

To determine whether your hardware load balancer supports the necessary features required by Lync Server 2013, see "Lync Server 2010 Load Balancer Partners" at http://go.microsoft.com/fwlink/p/?linkId=202452.

Hardware Load Balancer Requirements

for Edge Servers Running the A/V Edge Service

Following are the hardware load balancer requirements for Edge Servers running the A/V Edge service:

- Turn off TCP nagling for both internal and external ports 443. Nagling is the process of combining several small packets into a single, larger packet for more efficient transmission.
- Turn off TCP nagling for external port range 50,000 – 59,999.
- Do not use NAT on the internal or external firewall.
- The edge internal interface must be on a different network than the Edge Server external interface and routing between them must be disabled.
- The external interface of the Edge Server running the A/V Edge Service must use publically routable IP addresses and no NAT or port translation on any of the edge external IP addresses.

Hardware Load Balancer Requirements

Cookie-based affinity requirements are greatly reduced in Lync Server 2013 for Web services. If you are deploying Lync Server 2013 and will not retain any Lync Server 2010 Front End Servers or Front End pools, you do not need cookie-based persistence. However, if you will temporarily or permanently retain any Lync Server 2010 Front End Servers or Front End pools, you still use cookie-based persistence as it is deployed and configured for Lync Server 2010.

Note:

If you decide to use cookie-based affinity even though your deployment does not require it, there is no negative impact to doing so.

For deployments that **will not use** cookie-based affinity:

- On the reverse proxy publishing rule for port 4443, set **Forward host header** to True. This will ensure that the original URL is forwarded.

For deployments that **will use** cookie-based affinity:

- On the reverse proxy publishing rule for port 4443, set **Forward host header** to True. This will ensure that the original URL is forwarded.
- Hardware load balancer cookie MUST NOT be marked httpOnly
- Hardware load balancer cookie MUST NOT have an expiration time
- Hardware load balancer cookie MUST be named **MS-WSMAN** (This is the value that the Web services expect, and cannot be changed)
- Hardware load balancer cookie MUST be set in every HTTP response for which the incoming HTTP request did not have a cookie, regardless of whether a previous HTTP response on that same TCP connection had already obtained a cookie. If the load balancer optimizes cookie insert to only occur once per TCP connection, that optimization MUST NOT be used

Note:

Typical hardware load balancer configurations use source-address affinity and a 20 min. TCP session lifetime, which is fine for Lync Server and Lync 2013 clients because session state is maintained through client usage and/or and application interaction.

If you are deploying mobile devices, your hardware load balancer must be able to load balance individual request within a TCP session (in effect, you must be able to load balance an individual request based on the target IP address).

Warning:

F5 hardware load balancers have a feature called OneConnect that ensures each request within a TCP connection is individually load balanced. If you are deploying mobile devices, ensure your hardware load balancer vendor supports the same functionality. The latest Apple iOS mobile apps require Transport Layer Security (TLS) version 1.2. F5 provides specific settings for this.
For details on third party hardware load balancers, see http://go.microsoft.com/fwlink/p/?linkId=230700

Following are the hardware load balancer requirements for Director and Front End pool Web Services:

- For internal Web Services VIPs, set Source_addr persistence (internal port 80, 443) on the hardware load balancer. For Lync Server 2013, Source_addr persistence means that multiple connections coming from a single IP address are always sent to one server to maintain session state.
- Use TCP idle timeout of 1800 seconds.
- On the firewall between the reverse proxy and the next hop pool’s hardware load balancer, create a rule to allow https: traffic on port 4443, from the reverse proxy to the hardware load balancer. The hardware load balancer must be configured to listen on ports 80, 443, and 4443.

Summary of Hardware Load Balancer Affinity Requirements

Client/user location	External web services FQDN affinity requirements	Internal web services FQDN affinity requirements
Lync Web App (internal and external users) Mobile device (internal and external users)	No affinity	Source address affinity
Lync Web App (external users only) Mobile device (internal and external users)	No affinity	Source address affinity
Lync Web App (internal users only) Mobile device (not deployed)	No affinity	Source address affinity

Port Monitoring for Hardware Load Balancers

You define port monitoring on the hardware load balancers to determine when specific services are no longer available due to hardware or communications failure. For example, if the Front End Server service (RTCSRV) stops because the Front End Server or Front End pool fails, the HLB monitoring should also stop receiving traffic on the Web Services. You implement port monitoring on the HLB to monitor the following:

Front End Server User Pool – HLB Internal Interface

Virtual IP/Port	Node Port	Node Machine/ Monitor	Persistence Profile	Notes

<pool>web-int_mco_443_vs 443	443	Front End 5061	Source	HTTPS
<pool>web-int_mco_80_vs 80	80	Front End 5061	Source	HTTP

Front End Server User Pool – HLB External Interface

Virtual IP/Port	Node Port	Node Machine/ Monitor	Persistence Profile	Notes
<pool>web_mco_443_vs 443	4443	Front End 5061	None	HTTPS
<pool>web_mco_80_vs 80	8080	Front End 5061	None	HTTP

1.3.3.4 Domain Name System (DNS) Requirements

Domain Name System (DNS) Requirements

Microsoft Lync Server 2013 > Planning > Network Planning for Lync Server >

Topic Last Modified: *2012-06-18*

To deploy Lync Server, you must create Domain Name System (DNS) records that enable the discovery of clients and servers, and, optionally, support for automatic client sign-in if your organization wants to support it.

Lync Server uses DNS in the following ways:

- To discover internal servers or pools for server-to-server communications.
- To allow clients to discover the Front End pool or Standard Edition server used for various SIP transactions.
- To allow unified communications (UC) devices that are not logged on to discover the Front End pool or Standard Edition server running Device Update Web Service, obtain updates, and send logs.
- To allow external servers and clients to connect to Edge Servers or the HTTP reverse proxy for instant messaging (IM) or conferencing.
- To allow external UC devices to connect to Device Update Web service through Edge Servers or the HTTP reverse proxy and obtain updates.
- To allow mobile clients to automatically discover Web Services resources without requiring users to manually enter URLs in device settings.
- Determine DNS Requirements
- DNS Requirements for Front End Pools
- DNS Requirements for Standard Edition Servers
- DNS Requirements for Simple URLs
- DNS Requirements for Automatic Client Sign-In
- DNS Requirements for Mobility

- DNS Load Balancing

1.3.3.4.1 Determine DNS Requirements

Determine DNS Requirements

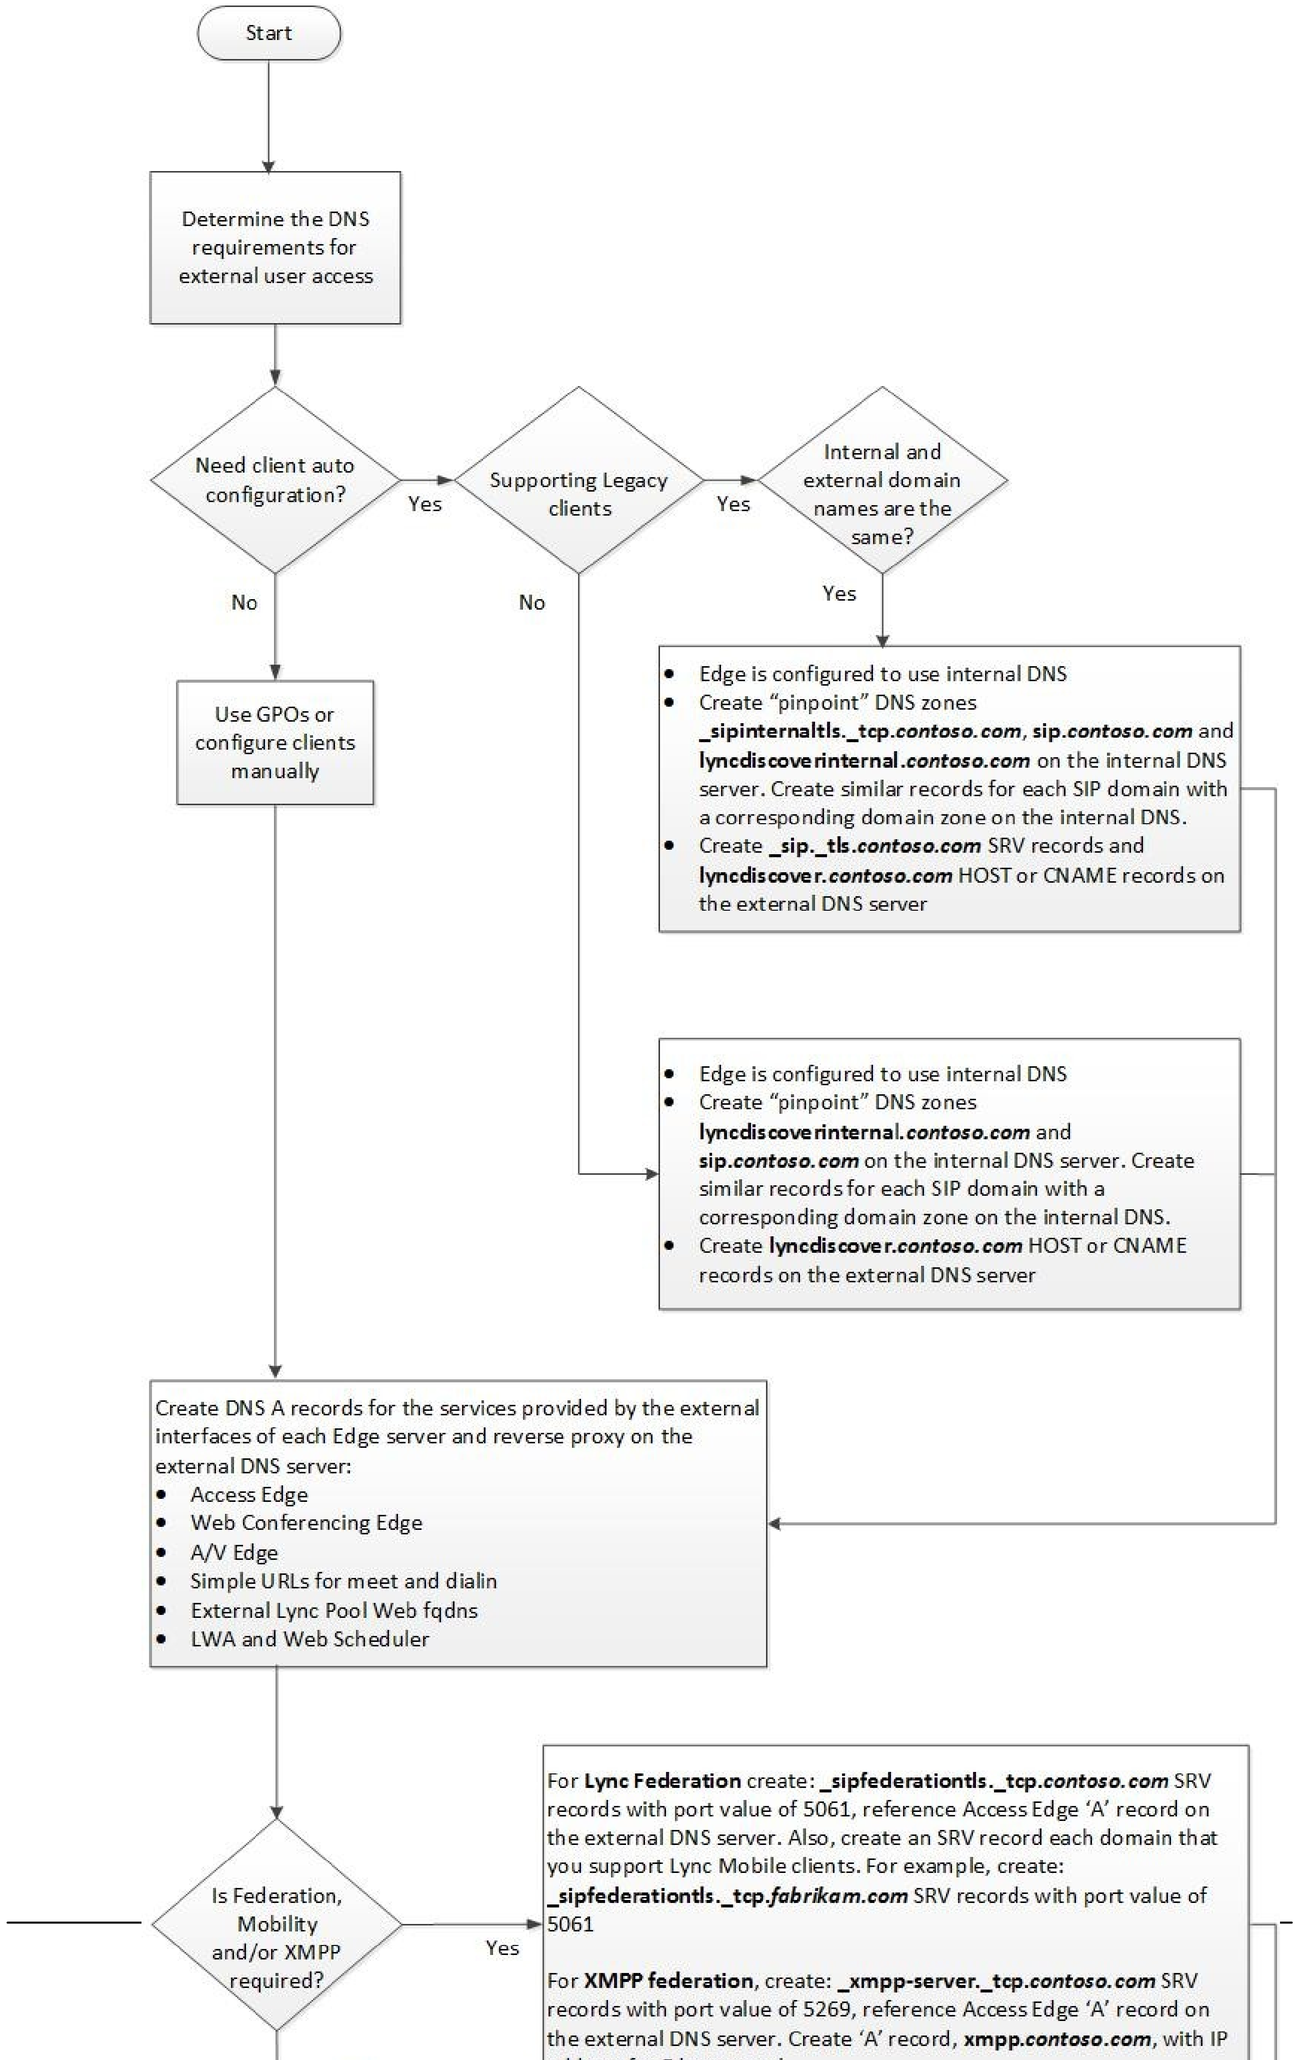
Planning > Network Planning for Lync Server > Domain Name System (DNS) Requirements >

Topic Last Modified: *2013-02-22*

Use the following flow chart to determine Domain Name System (DNS) requirements. Changes for the Cumulative Updates for Lync Server 2013: February 2013 are noted where they apply.

Important:

Microsoft Lync Server 2013 supports the use of IPv6 addressing. To use IPv6 addresses, you must also provide support for IPv6 DNS and configure DNS host AAAA (known as “quad-A”) records. In deployments where both IPv4 and IPv6 are being used, it is best to configure and maintain both host A records for IPv4 and host AAAA for IPv6. Even if your deployment has transitioned fully to IPv6, IPv4 DNS host records may still be required when external users are still using IPv4.



Start
Need client auto configuration?
Yes
No
Supporting Legacy clients
Yes
No
Internal and external domain names are the same?
Yes
Is Federation, Mobility and/or XMPP required?
Yes

Determine the DNS requirements for external user access

Use GPOs or configure clients manually

- Edge is configured to use internal DNS
- Create "pinpoint" DNS zones **_sipinternaltls._tcp.*contoso.com***, **sip.*contoso.com*** and **lyncdiscoverinternal.*contoso.com*** on the internal DNS server. Create similar records for each SIP domain with a corresponding domain zone on the internal DNS.
- Create **_sip._tls.*contoso.com*** SRV records and **lyncdiscover.*contoso.com*** HOST or CNAME records on the external DNS server

- Edge is configured to use internal DNS
- Create "pinpoint" DNS zones **lyncdiscoverinternal.*contoso.com*** and **sip.*contoso.com*** on the internal DNS server. Create similar records for each SIP domain with a corresponding domain zone on the internal DNS.
- Create **lyncdiscover.*contoso.com*** HOST or CNAME records on the external DNS server

Create DNS A records for the services provided by the external interfaces of each Edge server and reverse proxy on the external DNS server:

- Access Edge
- Web Conferencing Edge
- A/V Edge
- Simple URLs for meet and dialin
- External Lync Pool Web fqdns
- LWA and Web Scheduler

For **Lync Federation** create: **_sipfederationtls._tcp.*contoso.com*** SRV records with port value of 5061, reference Access Edge 'A' record on the external DNS server. Also, create an SRV record each domain that you support Lync Mobile clients. For example, create: **_sipfederationtls._tcp.*fabrikam.com*** SRV records with port value of 5061

For **XMPP federation**, create: **_xmpp-server._tcp.*contoso.com*** SRV records with port value of 5269, reference Access Edge 'A' record on the external DNS server. Create 'A' record, **xmpp.*contoso.com***, with IP

Important:

By default the computer name of a computer that is not joined to a domain is a host name, not a fully qualified domain name (FQDN). Topology Builder uses FQDNs, not host names. So, you must configure a DNS suffix on the name of the computer to be deployed as an Edge Server that is not joined to a domain. **Use only standard characters** (including A–Z, a–z, 0–9, and hyphens) when assigning FQDNs of your Lync Servers, Edge Servers, and pools. Do not use Unicode characters or underscores. Nonstandard characters in an FQDN are often not supported by external DNS and public CAs (that is, when the FQDN must be assigned to the SN in the certificate). For additional details, see Configure DNS Host Records

How Lync Clients Locate Services

Microsoft Lync 2010, Lync 2013, and Lync Mobile are similar in how the client finds and accesses services in Lync Server 2013. The notable exception is the Lync Windows Store app that uses a different service location process. This section details two scenarios of how the clients locate services, first the traditional method using a series of SRV and A host records, second using only the Autodiscover service records. Cumulative updates to the desktop clients change the DNS location process from Lync Server 2010 For all clients, the DNS query process continues until a successful query is returned, or the list of possible DNS records is exhausted, and the final error is returned to the client.

For all clients **except** for the Lync Windows Store app During DNS lookup, SRV records are queried and returned to the client in the following order:

1. lyncdiscoverinternal.<*domain*>   A (host) record for the Autodiscover service on the internal Web services
2. lyncdiscover.<*domain*>   A (host) record for the Autodiscover service on the external Web services
3. _sipinternaltls._tcp.<*domain*>   SRV (service locator) record for internal TLS connections
4. _sipinternal._tcp.<*domain*>   SRV (service locator) record for internal TCP connections (performed only if TCP is allowed)
5. _sip._tls.<*domain*>   SRV (service locator) record for external TLS connections
6. sipinternal.<*domain*>   A (host) record for the Front End pool or Director, resolvable only on the internal network
7. sip.<*domain*>   A (host) record for the Front End pool or Director on the internal network, or the Access Edge service when the client is external
8. sipexternal.<*domain*>   A (host) record for the Access Edge service when the client is external

The Lync Windows Store app changes the process completely because it uses two records:

1. lyncdiscoverinternal.<*domain*>   A (host) record for the Autodiscover service on the internal Web services
2. lyncdiscover.<*domain*>   A (host) record for the Autodiscover service on the external Web services

There is no fallback to the other record types.

The difference between the methods used for newer clients as compared to older clients is that the Autodiscover service is becoming the preferred method to locate all services.

When a connection is successful, the Autodiscover Service returns all the Web Services URLs for the user's home pool, including the Mobility Service (known as Mcx by the virtual directory created for the service in IIS), Microsoft Lync Web App and Web scheduler URLs. However, both the internal Mobility Service URL and the external Mobility Service URL is associated with the external Web Services FQDN. Therefore, regardless of whether a mobile device is internal or external to the network, the device always connects to the Mobility Service externally through the reverse proxy.

If the Cumulative Updates for Lync Server 2013: February 2013 has been installed, the Autodiscover Service also returns references to Internal/UCWA, External/UCWA and UCWA. These entries refer to the Unified Communications Web API (UCWA) web component. Currently, only the entry UCWA is used and provides a reference to a URL for the web component. UCWA is used by Lync 2013 Mobile clients instead of the Mcx Mobility Service used by the Lync 2010 Mobile clients.

Note:

When creating SRV records, it is important to remember that they must point to a DNS A and AAAA (if you are using IPv6 addressing) record in the same domain in which the DNS SRV record is created. For example, if the SRV record is in contoso.com, the A and AAAA (if you are using IPv6 addressing) record it points to cannot be in fabrikam.com.

Tip:

The default configuration is to direct all mobile client traffic through the external site. You can modify settings to return only the internal URL, if this is more preferable for your requirements. With this configuration, users can use Lync mobile applications on their mobile devices only when they are inside the corporate network. To define this configuration, you use the **Set-CsMcxConfiguration** cmdlet.

Note:

Although mobile applications can also connect to other Lync Server 2013 services, such as Address Book Service, internal mobile application web requests go to the external web FQDN only for the Mobility Service. Other service requests, such as Address Book requests, do not require this configuration.

Mobile devices support manual discovery of services. In this case, each user must configure the mobile device settings with the full internal and external Autodiscover Service URIs, including the protocol and path, as follows:

- https://*<ExtPoolFQDN>*/Autodiscover/autodiscoverservice.svc/Root for external access
- https://*<IntPoolFQDN>*/AutoDiscover/AutoDiscover.svc/Root for internal access

We recommend that you use automatic discovery, rather than manual discovery. However, manual settings can be useful for troubleshooting mobile device connectivity issues.

Configuring Split-Brain DNS with Lync Server

Split-brain DNS is known by a number of names, for example, split DNS or split-horizon DNS. Simply, it describes a DNS configuration where there are two DNS zones with the same namespace – but one DNS zone services internal-only requests, and the other DNS zone services external-only requests. However, many of the DNS SRV and A records contained in the internal DNS will not be contained in the external DNS, and the reverse is also true. In cases where the same DNS record exists in both the internal and external DNS (for example, www.contoso.com), the IP address returned will be different based on where (internal or external) the query was initiated.

Important:

Currently, Split-Brain DNS is not supported for the mobility, or more specifically, the LyncDiscover and LyncDiscoverInternal DNS records. LyncDiscover must be defined on an external DNS server and LyncDiscoverInternal must be defined on an internal DNS server.

For the purposes of these topics, the term split-brain DNS will be used.

If you are configuring split-brain DNS, the following internal and external zone contain a summary of the types of DNS records required in each zone. For details, see Scenarios for External User Access.

Internal DNS:

- Contains a DNS zone called contoso.com for which it is authoritative
- The internal contoso.com zone contains:
  - DNS A and AAAA (if you are using IPv6 addressing) and SRV records for internal Lync Server 2013 client autoconfiguration (optional)
  - DNS A and AAAA (if you are using IPv6 addressing) or CNAME records for automatic discovery of Lync Server 2013 Web Services (optional)
  - DNS A and AAAA (if you are using IPv6 addressing) records for Front End pool name, Director or Director pool name, and all internal servers running Lync Server 2013 in the corporate network
  - DNS A and AAAA (if you are using IPv6 addressing) records for the Edge internal interface of each Lync Server 2013, Edge Server in the perimeter network
  - DNS A and AAAA (if you are using IPv6 addressing) records for the internal interface of each reverse proxy server in the perimeter network (optional for management of reverse proxy)
  - All Lync Server 2013 Edge Server internal edge interfaces in the perimeter network use the internal DNS zone for resolving queries to contoso.com
  - All servers running Lync Server 2013 and clients running Lync 2013 in the corporate network point to the internal DNS servers for resolving queries to contoso.com, or use of HOSTS file on each Edge server and list A and AAAA (if you are using IPv6 addressing) records for next hop server, specifically the Director or Director VIP, Front End pool VIP, or Standard Edition server

External DNS:

- Contains a DNS zone called contoso.com for which it is authoritative
- The external contoso.com zone contains:
  - DNS A and AAAA (if you are using IPv6 addressing) and SRV records for Lync Server 2013 client autoconfiguration (optional)
  - DNS A and AAAA (if you are using IPv6 addressing) or CNAME records for automatic discovery of Lync Server 2013 Web Services for use with mobility
  - DNS A and AAAA (if you are using IPv6 addressing) and SRV records for the Edge external interface of each Lync Server 2013, Edge Server or hardware load balancer virtual IP (VIP) in the perimeter network
  - DNS A and AAAA (if you are using IPv6 addressing) records for the external interface of the reverse proxy server or VIP for a pool of reverse proxy servers in the perimeter network

Automatic Configuration without Split-Brain DNS

Using split-brain DNS, a Lync Server 2013 user that signs in internally can take advantage of automatic configuration if the internal DNS zone contains a _sipinternaltls._tcp SRV record for each SIP domain in use. However, if you do not use split-brain DNS, internal automatic configuration of clients running Lync will not work unless one of the workarounds described in later in this section is implemented. This is because Lync Server 2013 requires the user's SIP URI to match the domain of the Front End pool designated for automatic configuration. This was also the case with earlier versions of Communicator.

For example, if you have two SIP domains in use, the following DNS service (SRV) records would be required:

- If a user signs in as bob@contoso.com the following SRV record will work for automatic configuration because the user's SIP domain (contoso.com) matches the domain of automatic configuration Front End pool):

_sipinternaltls._tcp.contoso.com. 86400 IN SRV 0 0 5061 pool01.contoso.com

- If a user signs in as alice@fabrikam.com the following DNS SRV record will work for automatic configuration of the second SIP domain.
  _sipinternaltls._tcp.fabrikam.com. 86400 IN SRV 0 0 5061 pool01.fabrikam.com

For comparison, if a user signs in as tim@litwareinc.com the following DNS SRV record will not work for automatic configuration, because the client's SIP domain (litwareinc.com) does not match the domain that the pool is in (fabrikam.com):

_sipinternaltls._tcp.litwareinc.com. 86400 IN SRV 0 0 5061 pool01.fabrikam.com

If automatic configuration is required for clients running Lync, select one of the following options:

- **Group Policy Objects** Use Group Policy objects (GPOs) to populate the correct server values.

  Note:
  This option does not enable automatic configuration, but it does automate the process of manual configuration, so if this approach is used, the SRV records associated with automatic configuration are not required.

- **Matching internal zone** Create a zone in the internal DNS that matches the external DNS zone (for example, contoso.com) and create DNS A and AAAA (if you are using IPv6 addressing) records corresponding to the Lync Server 2013 pool used for automatic configuration. For example, if a user is homed on pool01.contoso.net but signs into Lync as bob@contoso.com, create an internal DNS zone called contoso.com and inside it, create a DNS A and AAAA (if IPv6 addressing is used) record for pool01.contoso.com.
- **Pin-point internal zone** If you are creating an entire zone in the internal DNS is not an option, you can create pin-point (that is, dedicated) zones that correspond to the SRV records that are required for automatic configuration, and populate those zones using dnscmd.exe. Dnscmd.exe is required because the DNS user interface does not support creation of pin-point zones. For example, if the SIP domain is contoso.com and you have a Front End pool called pool01 that contains two Front End Servers, you need the following pin-point zones and A records in your internal DNS:

```
dnscmd . /zoneadd _sipinternaltls._tcp.contoso.com. /dsprimary
dnscmd . /recordadd _sipinternaltls._tcp.contoso.com. @ SRV 0 0 5061 po
dnscmd . /zoneadd pool01.contoso.com. /dsprimary
dnscmd . /recordadd pool01.contoso.com. @ A 192.168.10.90
dnscmd . /recordadd pool01.contoso.com. @ AAAA <IPv6 address>
dnscmd . /recordadd pool01.contoso.com. @ A 192.168.10.91
dnscmd . /recordadd pool01.contoso.com. @ AAAA <IPv6 address>
```

  If your environment contains a second SIP domain (for example, fabrikam.com), you need the following pin-point zones and A records in your internal DNS:

```
dnscmd . /zoneadd _sipinternaltls._tcp.fabrikam.com. /dsprimary
dnscmd . /recordadd _sipinternaltls._tcp.fabrikam.com. @ SRV 0 0 5061 p
dnscmd . /zoneadd pool01.fabrikam.com. /dsprimary
dnscmd . /recordadd pool01.fabrikam.com. @ A 192.168.10.90
dnscmd . /recordadd pool01.contoso.com. @ AAAA <IPv6 address>
dnscmd . /recordadd pool01.fabrikam.com. @ A 192.168.10.91
dnscmd . /recordadd pool01.contoso.com. @ AAAA <IPv6 address>
```

Note:
The Front End pool FQDN appears twice, but with two different IP addresses. This is because DNS load balancing is used, but if hardware load balancing is used, there would be only a single Front End pool entry. Also, the Front End pool FQDN values change between the contoso.com example and the fabrikam.com example, but the IP addresses remain the same. This is because users signing in from either SIP domain, use the same Front End pool for automatic configuration.

For details, see the DMTF blog article, "Communicator Automatic Configuration and Split-Brain DNS," at http://go.microsoft.com/fwlink/p/?linkId=200707.

Note:
The content of each blog and its URL are subject to change without notice.

Configuring the domain name system (DNS) for Disaster Recovery

To configure DNS to redirect Lync Server 2013 Web traffic to your disaster recovery and failover sites, you must be using a DNS provider that supports GeoDNS. You can set up your DNS records for Web to support disaster recovery, so that features that use Web services continue even if one entire Front End pool goes down. This disaster recovery feature supports the Autodiscover (Lyncdiscover URL), Meet and Dial-In simple URLs.

You define and configure additional DNS host (A and AAAA if using IPv6) records for internal and external resolution of Web services at your GeoDNS provider. The following details assume paired pools, geographically dispersed, and GeoDNS supported by your provider with either round-robin DNS, or configured to use Pool1 as primary, and fail over to Pool2 in the event of communications loss or hardware failure.

GeoDNS record (example)	Pool records (example)	CNAME records (example)	DNS settings (select one option)
Meet-int.geolb.contoso.com	Pool1InternalWebFQDN.contoso.com Pool2InternalWebFQDN.contoso.com	Meet.contoso.com alias to Pool1InternalWebFQDN.contoso.com Meet.contoso.com alias to Pool2InternalWebFQDN.contoso.com	Round Robin between pools Use primary, connect to secondary if failure
Meet-ext.geolb.contoso.com	Pool1ExternalWebFQDN.contoso.com Pool2ExternalWebFQDN.contoso.com	Meet.contoso.com alias to Pool1ExternalWebFQDN.contoso.com Meet.contoso.com alias to Pool2ExternalWebFQDN.contoso.com	Round Robin between pools Use primary, connect to secondary if failure
Dialin-int.geolb.contoso.com	Pool1InternalWebFQDN.contoso.com Pool2InternalWebFQDN.contoso.com	Dialin.contoso.com alias to Pool1InternalWebFQDN.contoso.com Dialin.contoso.com alias to Pool2InternalWebFQDN.contoso.com	Round Robin between pools Use primary, connect to secondary if failure
Dialin-ext.geolb.contoso.com	Pool1ExternalWebFQDN.contoso.com Pool2ExternalWebFQDN.contoso.com	Dialin.contoso.com alias to Pool1ExternalWebFQDN.contoso.com	Round Robin between pools Use primary, connect to secondary if failure

		Dialin.contoso.com alias to Pool2ExternalWebFQDN.contoso.com	
Lyncdiscoverint-int.geolb.contoso.com	Pool1InternalWebFQDN.contoso.com Pool2InternalWebFQDN.contoso.com	Lyncdiscoverinternal.contoso.com alias to Pool1InternalWebFQDN.contoso.com Lyncdiscoverinternal.contoso.com alias to Pool2InternalWebFQDN.contoso.com	Round Robin between pools Use primary, connect to secondary if failure
Lyncdiscover-ext.geolb.contoso.com	Pool1ExternalWebFQDN.contoso.com Pool2ExternalWebFQDN.contoso.com	Lyncdiscover.contoso.com alias to Pool1ExternalWebFQDN.contoso.com Lyncdiscover.contoso.com alias to Pool2ExternalWebFQDN.contoso.com	Round Robin between pools Use primary, connect to secondary if failure
Scheduler-int.geolb.contoso.com	Pool1InternalWebFQDN.contoso.com Pool2InternalWebFQDN.contoso.com	Scheduler.contoso.com alias to Pool1InternalWebFQDN.contoso.com Scheduler.contoso.com alias to Pool2InternalWebFQDN.contoso.com	Round Robin between pools Use primary, connect to secondary if failure
Scheduler-ext.geolb.contoso.com	Pool1ExternalWebFQDN.contoso.com Pool2ExternalWebFQDN.contoso.com	Scheduler.contoso.com alias to Pool1ExternalWebFQDN.contoso.com Scheduler.contoso.com alias to Pool2ExternalWebFQDN.contoso.com	Round Robin between pools Use primary, connect to secondary if failure

DNS Load Balancing

DNS load balancing is typically implemented at the application level. The application (for example, a client running Lync), tries to connect to a server in a pool by connecting to one of the IP addresses returned from the DNS A and AAAA (if IPv6 addressing is used) record query for the pool fully qualified domain name (FQDN).

For example, if there are three front end servers in a pool named pool01.contoso.com, the following will happen:

- Clients running Lync query DNS for pool01.contoso.com. The query returns three IP addresses and caches them as follows (not necessarily in this order):
  pool01.contoso.com 192.168.10.90
  pool01.contoso.com 192.168.10.91

pool01.contoso.com 192.168.10.92

- The client attempts to establish a Transmission Control Protocol (TCP) connection to one of the IP addresses. If that fails, the client tries the next IP address in the cache.
- If the TCP connection succeeds, the client negotiates TLS to connect to the primary registrar on pool01.contoso.com.
- If the client tries all cached entries without a successful connection, the user is notified that no servers running Lync Server 2013 are available at the moment.

Note:

DNS-based load balancing is different from DNS round robin (DNS RR) which typically refers to load balancing by relying on DNS to provide a different order of IP addresses corresponding to the servers in a pool. Typically DNS RR only enables load distribution, but does not enable failover. For example, if the connection to the one IP address returned by the DNS A and AAAA (if you are using IPv6 addressing) query fails, the connection fails. Therefore, DNS round robin by itself is less reliable than DNS-based load balancing. You can use DNS round robin in conjunction with DNS load balancing.

DNS load balancing is used for the following:

- Load balancing server-to-server SIP to the Edge Servers
- Load balancing Unified Communications Application Services (UCAS) applications such as Conferencing Auto Attendant, Response Group, and Call Park
- Preventing new connections to UCAS applications (also known as "draining")
- Load balancing all client-to-server traffic between clients and Edge Servers

DNS load balancing cannot be used for the following:

- Client-to-server web traffic to Director or Front End Servers

DNS load balancing and federated traffic:

If multiple DNS records are returned by a DNS SRV query, the Access Edge service always picks the DNS SRV record with the lowest numeric priority and highest numeric weight. The Internet Engineering Task Force document "A DNS RR for specifying the location of services (DNS SRV)" http://www.ietf.org/rfc/rfc2782.txt specifies that if there are multiple DNS SRV records defined, priority is first used, then weight. For example DNS SRV record A has a weight of 20 and a priority of 40 and DNS SRV record B has a weight of 10 and priority of 50. DNS SRV record A with priority 40 will be selected. The following rules apply to DNS SRV record selection:

- Priority is considered first. A client MUST attempt to contact the target host defined by the DNS SRV record with the lowest numbered priority it can reach. Targets with the same priority SHOULD be tried in an order defined by the weight field.
- The weight field specifies a relative weight for entries with the same priority. Larger weights SHOULD be given a proportionately higher probability of being selected. DNS administrators SHOULD use Weight 0 when there isn't any server selection to do. In the presence of records containing weights greater than 0, records with weight 0 should have a very small chance of being selected.

If multiple DNS SRV records with equal priority and weight are returned, the Access Edge service will select the SRV record that was received first from the DNS server.

DNS Requirements for Front End Pools

[Planning](#) > [Network Planning for Lync Server](#) > [Domain Name System (DNS) Requirements](#) >

Topic Last Modified: *2012-11-07*

This section describes the Domain Name System (DNS) records that are required for deployment of Front End pools.

DNS Records for Front End Pools

The following table specifies DNS requirements for a Lync Server 2013 Front End pool deployment.

DNS Requirements for a Front End Pool

Deployment scenario	DNS requirement
Front End pool with multiple Front End Servers and a hardware load balancer (whether or not DNS load balancing is also deployed on that pool)	When using both DNS load balancing and a hardware load balancer, you need to Host (A) records. Create an internal A record that resolves the fully qualified domain name (FQDN) of the Front End pool for DNS load balancing. Create an internal host (A) record for the internal Web services to the virtual IP (VIP) address of the load balancer. You must use the internal Web services name as defined in Topology Builder. For example, if you use both DNS load balancing and hardware load balancing, you would have an A record for each Front End Server in a pool for DNS load balancing, and an A record for the internal Web services pointing to the virtual IP of the hardware load balancer: • DNS load balancing: Pool01.contoso.net IP Address of pool 10.10.10.5 ⚠**Warning:** Each Front End Server will also have a distinct A record: .1.FE01.contoso.net 10.10.10.1 .2.FE02.contoso.net 10.10.10.2 .3.FE03.contoso.net 10.10.10.3 .4.FE04.contoso.net 10.10.10.4 • Hardware load balancing: WebInternal.contoso.net IP Address of HLB VIP 192.168.10.5 All traffic except for HTTP/HTTPS traffic will use the Pool01.contoso.net record. HTTP/HTTPS traffic will use the defined internal Web services address of 192.168.10.5
Front End pool with DNS load balancing deployed	A set of internal A records that resolve the FQDN of the pool to the IP address of each server in the pool. There must one A record for each server in the pool.

Front End pool with DNS load balancing deployed	A set of internal A records that resolve the FQDN of each server in the pool to the IP address of that server. For details, see DNS Load Balancing in the Planning documentation.
Front End pool with a single Front End Server and a dedicated back-end database but no load balancer	An internal A record that resolves the FQDN of the Front End pool to the IP address of the single Enterprise Edition Front End Server.
Automatic client sign-in	For each supported SIP domain, an SRV record for _sipinternaltls._tcp.<domain> over port 5061 that maps to the FQDN of the Front End pool that authenticates and redirects client requests for sign-in. For details, see DNS Requirements for Automatic Client Sign-In.
Device Update Web service discovery by unified communications (UC) devices	An internal A record with the name ucupdates-r2.<SIP domain> that resolves to the IP address of the Front End pool that hosts the Device Update Web service. In the situation where a UC device is turned on, but a user has never logged into the device, the A record allows the device to discover the Front End pool hosting Device Update Web service and obtain updates. Otherwise, devices obtain this information though in-band provisioning the first time a user logs in. ◆**Important:** If you have an existing deployment of Device Update Web service in Lync Server 2010, you have already created an internal A record with the name ucupdates.<*SIP domain*>. For Microsoft Office Communications Server 2007 R2, you must create an additional DNS A record with the name ucupdates-r2.<*SIP domain*>.
A reverse proxy to support HTTP traffic	An external A record that resolves the external web farm FQDN to the external IP address of the reverse proxy. Clients and UC devices use this record to connect to the reverse proxy. For details, see Determine DNS Requirements in the Planning documentation.

The following table shows an example of the DNS records required for the internal web farm FQDN.

Example DNS Records for Internal Web Farm FQDN

Internal web farm FQDN	Pool FQDN	DNS A record(s)
webcon.contoso.com	ee-pool.contoso.com	DNS A record for the ee-pool.contoso.com that resolves to the VIP address of the load balancer used by the Front End Servers. DNS A record for webcon.contoso.com that resolves to the VIP address of the load balancer used by the Front End Servers.

ee-pool.contoso.com	ee-pool.contoso.com	DNS A record for ee-pool.contoso.com that resolves to the virtual IP (VIP) address of the load balancer used by the Enterprise Edition Front End Servers in the Front End pool. Note that if you are using DNS load balancing on this pool, your Front End pool and internal web farm cannot have the same FQDN.

1.3.3.4.3 DNS Requirements for Standard Edition Servers

DNS Requirements for Standard Edition Servers

Planning > Network Planning for Lync Server > Domain Name System (DNS) Requirements >

Topic Last Modified: *2012-06-19*

This section describes the Domain Name System (DNS) records that are required for deployment of Standard Edition servers.

DNS Records for Standard Edition Servers

The following table specifies DNS requirements for Lync Server 2013 Standard Edition server deployment.

DNS Requirements for a Standard Edition Server

Deployment scenario	**DNS requirement**
Standard Edition server	An internal A record that resolves the fully qualified domain name (FQDN) of the server to its IP address.
Automatic client sign-in	For each supported SIP domain, an SRV record for _sipinternaltls._tcp.<*domain*> over port 5061 that maps to the FQDN of the Standard Edition server that authenticates and redirects client requests for sign-in. For details, see DNS Requirements for Automatic Client Sign-In.
Device Update Web service discovery by unified communications (UC) devices	An internal A record with the name ucupdates-r2.<*SIP domain*> that resolves to the IP address of the Standard Edition server hosting Device Update Web service. In the situation where a UC device is turned on, but a user has never logged into the device, the A record allows the device to discover the server hosting Device Update Web service and obtain updates. Otherwise, devices obtain the server information

	though in-band provisioning the first time a user logs in.
A reverse proxy to support HTTP traffic	An external A record that resolves the external web farm FQDN to the external IP address of the reverse proxy. Clients and UC devices use this record to connect to the reverse proxy. For details, see Determine DNS Requirements in the Planning documentation.

1.3.3.4.4 DNS Requirements for Simple URLs

DNS Requirements for Simple URLs

Planning > Network Planning for Lync Server > Domain Name System (DNS) Requirements >

Topic Last Modified: *2013-02-22*

Lync Server 2013 supports simple URLs, which make joining meetings easier for your users, and make getting to Lync Server administrative tools easier for your administrators. For details about simple URLs, see Planning for Simple URLs.

Lync Server supports the following three simple URLs: Meet, Dial-In, and Admin. You are required to set up simple URLs for Meet and Dial-In, and the Admin simple URL is optional. The Domain Name System (DNS) records that you need to support simple URLs depend on how you have defined these simple URLs, and whether you want to support disaster recovery for Simple URLs.

Simple URL Option 1

In Option 1, you create a new base URL for each simple URL.

Note:

When a user clicks a simple URL meeting link, the server that the DNS A record resolves to determines the correct client software to start. After the client software is started, it automatically communicates with the pool where the conference is hosted. This way, users are directed to the appropriate server for meeting content no matter which server or pool the simple URL DNS A records resolve to.

Simple URL Option 1

Simple URL	Example
Meet	https://meet.contoso.com, https://meet.fabrikam.com, and so on (one for each SIP domain in your organization)
Dial-in	https://dialin.contoso.com
Admin	https://admin.contoso.com

If you use Option 1, you must define the following:

- For each Meet simple URL, you need a DNS A record that resolves the URL to the IP address of the Director, if you have one deployed. Otherwise, it should resolve to the IP address of the load balancer of a Front End pool. If you have not deployed a pool and are using a Standard Edition server deployment, the DNS A record must resolve to the IP address of one Standard Edition server in

your organization.
If you have more than one SIP domain in your organization and you use this option, you must create Meet simple URLs for each SIP domain and you need a DNS A record for each Meet simple URL. For example, if you have both contoso.com and fabrikam.com, you will create DNS A records for both https://meet.contoso.com and https://meet.fabrikam.com.
Alternatively, if you have multiple SIP domains and you want to minimize the DNS record and certificate requirements for these simple URLs, use Option 3 as described later in this topic.

- For the Dial-in simple URL, you need a DNS A record that resolves the URL to the IP address of the Director, if you have one deployed. Otherwise, it should resolve to the IP address of the load balancer of a Front End pool. If you have not deployed a pool and are using a Standard Edition server deployment, the DNS A record must resolve to the IP address of one Standard Edition server in your organization.
- The Admin simple URL is internal only. It requires a DNS A record that resolves the URL to the IP address of the Director, if you have one deployed. Otherwise, it should resolve to the IP address of the load balancer of a Front End pool. If you have not deployed a pool and are using a Standard Edition server deployment, the DNS A record must resolve to the IP address of one Standard Edition server in your organization.

Simple URL Option 2

With Option 2, the Meet, Dial-in, and Admin simple URLs all have a common base URL, such as lync.contoso.com. Therefore, you need only one DNS A record for these simple URLs, which resolves lync.contoso.com to the IP address of a Director pool or Front End pool. If you have not deployed a pool and are using a Standard Edition server deployment, the DNS A record must resolve to the IP address of one Standard Edition server in your organization.

Note that if you have more than one SIP domain in your organization, you must still create Meet simple URLs for each SIP domain and you need a DNS A record for each Meet simple URL. In this example, while three simple URLs are all based on lync.contoso.com, an additional Meet simple URL for fabrikam.com is set up with a different base URL. In this example, you must create DNS A records for both https://lync.contoso.com and https://lync.fabrikam.com. Simple URL Option 3 shows another way to handle naming and DNS A records if you have multiple SIP domains.

Simple URL Option 2

Simple URL	**Example**
Meet	https://lync.contoso.com/Meet, https://lync.fabrikam.com/Meet, and so on (one for each SIP domain in your organization)
Dial-in	https://lync.contoso.com/Dialin
Admin	https://lync.contoso.com/Admin

Simple URL Option 3

Option 3 is most useful if you have many SIP domains, and you want them to have separate simple URLs but want to minimize the DNS record and certificate requirements for these simple URLs. In this example, you need only one DNS A record, which resolves lync.contoso.com to the IP address of a Director pool or Front End pool.

Simple URL Option 3

Simple URL	Example
Meet	https://lync.contoso.com/contosoSIPdomain/Meet https://lync.contoso.com/fabrikamSIPdomain/Meet
Dial-in	https://lync.contoso.com/contosoSIPdomain/Dialin
Admin	https://lync.contoso.com/contosoSIPdomain/Admin

Disaster Recovery Option for Simple URLs

If you have multiple sites that contain Front End pools and your DNS provider supports GeoDNS, you can set up your DNS records for Simple URLs to support disaster recovery, so that Simple URL functionality continues even if one entire Front End pool goes down. This disaster recovery feature supports the Meet and Dial-In simple URLs.

To configure this, create two GeoDNS addresses. Each address has two DNS A or CNAME records that resolve to two pools which are paired together for disaster recovery purposes. One GeoDNS address is used for internal access, and resolves to the internal web FQDN or load balancer IP address for the two pools. The other GeoDNS address is used for external access and resolves to the external web FQDN or load balancer IP address for the two pools. The following is an example for the Meet simple URL, using the FQDNs for the pools.

```
Meet-int.geolb.contoso.com
     Pool1InternalWebFQDN.contoso.com
     Pool2InternalWebFQDN.contoso.com
```

```
Meet-ext.geolb.contoso.com
     Pool1ExternalWebFQDN.contoso.com
     Pool2ExternalWebFQDN.contoso.com
```

Then create CNAME records that resolve your Meet simple URL (such as meet.contoso.com) to the two GeoDNS addresses.

Note:

If your network uses *hairpinning* (routing all your Simple URL traffic through the external link, including traffic that comes from within your organization), then you can just configure the external GeoDNS address and resolve your Meet simple URL to only that external address.

When you use this method, you can configure each GeoDNS address to use either a round robin method to distribute requests to the two pools, or to connect primarily to one pool (such as the pool located geographically closer) and use the other pool only in case of connectivity failure.

You can set up the same configuration for the Dial-In simple URL. To do so, create additional records like those in the previous example, substituting `dialin` for `meet` in the DNS records. For the Admin simple URL, use one of the three options listed earlier in this section.

Once this configuration is set up, you must use a monitoring application to set up HTTP monitoring to watch for failures. For external access, monitor to make sure that HTTPS GET autodiscovery requests to the the external web FQDN or load balancer IP address for the two pools are successful. For example, the following requests must not contain any

ACCEPT header and must return **200 OK**.

```
HTTPS GET Pool1ExternalWebFQDN.contoso.com/autodiscover/autodiscoverservice.svc/r
HTTPS GET Pool2ExternalWebFQDN.contoso.com/autodiscover/autodiscoverservice.svc/r
```

For internal access, you must monitor port 5061 on the internal web FQDN or load balancer IP address for the two pools. If any connectivity failures are detected, the VIP for these pools must close ports 80, 443 and 444.

1.3.3.4.5 DNS Requirements for Automatic Client Sign-In

DNS Requirements for Automatic Client Sign-In

Planning > Network Planning for Lync Server > Domain Name System (DNS) Requirements >

Topic Last Modified: *2012-06-19*

This section explains the Domain Name System (DNS) records that are required for automatic client sign-in. When you deploy your Standard Edition servers or Front End pools, you can configure your clients to use automatic discovery to sign in to the appropriate Standard Edition server or Front End pool. If you plan to require your clients to connect manually to Lync Server 2013, you can skip this topic.

To support automatic client sign-in, you must:

- Designate a single server or pool to distribute and authenticate client sign-in requests. This can be an existing server or pool in your organization that hosts users, or you can designate a dedicated server or pool for this purpose that hosts no users. For high availability, we recommend that you designate a Front End pool for this function.
- Create an internal DNS SRV record to support automatic client sign-in for this server or pool.

Note:

In the following record requirements, SIP domain refers to the host portion of the SIP URIs assigned to users. For example, if SIP URIs are of the form *@contoso.com, contoso.com is the SIP domain. The SIP domain is often different from the internal Active Directory domain. An organization can also support multiple SIP domains.

To enable automatic configuration for your clients, you must create an internal DNS SRV record that maps one of the following records to the fully qualified domain name (FQDN) of the Front End pool or Standard Edition server that distributes sign-in requests from Lync clients:

- _sipinternaltls._tcp.<*domain*> - for internal TLS connections

You only need to create a single SRV record for the Front End pool or Standard Edition server or that will distribute sign-in requests.

The following table shows some example records required for the fictitious company Contoso, which supports SIP domains of contoso.com and retail.contoso.com.

Example of DNS Records Required for Automatic Client Sign-in with Multiple SIP Domains

FQDN of Front End pool used to distribute sign-in requests	SIP domain	DNS SRV record

pool01.contoso.com	contoso.com	An SRV record for _sipinternaltls._tcp.contoso.com domain over port 5061 that maps to pool01.contoso.com
pool01.contoso.com	retail.contoso.com	An SRV record for _sipinternaltls._tcp.retail.contoso.com domain over port 5061 that maps to pool01.contoso.com

Note:

By default, queries for DNS records adhere to strict domain name matching between the domain in the user name and the SRV record. If you prefer that client DNS queries use suffix matching instead, you can configure the DisableStrictDNSNaming Group Policy. For details, see Planning for Clients and Devices in Lync Server 2013 in the Planning documentation.

Example of the Certificates and DNS Records Required for Automatic Client Sign-In

This example uses the same example names in the preceding table. The Contoso organization supports the SIP domains of contoso.com and retail.contoso.com, and all of its users have a SIP URI in one of the following forms:

- <*user*>@retail.contoso.com
- <*user*>@contoso.com

1.3.3.4.6 DNS Requirements for Mobility

DNS Requirements for Mobility

Planning > Network Planning for Lync Server > Domain Name System (DNS) Requirements >

Topic Last Modified: *2012-11-13*

When you deploy the Lync Server 2013 mobility feature, you can use the new URLs that are available with the Microsoft Lync Server 2013 Autodiscover Service, or you can use your existing Web Services URLs. If you use your existing URLs, users need to manually enter the URLs in their mobile device settings. This option is typically used for troubleshooting. When you use the new URLs, mobile clients can automatically discover Lync Server 2013 resources. When you support automatic discovery, you need to add new Domain Name System (DNS) records. This section describes the DNS records that are required for automatic discovery.

To support automatic discovery, you need to create the following DNS records for each SIP domain:

- An internal DNS record to support mobile users who connect from within your organization's network
- An external, or public, DNS record to support mobile users who connect from the Internet

The internal automatic discovery URL should not be addressable from outside your network. The external automatic discovery URL should not be addressable from within your network. However, if you cannot meet this requirement for the external URL, mobile client functionally should not be affected.

The DNS records can be either CNAME records or A (host) records.

Internal DNS records

You need to create one of the following internal DNS records:

Record type	Host name or SRV definition	Resolves to
CNAME	lyncdiscoverinternal.*<sipdomain>*	Internal Web Services fully qualified domain name (FQDN) for your Director pool, if you have one, or for your Front End pool if you do not have a Director
A (host)	lyncdiscoverinternal.*<sipdomain>*	Internal Web Services IP address (virtual IP (VIP) address if you use a load balancer) of your Director pool, if you have one, or of your Front End pool if you do not have a Director

External DNS records

You need to create one of the following external DNS records:

Record type	Host name	Resolves to
CNAME	lyncdiscover. *<sipdomain>*	External Web Services FQDN for your Director pool, if you have one, or for your Front End pool if you do not have a Director
A (host)	lyncdiscover. *<sipdomain>*	External or public IP address (VIP address if you use a load balancer) of the reverse proxy
SRV	_sipfederationtls._tcp. *<sipdomain>* Resolves to host (A or AAAA) record for the Access Edge service	To support Push Notification Service and Apple Push Notification service, you create one SRV record for each SIP domain that has Microsoft Lync Mobile clients. **Important:** This requirement applies only to Microsoft Lync Mobile clients on Apple or Microsoft based mobile devices. Andriod and Nokia Symbian devices do not use push notification.

Note:

Lyncdiscover, also known as autodiscover, traffic goes through the reverse proxy. SRV record points to a record that resolves through the Access Edge service.

1.3.3.4.7 DNS Load Balancing

DNS Load Balancing

Planning > Network Planning for Lync Server > Domain Name System (DNS) Requirements >

Topic Last Modified: *2013-01-23*

Lync Server enables DNS load balancing, a software solution that can greatly reduce the administration overhead for load balancing on your network. DNS load balancing balances the network traffic that is unique to Lync Server, such as SIP traffic and media traffic.

If you deploy DNS load balancing, your organization's administration overhead for hardware load balancers will be minimized. Additionally, complex troubleshooting of problems related to misconfiguration of load balancers for SIP traffic will be eliminated. You can also prevent server connections so that you can take servers offline. DNS load balancing also ensures that hardware load balancer problems do not affect elements of SIP traffic such as basic call routing.

If you use DNS load balancing, you may also be able to purchase lower-cost hardware load balancers than if you used the hardware load balancers for all types of traffic. You should use load balancers that have passed interoperability qualification testing with Lync Server. For details about load balancer interoperability testing, see "Lync Server 2010 Load Balancer Partners" at http://go.microsoft.com/fwlink/p/?linkId=202452.

DNS load balancing is supported for Front End pools, Edge Server pools, Director pools, and stand-alone Mediation Server pools.

DNS Load Balancing on Front End Pools and Director Pools

You can use DNS load balancing for the SIP traffic on Front End pools and Director pools. With DNS load balancing deployed, you still need to also use hardware load balancers for these pools, but only for client-to-server HTTPS traffic. The hardware load balancer is used for HTTPS traffic from clients over ports 443 and 80.

Although you still need hardware load balancers for these pools, their setup and administration will be primarily for HTTPS traffic, which the administrators of hardware load balancers are accustomed to.

DNS Load Balancing and Supporting Older Clients and Servers

DNS load balancing supports automatic failover only for servers running Lync Server 2013 or Lync Server 2010, and for Lync 2013 and Lync 2010 clients. Earlier versions of clients and Office Communications Server can still connect to pools running DNS load balancing, but if they cannot make a connection to the first server that DNS load balancing refers them to, they are unable to fail over to another server in the pool.

Additionally, if you are using Exchange UM, you must use a minimum of Exchange 2010 SP1 to get support for Lync Server DNS load balancing. If you use an earlier version of Exchange, your users will not have failover capabilities for these Exchange UM scenarios:

- Playing their Enterprise Voice voice mail on their phone
- Transferring calls from an Exchange UM Auto Attendant

All other Exchange UM scenarios will work properly.

Deploying DNS Load Balancing on Front End Pools and Director Pools

Deploying DNS load balancing on Front End pools and Director pools requires you to perform a couple of extra steps with FQDNs and DNS records.

- A pool that uses DNS load balancing must have two FQDNs: the regular pool FQDN that is used by DNS load balancing (such as pool01.contoso.com), and resolves to the physical IPs of the servers in the pool, and another FQDN for the pool's Web services (such as web01.contoso.com), which resolves to virtual IP address of the pool.
  In Topology Builder, if you want to deploy DNS load balancing for a pool, to create this extra FQDN for the pool's Web services you must select the **Override internal Web Services pool FQDN** check box and type the FQDN, in the **Specify the Web Services URLs for this Pool** page.
- To support the FQDN used by DNS load balancing, you must provision DNS to resolve the pool FQDN (such as pool01.contoso.com) to the IP addresses of all the servers in the pool (for example, 192.168.1.1, 192.168.1.2, and so on). You should include only the IP addresses of servers that are currently deployed.

⚠**Warning:**
If you have more than one Front End pool or Front End Server the external Web services FQDN must be unique. For example, if you define the external Web services FQDN of a Front End Server as **pool01.contoso.com**, you cannot use **pool01.contoso.com** for another Front End pool or Front End Server. If you are also deploying Directors, the external Web services FQDN defined for any Director or Director pool must be unique from any other Director or Director pool as well as any Front End pool or Front End Server. If decide to override the Internal web services with a self-defined FQDN, each FQDN must be unique from any other Front End pool, Director or a Director pool.

DNS Load Balancing on Edge Server Pools

You can deploy DNS load balancing on Edge Server pools. If you do, you must be aware of some considerations.

Using DNS load balancing on your Edge Servers causes a loss of failover ability in the following scenarios:

- Federation with organizations that are running versions of Office Communications Server released prior to Lync Server 2010.
- Instant message exchange with users of public instant messaging (IM) services, such as Windows Live, AOL, and Yahoo!, in addition to XMPP-based providers and servers, such as Google Talk.

Important:
• Google Talk is currently the only supported XMPP partner. • As of September 1st, 2012, the Microsoft Lync Public IM Connectivity User Subscription License ("PIC USL") is no longer available for purchase for new or renewing agreements. Customers with active licenses will be able to continue to federate with Yahoo! Messenger until the service shut down date (exact date TBD, but no sooner than June 2013). • The PIC USL is a per-user per-month subscription license that is required for Lync Server or Office Communications Server to federate with Yahoo! Messenger. Microsoft's ability to provide this service has been contingent upon support from Yahoo!, the underlying agreement for which is winding down. • More than ever, Lync is a powerful tool for connecting across organizations and with individuals around the world. Federation with Windows Live Messenger requires no additional user/device licenses beyond the Lync Standard CAL. Skype federation will be added to this list, enabling Lync users to reach hundreds of millions of people with IM and voice.

These scenarios will work as long as all Edge Servers in the pool are up and running, but if one Edge Server is unavailable, any requests for these scenarios that are sent to it will fail, instead of routing to another Edge Server.

Using DNS load balancing also causes a loss of failover ability for these Exchange UM scenarios for remote Exchange UM users:

- Playing their Enterprise Voice voice mail on their phone
- Transferring calls from an Exchange UM Auto Attendant

All other Exchange UM scenarios will work properly.

The internal Edge interface and external Edge interface must use the same type of load balancing. You cannot use DNS load balancing on one Edge interface and hardware load balancing on the other Edge interface.

Deploying DNS Load Balancing on Edge Server Pools

To deploy DNS load balancing on the external interface of your Edge Server pool, you need the following DNS entries:

- For the Access Edge service, you need one entry for each server in the pool. Each entry must resolve the FQDN of the Access Edge service (for example, sip.contoso.com) to the IP address of the Access Edge service on one of the Edge Servers in the pool.
- For the Web Conferencing Edge service, you need one entry for each server in the pool. Each entry must resolve the FQDN of the Web Conferencing Edge service (for example, webconf.contoso.com) to the IP address of the Web Conferencing Edge service on one of the Edge Servers in the pool.
- For the Audio/Video Edge service, you need one entry for each server in the pool. Each entry must resolve the FQDN of the Audio/Video Edge service (for example, av.contoso.com) to the IP address of the A/V Edge service on one of the Edge Servers in the pool.

To deploy DNS load balancing on the internal interface of your Edge Server pool, you must add one DNS A record, which resolves the internal FQDN of the Edge Server pool to the IP address of each server in the pool.

Using DNS Load Balancing on Mediation Server Pools

You can use DNS load balancing on stand-alone Mediation Server pools. All SIP and media traffic is balanced by DNS load balancing.

To deploy DNS load balancing on a Mediation Server pool, you must provision DNS to resolve the pool FQDN (for example, mediationpool1.contoso.com) to the IP addresses of all the servers in the pool (for example, 192.168.1.1, 192.168.1.2, and so on).

Blocking Traffic to a Server With DNS Load Balancing

If you use DNS load balancing and you need to block traffic to a specific computer, it is not sufficient to just remove the IP address entries from the Pool FQDN. You must remove the DNS entry for the computer as well.

Note that for server-to-server traffic, Lync Server 2013 uses topology-aware load balancing. Servers read the published topology in the Central Management store to obtain the FQDNs of servers in the topology, and automatically distribute the traffic among the servers. To block a server from receiving server-to-server traffic, you must remove the server from the topology.

1.3.3.4.8 DNS Requirements for Persistent Chat Servers

DNS Requirements for Persistent Chat Servers

Planning > Network Planning for Lync Server > Domain Name System (DNS) Requirements >

Topic Last Modified: *2012-06-28*

This section describes the Domain Name System (DNS) records that are required for deployment of Persistent Chat Servers.

DNS Records for Persistent Chat Servers

The following table specifies DNS requirements for Persistent Chat Server deployment.

DNS Requirements for a Persistent Chat Server

Deployment scenario	DNS requirement
One Persistent Chat Server	An internal A record that resolves the fully qualified domain name (FQDN) of the server to its IP address.
Persistent Chat pool	An internal A record that resolves the fully qualified domain name (FQDN) of the servers to its IP address. **Example** PersistentChatServer01.contoso.com 10.10.10.1 PersistentChatServer02.contoso.com 10.10.10.2 An internal A record that resolves the fully qualified domain name (FQDN) of the servers to its IP address. **Example** PersistentChatPool.contoso.com 10.10.10.1 PersistentChatPool.contoso.com 10.10.10.2

1.3.3.4.9 DNS Requirements for Edge Servers and Features

DNS Requirements for Edge Servers and Features

Planning > Network Planning for Lync Server > Domain Name System (DNS) Requirements >

Topic Last Modified: *2013-01-26*

Lync Server 2013 Edge Servers, Edge pools, and reverse proxies have specific requirements for domain name system (DNS) records. In Lync Server 2013 when IPv4 and IPv6 are in use, you must plan for both host A and AAAA records.

The topics listed below define the use of DNS records for your deployment planning:

- DNS Summary - Single Consolidated Edge with Private IP Addresses Using NAT
- DNS Summary - Single Consolidated Edge with Public IP Addresses
- DNS Summary - Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT
- DNS Summary - Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses
- DNS Summary - Scaled Consolidated Edge with Hardware Load Balancers
- DNS Summary - Reverse Proxy
- DNS Summary - Lync Server and Office Communications Server Federation
- DNS Summary - Public Instant Messaging Connectivity
- DNS Summary - Extensible Messaging and Presence Protocol (XMPP) Federation

1.3.3.4.9.1 DNS Summary - Single Consolidated Edge with Private IP Addresses Using NAT

DNS Summary - Single Consolidated Edge with Private IP Addresses Using NAT

Network Planning for Lync Server > Domain Name System (DNS) Requirements > DNS Requirements for Edge Servers and Features >

Topic Last Modified: *2012-09-08*

DNS record requirements for remote access to Lync Server 2013 are fairly straightforward compared to those for certificates and ports. Also, many records are optional, depending on how you configure clients running Lync 2013 and whether you enable federation.

For details about Lync 2013 DNS requirements, see Determine DNS Requirements.

For details about automatic configuration of clients running Lync 2013 if split-brain DNS is not configured, see “Automatic Configuration without Split-Brain DNS” in Determine DNS Requirements.

The following table contains a summary of the DNS records that are required to support the single consolidated edge topology shown in the Single Consolidated Edge Topology figure. Note that certain DNS records are required only for automatic configuration of Lync 2013 and Lync 2010 clients. If you plan to use group policy objects (GPOs) to configure Lync clients, the associated automatic configuration records are not necessary.

IMPORTANT: Edge Server Network Adapter Requirements

To avoid routing issues, verify that there are at least two network adapters in your Edge Servers and that the default gateway is set only on the network adapter associated with the external interface. For example, as shown in the Single Consolidated Edge Topology figure in Single Consolidated Edge with Private IP Addresses and NAT, the default gateway would point to the external firewall (10.45.16.1).

You can configure two network adapters in your Edge Server as follows:

- **Network adapter 1 (Internal Interface)**
  Internal interface with 172.25.33.10 assigned.
  No default gateway is defined.
  Ensure that there is a route from the network containing the Edge internal interface to any networks that contain servers running Lync Server 2013 or Lync Server 2013 clients (for example, from 172.25.33.0 to 192.168.10.0).
- **Network adapter 2 (External Interface)**
  Three private IP addresses are assigned to this network adapter, for example 10.45.16.10 for Access Edge, 10.45.16.20 for Web Conferencing Edge, 10.45.16.30 for AV Edge

  Note:

  It is possible, though not recommended, to use a single IP address for all three Edge service interfaces. Though this does save IP addresses, it requires different port numbers for each service. The default port number is 443/TCP, which ensures that most remote firewalls will allow the traffic. Changing the port values to (for example) 5061/TCP for the Access Edge, 444/TCP for the Web Conferencing Edge and 443/TCP for the AV Edge might cause problems for remote users where a firewall that they are behind does not allow the traffic over 5061/TCP and 444/TCP. Additionally, three distinct IP addresses makes troubleshooting easier due to being able to filter on IP address.

  Access Edge IP address is primary with default gateway set to integrated router (10.45.16.1).
  Web conferencing and A/V Edge IP addresses secondary.

Tip:

Configuring the Edge Server with two network adapters is one of two options. The other option is to use one network adapter for the internal side and three network adapters for the external side of the Edge Server. The main benefit of this option is a distinct network adapter per Edge Server service, and potentially more concise data collection when troubleshooting is necessary

DNS Records Required for Single Consolidated Edge with Private IP Addresses Using NAT (Example)

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
External DNS/A	sip.contoso.com	131.107.155.10	Access Edge external interface (Contoso) Repeat as necessary for all SIP domains with Lync enabled users
External DNS/A	webcon.contoso.com	131.107.155.20	Web Conferencing Edge external interface
External DNS/A	av.contoso.com	131.107.155.30	A/V Edge external interface
External DNS/ SRV/443	_sip._tls.contoso.com	sip.contoso.com	Access Edge external interface. Required for automatic configuration of Lync 2013 and Lync 2010 clients to work externally. Repeat as necessary for all SIP domains with Lync enabled users.

External DNS/ SRV/5061	_sipfederationtls._tcp .contoso.com	sip.contoso.com	SIP Access Edge external interface Required for automatic DNS discovery of federated partners known as "Allowed SIP Domain" (called enhanced federation in previous releases).Repeat as necessary for all SIP domains with Lync enabled users
Internal DNS/A	lsedge.contoso.net	172.25.33.10	Consolidated Edge internal interface

Important:

The records listed in the previous table are shown with either a *.net* extension or a *.com* extension to highlight which zone they need to reside in if you are not using split-brain DNS. If you are using split-brain DNS, all records would be in the same *.com* zone, with the only distinction being whether they are in the internal or external DNS zone version. For details, see "Split-Brain DNS" in Determine DNS Requirements.

Records Required for Federation

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5061	_sipfederationtls._tcp .contoso.com	sip.contoso.com	SIP Access Edge external interface Required for automatic DNS discovery of your federation to other potential federation partners, and is known as "Allowed SIP Domains" (called enhanced federation in previous releases).Repeat as necessary for all SIP domains with Lync enabled users **Important:** This SRV record is required for mobility and the push notification clearing house

DNS Summary – Public Instant Messaging Connectivity

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
External DNS/A	sip.contoso.com	Access Edge service interface	Access Edge external interface (Contoso) Repeat as necessary for all SIP domains with Lync enabled users

DNS Summary for Extensible Messaging and Presence Protocol

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5269	_xmpp-server._tcp.contoso.com	xmpp.contoso.com	XMPP proxy external interface on the Access Edge service or Edge pool.Repeat as necessary for all internal SIP domains with Lync enabled users where contact with XMPP contacts is allowed through the configuration of the External Access Policy through a global policy, site policy where the user is located, or user policy applied to the Lync-enabled user. An allowed XMPP domain must also be configured in the XMPP Federated Partners policy. See topics in **See Also** for additional details
External DNS/A	xmpp.contoso.com (for example)	IP address of Access Edge service on your Edge Server or Edge pool hosting XMPP proxy	Points to the Access Edge service or Edge pool that hosts the XMPP proxy service. Typically, the SRV record that you create will point to this host (A or AAAA) record

1.3.3.4.9.2 DNS Summary - Single Consolidated Edge with Public IP Addresses

DNS Summary - Single Consolidated Edge with Public IP Addresses

Network Planning for Lync Server > Domain Name System (DNS) Requirements > DNS Requirements for Edge Servers and Features >

Topic Last Modified: *2012-09-08*

DNS record requirements for remote access to Lync Server 2013 are fairly straightforward compared to those for certificates and ports. Also, many records are optional, depending on how you configure clients running Lync 2013 and whether you enable federation.

For details about Lync 2013 DNS requirements, see Determine DNS Requirements.

For details about automatic configuration of clients running Lync 2013 if split-brain DNS is not configured, see “Automatic Configuration without Split-Brain DNS” in Determine DNS Requirements.

The following table contains a summary of the DNS records that are required to support the single consolidated edge topology shown in the Single Consolidated Edge Topology figure. Note that certain DNS records are required only for automatic configuration of Lync 2013 and Lync 2010 clients. If you plan to use group policy objects (GPOs) to configure Lync clients, the associated automatic configuration records are not necessary.

IMPORTANT: Edge Server Network Adapter Requirements

To avoid routing issues, verify that there are at least two network adapters in your Edge Servers and that the default gateway is set only on the network adapter associated with the external interface. For example, as shown in the Single Consolidated Edge Topology with Public IP Addresses figure in Single Consolidated Edge with Public IP Addresses, the default gateway would point to the external router at your Internet perimeter or firewall that can provide a public IP addresses. The network relationship for Edge Server interfaces is a route relationship instead of a NAT relationship.

You can configure two network adapters in your Edge Server as follows:

- **Network adapter 1 (Internal Interface)**
  Internal interface with 172.25.33.10 assigned.
  No default gateway is defined.
  Ensure that there is a route from the network containing the Edge internal interface to any networks that contain servers running Lync Server 2013 or Lync Server 2013 clients (for example, from 172.25.33.0 to 192.168.10.0).
- **Network adapter 2 (External Interface)**
  Three public IP addresses are assigned to this network adapter, for example 131.107.155.10 for Access Edge, 131.107.155.20 for Web Conferencing Edge, 131.107.155.30 for AV Edge.

  > **Note:**
  > It is possible, though not recommended, to use a single IP address for all three Edge service interfaces. Though this does save IP addresses, it requires different port numbers for each service. The default port number is 443/TCP, which ensures that most remote firewalls will allow the traffic. Changing the port values to (for example) 5061/TCP for the Access Edge, 444/TCP for the Web Conferencing Edge and 443/TCP for the AV Edge might cause problems for remote users where a firewall that they are behind does not allow the traffic over 5061/TCP and 444/TCP. Additionally, three distinct IP addresses makes troubleshooting easier due to being able to filter on IP address.

  The Access Edge public IP address is primary with default gateway set to the public router (131.107.155.1).
  Web conferencing and A/V Edge public IP addresses are additional IP addresses in the **Advanced** section of the properties of **Internet Protocol**

Version 4 (TCP/IPv4) and **Internet Protocol Version 6 (TCP/IPv6)** of the **Local Area Connection Properties** in Windows Server.

Tip:

Configuring the Edge Server with two network adapters is one of two options. The other option is to use one network adapter for the internal side and three network adapters for the external side of the Edge Server. The main benefit of this option is a distinct network adapter per Edge Server service, and potentially more concise data collection when troubleshooting is necessary

DNS Records Required for Single Consolidated Edge with Public IP Addresses (Example)

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
External DNS/A	sip.contoso.com	131.107.155.10	Access Edge external interface (Contoso) Repeat as necessary for all SIP domains with Lync enabled users
External DNS/A	webcon.contoso.com	131.107.155.20	Web Conferencing Edge external interface
External DNS/A	av.contoso.com	131.107.155.30	A/V Edge external interface
External DNS/ SRV/443	_sip._tls.contoso.com	sip.contoso.com	Access Edge external interface. Required for automatic configuration of Lync 2013 and Lync 2010 clients to work externally. Repeat as necessary for all SIP domains with Lync enabled users.
External DNS/ SRV/5061	_sipfederationtls._tcp .contoso.com	sip.contoso.com	SIP Access Edge external interface Required for automatic DNS discovery of federated partners known as "Allowed SIP Domain" (called enhanced federation in previous releases).Repeat as necessary for all SIP domains with Lync enabled users
Internal DNS/A	lsedge.contoso.net	172.25.33.10	Consolidated Edge internal interface

Important:

The records listed in the previous table are shown with either a *.net* extension or a *.com* extension to highlight which zone they need to reside in if you are not using split-brain DNS. If you are using split-brain DNS, all records would be in the same zone, with the only distinction being whether they are in the internal or external version. For details, see "Split-Brain DNS" in Determine DNS Requirements.

Records Required for Federation

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5061	_sipfederationtls._tcp .contoso.com	sip.contoso.com	SIP Access Edge external interface Required for automatic DNS discovery of your federation to other potential federation partners, and is known as "Allowed SIP Domains" (called enhanced federation in previous releases).Repeat as necessary for all SIP domains with Lync enabled users ◆**Important:** This SRV record is required for mobility and the push notification clearing house

DNS Summary – Public Instant Messaging Connectivity

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
External DNS/A	sip.contoso.com	Access Edge service interface	Access Edge external interface (Contoso) Repeat as necessary for all SIP domains with Lync enabled users

DNS Summary for Extensible Messaging and Presence Protocol

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5269	_xmpp-server._tcp.contoso.com	xmpp.contoso.com	XMPP proxy external interface on the Access Edge service or Edge pool.Repeat as necessary for all

			internal SIP domains with Lync enabled users where contact with XMPP contacts is allowed through the configuration of the External Access Policy through a global policy, site policy where the user is located, or user policy applied to the Lync-enabled user. An allowed XMPP domain must also be configured in the XMPP Federated Partners policy. See topics in **See Also** for additional details
External DNS/A	xmpp.contoso.com (for example)	IP address of Access Edge service on your Edge Server or Edge pool hosting XMPP proxy	Points to the Access Edge service or Edge pool that hosts the XMPP proxy service. Typically, the SRV record that you create will point to this host (A or AAAA) record

1.3.3.4.9.3 DNS Summary - Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT

DNS Summary - Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT

Network Planning for Lync Server > Domain Name System (DNS) Requirements > DNS Requirements for Edge Servers and Features >

Topic Last Modified: *2012-09-08*

DNS record requirements for remote access to Lync Server 2013 are fairly straightforward compared to those for certificates and ports. Also, many records are optional, depending on how you configure clients running Lync 2013 and whether you enable federation.

For details about Lync 2013 DNS requirements, see Determine DNS Requirements.

For details about configuring automatic configuration of Lync 2013 clients if split-brain DNS is not configured, see the "Automatic Configuration without Split Brain DNS" section in Determine DNS Requirements.

The following table contains a summary of the DNS records that are required to support the single consolidated edge topology shown in the Single Consolidated Edge Topology figure. Note that certain DNS records are required only for automatic configuration of Lync 2013 clients. If you plan to use group policy objects (GPOs) to configure Lync clients, the associated records are not necessary.

IMPORTANT: Edge Server Network Adapter Requirements

To avoid routing issues, verify that there are at least two network adapters in your Edge Servers and that the default gateway is set only on the network adapter associated with the external interface. For example, as shown in the Scaled Consolidated Edge Scenario figure in Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT, the default gateway would point to the external firewall.

You can configure two network adapters in each of your Edge Server as follows:

- **Network adapter 1 - Node 1 (Internal Interface)**
  Internal interface with 172.25.33.10 assigned.
  No default gateway is defined.
  Ensure that there is a route from the network containing the Edge internal interface to any networks that contain servers running Lync Server 2013 or Lync Server 2013 clients (for example, from 172.25.33.0 to 192.168.10.0).
- **Network adapter 1 - Node 2 (Internal Interface)**
  Internal interface with 172.25.33.11 assigned.
  No default gateway is defined.
  Ensure that there is a route from the network containing the Edge internal interface to any networks that contain servers running Lync Server 2013 or Lync Server 2013 clients (for example, from 172.25.33.0 to 192.168.10.0).
- **Network adapter 2 Node 1 (External Interface)**
  Three private IP addresses are assigned to this network adapter, for example 10.45.16.10 for Access Edge, 10.45.16.20 for Web Conferencing Edge, 10.45.16.30 for AV Edge.

  Note:
  It is possible, though not recommended, to use a single IP address for all three Edge service interfaces. Though this does save IP addresses, it requires different port numbers for each service. The default port number is 443/TCP, which ensures that most remote firewalls will allow the traffic. Changing the port values to (for example) 5061/TCP for the Access Edge, 444/TCP for the Web Conferencing Edge and 443/TCP for the AV Edge might cause problems for remote users where a firewall that they are behind does not allow the traffic over 5061/TCP and 444/TCP. Additionally, three distinct IP addresses makes troubleshooting easier due to being able to filter on IP address.

  The Access Edge public IP address is primary with default gateway set to the integrated router (10.45.16.1).
  Web conferencing and A/V Edge private IP addresses are additional IP addresses in the **Advanced** section of the properties of **Internet Protocol Version 4 (TCP/IPv4)** and **Internet Protocol Version 6 (TCP/IPv6)** of the **Local Area Connection Properties** in Windows Server.
- **Network adapter 2 Node 2 (External Interface)**
  Three private IP addresses are assigned to this network adapter, for example 10.45.16.11 for Access Edge, 10.45.16.21 for Web Conferencing Edge, 10.45.16.31 for AV Edge.
  The Access Edge public IP address is primary with default gateway set to the integrated router (10.45.16.1).
  Web conferencing and A/V Edge private IP addresses are additional IP addresses in the **Advanced** section of the properties of **Internet Protocol Version 4 (TCP/IPv4)** and **Internet Protocol Version 6 (TCP/IPv6)** of the **Local Area Connection Properties** in Windows Server.

Tip:
Configuring the Edge Server with two network adapters is one of two options. The other option is to use one network adapter for the internal side and three network adapters for the external side of the Edge Server. The main benefit of this option is a distinct

network adapter per Edge Server service, and potentially more concise data collection when troubleshooting is necessary

DNS Records Required for Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT (Example)

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
External DNS/A	sip.contoso.com	131.107.155.10 and 131.107.155.11	Access Edge external interface (Contoso) Repeat as necessary for all SIP domains with Lync enabled users
External DNS/A	webcon.contoso.com	131.107.155.20 and 131.107.155.21	Web Conferencing Edge external interface
External DNS/A	av.contoso.com	131.107.155.30 and 131.107.155.31	A/V Edge external interface
External DNS/ SRV/443	_sip._tls.contoso.com	sip.contoso.com	Access Edge external interface. Required for automatic configuration of Lync 2013 and Lync 2010 clients to work externally. Repeat as necessary for all SIP domains with Lync enabled users.
External DNS/ SRV/5061	_sipfederationtls._tcp .contoso.com	sip.contoso.com	SIP Access Edge external interface. Required for automatic DNS discovery of federated partners known as “Allowed SIP Domain” (called enhanced federation in previous releases). Repeat as necessary for all SIP domains with Lync enabled users
Internal DNS/A	lsedge.contoso.net	172.25.33.10 and 172.25.33.11	Consolidated Edge internal interface

Records Required for Federation

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5061	_sipfederationtls._tcp .contoso.com	sip.contoso.com	SIP Access Edge external interface Required for automatic DNS discovery of your

			federation to other potential federation partners, and is known as "Allowed SIP Domains" (called enhanced federation in previous releases).Repeat as necessary for all SIP domains with Lync enabled users **Important:** This SRV record is required for mobility and the push notification clearing house

DNS Summary – Public Instant Messaging Connectivity

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
External DNS/A	sip.contoso.com	Access Edge service interface	Access Edge external interface (Contoso) Repeat as necessary for all SIP domains with Lync enabled users

DNS Summary for Extensible Messaging and Presence Protocol

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5269	_xmpp-server._tcp.contoso.com	xmpp.contoso.com	XMPP proxy external interface on the Access Edge service or Edge pool.Repeat as necessary for all internal SIP domains with Lync enabled users where contact with XMPP contacts is allowed through the configuration of the External Access Policy through a global policy, site policy where the user is located, or user policy applied to the Lync-enabled user. An

			allowed XMPP domain must also be configured in the XMPP Federated Partners policy. See topics in **See Also** for additional details
External DNS/A	xmpp.contoso.com (for example)	IP address of Access Edge service on your Edge Server or Edge pool hosting XMPP proxy	Points to the Access Edge service or Edge pool that hosts the XMPP proxy service. Typically, the SRV record that you create will point to this host (A or AAAA) record

1.3.3.4.9.4 DNS Summary - Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses

DNS Summary - Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses

Network Planning for Lync Server > Domain Name System (DNS) Requirements > DNS Requirements for Edge Servers and Features >

Topic Last Modified: *2012-10-20*

DNS record requirements for remote access to Lync Server 2013 are fairly straightforward compared to those for certificates and ports. Also, many records are optional, depending on how you configure clients running Lync 2013 and whether you enable federation.

For details about Lync 2013 DNS requirements, see Determine DNS Requirements.

For details about configuring automatic configuration of Lync 2013 clients if split-brain DNS is not configured, see the "Automatic Configuration without Split Brain DNS" section in Determine DNS Requirements.

The following table contains a summary of the DNS records that are required to support the single consolidated edge topology shown in the Single Consolidated Edge Topology figure. Note that certain DNS records are required only for automatic configuration of Lync 2013 clients. If you plan to use group policy objects (GPOs) to configure Lync clients, the associated records are not necessary.

IMPORTANT: Edge Server Network Adapter Requirements

To avoid routing issues, verify that there are at least two network adapters in your Edge Servers and that the default gateway is set only on the network adapter associated with the external interface. For example, as shown in the Scaled Consolidated Edge Scenario figure in Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses , the default gateway would point to the external firewall.

You can configure two network adapters in each of your Edge Server as follows:

- **Network adapter 1 - Node 1 (Internal Interface)**
  Internal interface with 172.25.33.10 assigned.
  No default gateway is defined.
  Ensure that there is a route from the network containing the Edge internal interface to any networks that contain servers running Lync Server 2013 or Lync Server 2013 clients (for example, from 172.25.33.0 to 192.168.10.0).
- **Network adapter 1 - Node 2 (Internal Interface)**
  Internal interface with 172.25.33.11 assigned.
  No default gateway is defined.
  Ensure that there is a route from the network containing the Edge internal interface to any networks that contain servers running Lync Server 2013 or Lync Server 2013 clients (for example, from 172.25.33.0 to 192.168.10.0).
- **Network adapter 2 Node 1 (External Interface)**
  Three private IP addresses are assigned to this network adapter, for example 131.107.155.10 for Access Edge service, 131.107.155.20 for Web Conferencing Edge service, 131.107.155.30 for A/V Edge service.
  The Access Edge service public IP address is primary with default gateway set to the public router (131.107.155.1).
  Web Conferencing Edge service and A/V Edge service private IP addresses are additional IP addresses in the **Advanced** section of the properties of **Internet Protocol Version 4 (TCP/IPv4)** and **Internet Protocol Version 6 (TCP/IPv6)** of the **Local Area Connection Properties** in Windows Server.

  Note:

  It is possible, though not recommended, to use a single IP address for all three Edge service interfaces. Though this does save IP addresses, it requires different port numbers for each service. The default port number is 443/TCP, which ensures that most remote firewalls will allow the traffic. Changing the port values to (for example) 5061/TCP for the Access Edge service, 444/TCP for the Web Conferencing Edge service and 443/TCP for the A/V Edge service might cause problems for remote users where a firewall that they are behind does not allow the traffic over 5061/TCP and 444/TCP. Additionally, three distinct IP addresses makes troubleshooting easier due to being able to filter on IP address.

- **Network adapter 2 Node 2 (External Interface)**
  Three private IP addresses are assigned to this network adapter, for example 131.107.155.11 for Access Edge service, 131.107.155.21 for Web Conferencing Edge service, 131.107.155.31 for A/V Edge service.
  The Access Edge service public IP address is primary with default gateway set to the public router (131.107.155.1).
  Web Conferencing Edge service and A/V Edge service private IP addresses are additional IP addresses in the **Advanced** section of the properties of **Internet Protocol Version 4 (TCP/IPv4)** and **Internet Protocol Version 6 (TCP/IPv6)** of the **Local Area Connection Properties** in Windows Server.

Tip:

Configuring the Edge Server with two network adapters is one of two options. The other option is to use one network adapter for the internal side and three network adapters for the external side of the Edge Server. The main benefit of this option is a distinct network adapter per Edge Server service, and potentially more concise data collection when troubleshooting is necessary

DNS Records Required for Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses (Example)

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
External DNS/A	sip.contoso.com	131.107.155.10 and 131.107.155.11	Access Edge service external interface (Contoso) Repeat as necessary for all SIP

			domains with Lync enabled users
External DNS/A	webcon.contoso.com	131.107.155.20 and 131.107.155.21	Web Conferencing Edge service external interface
External DNS/A	av.contoso.com	131.107.155.30 and 131.107.155.31	A/V Edge service external interface
External DNS/ SRV/443	_sip._tls.contoso.com	sip.contoso.com	Access Edge service external interface. Required for automatic configuration of Lync 2013 and Lync 2010 clients to work externally. Repeat as necessary for all SIP domains with Lync enabled users.
External DNS/ SRV/5061	_sipfederationtls._tcp .contoso.com	sip.contoso.com	Access Edge service external interface Required for automatic DNS discovery of federated partners known as "Allowed SIP Domain" (called enhanced federation in previous releases). Repeat as necessary for all SIP domains with Lync enabled users
Internal DNS/A	lsedge.contoso.net	172.25.33.10 and 172.25.33.11	Consolidated Edge internal interface

Records Required for Federation

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5061	_sipfederationtls._tcp .contoso.com	sip.contoso.com	SIP Access Edge service external interface Required for automatic DNS discovery of your federation to other potential federation partners, and is known as "Allowed SIP Domains" (called enhanced federation in previous releases). ◆**Important:**

			Repeat as necessary for all SIP domains with Lync enabled users and Microsoft Lync Mobile clients that use either the Push Notification Service or the Apple Push Notification service

DNS Summary – Public Instant Messaging Connectivity

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
External DNS/A	sip.contoso.com	Access Edge service interface	Access Edge service external interface (Contoso)Repeat as necessary for all SIP domains with Lync enabled users

DNS Summary for Extensible Messaging and Presence Protocol

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5269	_xmpp-server._tcp.contoso.com	xmpp.contoso.com	XMPP proxy external interface on the Access Edge service or Edge pool.Repeat as necessary for all internal SIP domains with Lync enabled users where contact with XMPP contacts is allowed through the configuration of the External Access Policy through a global policy, site policy where the user is located, or user policy applied to the Lync-enabled user. An allowed XMPP domain must also be configured in the XMPP Federated Partners policy. See topics in **See Also** for additional details

External DNS/A	xmpp.contoso.com (for example)	IP address of Access Edge service on your Edge Server or Edge pool hosting XMPP proxy	Points to the Access Edge service or Edge pool that hosts the XMPP proxy service. Typically, the SRV record that you create will point to this host (A or AAAA) record

1.3.3.4.9.5 DNS Summary - Scaled Consolidated Edge w ith Hardw are Load Balancers

DNS Summary - Scaled Consolidated Edge with Hardware Load Balancers

Network Planning for Lync Server > Domain Name System (DNS) Requirements > DNS Requirements for Edge Servers and Features >

Topic Last Modified: *2013-01-27*

DNS record requirements for remote access to Lync Server 2013 are fairly straightforward compared to those for certificates and ports. Also, many records are optional, depending on how you configure clients running Lync 2013 and whether you enable federation.

For details about Lync 2013 DNS requirements, see Determine DNS Requirements.

For details about configuring automatic configuration of Lync 2013 clients if split-brain DNS is not configured, see the "Automatic Configuration without Split Brain DNS" section in Determine DNS Requirements.

The following table contains a summary of the DNS records that are required to support the Scaled Consolidated Edge Topology (Hardware Load Balanced) figure. Note that certain DNS records are required only for automatic configuration for Lync clients. If you plan to use group policy objects (GPOs) to configure Lync clients, the associated records are not necessary.

IMPORTANT: Edge Server Network Adapter Requirements

To avoid routing issues, verify that there are at least two network adapters in your Edge Servers and that the default gateway is set only on the network adapter associated with the external interface. For example, as shown in the Scaled Consolidated Edge Scenario figure in Scaled Consolidated Edge with Hardware Load Balancers, the default gateway would point to the external firewall.

You can configure two network adapters in each of your Edge Servers as follows:

- **Network adapter 1 (Internal Interface)**
  Internal interface with 172.25.33.10 assigned.
  No default gateway.
  Ensure there is a route from the network containing the Edge Server internal interface to any networks that contain Lync Server clients or servers running Lync Server (for example, from 172.25.33.0 to 192.168.10.0).
- **Network adapter 2 (External Interface)**
  Three public IP addresses are assigned to this network adapter, for example 131.107.155.10 for Access Edge service, 131.107.155.20 for Web

Conferencing Edge service, 131.107.155.30 for A/V Edge service.

Note:

The IP addresses that are assigned to the actual external network interfaces of the Edge Server may depend on which hardware load balancer you choose. Refer to the documentation for your hardware load balancer to understand the actual IP address requirements.
It is possible, though not recommended, to use a single IP address for all three Edge service interfaces. Though this does save IP addresses, it requires different port numbers for each service. The default port number is 443/TCP, which ensures that most remote firewalls will allow the traffic. Changing the port values to (for example) 5061/TCP for the Access Edge service, 444/TCP for the Web Conferencing Edge service and 443/TCP for the A/V Edge service might cause problems for remote users where a firewall that they are behind does not allow the traffic over 5061/TCP and 444/TCP. Additionally, three distinct IP addresses makes troubleshooting easier due to being able to filter on IP address.

Access Edge service IP address is primary with default gateway set to Internet-facing router (131.107.155.1).
Web Conferencing Edge service and A/V Edge service IP addresses secondary.

Tip:

Configuring the Edge Server with two network adapters is one of two options. The other option is to use one network adapter for the internal side and three network adapters for the external side of the Edge Server. The main benefit of this option is a distinct network adapter per Edge Server service, and potentially more concise data collection when troubleshooting is necessary

DNS Records Required for Scaled Consolidated Edge, Hardware Load Balanced (Example)

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
External DNS/A	sip.contoso.com	131.107.155.10	Access Edge service external interface (Contoso). Repeat as necessary for all SIP domains with Lync enabled users
External DNS/A	webcon.contoso.com	131.107.155.20	Web Conferencing Edge service external interface
External DNS/A	av.contoso.com	131.107.155.30	A/V Edge service external interface
External DNS/ SRV/443	_sip._tls.contoso.com	sip.contoso.com	Access Edge service external interface. Required for automatic configuration of Lync 2013 and Lync 2010 clients to work externally. Repeat as necessary for all SIP domains with Lync enabled users.
External DNS/ SRV/5061	_sipfederationtls._tcp .contoso.com	sip.contoso.com	SIP Access Edge service external interface Required for

			automatic DNS discovery of federated partners known as "Allowed SIP Domain" (called enhanced federation in previous releases). Repeat as necessary for all SIP domains with Lync enabled users and Microsoft Lync Mobile clients that use either the Push Notification Service or the Apple Push Notification service
Internal DNS/A	lsedge.contoso.net	172.25.33.10	Consolidated Edge internal interface

1.3.3.4.9.6 DNS Summary - Reverse Proxy

DNS Summary - Reverse Proxy

Network Planning for Lync Server > Domain Name System (DNS) Requirements > DNS Requirements for Edge Servers and Features >

Topic Last Modified: *2012-10-31*

You configure two network adapters in your reverse proxy as follows:

Reverse Proxy Network Adapter Requirements

- **Network adapter 1 (Internal Interface)** example
  Internal interface with 172.25.33.40 assigned.
  No default gateway is defined.
  Ensure there is a route from the network containing the reverse proxy internal interface to any networks that contain Lync Server Front End pool servers (for example, from 172.25.33.0 to 192.168.10.0).
- **Network adapter 2 (External Interface)** example
  A minimum of one public IP address is assigned to this network adapter.
  Gateway is defined to point to the router or integrated firewall in your outer perimeter. (10.45.16.1 in the scenario examples)

DNS Records Required for Reverse Proxy

Location/TYPE/Port	FQDN	IP address	Maps to/comments
External DNS/A	webext.contoso.com	Assigned listener for externally published resources	External web services from the internal deployment. Additional records can be defined and created for all pools and single servers for any SIP

			domain that will use this reverse proxy, and has defined external web services.
External DNS/A	webdirext.contoso.com	Assigned listener for externally published resources	External web services for the Directors or Director pools in your deployment. You can define as many Directors as there are distinct Directors, of which may be associated with other SIP domains. ◆**Important:** Defining the DNS records for and publishing the Directors is not an either the Front End pool or the Director decision. You must define and publish both the Director and the Front End pool external web services if you are using Directors. Specific traffic types (for authentication and other uses) will be sent to the Director first, if it is defined in the topology.
External DNS/A	dialin.contoso.com	Assigned listener for externally published resources	Dial-in conferencing published externally
External DNS/A	meet.contoso.com	Assigned listener for externally published resources	Conferences published externally
External DNS/A	officewebapps01.contoso.com	Assigned listener for Office Web Apps Server	Office Web Apps Server deployed internally or in the perimeter, and published for external client access
External DNS/A	lyncdiscover.contoso.com	Assigned listener for externally published resources	Lync Discover External record for externally published AutoDiscover, and includes Mobility, Microsoft Lync Web App, and scheduler Web app

External DNS/A	lsrp.contoso.com	Assigned listener for externally published resources	Reference record for the reverse proxy external name

1.3.3.4.9.7 DNS Summary - Lync Server and Office Communications Server Federation

DNS Summary - Lync Server and Office Communications Server Federation

See Also

Network Planning for Lync Server > Domain Name System (DNS) Requirements > DNS Requirements for Edge Servers and Features >

Topic Last Modified: *2012-10-20*

The domain name system (DNS) records that will be required for defining a federation with Office Communications Server or Lync Server partners is determined by your decision to either allow automatic DNS discovery of your domain by other perspective partners. If you publish the _sipfederationtls._tcp. <*SIP domain name*> SRV record, any other SIP federated domain will be able to “discover” your federation. You can control which federated domains can communicate with you by using the Allows domains and Blocked Domains settings in the Lync Server Control Panel, or by setting the allowed or blocked domains configuration using the Lync Server Management Shell and the **Get**, **Set**, **New**, **Remove-CsAllowedDomain** and **-CsBlockedDomain** PowerShell cmdlets. For additional information on how to configure theses settings and the use of the PowerShell cmdlets, see **Related Topics** at the end of this topic.

The DNS records summary table depicts the required entries for an open, or discoverable, federation. If you do not want to implement Federation Discovery, You can decide to not configure the _sipfederationtls._tcp. <*SIP domain name*> record.

Important:

There are specific scenarios in which you must have the _sipfederationtls._tcp. <*SIP domain name*> SRV record, but you do not want to have a discoverable federation. One such instance is where you have deployed mobility for your users. The mobility push notification clearinghouse (PNCH) is a special type of federation that is used for Microsoft Lync Mobile clients on Apple iPhone or Windows Phone. The _sipfederationtls._tcp. <*SIP domain name*> SRV record is used in the case of mobility and PNCH. To mitigate this issue and control your discoverability, clear the setting **Enable partner domain discovery** to turn off discovery.

Records Required for Federation

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5061	_sipfederationtls._tcp .contoso.com	sip.contoso.com	Access Edge service external interface Required for automatic DNS discovery of your federation to other potential federation partners, and is known as “Allowed SIP Domains” (called enhanced federation in

			previous releases).Repeat as necessary for all SIP domains with Lync enabled users **Important:** This SRV record is required for mobility and the push notification clearing house. In cases where there is more than one SIP domain, create and publish an SRV record for each domain that will have Lync Mobile clients. The Push Notification Service and Apple Push Notification service may not operate as expected if there is not an explicit SRV record for each SIP domain that the deployment supports.

1.3.3.5 Port Requirements

Port Requirements

Microsoft Lync Server 2013 > Planning > Network Planning for Lync Server >

Topic Last Modified: *2012-11-16*

Lync Server requires that specific ports on the firewall be open. Additionally, if Internet Protocol security (IPsec) is deployed in your organization, IPsec must be disabled over the range of ports used for the delivery of audio, video, and panorama video.

This section includes the following topics:

- Ports and Protocols for Internal Servers
- IPsec Exceptions
- Port Summary - Single Consolidated Edge with Private IP Addresses Using NAT
- Port Summary - Single Consolidated Edge with Public IP Addresses
- Port Summary - Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT
- Port Summary - Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses
- Port Summary - Scaled Consolidated Edge with Hardware Load Balancers
- Port Summary - Reverse Proxy
- Port Summary - Lync Server and Office Communications Server Federation
- Port Summary - Public Instant Messaging Connectivity
- Port Summary - Extensible Messaging and Presence Protocol (XMPP) Federation

1.3.3.5.1 Ports and Protocols for Internal Servers

Ports and Protocols for Internal Servers

Planning > Network Planning for Lync Server > Port Requirements >

Topic Last Modified: *2012-12-12*

This section summarizes the ports and protocols used by servers, load balancers, and clients in a Lync Server deployment.

Port and Protocol Details

Note:

Windows Firewall must be running before you start the Lync Server services on a server, because that is when Lync Server opens the required ports in the firewall.

For details about firewall configuration for edge components, see Determine External A/V Firewall and Port Requirements.

The following table lists the ports that need to be open on each internal server role.

Required Server Ports (by Server Role)

Server role	Service name	Port	Protocol	Notes
All Servers	SQL Browser	1434	UDP	SQL Browser for the local replicated copy of the the Central Management Store database.
Front End Servers	Lync Server Front-End service	5060	TCP	Optionally used by Standard Edition servers and Front End Servers for static routes to trusted services, such as remote call control servers.
Front End Servers	Lync Server Front-End service	5061	TCP (TLS)	Used by Standard Edition servers and Front End pools for all internal SIP communications between servers (MTLS), for SIP communications between Server and Client (TLS) and for SIP communications between Front End Servers and Mediation Servers (MTLS). Also used for communications with Monitoring Server.
Front End Servers	Lync Server Front-End service	444	HTTPS TCP	Used for HTTPS communication between the Focus (the Lync

				Server component that manages conference state) and the individual servers. This port is also used for TCP communication between Survivable Branch Appliances and Front End Servers.
Front End Servers	Lync Server Front-End service	135	DCOM and remote procedure call (RPC)	Used for DCOM based operations such as Moving Users, User Replicator Synchronization, and Address Book Synchronization.
Front End Servers	Lync Server IM Conferencing service	5062	TCP	Used for incoming SIP requests for instant messaging (IM) conferencing.
Front End Servers	Lync Server Web Conferencing service	8057	TCP (TLS)	Used to listen for Persistent Shared Object Model (PSOM) connections from client.
Front End Servers	Lync Server Web Conferencing Compatibility service	8058	TCP (TLS)	Used to listen for Persistent Shared Object Model (PSOM) connections from the Live Meeting client and previous versions of Lync Server.
Front End Servers	Lync Server Audio/Video Conferencing service	5063	TCP	Used for incoming SIP requests for audio/video (A/V) conferencing.
Front End Servers	Lync Server Audio/Video Conferencing service	57501-65335	TCP/UDP	Media port range used for video conferencing.
Front End Servers	Lync Server Web Compatibility	80	HTTP	Used for communication

	service			from Front End Servers to the web farm FQDNs (the URLs used by IIS web components) when HTTPS is not used.
Front End Servers	Lync Server Web Compatibility service	443	HTTPS	Used for communication from Front End Servers to the web farm FQDNs (the URLs used by IIS web components).
Front End Servers	Lync Server Web Compatibility service	8080	TCP and HTTP	Used by web components for external access.
Front End Servers	Web server component	4443	HTTPS	
Front End Servers	Web server component	8060	TCP (MTLS)	
Front End Servers	Web server component	8061	TCP (MTLS)	
Front End Servers	Mobility Services component	5086	TCP (MTLS)	SIP port used by Mobility Services internal processes
Front End Servers	Mobility Services component	5087	TCP (MTLS)	SIP port used by Mobility Services internal processes
Front End Servers	Mobility Services component	443	HTTPS	
Front End Servers	Lync Server Conferencing Attendant service (dial-in conferencing)	5064	TCP	Used for incoming SIP requests for dial-in conferencing.
Front End Servers	Lync Server Conferencing Attendant service (dial-in conferencing)	5072	TCP	Used for incoming SIP requests for Attendant (dial in conferencing).
Front End Servers that also run a Collocated Mediation Server	Lync Server Mediation service	5070	TCP	Used by the Mediation Server for incoming requests from the Front End

				Server to the Mediation Server.
Front End Servers that also run a Collocated Mediation Server	Lync Server Mediation service	5067	TCP (TLS)	Used for incoming SIP requests from the PSTN gateway to the Mediation Server.
Front End Servers that also run a Collocated Mediation Server	Lync Server Mediation service	5068	TCP	Used for incoming SIP requests from the PSTN gateway to the Mediation Server.
Front End Servers that also run a Collocated Mediation Server	Lync Server Mediation service	5081	TCP	Used for outgoing SIP requests from the Mediation Server to the PSTN gateway.
Front End Servers that also run a Collocated Mediation Server	Lync Server Mediation service	5082	TCP (TLS)	Used for outgoing SIP requests from the Mediation Server to the PSTN gateway.
Front End Servers	Lync Server Application Sharing service	5065	TCP	Used for incoming SIP listening requests for application sharing.
Front End Servers	Lync Server Application Sharing service	49152-65335	TCP	Media port range used for application sharing.
Front End Servers	Lync Server Conferencing Announcement service	5073	TCP	Used for incoming SIP requests for the Lync Server Conferencing Announcement service (that is, for dial-in conferencing).
Front End Servers	Lync Server Call Park service	5075	TCP	Used for incoming SIP requests for the Call Park application.
Front End Servers	Lync Server Audio Test service	5076	TCP	Used for incoming SIP requests for the Audio Test service.
Front End Servers	Not applicable	5066	TCP	Used for outbound

				Enhanced 9-1-1 (E9-1-1) gateway.
Front End Servers	Lync Server Response Group service	5071	TCP	Used for incoming SIP requests for the Response Group application.
Front End Servers	Lync Server Response Group service	8404	TCP (MTLS)	Used for incoming SIP requests for the Response Group application.
Front End Servers	Lync Server Bandwidth Policy Service	5080	TCP	Used for call admission control by the Bandwidth Policy service for A/V Edge TURN traffic.
Front End Servers	Lync Server Bandwidth Policy Service	448	TCP	Used for call admission control by the Lync Server Bandwidth Policy Service.
Front End Servers where the Central Management store resides	Lync Server Master Replicator Agent service	445	TCP	Used to push configuration data from the Central Management store to servers running Lync Server.
All Servers	SQL Browser	1434	UDP	SQL Browser for local replicated copy of Central Management store data in local SQL Server instance
All internal servers	Various	49152-57500	TCP/UDP	Media port range used for audio conferencing on all internal servers. Used by all servers that terminate audio: Front End Servers (for Lync Server Conferencing Attendant service, Lync Server Conferencing

				Announcement service, and Lync Server Audio/ Video Conferencing service), and Mediation Server.
Directors	Lync Server Front-End service	5060	TCP	Optionally used for static routes to trusted services, such as remote call control servers.
Directors	Lync Server Front-End service	444	HTTPS TCP	Inter-server communication between Front End and Director. Additionally, client certificate publish (to Front End Servers) or validate if the client certificate has already been published.
Directors	Lync Server Web Compatibility service	80	TCP	Used for initial communication from Directors to the web farm FQDNs (the URLs used by IIS web components). In normal operation, will switch to HTTPS traffic, using port 443 and protocol type TCP.
Directors	Lync Server Web Compatibility service	443	HTTPS	Used for communication from Directors to the web farm FQDNs (the URLs used by IIS web components).
Directors	Lync Server Front-End service	5061	TCP	Used for internal communications between servers and for client connections.
Mediation Servers	Lync Server Mediation service	5070	TCP	Used by the Mediation Server for incoming requests from

				the Front End Server.
Mediation Servers	Lync Server Mediation service	5067	TCP (TLS)	Used for incoming SIP requests from the PSTN gateway.
Mediation Servers	Lync Server Mediation service	5068	TCP	Used for incoming SIP requests from the PSTN gateway.
Mediation Servers	Lync Server Mediation service	5070	TCP (MTLS)	Used for SIP requests from the Front End Servers.
Persistent Chat Front End Server	Persistent Chat SIP	5041	TCP (MTLS)	
Persistent Chat Front End Server	Persistent Chat Windows Communication Foundation (WCF)	881	TCP (TLS) and TCP (MTLS)	
Persistent Chat Front End Server	Persistent Chat File Transfer Service	443	TCP (TLS)	

Note:

Some remote call control scenarios require a TCP connection between the Front End Server or Director and the PBX. Although Lync Server no longer uses TCP port 5060, during remote call control deployment you create a trusted server configuration, which associates the RCC Line Server FQDN with the TCP port that the Front End Server or Director will use to connect to the PBX system. For details, see the **CsTrustedApplicationComputer** cmdlet in the Lync Server Management Shell documentation.

For your pools that use only hardware load balancing (not DNS load balancing), the following table shows the ports that need to open the hardware load balancers.

Hardware Load Balancer Ports if Using Only Hardware Load Balancing

Load Balancer	Port	Protocol
Front End Server load balancer	5061	TCP (TLS)
Front End Server load balancer	444	HTTPS
Front End Server load balancer	135	DCOM and remote procedure call (RPC)
Front End Server load balancer	80	HTTP
Front End Server load balancer	8080	TCP - Client and device retrieval of root certificate from Front End Server –

		clients and devices authenticated by NTLM
Front End Server load balancer	443	HTTPS
Front End Server load balancer	4443	HTTPS (from reverse proxy)
Front End Server load balancer	5072	TCP
Front End Server load balancer	5073	TCP
Front End Server load balancer	5075	TCP
Front End Server load balancer	5076	TCP
Front End Server load balancer	5071	TCP
Front End Server load balancer	5080	TCP
Front End Server load balancer	448	TCP
Mediation Server load balancer	5070	TCP
Front End Server load balancer (if the pool also runs Mediation Server)	5070	TCP
Director load balancer	443	HTTPS
Director load balancer	444	HTTPS
Director load balancer	5061	TCP
Director load balancer	4443	HTTPS (from reverse proxy)

Your Front End pools and Director pools that use DNS load balancing also must have a hardware load balancer deployed. The following table shows the ports that need to be open on these hardware load balancers.

Hardware Load Balancer Ports if Using DNS Load Balancing

Load Balancer	Port	Protocol
Front End Server load balancer	80	HTTP
Front End Server load balancer	443	HTTPS
Front End Server load balancer	8080	TCP - Client and device retrieval of root certificate from Front End Server – clients and devices authenticated by NTLM
Front End Server load balancer	4443	HTTPS (from reverse proxy)
Director load balancer	443	HTTPS

Director load balancer	444	HTTPS
Director load balancer	4443	HTTPS (from reverse proxy)

Required Client Ports

Component	Port	Protocol	Notes
Clients	67/68	DHCP	Used by Lync Server to find the Registrar FQDN (that is, if DNS SRV fails and manual settings are not configured).
Clients	443	TCP (TLS)	Used for client-to-server SIP traffic for external user access.
Clients	443	TCP (PSOM/TLS)	Used for external user access to web conferencing sessions.
Clients	443	TCP (STUN/MSTURN)	Used for external user access to A/V sessions and media (TCP)
Clients	3478	UDP (STUN/MSTURN)	Used for external user access to A/V sessions and media (TCP)
Clients	5061	TCP (MTLS)	Used for client-to-server SIP traffic for external user access.
Clients	6891-6901	TCP	Used for file transfer between Lync clients and previous clients (clients of Microsoft Office Communications Server 2007 R2, Microsoft Office Communications Server 2007, and Live Communications Server 2005).
Clients	1024-65535 *	TCP/UDP	Audio port range (minimum of 20 ports required)
Clients	1024-65535 *	TCP/UDP	Video port range (minimum of 20 ports required).
Clients	1024-65535 *	TCP	Peer-to-peer file transfer (for conferencing file

			transfer, clients use PSOM).
Clients	1024-65535 *	TCP	Application sharing.
Aastra 6721ip common area phone Aastra 6725ip desk phone HP 4110 IP Phone (common area phone) HP 4120 IP Phone (desk phone) Polycom CX500 IP common area phone Polycom CX600 IP desk phone Polycom CX700 IP desk phone Polycom CX3000 IP conference phone	67/68	DHCP	Used by the listed devices to find the Lync Server certificate, provisioning FQDN, and Registrar FQDN.

***** To configure specific ports for these media types, use the CsConferencingConfiguration cmdlet (ClientMediaPortRangeEnabled, ClientMediaPort, and ClientMediaPortRange parameters).

Note:

The set programs for Lync clients automatically create the required operating-system firewall exceptions on the client computer.

Note:

The ports that are used for external user access are required for any scenario in which the client must traverse the organization’s firewall (for example, any external communications or meetings hosted by other organizations).

1.3.3.5.2 IPsec Exceptions

IPsec Exceptions

Planning > Network Planning for Lync Server > Port Requirements >

Topic Last Modified: *2012-06-27*

For enterprise networks where Internet Protocol security (IPsec) (see IETF RFC 4301-4309) has been deployed, IPsec must be disabled over the range of ports used for the delivery of audio, video, and panorama video. The recommendation is motivated by the need to avoid any delay in the allocation of media ports due to IPsec negotiation.

The following table explains the recommended IPsec exception settings.

Recommended IPsec Exceptions

Rule name	Source IP	Destination IP	Protocol	Source port	Destination port	Authentication Requirement
A/V Edge Server Internal Inbound	Any	A/V Edge Server Internal	UDP and TCP	Any	Any	Do not authenticate
A/V Edge Server External Inbound	Any	A/V Edge Server External	UDP and TCP	Any	Any	Do not authenticate
A/V Edge Server Internal Outbound	A/V Edge Server Internal	Any	UDP & TCP	Any	Any	Do not authenticate
A/V Edge Server External Outbound	A/V Edge Server External	Any	UDP and TCP	Any	Any	Do not authenticate
Mediation Server Inbound	Any	Mediation Server(s)	UDP and TCP	Any	Any	Do not authenticate
Mediation Server Outbound	Mediation Server(s)	Any	UDP and TCP	Any	Any	Do not authenticate
Conferencing Attendant Inbound	Any	Front End Server running Conferencing Attendant	UDP and TCP	Any	Any	Do not authenticate
Conferencing Attendant Outbound	Front End Server running Conferencing Attendant	Any	UDP and TCP	Any	Any	Do not authenticate
A/V Conferencing Inbound	Any	Front End Servers	UDP and TCP	Any	Any	Do not authenticate
A/V Conferencing Outbound	Front End Servers	Any	UDP and TCP	Any	Any	Do not authenticate
Exchange Inbound	Any	Exchange Unified Messaging	UDP and TCP	Any	Any	Do not authenticate
Application Sharing Servers Inbound	Any	Application Sharing Servers	TCP	Any	Any	Do not authenticate

Application Sharing Server Outbound	Application Sharing Servers	Any	TCP	Any	Any	Do not authenticate
Exchange Outbound	Exchange Unified Messaging	Any	UDP and TCP	Any	Any	Do not authenticate
Clients	Any	Any	UDP	Specified media port range	Any	Do not authenticate

1.3.3.5.3 Port Summary - Single Consolidated Edge with Private IP Addresses Using NAT

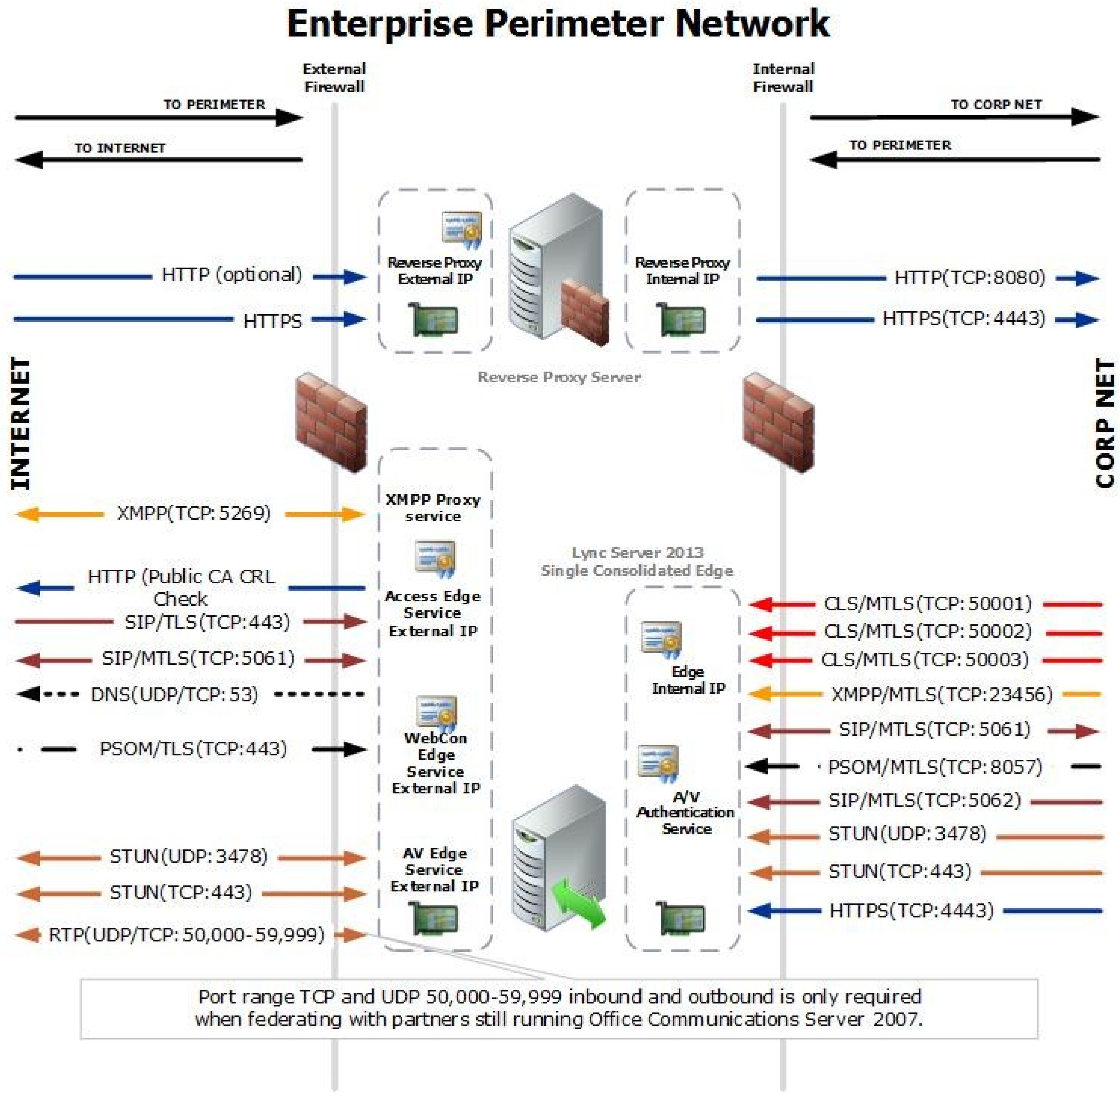
Port Summary - Single Consolidated Edge with Private IP Addresses Using NAT

Planning > Network Planning for Lync Server > Port Requirements >

Topic Last Modified: *2013-02-22*

The Lync Server 2013, Edge Server functionality described in this scenario architecture is very similar to what was implemented in Lync Server 2010. The most noticeable addition is the port **5269 over TCP** entry for the extensible messaging and presence protocol (XMPP). Lync Server 2013 optionally deploys an XMPP proxy on the Edge Server or Edge pool and the XMPP gateway server on the Front End Server or Front End pool.

In addition to IPv4, the Edge Server now supports IPv6. For clarity, only IPv4 is used in the scenarios.



Port and Protocol Details

We recommend that you open only the ports required to support the functionality for which you are providing external access.

For remote access to work for any edge service, it is mandatory that SIP traffic is allowed to flow bi-directionally as shown in the Inbound/Outbound edge traffic figure. Stated another way, the SIP messaging to and from the Access Edge service is involved in instant messaging (IM), presence, web conferencing, audio/video (A/V), and federation.

Firewall Summary for Single Consolidated Edge with Private IP Addresses using NAT: External Interface

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
XMPP/TCP/5269	Any	XMPP Proxy service (shares IP address with Access Edge service)	XMPP Proxy service accepts traffic from XMPP contacts in defined XMPP

			federations
Access/HTTP/TCP/80	Edge Server Access Edge service	Any	Certificate revocation/ CRL check and retrieval
Access/DNS/TCP/53	Edge Server Access Edge service	Any	DNS query over TCP
Access/DNS/UDP/53	Edge Server Access Edge service	Any	DNS query over UDP
Access/SIP(TLS)/ TCP/443	Any	Edge Server Access Edge service	Client-to-server SIP traffic for external user access
Access/SIP(MTLS)/ TCP/5061	Any	Edge Server Access Edge service	For federated and public IM connectivity using SIP
Access/SIP(MTLS)/ TCP/5061	Edge Server Access Edge service	Any	For federated and public IM connectivity using SIP
Web Conferencing/ PSOM(TLS)/TCP/443	Any	Edge Server Web Conferencing Edge service	Web Conferencing media
A/V/RTP/TCP/50,000-59,999	Edge Server A/V Edge service	Any	Required for federating with partners running Office Communications Server 2007, Office Communications Server 2007 R2, Lync Server 2010 and Lync Server 2013.
A/V/RTP/UDP/50,000-59,999	Edge Server A/V Edge service	Any	Required only for federation with partners running Office Communications Server 2007.
A/V/RTP/TCP/50,000-59,999	Any	Edge Server A/V Edge service	Required only for federation with partners running Office Communications Server 2007
A/V/RTP/UDP/50,000-59,999	Any	Edge Server A/V Edge service	Required only for federation with partners running Office Communications Server 2007
A/V/STUN,MSTURN/ UDP/3478	Edge Server A/V Edge service	Any	3478 outbound is used to determine

			the version of Edge Server that Lync Server is communicating with and also for media traffic from Edge Server-to-Edge Server. Required for federation with Lync Server 2010, Windows Live Messenger, and Office Communications Server 2007 R2, and also if multiple Edge pools are deployed within a company.
A/V/STUN,MSTURN/ UDP/3478	Any	Edge Server A/V Edge service	STUN/TURN negotiation of candidates over UDP/3478
A/V/STUN,MSTURN/ TCP/443	Any	Edge Server A/V Edge service	STUN/TURN negotiation of candidates over TCP/443
A/V/STUN,MSTURN/ TCP/443	Edge Server A/V Edge service	Any	STUN/TURN negotiation of candidates over TCP/443

Firewall Summary for Single Consolidated Edge with Private IP Addresses Using NAT: Internal Interface

Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Comments
XMPP/MTLS/ TCP/23456	Any (can be defined as Standard Edition server IP, Standard Edition server IP address, or pool IP address running the XMPP Gateway service)	Edge Server internal interface	Outbound XMPP traffic from XMPP Gateway service running on Front End Server or Front End pool
SIP/MTLS/TCP/5061	Any (can be defined as Director, Director pool IP address, Front End Server or Front End pool IP address)	Edge Server internal interface	Outbound SIP traffic (from Director, Director pool IP address, Front End Server or Front End pool IP address) to Edge Server internal interface
SIP/MTLS/TCP/5061	Edge Server internal interface	Any (can be defined as Director, Director pool IP address, Front End Server or Front	Inbound SIP traffic (to Director, Director pool IP address, Front End Server or Front End

		End pool IP address)	pool IP address) from Edge Server internal interface
PSOM/MTLS/TCP/8057	Any (can be defined as Front End Server IP address, or each Front End Server IP address in a Front End pool)	Edge Server internal interface	Web conferencing traffic from Front End Server or each Front End Server if in a pool, to Edge Server internal interface
SIP/MTLS/TCP/5062	Any (can be defined as Front End Server IP address, or Front End pool IP address or any Survivable Branch Appliance or Survivable Branch Server using this Edge Server)	Edge Server internal interface	Authentication of A/V users (A/V authentication service) from Front End Server or Front End pool IP address or any Survivable Branch Appliance or Survivable Branch Server using this Edge Server
STUN/MSTURN/ UDP/3478	Any	Edge Server internal interface	Preferred path for A/V media transfer between internal and external users, Survivable Branch Appliance or Survivable Branch Server
STUN/MSTURN/ TCP/443	Any	Edge Server internal interface	Fallback path for A/V media transfer between internal and external users, Survivable Branch Appliance or Survivable Branch Server if UDP communication cannot be established, TCP is used for file transfer and desktop sharing
HTTPS/TCP/4443	Any (can be defined as the Front End Server IP address, or pool that holds the Central Management store)	Edge Server internal interface	Replication of changes from the Central Management store to the Edge Server
MTLS/TCP/50001	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line

			(ClsController.exe) or agent (ClsAgent.exe) commands and log collection
MTLS/TCP/50002	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection
MTLS/TCP/50003	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection

Firewall Summary for Federation

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
Access/SIP(MTLS)/ TCP/5061	Access Edge service public IP address	Any	For federated and public IM connectivity using SIP

Firewall Summary – Public Instant Messaging Connectivity

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
Access/SIP(MTLS)/ TCP/5061	Public IM connectivity partners	Edge Server Access Edge service	For federated and public IM connectivity using SIP
Access/SIP(MTLS)/ TCP/5061	Edge Server Access Edge service	Public IM connectivity partners	For federated and public IM connectivity using SIP
Access/SIP(TLS)/ TCP/443	Clients	Edge Server Access Edge service	Client-to-server SIP traffic for external

			user access
A/V/RTP/TCP/50,000-59,999	Edge Server A/V Edge service	Live Messenger clients	Used for A/V sessions with Windows Live Messenger if public IM connectivity is configured.
A/V/STUN,MSTURN/UDP/3478	Edge Server A/V Edge service	Live Messenger clients	Required for public IM connectivity with Windows Live Messenger
A/V/STUN,MSTURN/UDP/3478	Live Messenger clients	Edge Server A/V Edge service	Required for public IM connectivity with Windows Live Messenger

Firewall Summary for Extensible Messaging and Presence Protocol

Protocol/TCP or UDP/Port	Source (IP address)	Destination (IP address)	Comments
XMPP/TCP/5269	Any	Edge Server Access Edge serviceinterface IP address	Standard server-to-server communication port for XMPP. Allows communication to the Edge Server XMPP proxy from federated XMPP partners
XMPP/TCP/5269	Edge Server Access Edge service interface IP address	Any	Standard server-to-server communication port for XMPP. Allows communication from the Edge Server XMPP proxy to federated XMPP partners
XMPP/MTLS/TCP/23456	Any	Each internal Edge Server Interface IP	Internal XMPP traffic from the XMPP Gateway on the Front End Server or Front End pool to the Edge Server internal IP address or each Edge pool member’s internal IP address

1.3.3.5.4 Port Summary - Single Consolidated Edge w ith Public IP Addresses

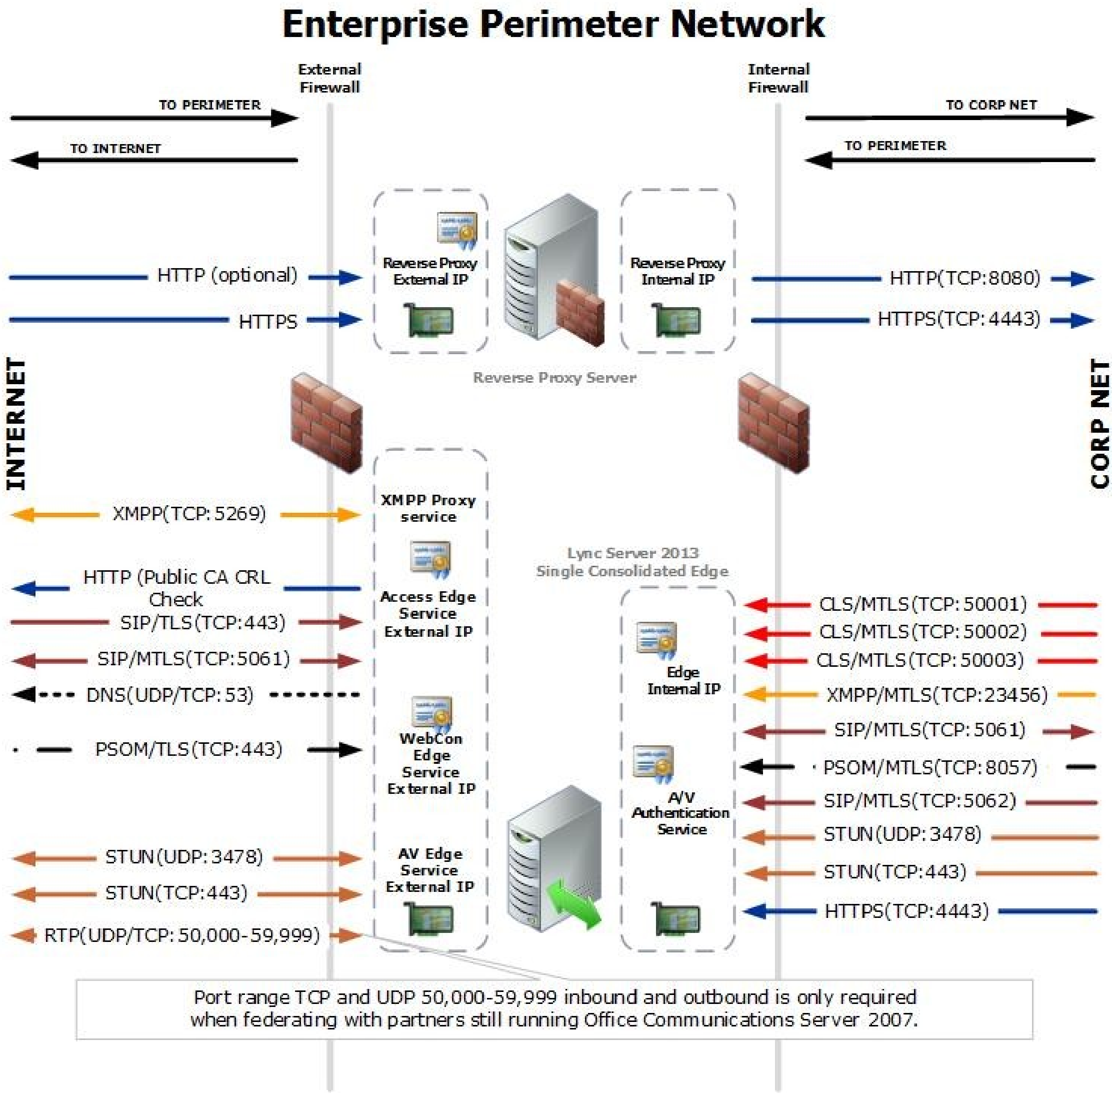
Port Summary - Single Consolidated Edge with Public IP Addresses

Planning > Network Planning for Lync Server > Port Requirements >

Topic Last Modified: *2013-02-21*

The Lync Server 2013, Edge Server functionality described in this scenario architecture is very similar to what was implemented in Lync Server 2010. The most noticeable addition is the port **5269 over TCP** entry for the extensible messaging and presence protocol (XMPP). Lync Server 2013 optionally deploys an XMPP proxy on the Edge Server or Edge pool and the XMPP gateway server on the Front End Server or Front End pool. Planning information for the reverse proxy and federation are found in Scenarios for Reverse Proxy and Scenarios for Federation, Public Instant Messaging Connectivity, and XMPP Federation sections, respectively.

In addition to IPv4, the Edge Server now supports IPv6. For clarity, only IPv4 is used in the scenarios.



Port range TCP and UDP 50,000-59,999 inbound and outbound is only required when federating with partners still running Office Communications Server 2007.

Port and Protocol Details

We recommend that you open only the ports required to support the functionality for which you are providing external access.

For remote access to work for any edge service, it is mandatory that SIP traffic is allowed to flow bidirectionally as shown in the Inbound/Outbound edge traffic figure. Stated another way, the SIP messaging to and from the Access Edge service is involved in instant messaging (IM), presence, web conferencing, audio/video (A/V) and federation.

Firewall Summary for Single Consolidated Edge with Public IP Addresses: External Interface

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
XMPP/TCP/5269	Any	XMPP Proxy service (shares IP address with Access Edge service)	XMPP Proxy service accepts traffic from XMPP contacts in defined XMPP federations
Access/HTTP/TCP/80	Edge Server Access Edge service public IP address	Any	Certificate revocation/ CRL check and retrieval
Access/DNS/TCP/53	Edge Server Access Edge service public IP address	Any	DNS query over TCP
Access/DNS/UDP/53	Edge Server Access Edge service public IP address	Any	DNS query over UDP
Access/SIP(TLS)/ TCP/443	Any	Edge Server Access Edge service public IP address	Client-to-server SIP traffic for external user access
Access/SIP(MTLS)/ TCP/5061	Any	Edge Server Access Edge service public IP address	For federated and public IM connectivity using SIP
Access/SIP(MTLS)/ TCP/5061	Edge Server Access Edge service public IP address	Any	For federated and public IM connectivity using SIP
Web Conferencing/ PSOM(TLS)/TCP/443	Any	Edge Server Web Conferencing Edge service public IP address	Web Conferencing media
A/V/RTP/TCP/50,000-59,999	Edge Server Access Edge service public IP address	Any	Required for federating with partners running Office Communications Server 2007, Office Communications Server 2007 R2, Lync Server 2010 and Lync Server 2013.
A/V/RTP/UDP/50,000-59,999	Edge Server A/V Edge service public IP address	Any	Required only for federation with partners running Office Communications

			Server 2007
A/V/RTP/TCP/50,000-59,999	Any	Edge Server A/V Edge service public IP address	Required only for federation with partners running Office Communications Server 2007.
A/V/RTP/UDP/50,000-59,999	Any	Edge Server A/V Edge service public IP address	Required only for federation with partners running Office Communications Server 2007.
A/V/STUN,MSTURN/UDP/3478	Edge Server A/V Edge service public IP address	Any	3478 outbound is used to determine the version of Edge Server that Lync Server is communicating with and also for media traffic from Edge Server-to-Edge Server. Required for federation with Lync Server 2010, Windows Live Messenger, and Office Communications Server 2007 R2, and also if multiple Edge pools are deployed within a company.
A/V/STUN,MSTURN/UDP/3478	Any	Edge Server A/V Edge service public IP address	STUN/TURN negotiation of candidates over UDP/3478
A/V/STUN,MSTURN/TCP/443	Any	Edge Server A/V Edge service public IP address	STUN/TURN negotiation of candidates over TCP/443
A/V/STUN,MSTURN/TCP/443	Edge Server A/V Edge service public IP address	Any	STUN/TURN negotiation of candidates over TCP/443

Firewall Summary for Single Consolidated Edge with Public IP Addresses: Internal Interface

Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Comments
XMPP/MTLS/TCP/23456	Any (can be defined as Standard Edition server IP, Standard Edition server IP	Edge Server internal interface	Outbound XMPP traffic from XMPP Gateway service running on Front End Server or

	address, or pool IP address running the XMPP Gateway service)		Front End pool
SIP/MTLS/TCP/5061	Any (can be defined as Director, Director pool IP address, Front End Server or Front End pool IP address)	Edge Server IP, or pool that holds the internal interface	Outbound SIP traffic (from Director, Director pool IP address, Front End Server or Front End pool IP address) to Edge Server internal interface
SIP/MTLS/TCP/5061	Edge Server internal interface	Any (can be defined as Director, Director pool IP address, Front End Server or Front End pool address)	Inbound SIP traffic (to Director, Director pool IP address, Front End Server or Front End pool IP address) from Edge Server internal interface
PSOM/MTLS/TCP/8057	Any (can be defined as Front End Server IP address, or each Front End Server IP address in a Front End pool)	Edge Server internal interface	Web conferencing traffic from Front End Server or each Front End Server if in a pool, to Edge Server internal interface
SIP/MTLS/TCP/5062	Any (can be defined as Front End Server IP address, or Front End pool IP address or any Survivable Branch Appliance or Survivable Branch Server using this Edge Server)	Edge Server internal interface	Authentication of A/V users (A/V authentication service) from Front End Server or Front End pool IP address or any Survivable Branch Appliance or Survivable Branch Server using this Edge Server
STUN/MSTURN/ UDP/3478	Any	Edge Server internal interface	Preferred path for A/V media transfer between internal and external users, Survivable Branch Appliance or Survivable Branch Server
STUN/MSTURN/ TCP/443	Any	Edge Server internal interface	Fallback path for A/V media transfer between internal and external users, Survivable Branch Appliance or Survivable Branch Server if UDP communication cannot be established, TCP is used for file transfer and desktop sharing

HTTPS/TCP/4443	Any (can be defined as the Front End Server IP address, or pool that holds the Central Management store)	Edge Server internal interface	Replication of changes from the Central Management store to the Edge Server
MTLS/TCP/50001	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection
MTLS/TCP/50002	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection
MTLS/TCP/50003	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection

Firewall Summary for Federation

Role/Protocol/TCP or UDP/Port	**Source IP address**	**Destination IP address**	**Notes**
Access/SIP(MTLS)/ TCP/5061	Access Edge service public IP address	Any	For federated and public IM connectivity using SIP

Firewall Summary – Public Instant

Messaging Connectivity

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
Access/SIP(MTLS)/ TCP/5061	Public IM connectivity partners	Edge Server Access Edge service	For federated and public IM connectivity using SIP
Access/SIP(MTLS)/ TCP/5061	Edge Server Access Edge service	Public IM connectivity partners	For federated and public IM connectivity using SIP
Access/SIP(TLS)/ TCP/443	Clients	Edge Server Access Edge service	Client-to-server SIP traffic for external user access
A/V/RTP/TCP/50,000-59,999	Edge Server A/V Edge service	Live Messenger clients	Used for A/V sessions with Windows Live Messenger if public IM connectivity is configured.
A/V/STUN,MSTURN/ UDP/3478	Edge Server A/V Edge service	Live Messenger clients	Required for public IM connectivity with Windows Live Messenger
A/V/STUN,MSTURN/ UDP/3478	Live Messenger clients	Edge Server A/V Edge service	Required for public IM connectivity with Windows Live Messenger

Firewall Summary for Extensible Messaging and Presence Protocol

Protocol/TCP or UDP/Port	Source (IP address)	Destination (IP address)	Comments
XMPP/TCP/5269	Any	Edge Server Access Edge service interface IP address	Standard server-to-server communication port for XMPP. Allows communication to the Edge Server XMPP proxy from federated XMPP partners
XMPP/TCP/5269	Edge Server Access Edge service interface IP address	Any	Standard server-to-server communication port for XMPP. Allows communication from the Edge Server XMPP proxy to federated XMPP partners
XMPP/MTLS/ TCP/23456	Any	Each internal Edge Server Interface IP	Internal XMPP traffic from the XMPP

			Gateway on the Front End Server or Front End pool to the Edge Server internal IP address or each Edge pool member’s internal IP address

1.3.3.5.5 Port Summary - Scaled Consolidated Edge, DNS Load Balancing w ith Private IP Addresses Using NAT

Port Summary - Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT

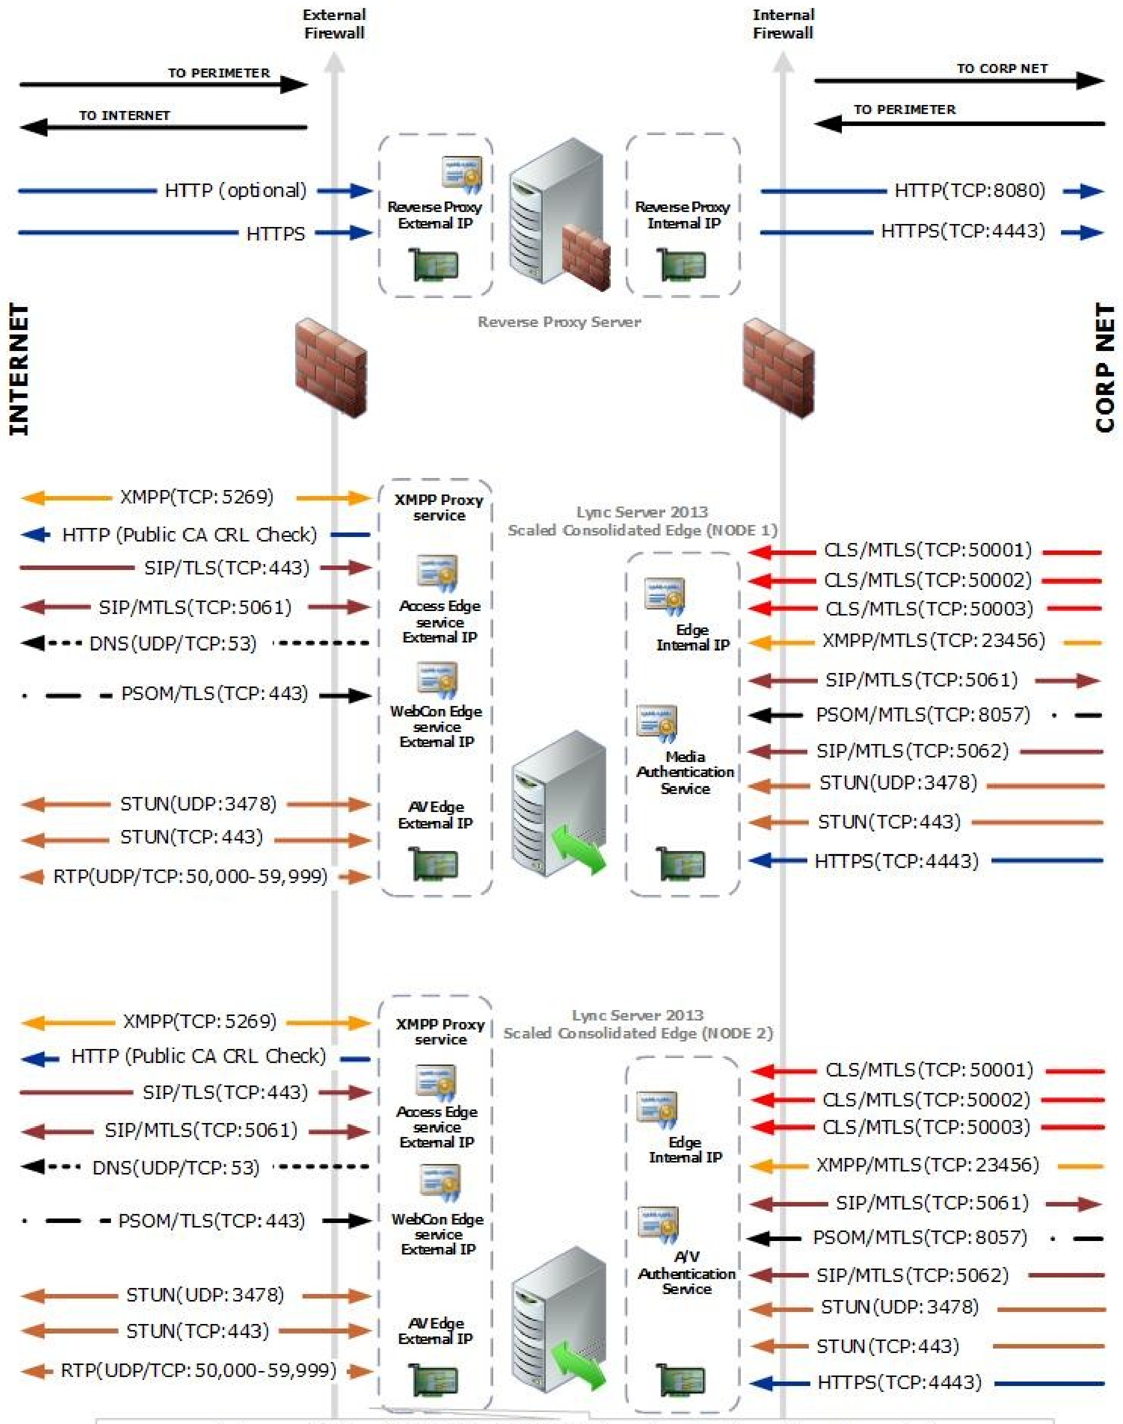
Planning > Network Planning for Lync Server > Port Requirements >

Topic Last Modified: *2012-12-04*

The Lync Server 2013, Edge Server functionality described in this scenario architecture is very similar to what was implemented in Lync Server 2010. The most noticeable addition is the port **5269 over TCP** entry for the extensible messaging and presence protocol (XMPP). Lync Server 2013 optionally deploys an XMPP proxy on the Edge Server or Edge pool and the XMPP gateway server on the Front End Server or Front End pool.

In addition to IPv4, the Edge Server now supports IPv6. For clarity, only IPv4 is used in the scenarios.

Enterprise Perimeter Network



Port range TCP and UDP 50,000-59,999 inbound and outbound is only required when federating with partners still running Office Communications Server 2007. (Applies to all nodes in the pool.)

Port and Protocol Details

It is recommended that you open only the ports required to support the functionality for

which you are providing external access.

For remote access to work for any edge service, it is mandatory that SIP traffic is allowed to flow bi-directionally as shown in the Inbound/Outbound edge traffic figure. Stated another way, the SIP messaging to and from the Access Edge service is involved in instant messaging (IM), presence, web conferencing, audio/video (A/V) and federation.

Firewall Summary for Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT: External Interface – Node 1 and Node 2 (Example)

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
XMPP/TCP/5269	Any	XMPP Proxy service (shares IP address with Access Edge service)	XMPP Proxy service accepts traffic from XMPP contacts in defined XMPP federations
XMPP/TCP/5269	XMPP Proxy service (shares IP address with Access Edge service)	Any	XMPP Proxy service sends traffic to XMPP contacts in defined XMPP federations
Access/HTTP/TCP/80	Edge Server Access Edge service	Any	Certificate revocation/ CRL check and retrieval
Access/DNS/TCP/53	Edge Server Access Edge service	Any	DNS query over TCP
Access/DNS/UDP/53	Edge Server Access Edge service	Any	DNS query over UDP
Access/SIP(TLS)/ TCP/443	Any	Edge Server Access Edge service	Client-to-server SIP traffic for external user access
Access/SIP(MTLS)/ TCP/5061	Any	Edge Server Access Edge service	For federated and public IM connectivity using SIP
Access/SIP(MTLS)/ TCP/5061	Edge Server Access Edge service	Any	For federated and public IM connectivity using SIP
Web Conferencing/ PSOM(TLS)/TCP/443	Any	Edge Server Web Conferencing Edge service	Web Conferencing media
A/V/RTP/TCP/50,000-59,999	Edge Server A/V Edge service	Any	Required for federating with partners running Office Communications Server 2007, Office Communications Server 2007 R2, Lync Server 2010 and Lync Server 2013.
A/V/RTP/UDP/50,000-	Edge Server A/V Edge	Any	Required only for

59,999	service		federation with partners running Office Communications Server 2007.
A/V/RTP/TCP/50,000-59,999	Any	Edge Server A/V Edge service	Required only for federation with partners running Office Communications Server 2007
A/V/RTP/UDP/50,000-59,999	Any	Edge Server A/V Edge service	Required only for federation with partners running Office Communications Server 2007
A/V/STUN,MSTURN/UDP/3478	Edge Server A/V Edge service	Any	3478 outbound is used to determine the version of Edge Server that Lync Server is communicating with and also for media traffic from Edge Server-to-Edge Server. Required for federation with Lync Server 2010, Windows Live Messenger, and Office Communications Server 2007 R2, and also if multiple Edge pools are deployed within a company.
A/V/STUN,MSTURN/UDP/3478	Any	Edge Server A/V Edge service	STUN/TURN negotiation of candidates over UDP/3478
A/V/STUN,MSTURN/TCP/443	Any	Edge Server A/V Edge service	STUN/TURN negotiation of candidates over TCP/443
A/V/STUN,MSTURN/TCP/443	Edge Server A/V Edge service	Any	STUN/TURN negotiation of candidates over TCP/443

Firewall Summary for Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT: Internal Interface – Node 1 and Node 2 (Example)

Protocol/TCP or	Source IP address	Destination IP	Comments

UDP/Port		**address**	
XMPP/MTLS/ TCP/23456	Any (can be defined as Front End Server address, or Front End pool IP address running the XMPP Gateway service)	Edge Server internal interface IP address	Outbound XMPP traffic from XMPP Gateway service running on Front End Server or Front End pool
SIP/MTLS/TCP/5061	Any (can be defined as Director, Director pool IP address, Front End Server or Front End pool IP address)	Edge Server internal interface	Outbound SIP traffic (from Director, Director pool IP address, Front End Server or Front End pool IP address) to Edge Server internal interface
SIP/MTLS/TCP/5061	Edge Server internal interface	Any (can be defined as Director, Director pool IP address, Front End Server or Front End pool IP address)	Inbound SIP traffic (to Director, Director pool IP address, Front End Server or Front End pool IP address) from Edge Server internal interface
PSOM/MTLS/TCP/8057	Any (can be defined as Front End Server IP address, or each Front End Server IP address in a Front End pool)	Edge Server internal interface	Web conferencing traffic from Front End Server or each Front End Server if in a pool, to Edge Server internal interface
SIP/MTLS/TCP/5062	Any (can be defined as Front End Server IP address, or Front End pool IP address or any Survivable Branch Appliance or Survivable Branch Server using this Edge Server)	Edge Server internal interface	Authentication of A/V users (A/V authentication service) from Front End Server or Front End pool IP address or any Survivable Branch Appliance or Survivable Branch Server using this Edge Server
STUN/MSTURN/ UDP/3478	Any	Edge Server internal interface	Preferred path for A/V media transfer between internal and external users, Survivable Branch Appliance or Survivable Branch Server
STUN/MSTURN/ TCP/443	Any	Edge Server internal interface	Fallback path for A/V media transfer between internal and external users, Survivable Branch Appliance or Survivable Branch

			Server if UDP communication cannot be established, TCP is used for file transfer and desktop sharing
HTTPS/TCP/4443	Any (can be defined as the Front End Server IP address, or pool that holds the Central Management store)	Edge Server internal interface	Replication of changes from the Central Management store to the Edge Server
MTLS/TCP/50001	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection
MTLS/TCP/50002	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection
MTLS/TCP/50003	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection

Firewall Summary for Federation

Role/Protocol/TCP or UDP/Port	**Source IP address**	**Destination IP address**	**Notes**
Access/SIP(MTLS)/	Access Edge service	Any	For federated and

TCP/5061	public IP address		public IM connectivity using SIP

Firewall Summary – Public Instant Messaging Connectivity

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
Access/SIP(MTLS)/ TCP/5061	Public IM connectivity partners	Edge Server Access Edge service	For federated and public IM connectivity using SIP
Access/SIP(MTLS)/ TCP/5061	Edge Server Access Edge service	Public IM connectivity partners	For federated and public IM connectivity using SIP
Access/SIP(TLS)/ TCP/443	Clients	Edge Server Access Edge service	Client-to-server SIP traffic for external user access
A/V/RTP/TCP/50,000-59,999	Edge Server A/V Edge service	Live Messenger clients	Used for A/V sessions with Windows Live Messenger if public IM connectivity is configured.
A/V/STUN,MSTURN/ UDP/3478	Edge Server A/V Edge service	Live Messenger clients	Required for public IM connectivity with Windows Live Messenger
A/V/STUN,MSTURN/ UDP/3478	Live Messenger clients	Edge Server A/V Edge service	Required for public IM connectivity with Windows Live Messenger

Firewall Summary for Extensible Messaging and Presence Protocol

Protocol/TCP or UDP/Port	Source (IP address)	Destination (IP address)	Comments
XMPP/TCP/5269	Any	Edge Server Access Edge service interface IP address	Standard server-to-server communication port for XMPP. Allows communication to the Edge Server XMPP proxy from federated XMPP partners
XMPP/TCP/5269	Edge Server Access Edge service interface IP address	Any	Standard server-to-server communication port for XMPP. Allows communication from

			the Edge Server XMPP proxy to federated XMPP partners
XMPP/MTLS/ TCP/23456	Any	Each internal Edge Server interface IP	Internal XMPP traffic from the XMPP Gateway on the Front End Server or Front End pool to the Edge Server internal IP address or each Edge pool member’s internal IP address

MTLS/TCP/50001	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection
MTLS/TCP/50002	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection
MTLS/TCP/50003	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection

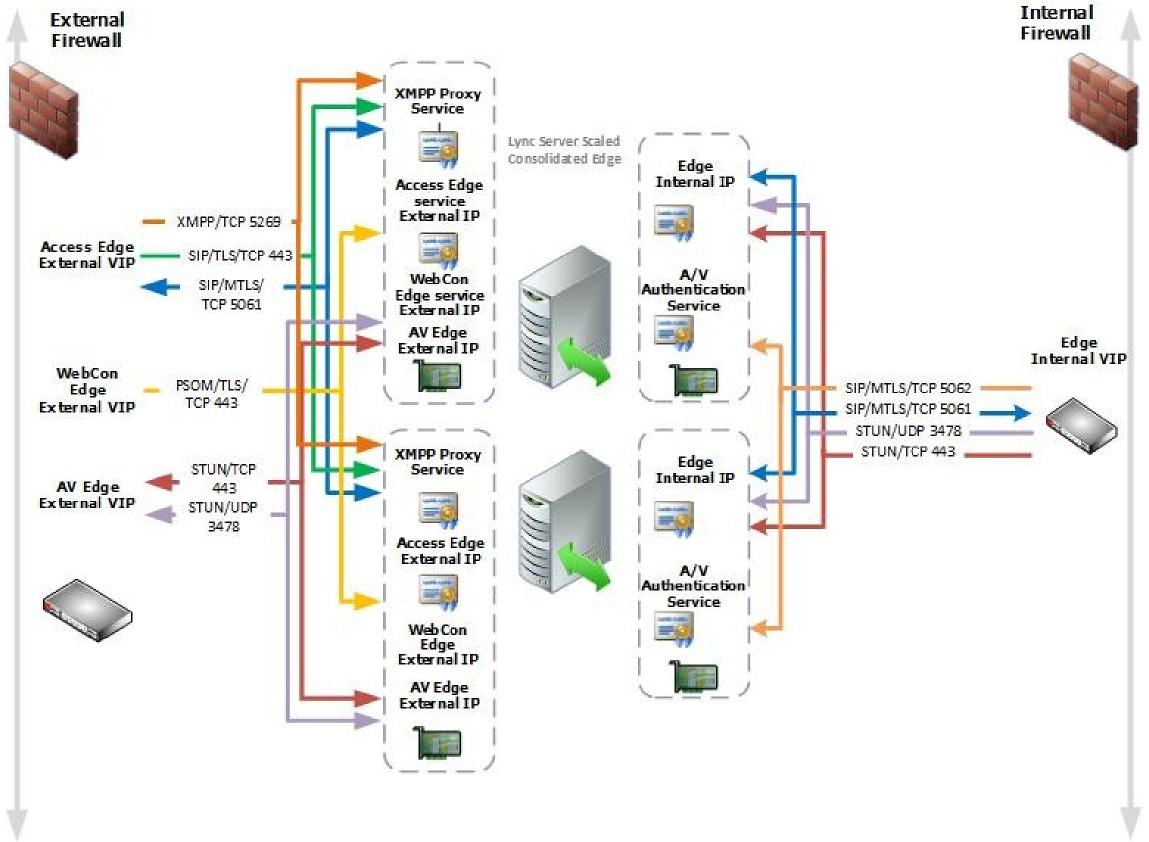
Hardware load balancers have specific requirements when deployed to provide availability and load balancing for Lync Server. The requirements are defined in the following figure and tables. Third party vendors may use different terminology for the requirements defined here. It will be necessary to map the requirements of Lync Server to the features and configuration options provided by your hardware load balancer vendor.

When configuring hardware load balancers, consider the following requirements:

- Source Network Address Translation (SNAT) can be configured on the hardware load balancer (HLB) for Access Edge service and Web Conferencing Edge service
- SNAT cannot be configured on the A/V Edge service– the A/V Edge service must respond with the real server address, not the HLB virtual IP (VIP), for simple traversal of UDP over NAT (STUN)/traversal using relay NAT (TURN)/ federation TURN (FTURN) to work properly
- Public IP addresses are used on each server interface and on the VIPs of the HLB, and your public IP address requirements are N+1, where there is a public IP address for each real server interface and one for each HLB VIP. Where you have 2 Edge servers in the pool, this results in 6 public IP addresses, where 3 are used for the HLB VIPs, and one for each Edge server interface (a total of six for the servers)
- For the Access Edge service and Web Conferencing Edge service, (and using NAT on the HLB) the client contacts the VIP, the VIP changes the source IP address from the client to its own IP address. The server interface addresses the return address to the VIP, the VIP changes the source address from the server interface IP address and sends the packet to the client
- For the A/V Edge service, the VIP must NOT change the source IP address, and the real server address is returned to the client directly – you cannot configure NAT on the HLB for AV traffic
- For AV, the external firewall will retain the real server public IP address for all packets
- Once established, client to A/V Edge service communication is to the real server, not the HLB
- Internal edge to internal servers and clients must be routed, and persistent routes are set for all internal networks that host servers or clients
- The HLB Access Edge service VIP will act as the default gateway for each Edge server interface



External Port Settings Required for Scaled Consolidated Edge, Hardware Load Balanced: External Interface Virtual IPs

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
XMPP/TCP/5269	Any	XMPP Proxy service (shares IP address with Access Edge service)	XMPP Proxy service accepts traffic from XMPP contacts in defined XMPP federations
XMPP/TCP/5269	XMPP Proxy service (shares IP address with Access Edge service)	Any	XMPP Proxy service sends traffic to XMPP contacts in defined XMPP federations
Access/SIP(TLS)/ TCP/443	Any	Access Edge service public VIP address	Client-to-server SIP traffic for external user access
Access/SIP(MTLS)/ TCP/5061	Any	Access Edge service public VIP address	SIP signaling, federated and public IM connectivity using SIP
Access/SIP(MTLS)/ TCP/5061	Access Edge service public VIP address	Federated partner	SIP signaling, federated and public IM connectivity using SIP

Web Conferencing/ PSOM(TLS)/TCP/443	Any	Edge Server Web Conferencing Edge service public VIP address	Web Conferencing media
A/V/STUN,MSTURN/ UDP/3478	Any	Edge Server A/V Edge service public VIP address	STUN/TURN negotiation of candidates over UDP/3478
A/V/STUN,MSTURN/ TCP/443	Any	Edge Server A/V Edge service public VIP address	STUN/TURN negotiation of candidates over TCP/443

Firewall Summary for Scaled Consolidated Edge, Hardware Load Balanced: Internal Interface Virtual IPs

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
Access/SIP(MTLS)/ TCP/5061	Any (can be defined as Director, Director pool virtual IP address, Front End Server or Front End pool virtual IP address)	Edge Server Internal VIP interface	Outbound SIP traffic (from Director, Director pool virtual IP address, Front End Server or Front End pool virtual IP address)to Internal Edge VIP
Access/SIP(MTLS)/ TCP/5061	Edge Server Internal VIP interface	Any (can be defined as Director, Director pool virtual IP address, Front End Server or Front End pool virtual IP address)	Inbound SIP traffic (to Director, Director pool virtual IP address, Front End Server or Front End pool virtual IP address) from Edge Server internal interface
SIP/MTLS/TCP/5062	Any (can be defined as Front End Server IP address, or Front End pool IP address or any Survivable Branch Appliance or Survivable Branch Server using this Edge Server)	Edge Server Internal VIP interface	Authentication of A/V users (A/V authentication service) from Front End Server or Front End pool IP address or any Survivable Branch Appliance or Survivable Branch Server using this Edge Server
STUN/MSTURN/ UDP/3478	Any	Edge Server Internal VIP interface	Preferred path for A/V media transfer between internal and external users
STUN/MSTURN/ TCP/443	Any	Edge Server Internal VIP interface	Fallback path for A/V media transfer between internal and external users if UDP communication cannot

			be established, TCP is used for file transfer and desktop sharing
STUN/MSTURN/ TCP/443	Edge Server Internal VIP interface	Any	Fallback path for A/V media transfer between internal and external users if UDP communication cannot be established, TCP is used for file transfer and desktop sharing

1.3.3.5.8 Port Summary - Reverse Proxy

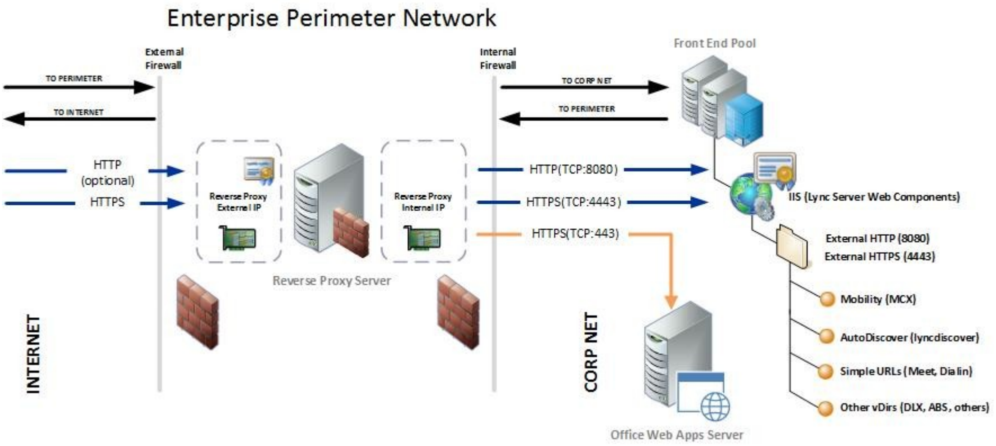
Port Summary - Reverse Proxy

Planning > Network Planning for Lync Server > Port Requirements >

Topic Last Modified: *2013-02-15*

The reverse proxy has minimal requirements for firewall and port/protocol.

- External firewall requirements are the HTTPS/TCP/443 and the optional HTTP/ TCP/80. HTTPS is used for SSL and TLS secure communications through the reverse proxy. HTTP is used if you choose to allow access to the Autodiscover Service when modifying certificates might prove difficult or not cost justified.
- Clients expect to contact the Office Web Apps Server on HTTPS. The Office Web Apps Server expects communication from internal clients on HTTPS/ TCP/443. The recommended configuration is to allow HTTPS/TCP/443 from the reverse proxy to the Office Web Apps Server.
- Port 8080 is used to route traffic from the reverse proxy internal interface to the Front End Server, Front End pool virtual IP (VIP) or the optional Director or Director pool VIP. Port TCP 8080 is required for mobile devices running Lync to locate the Autodiscover Service in situations where modifying the external web service publishing rule certificate is undesirable (for example, if you have a large number of SIP domains). If you choose to acquire new certificates with the necessary SAN entries, the port TCP 8080 is not needed and is optional.
- Port 4443 is used for traffic from the reverse proxy internal interface to the Front End Server, Front End pool virtual IP (VIP) or the optional Director or Director pool VIP



Caution:
Do not confuse the 4443 over TCP from the reverse proxy to the internal deployment for the port 4443 over TCP traffic from the Standard Edition server or the Front End pool that manages the Central Management store role.

Port and Protocol Details

Firewall Details for Reverse Proxy Server: External Interface

Protocol/TCP or UDP/Port	Source IP Address	Destination IP Address	Notes
HTTP/TCP/80	Any	Reverse proxy listener	(Optional) Redirection to HTTPS if user enters http://<*publishedSiteFQDN*>. Also required if using Office Web Apps for conferencing and the Autodiscover Service for mobile devices running Lync in situations where the organization does not want to modify the external web service publishing rule certificate.
HTTPS/TCP/443	Any	Reverse proxy listener	Address book downloads, Address Book Web Query service, Autodiscover, client updates, meeting content, device updates, group expansion, Office Web Apps for conferencing, dial-in conferencing, and meetings.

Firewall Details for Reverse Proxy Server: Internal Interface

Protocol/TCP or UDP/Port	Source IP Address	Destination IP Address	Notes
HTTP/TCP/8080	Internal reverse proxy interface	Front End Server, Front End pool, Director, Director pool	Required if using the Autodiscover Service for mobile devices running Lync in situations where the organization does not want to modify the external web service publishing rule certificate.

			Traffic sent to port 80 on the reverse proxy external interface is redirected to a pool on port 8080 from the reverse proxy internal interface so that the pool Web Services can distinguish it from internal web traffic.
HTTPS/TCP/4443	Internal reverse proxy interface	Front End Server, Front End pool, Director, Director pool	Traffic sent to port 443 on the reverse proxy external interface is redirected to a pool on port 4443 from the reverse proxy internal interface so that the pool web services can distinguish it from internal web traffic.
HTTPS/TCP/443	Internal reverse proxy interface	Office Web Apps for conferencing	

1.3.3.5.9 Port Summary - Lync Server and Office Communications Server Federation

Port Summary - Lync Server and Office Communications Server Federation

See Also

Planning > Network Planning for Lync Server > Port Requirements >

Topic Last Modified: *2012-10-20*

Port, protocol and firewall requirements for federation with Microsoft Lync Server 2013, Lync Server 2010 and Office Communications Server are similar to those for the deployed Edge Server. Clients initiate communication with the Access Edge service over TLS/SIP/TCP 443. Federated partners however, will initiate communications to the Access Edge service over MTLS/SIP/TCP 5061.

Firewall Summary for Federation

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
Access/SIP(MTLS)/TCP/5061	Access Edge service public IP address	Any	For federated and public IM connectivity using SIP

Scenarios for External User Access

1.3.3.5.10 Port Summary - Public Instant Messaging Connectivity

Port Summary - Public Instant Messaging Connectivity

See Also

Planning > Network Planning for Lync Server > Port Requirements >

Topic Last Modified: *2013-02-16*

To configure your firewall for ports and protocols necessary to support public instant messaging connectivity, first note that SIP/MTLS/TCP 5061 is bidirectional to account for the ability of contacts in the public IM provider to contact Lync clients, or for Lync to contact public IM contacts.

Windows Live Messenger can participate in audio/video communications with Lync clients. This accounts for the very similar firewall port and protocol configuration that you would typically have on the firewall to support Lync clients as external users.

> **Important:**
>
> More than ever, Lync is a powerful tool for connecting across organizations and with individuals around the world. Federation with Windows Live Messenger requires no additional user/device licenses beyond the Lync Standard Client Access License (CAL). Skype federation will be added to this list, enabling Lync users to reach hundreds of millions of people with IM and voice.
> Federation with Messenger client contacts will officially end on March 15, 2013, except for mainland China. Skype will become the federation client for federated users who previously used Messenger.

Firewall Summary – Public Instant Messaging Connectivity

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
Access/SIP(MTLS)/ TCP/5061	Public IM connectivity partners	Edge Server Access interface	For federated and public IM connectivity that use SIP.
Access/SIP(MTLS)/ TCP/5061	Edge Server Access interface	Public IM connectivity partners	For federated and public IM connectivity that use SIP.
Access/SIP(TLS)/ TCP/443	Clients	Edge Server Access interface	Client-to-server SIP traffic for external user access.
A/V/RTP/TCP/50,000-59,999	Edge Server Access interface	Live Messenger clients	Used for A/V sessions with Windows Live Messenger if public IM connectivity is configured.
A/V/STUN,MSTURN/ UDP/3478	Edge Server Access interface	Live Messenger clients	Required for public IM connectivity with Windows Live Messenger.
A/V/STUN,MSTURN/	Live Messenger	Edge Server Access	Required for public IM

UDP/3478	clients	interface	connectivity with Windows Live Messenger.

1.3.3.5.11 Port Summary - Extensible Messaging and Presence Protocol (XMPP) Federation

Port Summary - Extensible Messaging and Presence Protocol (XMPP) Federation

See Also

Planning > Network Planning for Lync Server > Port Requirements >

Topic Last Modified: *2012-10-20*

The ports and protocols defined for the extensible messaging and presence protocol (XMPP) proxy deployed on the Edge Server allow communications from the XMPP federated partner to the Edge Server, and also allows communication from your Edge Server to the XMPP federated partner. A rule is also defined on the internal-facing firewall from the Front End Server or Front End pool to the Edge Server or Edge pool.

Firewall Summary for Extensible Messaging and Presence Protocol

Protocol/TCP or UDP/Port	Source (IP address)	Destination (IP address)	Comments
XMPP/TCP/5269	Any	Access Edge service interface IP address	Standard server-to-server communication port for XMPP. Allows communication to the Edge Server XMPP proxy from federated XMPP partners
XMPP/TCP/5269	Access Edge service interface IP address	Any	Standard server-to-server communication port for XMPP. Allows communication from the Edge Server XMPP proxy to federated XMPP partners
XMPP/MTLS/23456	Any	Internal Edge Server Interface IP	Internal XMPP traffic from the XMPP Gateway on the Front End Server or Front End pool to the Edge Server

1.3.3.6 Network Bandwidth Requirements for Media Traffic

Network Bandwidth Requirements for Media Traffic

Microsoft Lync Server 2013 > Planning > Network Planning for Lync Server >

Topic Last Modified: *2012-10-22*

An important part of network planning is ensuring that your network can handle the media traffic generated by Lync Server. This section helps you plan for that media traffic.

Media Traffic Network Usage

The media traffic bandwidth usage can be challenging to calculate because of the number of different variables, such as codec usage, resolution, and activity levels. The bandwidth usage is a function of the codec used and the activity of the stream, both of which vary between scenarios. The following table lists the audio codecs commonly used in Lync Server 2013 scenarios.

Audio Codec Bandwidth

Audio codec	Scenarios	Audio payload bitrate (KBPS)	Bandwidth audio payload and IP header only (Kbps)	Bandwidth audio payload, IP header, UDP, RTP and SRTP (Kbps)	Bandwidth audio payload, IP header, UDP, RTP, SRTP and forward error correction (Kbps)
RTAudio Wideband	Peer-to-peer	29.0	45.0	57.0	86.0
RTAudio Narrowband	Peer-to-peer, PSTN	11.8	27.8	39.8	51.6
G.722	Conferencing	64.0	80.0	95.6	159.6
G.722 Stereo	Peer-to-peer, Conferencing	128.0	144.0	159.6	223.6
G.711	PSTN	64.0	80.0	92.0	156.0
Siren	Conferencing	16.0	32.0	47.6	63.6

The bandwidth numbers in the previous table are based on 20ms packetization (50 packets per second) and for Siren and G.722 include the additional secure real-time transport protocol (SRTP) overhead from conferencing scenarios and assume the stream is 100% active. Forward Error Correction (FEC) is dynamically used when there is packet loss on the link to help maintain the quality of the audio stream.

The stereo version of the G.722 codec is used by systems based on the Lync 2013 Meeting Room Edition, which enables stereo microphone capture to allow listeners to better distinguish multiple talkers in the meeting room.

For video, the default codec is the H.264/MPEG-4 Part 10 Advanced Video Coding standard together with its scalable video coding extensions for temporal scalability. To maintain interoperability with Lync 2010 or Office Communicator 2007 R2 clients, the RTVideo codec is still used for peer-to-peer calls between Lync 2013 and legacy clients. In conference sessions with both, Lync 2013 and legacy clients the Lync 2013 endpoint may encode the video using both video codecs and send the H.264 bitstream to the Lync 2013 and the RTVideo bitstream to Lync 2010 or Office Communicator 2007 R2 clients.

The bandwidth required depends on the resolution, quality, and frame rate. For each resolution, there are two interesting bit rates:

- **Maximum payload bitrate** This is the bitrate that a Lync 2013 endpoint will use for resolution at the maximum frame rate supported for this resolution. This value is interesting because it allows the highest quality and frame rate video.
- **Minimum payload bitrate** This is the bitrate below which a Lync 2013 endpoint will switch to the next lower resolution. In order to guarantee a certain resolution, the available video payload bitrate must not fall below this minimum bitrate for that resolution. This value is interesting so that you can understand the lowest value possible in cases where the maximum bitrate is not available or practical. For some users, such a low bitrate video might be considered an unacceptable video experience, so use caution when considering these minimum video payload bitrates. Note that for video scenes with little or no movement of the user the actual bitrate may temporarily also fall below the minimum bitrate.

Lync 2013 supports many more resolutions. This allows you to better adjust to different network bandwidth and receiving client capabilities. In addition the default aspect ratio for Lync 2013 has been changed to 16:9. The 4:3 aspect ratio is still supported for webcams which don't allow capture in 16:9 aspect ratio.

Video Resolution Bandwidth

Video codec	Resolution and aspect ratio	Maximum video payload bitrate (Kbps)	Minimum video payload bitrate (Kbps)
H.264	320x180 (16:9) 212x160 (4:3)	250	15
H.264/RTVideo	424x240 (16:9)) 320x240 (4:3	350	100
H.264	480x270 (16:9) 424x320 (4:3)	450	200
H.264/RTVideo	640x360 (16:9) 640x480 (4:3)	800	300
H.264	848x480 (16:9)	1500	400
H.264	960x540 (16:9)	2000	500
H.264/RTVideo	1280x720 (16:9)	2500	700
H.264	1920x1080 (16:9)	4000	500

H.264/RTVideo	960x144 (20:3)	500	15
H.264	1280x192 (20:3)	1000	250
H.264	1920x288 (20:3)	2000	500

Video FEC is included in the video payload bitrate when it is used so there are not separate values with video FEC and without video FEC.

Endpoints do not stream audio or video packets continuously. Depending on the scenario there are different levels of stream activity which indicate how often packets are sent for a stream. The activity of a stream depends on the media and the scenario, and does not depend on the codec being used. In a peer-to-peer scenario:

- Endpoints send audio streams only when the users speak.
- Both participants receive audio streams.
- If video is used, both endpoints send and receive video streams during the entire call.
- For video scenes with little or no movement the actual bitrate may temporarily be very low as the video codec will skip encoding regions of the video without change.

In a conferencing scenario:

- Endpoints send audio streams only when the users speak.
- All participants receive audio streams.
- If video is used, all participants can receive up to five receive video streams and one panoramic (for example, aspect ratio 20:3) video stream. By default the five receive video streams are based on active speaker history but users can also manually select the participants from which they want to receive a video stream.
- Each participant that turns on the user's send video stream will send one or more video streams. Lync 2013 add the capability of sending up to five video streams to optimize the video quality for all the receiving clients. The actual number of video streams being sent is determined by the sender based on CPU capability, available uplink bandwidth, and the number of receiving clients requesting a certain video stream. The most common case is that one H.264 and one RTVideo video stream are being sent in case a legacy client joins the conference. Another common scenario is that several H.264 video streams (for example, with different video resolutions) are sent to accommodate different receiver requests.

In addition to the bandwidth required for the real-time transport protocol (RTP) traffic for audio and video media, bandwidth is required for real-time transport control protocol (RTCP). RTCP is used for reporting statistics and out-of-band control of the RTP stream. For planning, use the bandwidth numbers in the following table for RTCP traffic. These values represent the maximum bandwidth used for RTCP and differ between audio and video streams because of differences in the control data

RTCP Bandwidth

Media	**RTCP maximum bandwidth (Kbps)**
Audio	5
Video (Only H.264 or RTVideo being sent/ received)	10
Video (H.264 and RTVideo being sent/ received)	15

For capacity planning purposes, the following two bandwidths are of interest:

- **Maximum bandwidth without FEC** The maximum bandwidth that a stream will consume, including the typical activity of the stream and the typical codec used in the scenario without FEC. This is the bandwidth when the stream is at 100% activity and there is no packet loss triggering the use of FEC. This is interesting for computing how much bandwidth must be allocated to allow the codec to be used in a given scenario.
- **Maximum bandwidth with FEC** The maximum bandwidth that a stream consumes, including the typical activity of the stream and the typical codec used in the scenario with FEC. This is the bandwidth when the stream is at 100% activity and there is packet loss triggering the use of FEC to improve quality. This is interesting for computing how much bandwidth must be allocated to allow the codec to be used in a given scenario and allow the use of FEC to preserve quality under packet-loss conditions.

The following tables also list an additional bandwidth value, **Typical bandwidth**. This is the average bandwidth that a stream consumes, including the typical activity of the stream and the typical codec used in the scenario. This bandwidth can be used for approximating how much bandwidth at any given time is being consumed by media traffic but should not be used for capacity planning, because individual calls will exceed this value when the activity level is higher than average. The typical video stream bandwidth in the tables below is based on a mix of different video resolutions as observed in measured customer data. For example, in peer-to-peer sessions a majority of users would use the default video render window whereas some percentage of users would increase or maximize the Lync application to allow higher video resolutions.

The following tables provide these three bandwidth values for the various scenarios.

Audio/Video Capacity Planning for Peer-to-Peer Sessions

Media	**Codec**	**Typical stream bandwidth (Kbps)**	**Maximum stream bandwidth without FEC**	**Maximum stream bandwidth with FEC**
Audio	RTAudio Wideband	39.8	62	91
Audio	RTAudio Narrowband	29.3	44.8	56.6
Main video when calling Lync 2013 endpoints	H.264	460	4010 (for maximum resolution of 1920x1080)	Not applicable
Main video when calling Lync 2010 or Office Communicator 2007 R2 endpoints	RTVideo	460	2510 (for maximum resolution of 1280x720)	Not applicable
Panoramic video when calling Lync 2013 endpoints	H.264	190	2010 (for maximum resolution of 1920x288)	Not applicable
Panoramic video when calling Lync 2010 or Office Communicator 2007 R2	RTVideo	190	510 (for maximum resolution of 960x144)	Not applicable

endpoints				

Audio/Video Capacity Planning for Conferences

Media	Typical codec	Typical stream bandwidth (Kbps)	Maximum stream bandwidth without FEC	Maximum stream bandwidth with FEC
Audio	G.722	46.1	100.6	164.6
Audio	Siren	25.5	52.6	68.6
Main video receive	H.264 and/or RTVideo	260	8015	Not applicable
Main video send	H.264 and/or RTVideo	270	8015	Not applicable
Panoramic video receive	H.264 and/or RTVideo	190	2010 (for maximum resolution of 1920x288)	Not applicable
Panoramic video send	H.264 and/or RTVideo	190	2515 (for sending bitstreams using multiple resolutions/ codecs	Not applicable

For the main video the typical and maximum stream bandwidth is the aggregated bandwidth over all received video streams and over all send video streams respectively. Even with multiple video streams the typical video bandwidth is smaller than in the peer-to-peer scenario because many video conferences are using content sharing that leads to much smaller video windows and thus smaller video resolutions. The maximum supported aggregated video payload bandwidth is 8000 Kbps for both, send and receive streams which would be used e.g. if there are two incoming 1920x1080p video streams.

The typical stream bandwidth for panoramic video is based on currently available devices that only stream up to 960x144 panoramic video. Once devices with 1920x288 panoramic video become available the typical stream bandwidth is expected to increase.

Audio Capacity Planning for PSTN

Media	Typical codec	Typical stream bandwidth (Kbps)	Maximum stream bandwidth without FEC	Maximum stream bandwidth with FEC
Audio	G.711	64.8	97	161
Audio	RTAudio Narrowband	30.9	44.8	56.6

The network bandwidth numbers in these tables represent one-way traffic only and include 5 Kbps for RTCP traffic overhead for each stream. For video the maximum video bit rate is used for computing the maximum stream.

1.3.3.7 Managing Quality of Service (QoS)

Managing Quality of Service (QoS)

Microsoft Lync Server 2013 > Planning > Network Planning for Lync Server >

Topic Last Modified: *2013-02-21*

Quality of Service (QoS) is a networking technology used in some organizations to help provide an optimal end-user experience for audio and video communications. QoS is most-commonly used on networks where bandwidth is limited: with a large number of network packets competing for a relatively small amount of available bandwidth, Quality of Service provides a way for administrators to assign higher priorities to packets carrying audio or video data. By giving these packets a higher priority, audio and video communications are likely to complete faster, and with less interruption, than network sessions involving things like file transfers, web browsing, or database backups. That's because network packets used for file transfers or database backups are assigned a "best effort" priority.

Note:

As a general rule, Quality of Service applies only to communication sessions on your internal network. When you implement QoS, you configure your servers and routers to support packet marking; however, you configure these devices to support packet marking in a particular manner. You cannot assume that Quality of Service will be supported on the Internet or on other networks. Even if Quality if Service is supported on other networks, there is no guarantee that QoS will be configured the same way that you configured the service on your network.

Microsoft Lync Server 2013 does not require Quality of Service; if you do not currently use QoS there is no requirement that you install the service before installing Lync Server 2013. If you experience a considerable amount of packet loss on your network the recommended way to alleviate this problem is to add additional bandwidth. If adding more bandwidth is not possible, then you might want to implement Quality of Service instead.

Lync Server 2013 offers full support for Quality of Service: that means that organizations that are already using QoS can easily integrate Lync Server into their existing network infrastructure. In order to do this you must perform the following tasks:

- Enabling QoS for Devices that Are Not Based on Windows. By default, QoS is disabled for computers and other devices (such as iPhones) that run other operating systems. Although you can use Lync Server to enable and disable Quality of Service for devices, you typically cannot use the product to modify the DSCP codes used by these devices.
- Configuring Port Ranges for Your Conferencing, Application, and Mediation Servers. You must reserve a unique set of ports for different packet types, such as audio and video. With Lync Server 2013 you do not enable or disable Quality of Service by, say, setting a property value to True or to False. Instead, you enable Quality of Service by configuring port ranges and then creating and applying Group Policy. If you later decide not to use QoS you can “disable” Quality of Service simply by removing the appropriate Group Policy objects.
- Configuring Port Ranges for Your Edge Servers. Although not required, you can configure your Edge servers to use the same port ranges as your other servers.
- Configuring Port Ranges for Your Microsoft Lync Clients. These port ranges apply only to client computers and are typically not the same as the port ranges configured on your servers.
- Configuring a Quality of Service Policy for Your Conferencing, Application, and Mediation Servers. These policies determine the DSCP codes that are applied to different packet types.

- Configuring a Quality of Service Policy for Your A/V Edge Servers. This should only be done for the internal side of your Edge servers. That's because Quality of Service is designed for use on your internal network and not on the Internet.
- Configuring Quality of Service Policies for Clients Running on Windows 7 or Windows 8. Note that Microsoft Lync Server 2013 does not support QoS for other Windows operating systems, such as Windows Vista or Windows XP.
- Configuring Quality of Service on Microsoft Lync Phone Edition Devices. By default, QoS is enabled for Lync Phone Edition devices. However, you might want to change the default DSCP value in order to ensure that all audio packets in your organization use the same DSCP code.

Note:

If you are using Microsoft Windows Server 2012 you might be interested in the new set of Windows PowerShell cmdlets available for managing Quality of Service on that platform. For more information, see Network Quality of Service Cmdlets in Windows PowerShell at http://go.microsoft.com/fwlink/p/?LinkId=285379.

1.3.4 Capacity Planning

Capacity Planning

Microsoft Lync Server 2013 > Planning >

Topic Last Modified: *2012-10-04*

The topics in this section help you understand how to plan and deploy Lync Server 2013 so that you can adequately plan for the number of users in your organization and plan for the server load that their activities generate.

- Capacity Planning Using the User Models
- Estimating Voice Usage and Traffic
- Deployment Guidelines for Mediation Server
- Lync Server 2013 User Models

1.3.4.1 Capacity Planning Using the User Models

Capacity Planning Using the User Models

Microsoft Lync Server 2013 > Planning > Capacity Planning >

Topic Last Modified: *2013-03-12*

This section provides guidance on how many servers you need at a site for the number of users at that site, according to the usage described in Lync Server 2013 User Models.

Tested Hardware Platform

All the performance results and deployment recommendations in this section are based on performance testing on servers running the hardware described in the following table. We recommend that you use similar hardware. If you use less powerful hardware, you may experience functionality problems or poor performance. Note that these hardware recommendations are higher than those of previous versions of Lync Server.

Hardware Used in Performance Testing

Hardware component	Recommended
CPU	64-bit dual processor, hex-core, 2.26 gigahertz

	(GHz) or higher Intel Itanium processors are not supported for Lync Server server roles.
Memory	32 gigabytes (GB)
Disk	• 8 or more 10,000-RPM hard disk drives with at least 72 GB free disk space. Two of the disks should use RAID 1, and six should use RAID 10. - OR - • Solid state drives (SSDs) which provide performance similar to 8 10,000-RPM mechanical disk drives.
Network	• 1 dual-port network adapter, 1 Gbps or higher (2 recommended, which requires teaming with a single MAC address and single IP address)

Summary of Results

The following table summarizes these recommendations.

Server role	Maximum number of users supported
Front End pool with twelve Front End Servers and one Back End Server or a mirrored pair of Back End Servers.	80,000 unique users simultaneously logged in, plus 50% multiple points of presence (MPOP) representing non-mobile instances, plus 40% of users enabled for Mobility for a total of 152,000 endpoints.
A/V Conferencing	The A/V Conferencing service provided by a Front End pool supports the pool's conferences assuming a maximum conference size of 250 users, and only one such large conference running at a time. **Note:** Additionally, you can support large conferences of between 250 and 1000 users by deploying a separate Front End pool with two Front End Servers to host the large conferences. For details, see Supporting Large Meetings Using Lync Server 2013.
One Edge Server	12,000 concurrent remote users
One Director	12,000 concurrent remote users
Monitoring and Archiving	In Lync Server 2013, the Monitoring and Archiving front end services now run on each Front End Server, instead of on separate server roles. Monitoring and Archiving each still require their own database stores. If you also run Exchange 2013, you can keep your Archiving data in Exchange, rather than in a dedicated SQL database.

One Mediation Server	Mediation Server collocated with Front End Server runs on every Front End Server in a pool, and should provide enough capacity for the users in the pool. For stand-alone Mediation Server, see the "Mediation Server" section later in this topic.
One Standard Edition server	We strongly recommend that if you use Standard Edition servers to host users, you always use two servers, paired using the recommendations in Planning for High Availability and Disaster Recovery. Each server in the pair can host up to 2,500 users, and if one server fails the remaining server can support 5,000 users in a failover scenario. If your deployment includes a lot of audio or video traffic, server performance may suffer even if you have fewer than 2,500 users per server. In this case, you should consider adding more Standard Edition servers or moving to Lync Server Enterprise Edition.

Front End Server

In a Front End pool, you should have one Front End Server for every 6,660 users homed in the pool, assuming that hyper-threading is enabled on all servers in the pool, and that the server hardware meets the recommendations in Server Hardware Platforms. The maximum number of users in one Front End pool is 80,000, assuming that hyper-threading is enabled on all the servers in the pool. If you have more than 80,000 users at a site, you can deploy more than one Front End pool.

When you account for the number of users in a Front End pool, include the users homed on Survivable Branch Appliances and Survivable Branch Servers at branch offices that are associated with this Front End pool.

When an active server is unavailable, its connections are transferred automatically to the other servers in the pool. For example, if you have 30,000 users and five Front End Servers, then if one server is unavailable, the connections of 6000 users need to be transferred to the other four servers. The remaining four servers will each have 7500 users, which is a larger number than recommended.

If instead you had started with six Front End Servers for your 30,000 users and subsequently one became unavailable, a total of 5000 users will be moved to the remaining five servers. These five servers will each host 6000 users, which is in the recommended range.

The maximum number of users in a Front End pool is 80,000. The maximum number of Front End Servers in a pool is 12.

For a Front End pool with 80,000 users, twelve Front End Servers is sufficient for performance, in typical deployments that follow the Lync Server 2013 User Models. Deployments designed to support disaster recovery failover assume that a maximum of 40,000 users can be hosted in each of two paired Front End pools, in which each pool has enough Front End Servers to accommodate the users in both pools should one pool need to be failed over to the other.

The number of users supported with good performance by a particular Front End pool may differ from these numbers for the following reasons:

- The hardware for your Front End Servers does not meet the recommendations in Server Hardware Platforms.
- Your organization’s usage differs significantly from the user models, such as significantly more conferencing traffic.

Important:

In Lync Server 2013, the presence databases are now hosted on Front End Servers, unlike in Lync Server 2010 where they were hosted on the Back End Server. This means that the disk performance and capacity of your Front End Servers should not be compromised from the recommendations listed earlier in this section and in Server Hardware Platforms, regardless of the number of users hosted by your Front End Servers.

The following table shows the average bandwidth for IM and presence, given the user model, as defined in Lync Server 2013 User Models.

Average bandwidth per user	Bandwidth requirements per Front End Server with 6,660 users
1.3 Kpbs	13 Mbps

Note:

To improve the media performance of the co-located A/V Conferencing and Mediation Server functionality on your Front End Servers, you should enable receive-side scaling (RSS) on the network adapters on your Front End Servers. RSS enables incoming packets to be handled in parallel by multiple processors on the server. For details, see "Receive-Side Scaling Enhancements in Windows Server 2008" at http://go.microsoft.com/fwlink/p/?linkId=268731. For details about how to enable RSS, see your network adapter documentation.

Conferencing Maximums

Given the user model that 5% of users in a pool may be in a conference at any one time, a pool of 80,000 users could have about 4,000 users in conferences at one time. These conferences are expected to be a mix of media (some IM-only, some IM with audio, some audio/video, for example) and number of participants. There is no hard limit for the actual number of conferences allowed, and actual usage determines the actual performance. For example, if your organization has many more mixed-mode conferences than are assumed in the user model, you might need to deploy more Front End Servers or A/V Conferencing Servers than the recommendations in this document. For details about the assumptions in the user model, see Lync Server 2013 User Models.

The maximum supported conference size hosted by a regular Lync Server 2013 Front End pool which also hosts users is 250 participants. While a 250-user conference is happening, the pool still supports other conferences as well, such that a total of 5% of pool users are in concurrent conferences. For example, in a pool of twelve Front End Servers and 80,000 users, while the 250-user conference is happening, Lync Server supports 3,750 other users participating in smaller conferences.

Regardless of the number of users homed on the Front End pool or Standard Edition server, Lync Server supports a minimum of 125 other users participating in smaller conferences on the same pool or server which is hosting a 250-user conference.

To enable conferences with between 250 and 1000 users, you can set up a separate Front End pool just to host those conferences. This Front End pool will not host any users. For details, see Supporting Large Meetings Using Lync Server 2013.

If your organization has many more mixed-mode conferences than are assumed in the user model, you might need to deploy more Front End Servers than the recommendations in this document (up to a limit of 12 FEs). For details about the assumptions in the user model, see Lync Server 2013 User Models.

Edge Server

You should deploy one Edge Server for every 12,000 remote users who will access a site concurrently. At a minimum we recommend two Edge Servers for high availability. These recommendations assume that the hardware for your Edge Servers meets the recommendations in Server Hardware Platforms.

When you account for the number of users for the Edge Servers, include the users homed on Survivable Branch Appliances and Survivable Branch Servers at branch offices that are associated with a Front End pool at this site.

Note:
To improve the performance of the A/V Conferencing Edge service on your Edge Servers, you should enable receive-side scaling (RSS) on the network adapters on your Edge Servers. RSS enables incoming packets to be handled in parallel by multiple processors on the server. For details, see "Receive-Side Scaling Enhancements in Windows Server 2008" at http://go.microsoft.com/fwlink/p/?linkId=268731. For details about how to enable RSS, see your network adapter documentation.

Director

If you deploy the Director server role we recommend that you deploy one Director for every 12,000 remote users who will access a site concurrently. At a minimum we recommend two Directors for high availability. These recommendations assume that the hardware for your Edge Servers meets the recommendations in Server Hardware Platforms.

When you account for the number of users for the Directors, include the users homed on Survivable Branch Appliances and Survivable Branch Servers at branch offices that are associated with a Front End pool at this site.

Mediation Server

If you collocate Mediation Server with Front End Server, Mediation Server runs on every Front End Server in the pool, and should provide enough capacity for the users in the pool.

If you deploy a stand-alone Mediation Server pool, then how many Mediation Servers to deploy depends on many factors, including the hardware used for Mediation Server, the number of VoIP users you have, the number of gateway peers that each Mediation Server pool controls, the busy hour traffic through those gateways, and the percentage of calls with media that bypasses the Mediation Server.

The following tables provide a guideline for how many concurrent calls a Mediation Server can handle, assuming that the hardware for the Mediation Servers meets the requirements in Server Hardware Platforms and that hyper-threading is enabled. For details about Mediation Server scalability, see Estimating Voice Usage and Traffic and Deployment Guidelines for Mediation Server.

All the following tables assume usage as summarized in Lync Server 2013 User Models.

Stand-alone Mediation Server Capacity: 70% Internal Users, 30%

External users with non-bypass call capacity (media transcoding performed by Mediation Server)

Server hardware	Maximum number of calls	Maximum number of T1 lines	Maximum number of E1 lines
Dual processor, hex core, 2.26 GHz hyper-threaded CPU **with hyper-threading disabled**, with 32 GB memory and one dual-port network adapter card.	1100	46	35
Dual processor, hex core, 2.26 GHz hyper-threaded CPU, with 32 GB memory and one dual-port network adapter card.	1500	63	47

Note:
Although servers with 32 GB of memory were used for performance testing, servers with 16 GB of memory are supported for stand-alone Mediation Server, and are sufficient to provide the performance shown in this table.

Mediation Server Capacity (Mediation Server Collocated with Front End Server) 70% Internal Users, 30% External Users, Non-Bypass Call Capacity (Media Processing Performed by Mediation Server)

Server hardware	Maximum number of calls
Dual processor, hex core, 2.26 GHz hyper-threaded CPU, with 32 GB memory and 2 1GB network adapter cards.	150

Note:
This number is much smaller than the numbers for the stand-alone Mediation Server because the Front End Server has to handle other features and functions for the 6600 users homed on it, in addition to the transcoding needed for voice calls.

Note:
To improve the performance of the Mediation Server, you should enable receive-side scaling (RSS) on the network adapters on your Mediation Servers. RSS enables incoming packets to be handled in parallel by multiple processors on the server. For details, see "Receive-Side Scaling Enhancements in Windows Server 2008" at http://go.microsoft.com/fwlink/p/?linkId=268731. For details about how to enable RSS, see your network adapter documentation.

Back End Server

In Lync Server 2013, the presence databases are located on the Front End Servers instead of the Back End Server. This has resulted in a much simpler requirement for each Back End Server in Lync Server 2013, equivalent to the hardware requirement for the Front End Server. Contrast this to Lync Server 2010, where the Back End Server was required to be a much higher grade server with 25 disks. However, the workload of Back End Servers is still such that you should not fail to meet the hardware recommendations listed earlier in this section and in Server Hardware Platforms.

To provide high availability of your Back End Server, we recommend deploying server mirroring. For more information, see Back End Server High Availability.

Monitoring and Archiving

In Lync Server 2013, if you deploy Monitoring or Archiving, the front end functionality of these services runs on the Front End Servers, instead of on separate server roles. Monitoring and Archiving each still use their own database store, separate from the Back End store. Alternatively, if you have Exchange 2013 deployed, you can store instant message Archiving data in Exchange instead of in a dedicated SQL store.

The following table indicates approximately how much database storage is required per user per day for Monitoring and Archiving data.

	CDR (Monitoring)	**QoE (Monitoring)**	**Archiving**
Disk space required per user per day	49 KB	28 KB	57 KB

Microsoft used the hardware in the following table for the database server for Monitoring and Archiving during its performance testing. The testing collected the data of two Front End pools, each of which contained 80,000 users.

Hardware Used in Monitoring and Archiving Performance Testing

<table>
<tr><th>Hardware component</th><th>Recommended</th></tr>
<tr><td>CPU</td><td>64-bit dual processor, hex-core, 2.26 gigahertz (GHz) or higher</td></tr>
<tr><td>Memory</td><td>48 gigabytes (GB)</td></tr>
<tr><td>Disk</td><td>25 10,000-RPM hard disk drives with 300 GB on each disk, with the following configuration
<table>
<tr><th>Drive</th><th>RAID Configuration</th><th>Number of disks</th></tr>
<tr><td>CDR, QoE, and Archiving database data files, on a single drive</td><td>1+0</td><td>16</td></tr>
<tr><td>CDR database log file</td><td>1</td><td>2</td></tr>
<tr><td>QoE database log file</td><td>1</td><td>2</td></tr>
<tr><td>Archiving database log file</td><td>1</td><td>2</td></tr>
</table></td></tr>
<tr><td>Network</td><td><ul><li>1 dual-port network adapter, 1 Gbps or higher (2 recommended, which requires teaming with a single MAC address and single IP address)</li></ul></td></tr>
</table>

1.3.4.1.1 Estimating Voice Usage and Traffic

Estimating Voice Usage and Traffic

Planning > Capacity Planning > Capacity Planning Using the User Models >

Topic Last Modified: *2012-08-07*

The Microsoft Lync Server 2013, Planning Tool uses the following metric to estimate user traffic at each site and the number of ports that are required to support that traffic.

- For **Light traffic** (one PSTN call per user per hour), figure 15 users per port.
- For **Medium traffic** (2 PSTN calls per user per hour), figure 10 users per port.
- For **Heavy traffic** (3 or more PSTN per user calls per hour), figure 5 users per port.

The number of ports in turn determines the number of Mediation Servers and gateways that will be required. The public switched telephone network (PSTN) gateways that most organizations consider deploying range in size from 2 ports to as many as 960 ports. (There are even larger gateways, but these are used mainly by telephony service providers.)

For example, an organization with 10,000 users and medium traffic would require 1000 ports. The number of gateways required would equal the total number of ports required as determined by the total capacity of the gateways.

1.3.4.1.2 Deployment Guidelines for Mediation Server

Deployment Guidelines for Mediation Server

Planning > Capacity Planning > Capacity Planning Using the User Models >

Topic Last Modified: *2012-10-12*

This topic describes planning guidelines for Mediation Server deployment. After reviewing these guidelines, we recommend that you use the Planning Tool to create and view possible alternative topologies, which can serve as models for what the final tailored topology that you decide to deploy would look like.

Collocated or Stand-alone Mediation Server?

Mediation Server is by default collocated on the Standard Edition server or Front End Server in a Front End pool at central sites. The number of public switched telephone network (PSTN) calls that can be handled and the number of machines required in the pool will depend on the following:

- The number of gateway peers that the Mediation Server pool controls
- The high-volume traffic periods through those gateways
- The percentage of calls that are calls whose media bypass the Mediation

Server

When planning, be sure to take into account the media processing requirements for PSTN calls and A/V conferences that are not configured for media bypass, as well as the processing needed to handle signaling interactions for the number of busy-hour calls that need to be supported. If there is not enough CPU, then you must deploy a stand-alone pool of Mediation Servers; and PSTN gateways, IP-PBXs, and SBCs will need to be split into subsets that are controlled by the collocated Mediation Servers in one pool and the stand-alone Mediation Servers in one or more stand-alone pools.

If you deployed PSTN gateways, IP-PBXs, or Session Border Controllers (SBCs) that do not support the correct capabilities to interact with a pool of Mediation Servers, including the following, then they will need to be associated with a stand-alone pool consisting of a single Mediation Server:

- Perform network layer Domain Name System (DNS) load balancing across Mediation Servers in a pool (or otherwise route traffic uniformly to all Mediation Servers in a pool)
- Accept traffic from any Mediation Server in a pool

You can use the Microsoft Lync Server 2013, Planning Tool to evaluate whether collocating the Mediation Server with your Front End pool can handle the load. If your environment cannot meet these requirements, then you must deploy a stand-alone Mediation Server pool.

Central Site and Branch Site Considerations

Mediation Servers at the central site can be used to route calls for IP-PBXs or PSTN gateways at branch sites. If you deploy SIP trunks, however, you must deploy a Mediation Server at the site where each trunk terminates. Having a Mediation Server at the central site route calls for an IP-PBX or PSTN gateway at a branch site does not require the use of media bypass. However, if you can enable media bypass, doing so will reduce media path latency and, consequently, result in improved media quality because the media path is no longer required to follow the signaling path. Media bypass will also decrease the processing load on the pool.

Note:

Media bypass will not interoperate with every PSTN gateway, IP-PBX, and SBC. Microsoft has tested a set of PSTN gateways and SBCs with certified partners and has done some testing with Cisco IP-PBXs. Media bypass is supported only with products and versions listed on Unified Communications Open Interoperability Program – Lync Server at http://go.microsoft.com/fwlink/p/?LinkId=268730.

If branch site resiliency is required, a Survivable Branch Appliance or combination of a Front End Server, a Mediation Server, and a gateway must be deployed at the branch site. (The assumption with branch site resiliency is that presence and conferencing are not resilient at the site.) For guidance on branch site planning for voice, see Planning for Branch-Site Voice Resiliency.

For interactions with an IP-PBX, if the IP-PBX does not correctly support early media interactions with multiple early dialogs and RFC 3960 interactions, there can be clipping of the first few words of the greeting for incoming calls from the IP-PBX to Lync endpoints. This behavior can be more severe if a Mediation Server at a central site is routing calls for an IP-PBX where the route terminates at a branch site, because more time is needed for signaling to complete. If you experience this behavior, deploying a Mediation Server at the branch site is the only way to reduce clipping of the first few words.

Finally, if your central site has a TDM PBX, or if your IP-PBX does not eliminate the need for a PSTN gateway, then you must deploy a gateway on the call route connecting Mediation Server and the PBX.

Note:
To improve the media performance of standalone Mediation Server, you should enable receive-side scaling (RSS) on the network adapters on these servers. RSS enables incoming packets to be handled in parallel by multiple processors on the server. For details, see "Receive-Side Scaling Enhancements in Windows Server" at http://go.microsoft.com/fwlink/p/?LinkId=268731. For details about how to enable RSS, see your network adapter documentation.

1.3.4.2 Lync Server 2013 User Models

Lync Server 2013 User Models

Microsoft Lync Server 2013 > Planning > Capacity Planning >

Topic Last Modified: *2013-01-11*

The user models described here provide the basis for the capacity planning measurements and recommendations described in Capacity Planning Using the User Models.

Lync Server 2013 User Models

The following table describes the user model for registration, contacts, instant messaging (IM), and presence for Lync Server 2013.

Environment and Registration User Model

Category	Description
Deployment size and distribution	We model a large deployment with three central sites, with one Front End pool per site.
Percentage of Active Directory users	We assume that 70% of all Active Directory users in the organization are enabled for Lync Server. 80% of those enabled users are logged on to Lync Server each day (80% concurrency). The concurrent users are the basis for the numbers in the rest of this section.
Active Directory changes	We assume that 0.5% of total users are created and enabled for Lync in Active Directory each week, and that 0.5% of total users are disabled from Active Directory and from Lync each week. 5% of users have at least one Active Directory attribute changed each week.
Active Directory distribution groups	We assume that the number of Active Directory distribution groups in the organization is equal to three times the number of all users in Active Directory. The distribution groups have the following sizes: • 64% have 2-30 users • 13% have 31-50 users • 10% have 51-100 users • 13% have 101-500 users
Voice over IP (VoIP) users	60% of Lync Server users are enabled for unified communications (UC) (that is, their phone numbers are owned by Lync Server).
Registered client distribution	65% of clients run Lync 2013 software, including Lync and Lync Phone Edition.

	30% of clients running client software from a previous version of Lync. 5% of clients using Lync Web App. If mobility is enabled, we assume that 40% of users are using mobility concurrently with the other previously cited registered client options. In this case the client multiple point of presence (MPOP) ratio is 1:1.9. If mobility is disabled, the MPOP ratio is 1:1.5.
Remote user distribution	70% of users connecting internally. 30% of users connecting through an Edge Server and a Director.
Contact distribution	The maximum number of contacts a user has is 1,000. Less than 1% of users have 1,000 contacts. Less than 25% of users have 100 or more contacts. Average of 80 contacts for users with public cloud connectivity. Of these users: • 50% of the contacts are within the organization. 10% of those users are remote users, connecting from outside the firewall. • 40% of the contacts are public cloud users (such as users of AOL, Yahoo!, MSN, or Google Talk). • 10% of the contacts are from federated partners. **Important:** • As of September 1st, 2012, the Microsoft Lync Public IM Connectivity User Subscription License ("PIC USL") is no longer available for purchase for new or renewing agreements. Customers with active licenses will be able to continue to federate with Yahoo! Messenger until the service shut down date (exact date TBD, but no sooner than June 2013). • The PIC USL is a per-user per-month subscription license that is required for Lync Server or Office Communications Server to federate with Yahoo! Messenger. Microsoft's ability to provide this service has been contingent upon support from Yahoo!, the underlying agreement for which is winding down. • More than ever, Lync is a powerful tool for connecting across organizations and with individuals around the world.

	Federation with Windows Live Messenger requires no additional user/device licenses beyond the Lync Standard CAL. Skype federation will be added to this list, enabling Lync users to reach hundreds of millions of people with IM and voice. Average of 50 contacts for users without public cloud connectivity. Of these users: • 80% of the contacts are within the organization. 10% of those users are remote users, connecting from outside the firewall. • 20% of the contacts are from federated partners. Each user has 1 distribution group in their contact list. For performance testing, we assume that distribution groups are always expanded. 25% of a user's contacts use XMPP.
Session time	The average user logon session lasts 12 hours. All users log on within 120 minutes of the start of the session.

IM and Presence User Model

Category	Description
Peer-to-peer IM sessions	Each user averages six peer-to-peer IM sessions per day. 10 instant messages per session. Each message is matched by two SIP INFO messages and 2 SIP 200 OK messages (for the status indicators such as "<Name> is Typing")
Presence polling	Overall, we assume presence polling at an average of 60 polls per user per hour. For each user, assume an average of: • One poll per day of the presence of users in the user's organization tab (but not Contacts list). Average number of non-contacts in the user's organization tab is 15 users. Two contact card viewing operations per day. • One presence poll every time the user clicks another user to start a conversation, estimated at once per hour. • Six user searches per hour. Every time a search is performed, a batch poll is sent for everyone in the search result list. We assume the average size of search results is 20. If the search results stay on screen, the batch poll is refreshed every 5 minutes; we assume

	that there will be two such refreshes per hour. - When the user opens or previews an email in Outlook, a poll of the presence of users in the To: and CC: fields of the email, estimated at five emails per hour and four users per email.
Presence subscriptions	When one user adds another as a contact, the first user is *subscribing* to five categories of information about the second user. Updates of these categories of information are automatically sent to the first user. For each client, a single batch subscription request is sent to obtain the presence state of an average of 40 contacts, with an additional 40 dialogs to obtain presence for federated contacts. Presence for members of an expanded distribution group is found through persistent presence subscriptions, not polling, and is modeled as 1 expansion per user for each 2 hours. *Short subscriptions* happen when a user logs in, there is a batch subscription for all the user's contacts, and then the user soon logs off. We assume 6 short subscriptions per user per hour, where each subscription lasts 10 minutes.
Presence Publication	Presence state is published at an average of 4 publications per user per hour, with a maximum 6 per user per hour.
Presence Document Size	The average size of a complete presence document is assumed to be 4K, with a maximum of 25K.

The following table describes the user model for address book use.

Address Book Usage User Model

Address Book search mode	Usage
Address Book Web Query only (all queries performed by Address Book Web Query service)	Four prefix queries per user per day. 60 exact search queries per user per day. 40% of those are batched, with an average of 20 contacts per query. The other 60% of the queries are for a single contact. 25 photo queries per user per day. 24 are for a single photo, the other is a batch query with an average of 20 contacts. One total organization search query per user per day.
Mixed mode, both address book file and web queries used. This is the default mode.	Only two types of queries go to the network, the photo and total organizational search queries. 25 photo queries per user per day. 24 are

	for a single photo, the other is a batch query with an average of 20 contacts. One total organization search query per user per day.

The following table describes the conferencing model.

Conferencing Model

Category	Description
Scheduled meetings versus "Meet now" meetings	60% scheduled, 40% unscheduled. Of the scheduled meetings, we assume that 80% are assigned conferences, which are occurences of recurring conferences; 10% are one-time open meetings; 8% are one-time anonymous meetings, and 2% are one-time closed meetings.
Conferencing client distribution	For scheduled meetings: • 65% of conferencing users use Lync 2013. • 5% of conferencing users use Microsoft Lync Web App. • 30% of conferencing users use earlier clients, including Microsoft Lync 2010, Office Communicator 2007 R2, Office Communicator 2007, and Microsoft Office Communicator Web Access (2007 release). For unscheduled meetings: • 70% of conferencing users use Lync 2013. • 30% of conferencing users use earlier clients, including Microsoft Lync 2010, Office Communicator 2007 R2, Office Communicator 2007, and Microsoft Office Communicator Web Access (2007 release).
Meeting concurrency	5% of users will be in conferences during working hours. Thus, in an 80,000-user pool, as many as 4,000 users might be in conferences at any one time.
Meeting audio distribution	40% mixed VoIP audio and dial-in conferencing, with a 3:1 ratio of VoIP users to dial-in users. 35% VoIP audio only. 15% dial-in conferencing audio only. 10% no audio (IM-only conferences, with an average of five messages sent per user).
Media mix for conferences	75% of conferences are web conferences, which include audio plus some other collaboration modalities.

	For these conferences, the other collaboration methods are as follows: **Note:** These numbers add up to more than 100% because one conference can have multiple collaboration methods. - 50% add application sharing. We assume one users sends data at a peak of 1.1 MB per second. - 50% add instant messaging (with an average of 2 messages per user). - 20% add data collaboration, including PowerPoint or whiteboard In these, an average of 2 PowerPoint files presented per conference, with an average PowerPoint file size of 10 MB (without embedded video) or 30 MB (with embedded video). Average of 20 annotations per whiteboard. - 20% add video. Of these users, 70% are in conferences enabled for multiview video, where each user receives 2-3 video streams. - 15% add shared notes.
Meeting participant distribution	50% internal, authenticated users. 25% remote access, authenticated users. 15% anonymous users. 10% federated users.
Meeting join distribution	Users are simulated as joining the meeting within the first 5 minutes.

In regular Front End pools, Lync Server 2013 has a maximum supported meeting size of 250 users. Each pool can host one 250-user meeting at a time. While this large meeting is occurring, the pool can also host other smaller conferences. Additionally, you can support meetings of up to 1000 users by setting up a dedicated pool to host these meetings. For details, see Support for Large Meetings.

Conferences were simulated as follows:

- 85% of conferences had four participants.
- 10% of conferences had six participants.
- 5% of conferences had 11 participants.
- One large conference of 250 users.

The following table provides details about the user model for conferences involving dial-in users.

Dial-In Conferencing User Model

Category	Description
Authenticated/anonymous	70% of callers join as anonymous and are prompted for a recorded name. 30% join as authenticated users.

Call duration and music on hold	Average call duration without music on hold: 50 seconds. 50% of call-in users hear music on hold, for an average of 5 minutes.
Dual-tone multifrequency (DTMF)	15% of conferences that are dial-in only have phone leaders. 10% of mixed conferences that include dial-in users also have phone leaders. 20% of phone leaders use 2 DTMF commands per conference.
Announcement languages	Simulations use English as the announcement language.

The following table provides details about the user model for conference lobbies.

Conference Lobby User Model

Category	Description
Number of users in lobby	5% of dial-in users go through the lobby, and 25% of other users go through the lobby
Admitting from lobby	In simulations, all users were admitted by the presenter before client timeout.

The following table describes the user model for other peer-to-peer sessions.

Peer-to-Peer Sessions User Model

Category	Description
Application sharing	Each user participates in 5 peer-to-peer application sharing sessions per month, for an average of 0.25 sessions per day.
File transfer	Each user participates in 1 peer-to-peer file transfer session per month (as part of an IM session), for an average of 0.05 sessions per day. The average session file size transferred is 1 MB.

The following table describes the user model for policies.

Policies User Model

Category	Description
Conferencing, Presence, and Archiving Policies	We assume that there is one global policy, 10 tag conferencing policies, 4 Archiving policies, and 10 tag presence policies.
Voice Policy	We assume that there is one global policy and 2 tag policies per site. 100% of sites have a site policy, and 30% of users have a per-user policy assigned. We assume one dial plan per site and two routes per site.

Busy Hour

For peer-to-peer sessions, peak load is calculated using busy hour call attempts (BHCA). This voice industry term assumes that 50% of all calls for the day will be completed in 20% of the time. It is calculated using the following formula:

```
BHCA=(total calls * 0.5) / 1.6
```

Performance testing simulated busy hour by running VoIP and other peer-to-peer sessions at a busy hour load for at least 1.6 hours per day.

Conferencing peak load assumes that 75% of all conferences for an eight-hour day happen in 4 peak time hours. Those peak hours have 1.5 times the average conferencing load.

Enterprise Voice to PSTN Calls

The following assumptions apply to Enterprise Voice calls:

- 50% of users are enabled for Enterprise Voice, and 60% of these users are enabled for PSTN calling.
- Each of these users enabled for PSTN calling makes 4 PSTN calls during the busy hour. Each call duration is 3 minutes.
- 65% of these PSTN voice calls use media bypass.

Mobility

40% of registered users are assumed to be enabled for Mobility. For each user that has mobility enabled, we assume that the activity of the mobile client is additive to that of the other MPOP instances for that user, with the exception of conferencing interactions, for which the mobility client is just another client type that can be used to participate in conferences.

Persistent Chat

We assume that 25% of registered users will be involved in Persistent chat sessions, with the following characteristics:

- An average of 1.5 chat rooms per user
- Each chat room results in 12 polling requests per hour, targeting an average of 10 users each

Response Group and Call Park

We assume that 0.15% of registered users belong to response groups. We assume that 0.02% of registered users have parked calls at any given point of time.

1.3.5 Planning for High Availability and Disaster Recovery

Planning for High Availability and Disaster Recovery

Microsoft Lync Server 2013 > Planning >

Topic Last Modified: *2012-09-18*

As in Lync Server 2010, the main high availability scheme for most server roles in Lync Server 2013 is based on server redundancy via pooling. If a server running a certain server role fails, the other servers in the pool running the same role take the load of that server. This applies to Front End Servers, Edge Servers, Mediation Servers, and Directors.

Lync Server 2013 adds new disaster recovery measures for Front End pools by introducing geographical dispersement of your servers into two data centers to provide continuation of service should one entire pool or site go down.

Lync Server 2013 also enhances Back End Server high availability, by supporting synchronous SQL mirroring for your Back End databases.

This section explains these major high availability and disaster recovery features, and also covers what steps you can take for high availability and disaster recovery for your other server roles as well.

1.3.5.1 Front End Pool High Availability and Disaster Recovery

Front End Pool High Availability and Disaster Recovery

Microsoft Lync Server 2013 > Planning > Planning for High Availability and Disaster Recovery >

Topic Last Modified: *2012-09-17*

The topics in this section explain the high availability and disaster recovery abilities Front End pools in Lync Server 2013.

- Planning for Front End Pool Pairing
- User Experience During Pool Failure
- Back End Server High Availability
- File Sharing High Availability

1.3.5.1.1 Planning for Front End Pool Pairing

Planning for Front End Pool Pairing

Planning > Planning for High Availability and Disaster Recovery > Front End Pool High Availability and Disaster Recovery >

Topic Last Modified: *2012-09-28*

For the best disaster recovery abilities in Lync Server 2013, deploy pairs of Front End pools across two geographically dispersed sites. Each site contains a Front End pool which is paired with a corresponding Front End pool in the other site. Both sites are active, and the Lync Server Backup Service provides real-time data replication to keep the pools synchronized. The Backup Service is a new feature in Lync Server 2013, designed to support the disaster recovery solution. It is installed on a Front End pool when you pair the pool with another Front End pool.

If the pool in one site fails, you can fail over the users from that pool to the pool in the other site, which then provides services to all the users in both pools. For capacity planning purposes, each pool should be designed to handle the workloads of all users in both pools in the event of a disaster.

- Best Practices for Pairing Front End Pools
- Backup Registrar Relationships
- Recovery Time for Pool Failover and Pool Failback
- Central Management Store Failover
- Front End Pool Pairing Data Security

1.3.5.1.1.1 Best Practices for Pairing Front End Pools

Best Practices for Pairing Front End Pools

Planning for High Availability and Disaster Recovery > Front End Pool High Availability and Disaster Recovery > Planning for Front End Pool Pairing >

Topic Last Modified: *2013-02-19*

There is no restriction on the distance between two data centers that are to include Front End pools paired with each other. We recommend that you use two data centers in the same world region, with high-speed links between them. It is best if the two data centers are separated enough to avoid a single disaster hitting both at the same time.

Having two data centers across world regions is possible, but could incur higher data loss due to latency in data replication.

When you plan which pools to pair, you must keep in mind that only the following pairings are supported:

- Enterprise Edition pools can be paired only with other Enterprise Edition pools. Similarly, Standard Edition pools can be paired only with other Standard Edition pools.
- Physical pools can be paired only with other physical pools. Similarly, virtual pools can be paired only with other virtual pools.

Neither Topology Builder nor topology validation will prohibit pairing two pools in a way that does not follow these recommendations. For example, Topology Builder allows you to pair an Enterprise Edition pool with a Standard Edition pool. However, these types of pairings are not supported.

Each pool in a pair should have the capacity to serve all users from both pools in the event of a disaster.

If you pair Enterprise Edition pools, you can also implement high availability on the Back End Servers, but for pairs of Standard Edition pools only the disaster recovery measures are available.

1.3.5.1.1.2 Backup Registrar Relationships

Backup Registrar Relationships

Planning for High Availability and Disaster Recovery > Front End Pool High Availability and Disaster Recovery > Planning for Front End Pool Pairing >

Topic Last Modified: *2012-06-28*

In addition to providing disaster recovery ability, two paired pools serve as the backup Registrars for each other. In Lync Server 2013, backup Registrar relationships between Front End pools are always 1:1 and reciprocal. This means that if P1 is the backup for P2, then P2 must be the backup for P1, and neither can be the backup for any other Front End pool. This is a change from Lync Server 2010, in which Front End pool backup relationships could be many to one.

Even though backup relationships between two Front End pools must be 1:1 and symmetrical, each Front End pool can still also be the backup registrar for any number of Survivable Branch Appliances, just as in Lync Server 2010.

Note that Lync Server 2013 does not extend disaster recovery support to users homed on a Survivable Branch Appliance. If a Front End pool that serves as the backup for a Survivable Branch Appliance goes down, users signed into the Survivable Branch Appliance fall into resiliency mode even after users homed on the Front End pool are failed over to the backup Front End pool.

1.3.5.1.1.3 Recovery Time for Pool Failover and Pool Failback

Recovery Time for Pool Failover and Pool Failback

Planning for High Availability and Disaster Recovery > Front End Pool High Availability and Disaster Recovery > Planning for Front End Pool Pairing >

Topic Last Modified: *2012-09-10*

For pool failover and pool failback, the engineering target for recovery time objective (RTO) is 30 minutes. This is the time required for the failover to happen, after administrators have determined there was a disaster and initiated the failover procedures. It does not include the time for administrators to assess the situation and make a decision, nor does it include the time for users to sign in again after failover is complete.

For pool failover and pool failback, the engineering target for recovery point objective (RPO) is 30 minutes. This represents the time measure of data that could be lost due to the disaster, due to replication latency of the Backup Service. For example, if a pool goes down at 10:00 A.M., and the RPO is 30 minutes, data written to the pool between 9:30 A.M. and 10:00 A.M.might not have replicated to the backup pool, and would be lost.

All RTO and RPO numbers in this document assume that the two data centers are located within the same world region with high-speed, low-latency transport between the two sites. These numbers are measured for a pool with 40,000 concurrently active users and 200,000 users enabled for Lync with respect to a pre-defined user model where there is no backlog in data replication. They are subject to change based on performance testing and validation.

1.3.5.1.1.4 Central Management Store Failover

Central Management Store Failover

Planning for High Availability and Disaster Recovery > Front End Pool High Availability and Disaster Recovery > Planning for Front End Pool Pairing >

Topic Last Modified: *2012-10-18*

The Central Management store contains configuration data about servers and services in your Lync 2013 deployment. It provides a robust, schematized storage of the data needed to define, set up, maintain, administer, describe, and operate a Lync 2013 deployment. It also validates the data to ensure configuration consistency.

Each Lync deployment includes one Central Management store, which is hosted by the Back End Server of one Front End pool.

When you establish a pool pairing that includes the pool hosting the Central Management store, a backup Central Management store database is set up in the backup pool, and Central Management store services are installed in both pools. At any point in time, one of the two Central Management store databases is the active master, and the other is a standby. The content is replicated by the Backup Service from the active master to the standby.

During a pool failover that involves the pools hosting the Central Management store, the administrator must fail over the Central Management store before failing over the Front End pool.

After the disaster is repaired, it is not necessary to fail back the Central Management store. After repair, the Central Management store in the original backup pool can remain as the active master.

The engineering targets for Central Management store failover are 5 minutes for recovery time objective (RTO) and 5 minutes for recovery point objective (RPO).

1.3.5.1.1.5 Front End Pool Pairing Data Security

Front End Pool Pairing Data Security

Planning for High Availability and Disaster Recovery > Front End Pool High Availability and Disaster Recovery > Planning for Front End Pool Pairing >

Topic Last Modified: *2012-10-21*

The Backup Service is a data replication mechanism introduced in Lync Server 2013 that transfers user data and conference content between two paired Front End pools continuously across two data centers for disaster recovery purposes. The user data contains user SIP URIs as well as contact lists and settings. Conference content includes Microsoft PowerPoint 2010 uploads, as well as whiteboards used in conferences. From the source pool, user data and conference content are exported from the local storage, zipped, transferred to the target Pool, where it is unzipped and imported to local storage. The Backup Service assumes that the communications link between the two data centers is within the corporate network that is protected from the Internet. It does not encrypt the transferred data between the two data centers, nor is it natively encapsulated within a secure protocol, such as HTTPS. Therefore, man-in-the-middle attack from internal personnel within the corporate network is possible.

Evaluating Security Risks

Any enterprise which deploys Lync Server 2013 across multiple data centers and uses the disaster recovery feature must ensure that cross-data center traffic is protected by their corporate Intranet. Enterprises which care about internal attack protection must secure the communication links among the data centers.

The assumption that data centers of an enterprise are protected behind the corporate Intranet is standard. There are many other types of corporate sensitive data transferred among these data centers. The enterprise's IT infrastructure is at dire risk if these cross-data center links are not protected.

While the risk of man-in-the-middle attacks within the corporate network exists, it is relatively contained as compared to exposing the traffic to the Internet. Specifically, the user data exposed by Backup Service (such as SIP URIs) are generally available to all employees within the company via other means such as the Global Address Book by Exchange or other directory software. Hence, the focus should be on securing the WAN between the two data centers when the Backup Service is used to copy data between the two paired Pools.

Mitigating Security Risks

There are many ways to enhance security protection for the Backup Service traffic, ranging from restricting access to the data centers to securing the WAN transport between the two data centers. In most cases, enterprises deploying Lync Server 2013 might already have the required security infrastructure in place. For enterprises looking for guidance, Microsoft provides solution as an example of how to build a secure IT infrastructure. However, this does not imply that it is the only solution, nor does it imply that it is the preferred solution for Lync Server. We recommend that enterprise customers choose the solution suits their specific needs, based on their IT security infrastructure and requirements.The example Microsoft solution employs IPSec and Group Policy for Server and Domain Isolation. For details, see http://go.microsoft.com/fwlink/p/?LinkId=268544. For questions and comments, contact secwish@microsoft.com.

⚠**Warning:**

IPsec is not intended as a replacement for application-level security, such as SSL/TLS. One advantage of using IPsec is that it can provide network traffic security for existing applications without having to change them.Enterprises that want to just secure the transport between the two data centers should consult their respective networking hardware vendors about ways to set up secure WAN connections by using the vendor's equipment.

1.3.5.1.2 User Experience During Pool Failure

User Experience During Pool Failure

Planning > Planning for High Availability and Disaster Recovery > Front End Pool High Availability and Disaster Recovery >

Topic Last Modified: *2012-10-03*

If a pool is failed over, all users of the affected pool are forced to sign out and then sign into the backup pool. For a brief period users who sign into the backup pool may be in resiliency mode. In Resiliency mode, users are unable to perform tasks that would cause a persistent change on Lync Server, such as adding a contact. After the failover is complete, all users can get all services from the backup pool.

Any sessions a user has when the pool fails are disrupted, and the user must re-establish those sessions after failover to continue.

Users are not rehomed during failover or failback. Users who are homed on a pool that fails will be temporarily serviced by the backup pool. When the home pool is restored, the administrator can fail back these users to be serviced by their original home pool.

Note in Lync 2013, the Location Information Server database is not replicated to the backup pool. For best practice, the administrator should regularly back up the LIS database and use the latest backup copy to restore the LIS database in the backup pool after the failover.

User Experience During Failover

When a user is in a pool that fails, the user is logged out. Any peer-to-peer session the user was participating in is terminated, as are conferences organized by that user. The user cannot log back in until either the registrar resiliency timer expires or the administrator initiates failover procedures, whichever comes first. When the user logs back in, they will log in to the backup pool. If they log in before the failover has completed, they will be in Resiliency mode until failover is complete. Only then the user is able to establish new sessions or re-establish previous sessions.

User Experience During Failback

Pool failback can happen while an affected user is logged on to the backup pool, and the user remains logged on and working during the failback. Note that the failback process takes several minute to complete. For reference, it is expected to take up to 60 minutes for a pool of 20,000 users.

The following tables show more details about how a user with a Lync 2013 client or a Microsoft Lync 2010 client is affected during and after failback, and also how users in other pools see and interact with a user in a pool who is being failed back. Users with Microsoft Office Communicator 2007 R2 clients cannot sign in until the Front End pool is completely failed back.)

The term *affected user* refers to any user who was failed over from the home pool and is being serviced by the backup pool. By definition, any user originally homed on the backup pool is not an affected user.

User Experience for an Affected User in a Pool in Failback

User state or task	During failback	After failback completion
User state of user already logged in	User stays signed in and connected to backup pool. At some point user will be signed out and sign back in to the original home pool, in Resiliency mode.	User remains signed in and goes into regular mode.
New user logging in	User can sign in to the home pool in Resiliency mode.	User can sign in to the original home pool in regular mode.
Ongoing conferences organized by affected user	All modalities of conference are terminated. Rejoin button will appear, but no users can rejoin while the affected user is in Resiliency mode.	All modalities now work. Every participant needs to click to rejoin the conference.

Ongoing conferences organized by unaffected user	Conference continues and affected user can stay in the conference. Affected user is restricted to what he/she can do in Resiliency mode.	Conference continues, and affected user can stay in the conference and all modalities work after user exits Resiliency mode.
Scheduling or modifying scheduled meetings, creating ad-hoc conferences	Not possible while user is in Resiliency mode.	Available for all modalities.
Presence as seen by other users in the same pool	Presence unknown while user is signed into backup pool during Resiliency mode.	Shows the last presence state set by the user, and presence changes will now be reflected.
Contacts list and Address Book Service availability	Not available	Available
All peer-to-peer sessions and modalities	Available	Available

User Experience for a User Homed in an Unaffected Pool During Failback of Another Pool

User task	During failback	After failback completion
Viewing presence of affected user	Shows the last presence state set by the affected user.	Working. Unaffected users see updates made by affected users.
Ongoing conferences organized by affected user	All modalities of conference are terminated.	All modalities now work. Every participant needs to click to rejoin the conference.
Ongoing conferences organized by unaffected user	Conference continues, and affected user can stay in the conference and all modalities work.	Conference continues, and affected user can stay in the conference and all modalities work.
All peer-to-peer sessions and modalities	Available	Available

1.3.5.1.3 Back End Server High Availability

Back End Server High Availability

Planning > Planning for High Availability and Disaster Recovery > Front End Pool High Availability and Disaster Recovery >

Topic Last Modified: *2013-03-12*

To ensure high availability for your Back End Servers, you can deploy two Back End Servers for a single Front End pool, using synchronous SQL mirroring. This topology is optional, but is recommended to maintain your organization's business continuity. In the rest of this document, SQL mirroring means synchronous SQL mirroring, unless otherwise explicitly stated. Asynchronous SQL mirroring is not supported for Back End Server high availability in Lync Server 2013.

When you deploy this high availability solution, all Lync Server databases in the pool are mirrored, including the Central Management store, if it is located in this pool, as well as the Response Group application database and the Call Park application database, if those applications are running in the pool.

With SQL mirroring, you do not need to use shared storage for the servers. Each server keeps its copy of the databases in local storage.

You may choose to deploy SQL mirroring with or without a witness. We recommend using a witness because it enables failover of the Back End Server to be automatic. Otherwise, an administrator must manually invoke failover. Note that even if a witness is deployed, an administrator can manually invoke Back End Server failover, if necessary.

If you use a witness, you can use a single witness for multiple pairs of Back End Servers. There is no strict 1:1 correspondence between witnesses and pairs of Back End Servers. Deployments that use a single witness for multiple pairs of Back End Servers are not quite as resilient as topologies with a separate witness for each Back End Server pair.

Recovery Time for Automatic Back End Server Failover

For automatic Back End failover, the engineering target for recovery time objective (RTO) is 5 minutes. Because of the synchronous SQL mirroring, we do not anticipate data loss during Back End Server failures except in rare occasions when both the Front End Servers and the Back End Server go down simultaneously while data is being moved between the servers. The engineering target for recovery point objective (RPO) is 5 minutes.

User Experience During Back End Server Failure

User experience during a failure depends on the nature of the failure, and on your topology.

If you have a witness configured, and the principal fails, Back End Server failover happens automatically and quickly. Active users should not notice much interruption to their ongoing sessions.

If there is no witness configured, it will take some time for the administrator to manually invoke the failover. During that time, active users may be affected. They will continue their sessions as normal for about 30 minutes. If the primary is still not restored, or an administrator has not failed over to the backup, then users are switched to Resiliency mode, meaning that they are unable to perform tasks that require a persistent change on Lync Server (such as adding a contact).

If both the principal and the mirror Back End Servers fail, or if one of those servers and the witness fails, the Back End Server will become unavailable (even if it is the principal that is still working). In this case, active users are switched to Resiliency mode after some time.

SQL Clustering Topologies

SQL clustering topologies are not supported for new Lync Server 2013 deployments. For Back End Server high availability, SQL mirroring is the recommended and supported option.

If you are upgrading from a previous version of Lync Server and you have deployed an Enterprise Edition Front End pool that uses SQL clustering in that existing Lync Server topology, we recommend that you implement SQL Mirroring as a replacement for the existing SQL clustering deployment. However, continuing to use the existing SQL cluster with Lync Server 2013 is supported.

1.3.5.1.4 File Sharing High Availability

File Sharing High Availability

Planning > Planning for High Availability and Disaster Recovery > Front End Pool High Availability and Disaster Recovery >

Topic Last Modified: *2012-03-30*

To ensure high availability for Lync Server file sharing within a single data center, you can use the Distributed File System (DFS). DFS supports failover from one file server to another within the same data center. For a large scale deployment, we recommend that you use dedicated file servers that are paired using DFS.

Depending on your network's size, and the amount of resiliency you want, you can use one pair of servers to host all file shares in a site, or use one pair per Front End pool.

DFS is a best effort file replication mechanism, with no published recovery time objective (RTO) or recovery point objective (RPO) commitment. The failover between the DFS servers should be completed quickly, but data replication delay may prevent users from being able to continue work in progress when the failover happens.

If you use DFS and data store on the fileshare is critical, you should back up the file shares frequently, such as every 4 to 8 hours. When one file share goes down and replication is not up to date, you can use the backup to restore the content on the failed server to the other server that is paired with the server that is now unavailable.

1.3.5.2 Edge Server High Availability and Disaster Recovery

Edge Server High Availability and Disaster Recovery

Microsoft Lync Server 2013 > Planning > Planning for High Availability and Disaster Recovery >

Topic Last Modified: *2012-09-17*

As with other server roles, the best way for you to provide high availability for your Edge Servers is to deploy multiple Edge servers in pools in each site. If one Edge Server goes down, the other servers in the pool will continue to provide Edge services.

To enable disaster recovery procedures, you must have separate Edge Server pools deployed at separate sites. You do not need to explicitly pair Edge pools together as you do with Front End pools, but having multiple Edge pools still provides the availability to carry on if one entire Edge pool goes down. The following sections provide details on disaster recovery for the various functions of Edge Servers.

Remote Access

If you have multiple sites, each with a pool of Edge Servers, and one entire Edge pool fails, the remote access services will continue to function without needing administrator actions. Remote users will automatically be routed to the Edge Servers in another site, because all Edge Server pools in your organization have the same external FQDN.

To ensure that this automatic failover will work smoothly, be sure to add every Front End pool in your organization to the publishing rules on the Reverse Proxy at each site. This way, Front End Servers in one site can communicate with Edge Servers in every other site, if the Edge Servers in the same site as the Front End Servers are unavailable.

Federation

For federation relationships with other organizations running Lync Server, inbound federation requests will continue to work. Any federation requests that come to an Edge pool that is down will fail back and then connect to an Edge pool which is running.

Outbound federation is always set up through one published Edge pool or Edge Server in the organization. If this Edge pool has gone down, you must use Topology Builder to change the outbound federation route to use an Edge pool which is still running. For details, see Failing Over the Edge Pool Used for Lync Server Federation

XMPP Federation

For XMPP federation, both outbound and inbound traffic will fail if the Edge pool which is designated as the XMPP federation gateway goes down. To make XMPP federation work again, you must change XMPP federation to use a different Edge pool. For details, see Failing Over the Edge Pool Used for XMPP Federation.

Edge Pool Fails But Front End Pool Is Still Running

If an Edge pool fails at a site, but the Front End pool at that site is still running, you will need to change the Front End pool to use a different Edge pool at a different site while that first Edge pool is down. For more information, see Changing the Edge Pool Associated with a Front End Pool.

1.3.5.3 Planning for Enterprise Voice Resiliency

Planning for Enterprise Voice Resiliency

Microsoft Lync Server 2013 > Planning > Planning for High Availability and Disaster Recovery >

Topic Last Modified: *2012-09-22*

Voice resiliency refers to the ability of users to continue making and receiving calls if a central site that hosts Microsoft Lync Server 2010 becomes unavailable, whether through a wide area network (WAN) failure or another cause. If a central site fails, Enterprise Voice service must continue uninterrupted through seamless failover to a backup site. In the event of WAN failure, branch site calls must be redirected to a local PSTN gateway. This section discusses planning for voice resiliency in the event of central-site or WAN failure.

- Planning for Central Site Voice Resiliency
- Planning for Branch-Site Voice Resiliency

Planning for Central Site Voice Resiliency

See Also

Planning > Planning for High Availability and Disaster Recovery > Planning for Enterprise Voice Resiliency >

Topic Last Modified: *2012-09-28*

Increasingly, enterprises have multiple sites spread across the globe. Maintaining emergency services, access to help desk, and the ability to conduct critical business tasks when a central site is out of service is essential for any Enterprise Voice resiliency solution. When a central site becomes unavailable, the following conditions must be met:

- Voice failover must be provided.
- Users who ordinarily register with the Front End pool at the central site must be able to register with an alternative Front End pool. This can be done by creating multiple DNS SRV records, each of which resolves to a Director pool or Front End pool in each of your central sites. You can adjust the priority and weights of the SRV records so that users who are served by that central site get the corresponding Director and Front End pool ahead of those in other SRV records.
- Calls to and from users located at other sites must be rerouted to the PSTN.

This topic describes the recommended solution for securing central site voice resiliency.

Architecture and Topology

Planning for voice resiliency at a central site requires a basic understanding of the central role played by the Lync Server 2013 Registrar in enabling voice failover. The Lync Server Registrar is a server role that enables client registration and authentication and provides routing services. It resides along with other components on a Standard Edition server, Front End Server, Director, or Survivable Branch Appliance. A Registrar pool consists of Registrar Services running on the Front End pool and residing at the same site. The Front End pool must be load balanced. DNS load balancing is recommended, but hardware load balancing is acceptable. A Lync client discovers the Front End pool through the following discovery mechanism:

1. DNS SRV record
2. Autodiscovery Web Service (new in Lync Server 2013)
3. DHCP option 120

After the Lync client connects to the Front End pool, it is directed by the load balancer to one of the Front End Servers in the pool. That Front End Server, in turn, redirects the client to a preferred Registrar in the pool.

Each user enabled for Enterprise Voice is assigned to a particular Registrar pool, which becomes that user's primary Registrar pool. At a given site, hundreds or thousands of users typically share a single primary Registrar pool. To account for the consumption of central site resources by any branch site users that rely on the central site for presence, conferencing, or failover, we recommend that you consider each branch site user as though the user were a user registered with the central site. There are currently no limits on the number of branch site users, including users registered with a Survivable Branch Appliance.

To assure voice resiliency in the event of a central site failure, the primary Registrar pool must have a single designated backup Registrar pool located at another site. The backup can be configured by using Topology Builder resiliency settings. Assuming a resilient WAN link between the two sites, users whose primary Registrar pool is no longer available are automatically directed to the backup Registrar pool.

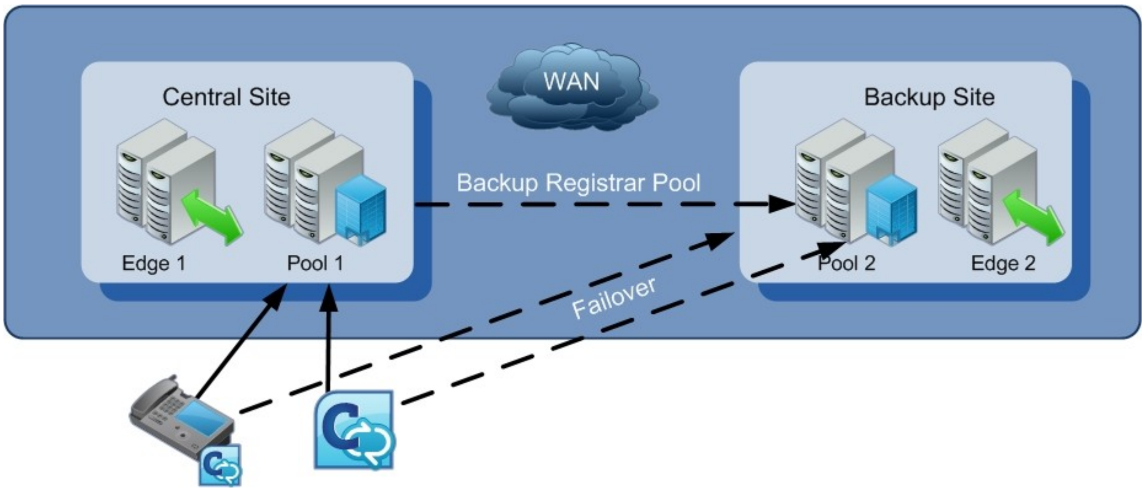
The following steps describe the client discovery and registration process:

1. A client discovers Lync Server through DNS SRV records. In Lync Server 2013, DNS SRV records can be configured to return more than one FQDN to the DNS SRV query. For example, if enterprise Contoso has three central sites (North America, Europe, and Asia-Pacific) and a Director pool at each central site, DNS SRV records can point to the Director pool FQDNs in each of the three locations. As long as the Director pool in one of the locations is available, the client can connect to the first hop Lync Server.

   Note:
   Using a Director pool is optional. A Front End pool can be used instead.

2. The Director pool informs the Lync client about the user's primary Registrar pool and backup Registrar pool.
3. The Lync client attempts to connect to the user's primary Registrar pool first. If the primary Registrar pool is available, the Registrar accepts the registration. If the primary Registrar pool is unavailable, the Lync client attempts to connect to the backup Registrar pool. If the backup Registrar pool is available and has determined that the user's primary Registrar pool is unavailable (by detecting a lack of heartbeat for a specified failover interval) the backup Registrar pool accepts the user's registration. After the backup Registrar detects that the primary Registrar is again available, the backup Registrar pool will redirect failover Lync clients to their primary pool.

The following figure shows the recommended topology for assuring central site resiliency. The two sites are connected by a resilient WAN link. If the central site becomes unavailable, users who are assigned to that pool are directed to the backup site for registration.



Requirements and Recommendations

The following requirements and recommendations for implementing central site voice resiliency are appropriate for most organizations:

- The sites in which the primary and backup Registrar pools reside should be connected by a resilient WAN link.
- Each central site must contain a Registrar pool consisting of one or more Registrars.
- Each Registrar pool must be load-balanced by using DNS load balancing or hardware load balancing.
- Each user must be assigned to a primary Registrar pool by using either the

Lync Server Management Shell **set-CsUser** cmdlet or the Lync Server Control Panel.
- The primary Registrar pool must have a single backup Registrar pool located in a different central site.
- The primary Registrar pool must be configured to fail over to the backup Registrar pool. By default, the primary Registrar is set to fail over to the backup Registrar pool after an interval of 300 seconds. You can change this interval by using the Lync Server 2013 Topology Builder.
- Configure a failover route, as described in the "Configuring a Failover Route" topic in the Planning documentation. When configuring the route, specify a gateway that is located at a different site from the gateway specified in the primary route.
- If the central site contained your primary management server and the site is likely to be down for an extended period, you will need to reinstall your management tools at the backup site; otherwise, you won't be able to change any management settings.

Dependencies

Lync Server depends on the following infrastructure and software components to assure voice resiliency:

Component	**Functional**
DNS	Resolving SRV records and A records for server-server and server-client connectivity
Exchange and Exchange Web Services (EWS)	Contact storage; calendar data
Exchange Unified Messaging and Exchange Web Services	Call logs, voice mail list, voice mail
DHCP Options 120	If DNS SRV is unavailable, the client will attempt to use DHCP Option 120 to discover the Registrar. For this to work, either a DHCP server must be configured or Lync Server 2013 DHCP must be enabled. For details, see Hardware and Software Requirements for Branch-Site Resiliency in Branch-Site Resiliency Requirements section.

Survivable Voice Features

If the preceding requirements and recommendations have been implemented, the following voice features will be provided by the backup Registrar pool:

- Outbound PSTN calls
- Inbound PSTN calls, if the telephony service provider supports the ability to fail over to a backup site
- Enterprise calls between users at both the same site and between two different sites
- Basic call handling, including call hold, retrieval, and transfer
- Two-party instant messaging and sharing audio and video between users at the same site
- Call forwarding, simultaneous ringing of endpoints, call delegation, and team call services, but only if both parties to call delegation, or all team members, are configured at the same site.
- Existing phones and clients continue to work.
- Call detail recording (CDR)

- Authentication and authorization

Depending on how they are configured, the following voice features may or may not work when a primary central site is out of service:

- Voice mail deposit and retrieval
  If you want to make Exchange UM available when the primary central site is out of service, you must do one of the following:
  - Change DNS SRV records so that the Exchange UM servers at the central site point to backup Exchange UM servers at another site.
  - Configure each user's Exchange UM dial plan to include Exchange UM servers at both the central site and the backup site, but designate the backup Exchange UM servers as disabled. If the primary site becomes unavailable, the Exchange administrator has to mark the Exchange UM servers at the backup site as enabled.

  If neither of the preceding solutions is possible, then Exchange UM will not be available in the event the central site becomes unavailable.
- Conferencing of all types
  A user who has failed over to a backup site can join a conference that is created or hosted by an organizer whose pool is available but cannot create or host a conference on his or her own primary pool, which is no longer available. Similarly, others users cannot join conferences that are hosted on the affected user's primary pool.

The following voice features do not work when a primary central site is out of service:

- Conference Auto-Attendant
- Presence and DND-based routing
- Updating call forwarding settings
- Response Group service and Call Park
- Provisioning new phones and clients
- Address Book Web Search

Planning for Branch-Site Voice Resiliency

1.3.5.3.2 Planning for Branch-Site Voice Resiliency

Planning for Branch-Site Voice Resiliency

Planning > Planning for High Availability and Disaster Recovery > Planning for Enterprise Voice Resiliency >

Topic Last Modified: *2012-09-21*

If you want to provide branch-site resiliency, that is, high-availability Enterprise Voice service, you have three options for doing so:

- Survivable Branch Appliance
- Survivable Branch Server
- A full Lync Server deployment at the branch site

This guide will help you evaluate which resiliency solution is best for your organization and, based on your resiliency solution, which PSTN-connectivity solution to use. It will also help you prepare to deploy the solution that you choose by describing prerequisites and other planning considerations.

- Branch-Site Resiliency Features
- Branch-Site Resiliency Solutions
- Branch-Site Resiliency Requirements

1.3.5.3.2.1 Branch-Site Resiliency Features

Branch-Site Resiliency Features

Planning for High Availability and Disaster Recovery > Planning for Enterprise Voice Resiliency > Planning for Branch-Site Voice Resiliency >

Topic Last Modified: *2012-10-10*

If you provide branch-site resiliency, if a branch site's WAN connection to a central site fails or if the central site is unreachable, the following voice features should continue to be available:

- Inbound and outbound public switched telephone network (PSTN) calls
- Enterprise calls between users at both the same site and between two different sites
- Basic call handling, including call hold, retrieval, and transfer
- Two-party instant messaging
- Call forwarding, simultaneous ringing of endpoints, call delegation, and team call services, but only if the delegator and delegate (for example, a manager and the manager's administrator), or all team members, are configured at the same site
- Call detail records (CDRs)
- PSTN dial-in conferencing with Conferencing Auto-Attendant
- Voice mail capabilities, if you configure voice mail rerouting settings. (For details, see Branch-Site Resiliency Requirements.)
- User authentication and authorization

The following features will be available only if your resiliency solution is a full-scale Lync Server deployment at the branch site:

- IM, web, and A/V conferencing
- Presence and Do Not Disturb (DND)-based routing (where calls are prevented from ringing on extensions that have DND activated)
- Updating call forwarding settings
- Response Group application and Call Park application
- Provisioning new phones and clients, but only if Active Directory Domain Services (AD DS) is present at the branch site.
- Enhanced 9-1-1 (E9-1-1)
  If E9-1-1 is deployed, and the SIP trunk at the central site is not available because the WAN link is down, then the Survivable Branch Appliance will route E9-1-1 calls to the local branch gateway. To enable this feature, the branch-site users' voice policies should route calls to the local gateway in the event of WAN failure.

1.3.5.3.2.2 Branch-Site Resiliency Solutions

Branch-Site Resiliency Solutions

Planning for High Availability and Disaster Recovery > Planning for Enterprise Voice Resiliency > Planning for Branch-Site Voice Resiliency >

Topic Last Modified: *2012-09-23*

There are obvious advantages to providing branch-site resiliency to your organization. Specifically, if you lose the connection to the central site, branch site users will continue to have Enterprise Voice service and voice mail (if you configure voice mail rerouting settings; for details, see Branch-Site Resiliency Requirements). However, for sites with fewer than 25 users, a resiliency solution may not provide a sufficient return on investment.

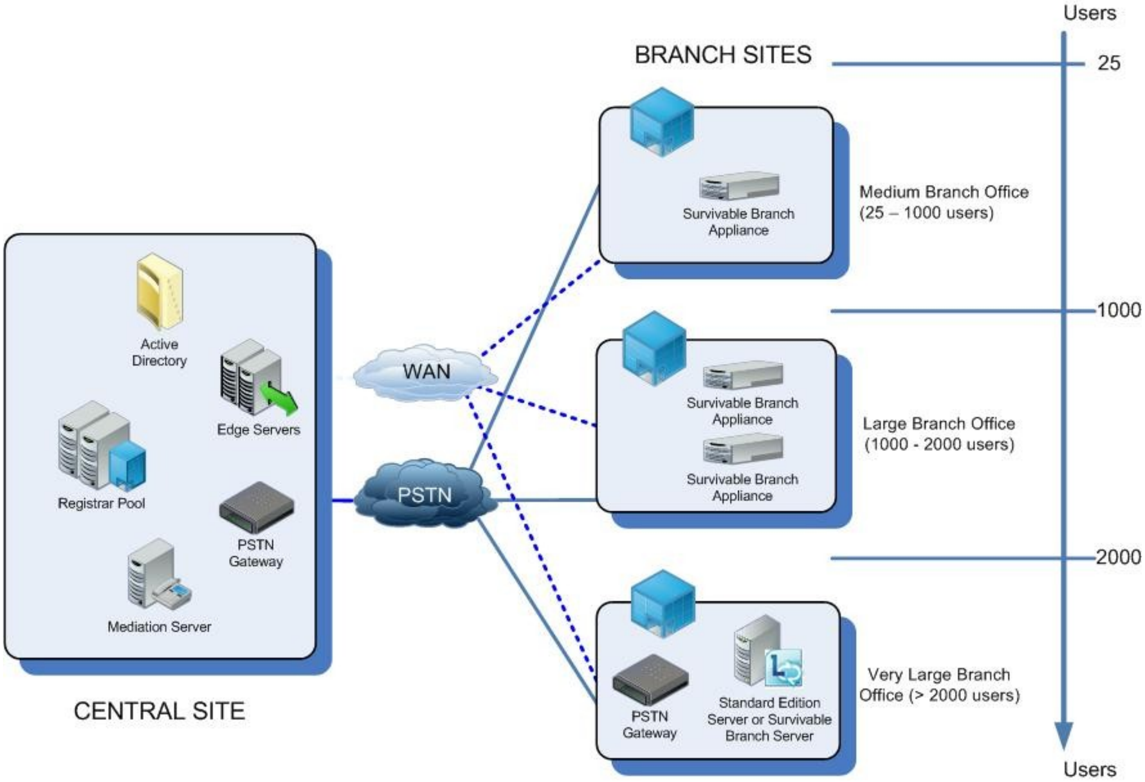
If you decide to provide branch-site resiliency, you have three options. The following table can help you determine the best option for your organization.

If you...	We recommend that you use a...
Host between 25 and 1000 users at your branch site, and if the return on investment does not support a full deployment or where local administrative support is unavailable	Survivable Branch Appliance The Survivable Branch Appliance is an industry-standard blade server with a Lync Server Registrar and Mediation Server running on Windows Server 2008 R2. The Survivable Branch Appliance also contains a public switched telephone network (PSTN) gateway. Qualified third-party devices (developed by Microsoft partners in the Survivable Branch Appliance (SBA) qualification/certification program) provide a continuous PSTN connection in the event of WAN failure, but this approach does not provide resilient presence and conferencing because these features depend on Front End Servers at the central site. For details about Survivable Branch Appliances, see "Survivable Branch Appliance Details," later in this topic. **Note:** If you decide to also use a SIP trunk with your Survivable Branch Appliance, contact your Survivable Branch Appliance vendor to learn about which service provider is best for your organization.
Host between 1000 and 2000 users at your branch site, lack a resilient WAN connection, and have trained Lync Server administrators available	Survivable Branch Server or two Survivable Branch Appliances. The Survivable Branch Server is a Windows Server meeting specified hardware requirements that has Lync Server Registrar and Mediation Server software installed on it. It must connect to either a PSTN gateway or a SIP trunk to a telephone service provider. For details about Survivable Branch Servers, see "Survivable Branch Server Details," later in this topic.
If you require presence and conferencing features in addition to voice features for up to 5000 users, and have trained Lync Server administrators available	Deploy as a central site with a Standard Edition server rather than as a branch site. A full-scale Lync Server deployment provides a continuous PSTN connection and resilient presence and conferencing in the event of WAN failure. For details about preparing for this solution, see Planning Primer: Planning for Your Organization, Determining Your System Requirements, Determining Your

	Infrastructure Requirements, and other relevant sections of the Planning documentation.

Resiliency Topologies

The following figure shows the recommended topologies for branch-site resiliency.



Users
BRANCH SITES
25

Standard Edition Server or Survivable Branch Server
Very Large Branch Office (> 2000 users)
Users
WAN
PSTN
Active Directory
Edge Servers
Registrar Pool
PSTN Gateway
Mediation Server
CENTRAL SITE

Survivable Branch Appliance Details

The Lync Server Survivable Branch Appliance includes the following components:

- A Registrar for user authentication, registration and call routing
- A Mediation Server for handling signaling between the Registrar and a PSTN gateway
- A PSTN gateway for routing calls to the PSTN as a fallback transport in the event of a WAN outage
- SQL Server Express for local user data storage

The Survivable Branch Appliance also includes PSTN trunks, analog ports, and an Ethernet adapter.

If the branch site’s WAN connection to a central site becomes unavailable, internal branch users continue to be registered with the Survivable Branch Appliance Registrar and obtain uninterrupted voice service by using the Survivable Branch Appliance connection to the PSTN. Branch site users who connect from home or other remote locations will be able to register with a Registrar server at a central site if the WAN link to the branch site is unavailable. These users will have full unified communications functionality, with the one exception that inbound calls to the branch site will go to voice mail. When the WAN connection becomes available, full functionality should be restored to branch site users. Neither the failover to the Survivable Branch Appliance nor the restoration of service requires the presence of an IT administrator.

Lync Server supports up to two Survivable Branch Appliance at a branch site.

Survivable Branch Appliance Deployment Overview

The Survivable Branch Appliance is manufactured by original equipment manufacturers in partnership with Microsoft and deployed on their behalf by value-added retailers. This deployment should occur only after Lync Server has been deployed at the central site, a WAN connection to the branch site is in place, and branch site users are enabled for Enterprise Voice.

For details about these phases, see Deploying a Survivable Branch Appliance or Server in the Deployment documentation.

Phase	Steps	User Rights
Set up Active Directory Domain Services for the Survivable Branch Appliance	**At the central site:** 1. Create a domain user account (or enterprise identity) for the technician who will install and activate the Survivable Branch Appliance at the branch site. 2. Create a computer account (with the applicable fully qualified domain name (FQDN)) for Survivable Branch Appliance in Active Directory Domain Services. 3. In Topology Builder, create and publish the Survivable Branch Appliance.	The technician user account must be a member of RTCUniversalSBATechnicians. The Survivable Branch Appliance must belong to the RTCSBAUniversalServices group, which happens automatically when you use Topology Builder.
Install, and activate the Survivable Branch Appliance.	**At the branch site:** 1. Connect the Survivable Branch Appliance to an Ethernet port and PSTN port. 2. Start the Survivable Branch Appliance. 3. Join the Survivable Branch Appliance to the domain, using the domain user account created for the Survivable Branch Appliance at the central site. Set the FQDN and IP address to match the FQDN created in the computer account. 4. Configure the Survivable Branch Appliance using the OEM user interface. 5. Test PSTN connectivity.	The technician user account must be a member of RTCUniversalSBATechnicians.

Survivable Branch Server Details

In Topology Builder create the branch site, add the Survivable Branch Server to that site, and then run the Lync Server Deployment Wizard on the computer where you want to install the role.

1.3.5.3.2.3 Branch-Site Resiliency Requirements

Branch-Site Resiliency Requirements

Planning for High Availability and Disaster Recovery > Planning for Enterprise Voice Resiliency > Planning for Branch-Site Voice Resiliency >

Topic Last Modified: *2012-10-18*

This topic will help you to prepare users for branch-site resiliency and voice mail survivability, and also specifies the relevant hardware and software requirements.

Preparing Branch Users for Branch-Site Resiliency

Prepare users for branch-site resiliency by setting their Registrar pool as the Survivable Branch Appliance (SBA) or Survivable Branch Server.

Registrar Assignments for Branch Users

Regardless of which branch-site resiliency solution you choose, you will need to assign a primary Registrar to each user. Branch site users should always register with the Registrar at the branch site, regardless of whether that Registrar resides in the Survivable Branch Appliance, Survivable Branch Server, or stand-alone Lync Server 2013 Standard or Enterprise Edition server. A domain name system (DNS) service (SRV) resource record is required so that a client can discover its Registrar pool. If the Survivable Branch Appliance becomes unavailable, this is how branch site clients will automatically discover the backup Registrar.

If a branch site does not have a DNS server, there are two alternative ways to configure discovery of the Survivable Branch Appliance or Survivable Branch Server:

- Configure DHCP option 120 on the branch site’s Dynamic Host Configuration Protocol (DHCP) server to point to the fully qualified domain name (FQDN) of the Survivable Branch Appliance or Survivable Branch Server.
- Configure the Survivable Branch Appliance or Survivable Branch Server to respond to DHCP 120 queries.

Voice Routing for Branch Users

We recommend that you create a separate user-level Voice over Internet Protocol (VoIP) policy for users in a branch site. This policy should include a primary route that uses the Survivable Branch Appliance or branch server gateway, and one or more backup routes that use a trunk with a public switched telephone network (PSTN) gateway at the central site. If the primary route is unavailable, the backup route that uses one or more central site gateways is used instead. This way, regardless of where a user is registered—on the branch site Registrar or the backup Registrar pool at the central site—the user’s VoIP policy is always in effect. This is an important consideration for failover scenarios. For example, if you need to rename the Survivable Branch Appliance or reconfigure the Survivable Branch Appliance to connect to a backup Registrar pool at the central site, then you must move branch site users to the central site for the duration. (For details about renaming or reconfiguring a Survivable Branch Appliance, see Appendix B: Managing a Survivable Branch Appliance in the Deployment documentation.) If those users do not have user-level VoIP policies or user-level dial plans, when the users are moved to another site, the site-level VoIP policies and site-level dial plans of the central site apply to the users by default, instead of the branch site site-level VoIP policies and dial plans,.

In this scenario, unless the site-level VoIP policies and site-level dial plans used by the backup Registrar pool can also apply to the branch site users, their calls will fail. For example, if users from a branch site located in Japan are moved to a central site in Redmond, then a dial plan with normalization rules that prepend +1425 to all 7-digit calls is unlikely to appropriately translate calls for those users.

Important:

When you create a branch office backup route, we recommend that you add two PSTN phone usage records to the branch office user policy and assign separate routes to each one. The first, or primary, route would direct calls to the gateway associated with the Survivable Branch Appliance (SBA) or branch server; the second, or backup, route would direct calls to the gateway at the central site. In directing calls, the SBA or branch server will attempt all routes assigned to the first PSTN usage record before attempting the second usage record.

To help ensure that inbound calls to branch site users will reach those users when the branch gateway or the Windows component of the Survivable Branch Appliance site is unavailable (which would happen, for example, if the Survivable Branch Appliance or branch gateway were down for maintenance), create a failover route on the gateway (or work with your Direct Inward Dialing (DID) provider) to redirect incoming calls to the backup Registrar pool at the central site. From there, the calls will be routed over the WAN link to branch users. Be sure that the route translates numbers to comply with the PSTN gateway or other trunk peer's accepted phone number formats. For details about creating a failover route, see Configuring a Failover Route. Also create service-level dial plans for the trunk associated with the gateway at the branch site to normalize incoming calls. If you have two Survivable Branch Appliances at a branch site, you can create a site-level dial plan for both unless a separate service-level plan for each is necessary.

Note:

To account for the consumption of central site resources by any branch site users that rely on the central site for presence, conferencing, or failover, we recommend that you consider each branch site user as if the user were registered with the central site. There are currently no limits on the number of branch site users, including users registered with a Survivable Branch Appliance.

We also recommend that you create a user-level dial plan and voice policy, and then assign it to branch site users. For details, see Create a Dial Plan and Create the VoIP Routing Policy for Branch Users in the Deployment documentation.

Routing Extension Numbers

When preparing dial plans and voice policies for branch site users, be sure to include normalization rules and translation rules that match the strings and number format used in the msRTCSIP-line (or Line URI) attribute, so that Lync 2013 calls enabled between branch site users and central site users will be routed correctly—particularly when calls must be rerouted over the PSTN because the WAN link is unavailable. Additionally, there are special considerations for dialed numbers that include extension numbers, rather just phone numbers.

Normalization rules and translations rules that match Line URIs that contain an extension number, whether exclusively or in addition to a full E.164 phone number, have additional requirements. This section describes several example scenarios to route calls for Line URIs with an extension number.

If your organization does not have Direct Inward Dial (DID) phone numbers configured for individual users and the Line URI of each user is configured with *only* an extension number, internal users can call one another by dialing only an extension number. However, you must configure normalization rules that can apply to calls from a branch site user to a central site user, that match the extension numbers.

In a scenario where the WAN link between a branch site and a central site is available, calls from branch site users to central site users do not require the matching normalization rule to translate the number because the call is not routed over the PSTN. For example:

Rule name	Description	Number pattern	Translation	Example
5digitExtensions	Does not translate 5-digit numbers	^(\d{5})$	$1	10001 is not translated

You must also accommodate extension numbers for specific scenarios, such as when the WAN link between a branch site and central site is unavailable and a call from a branch site must be routed over the PSTN. During a WAN outage, if a branch site user calls a central site user only by dialing the central site user's extension, you must have an outbound translation rule that adds the central site user's full phone number. If a user's Line URI contains your organization's full phone number and the user's unique extension number instead of a full phone number that is unique to the user, then you must have an outbound translation rule that adds your organization's full phone number instead. For example:

Description	Matching pattern	Translation	Example
Translates 5-digit numbers to a user's phone number and extension	^(\d{5})$	+14255550123;ext=$1	10001 is translated to +14255550123;ext=10001
Translates 5-digit numbers to your organization's phone number and a user's extension	^(\d{5})$	+14255550100;ext=$1	10001 is translated to +14255550100;ext=10001

In this scenario, if the trunk peer that handles rerouting to the PSTN does not support extension numbers, then the outbound translation rule must also remove the extension number. For example:

Description	Matching pattern	Translation	Example
Removes extension from phone numbers with extensions	^\+(\d*);ext=(\d*)$	+$1	+14255550123;ext=10001 is translated to +14255550123

Whether or not a WAN link is available, if your organization does not have DID numbers configured for individual users and the Line URI for a user contains your organization's phone number and the user's unique extension number, then you must configure your organization's phone number Line URI with a number that is reachable by the trunk peer or PSTN gateway at the branch site. You must also configure your organization's phone number Line URI to include its own unique extension for calls to be routed to that number.

For details about calls from a central site user to a branch site user when the WAN link between the sites is unavailable, see "Preparing for Voice Mail Survivability" later in this topic. For details about dial plans and normalization rules, including other sample rules, see Dial Plans and Normalization Rules in the Planning documentation and Configuring Dial Plans in the Deployment documentation. For details about outbound translation rules, see Translation Rules in the Planning documentation and Defining Translation Rules in the Deployment documentation.

Preparing for Voice Mail Survivability

Exchange Unified Messaging (UM) is usually installed only at a central site and not at branch sites. A caller should be able to leave a voice mail message, even if the WAN link between branch site and central site is unavailable. As a result, configuring the Line URI for the Exchange UM Auto Attendant phone number that provides voice mail for branch site users requires special considerations, in addition to the voice policy, dial plan, and normalization rules applicable to that voice mail number.

Survivable Branch Appliances (SBAs) and Survivable Branch Servers provide voice mail survivability for branch users during a WAN outage. Specifically, if you are using a Survivable Branch Appliance or Survivable Branch Server and the WAN becomes unavailable, the SBA or Survivable Branch Server reroutes unanswered calls over the PSTN to Exchange UM at the central site. With a SBA or Survivable Branch Server, users can also retrieve voice mail messages through the PSTN during a WAN outage. Finally, during a WAN outage the Survivable Branch Appliance or Survivable Branch Server queues missed-call notifications and then uploads them to the Exchange UM server when the WAN is restored. To help ensure that voice mail rerouting is resilient, be sure that you add an entry for the central site pool's FQDN and an entry for the Edge Server FQDN to the hosts file on the Survivable Branch Server. Otherwise, DNS resolution can time out if you do not have a DNS server at the branch site.

We recommend the following configurations for voice mail survivability for branch site users:

- An Microsoft Exchange administrator should configure Exchange UM Auto Attendant (AA) to accept messages only. This configuration disables all other generic functionality, such as transfer to a user or transfer to an operator, and limits the AA to only accepting messages. Alternatively, the Exchange administrator can use a generic AA or an AA customized to route the call to an operator.
- The Lync Server administrator should take the AA phone number and use that phone number as the **exchange um auto attendant** number in the voice mail rerouting settings for the Survivable Branch Appliance or branch server.
- The Lync Server administrator should get the Exchange UM subscriber access phone number and use that number as the **subscriber access** number in the voice mail rerouting settings for the Survivable Branch Appliance or Survivable Branch Server.
- The Lync Server administrator should configure Exchange UM so that only one dial plan is associated with all branch users who need access to voice mail during a WAN outage.
- When the WAN link is unavailable, calls to branch site users can be routed to the user's Exchange Unified Messaging (UM) voice mailbox, but only if the voice policy applied to the call specifies a voice mail phone number that is unique and does not include an extension number.

Hardware and Software Requirements for Branch-Site Resiliency

The hardware and software requirements vary, depending on your resiliency solution.

Requirements for Survivable Branch Appliances

Required hardware and software is built into the Survivable Branch Appliance. However, we also recommend that each branch site deploy a DHCP server to obtain client IP addresses; otherwise, when the DHCP lease expires, clients will not have IP connectivity.

If the enterprise DNS servers are located only in central sites, branch site users will be unable to access them during a WAN outage, and therefore Lync Server discovery that uses DNS SRV (service (SRV) resource record) will fail. To assure prompt rerouting during a WAN outage, DNS records must be cached at the branch site. If the branch router supports it, turn on DNS caching. Or, you can deploy a DNS server at the branch. This can be a stand-alone server or a version of the Survivable Branch Appliance that supports DNS capabilities. For details, contact your Survivable Branch Appliance provider.

Note:
It is not necessary to have a domain controller at a branch site. The Survivable Branch Appliance authenticates clients by using a special certificate that it sends the client in response to the client's certificate request when it signs in.

Lync clients can discover the Lync Server by using DHCP Option 120 (SIP Registrar Option). This can be configured in one of two ways:

- Configure the DHCP server at the branch site to reply to DHCP 120 queries, which return the FQDN of the Registrar on the Survivable Branch Appliance or Survivable Branch Server.
- Turn on Lync Server DHCP. When this is turned on, the Lync Server Registrar responds to DHCP Option 120 queries. Note that the Registrar does not respond to any DHCP queries other than DHCP Options 120.

Additionally, for larger branch sites that have multiple subnets, DHCP relay agents should be enabled to forward DHCP Option 120 queries to the DHCP Server (configuration 1) or to the Registrar (configuration 2).

Finally, branch site users must be configured for Enterprise Voice and provisioned with an appropriate unified communications endpoint.

Requirements for Survivable Branch Servers

The requirements for Survivable Branch Servers are the same as the requirements for any Lync Server server role. For details, see Determining Your Infrastructure Requirements in the Planning documentation.

Requirements for Full-Scale Lync Server Branch-Site Deployments

For details, see Determining Your Infrastructure Requirements in the Planning documentation.

Configuring a Failover Route

Planning for Enterprise Voice Resiliency > Planning for Branch-Site Voice Resiliency > Branch-Site Resiliency Requirements >

Topic Last Modified: *2012-09-21*

The following example shows how an administrator can define a failover route for use if the Dallas-GW1 is down for maintenance or is otherwise unavailable. The following tables illustrate the required configuration change.

Table 1. User Policy

User policy	Phone usage
Default Calling Policy	Local GlobalPSTNHopoff
Redmond Local Policy	RedmondLocal
Dallas Calling Policy	DallasUsers GlobalPSTNHopoff

Table 2. Routes

Route name	Number pattern	Phone usage	Trunk	Gateway

Redmond Local Route	^\+1(425|206|253)(\d{7})$	Local RedmondLocal	Trunk1 Trunk2	Red-GW1 Red-GW2
Dallas Local Route	^\+1(972|214|469)(\d{7})$	Local	Trunk3	Dallas-GW1
Universal Route	^\+?(\d*)$	GlobalPSTNHopoff	Trunk1 Trunk2 Trunk3	Red-GW1 Red-GW2 Dallas-GW1
Dallas Users Route	^\+?(\d*)$	DallasUsers	Trunk3	Dallas-GW1

In Table 1, a phone usage of GlobalPSTNHopoff is added after the DallasUsers phone usage in the Dallas Calling Policy. This enables calls with the Dallas Calling policy to use routes that are configured for the GlobalPSTNHopoff phone usage if a route for the DallasUsers phone usage is unavailable.

- Response Group Disaster Recovery Procedures

1.3.5.4.1.1 Planning for Response Group Disaster Recovery

Planning for Response Group Disaster Recovery

Planning for High Availability and Disaster Recovery > Call Management Features for High Availability and Disaster Recovery > Managing Response Groups During a Disaster >

Topic Last Modified: *2012-11-01*

This section describes some ways to prepare response groups for disaster recovery and provides an overview of the disaster recovery process.

Preparing for Response Group Disaster Recovery

Keep the following in mind when you prepare for and carry out disaster recovery procedures.

Note:

In a coexistence environment, only the Lync Server 2013 response groups are supported for the disaster recovery procedures described in this document.

- Plan for disaster recovery when you do your capacity planning. For disaster recovery capacity, each pool in a paired pool should be able to handle the workloads of all the response groups in both pools. For details about Response Group capacity planning, see Capacity Planning for Response Group.
- Take regular backup copies of all the response group configurations in all the Front End pools where you deployed the Response Group application by using the export procedure described in this document. For details, see Response Group Disaster Recovery Procedures. Keep the backup copies in a safe location.
- Keep a separate backup copy of all the original audio files you used for the Response Group application, including any recordings and music-on-hold files. Keep the backup files in a safe location.
- For Lync Server 2013 disaster recovery, all Response Group settings must have unique names across your deployment. This requirement applies to workflows, queues, agent groups, holiday sets, and hours of business. You should verify that this requirement is met when the primary and backup pools are still active, and before you need to initiate any failover procedure. If you encounter name conflicts while importing response group data to the backup pool, the import fails. To complete the import and failover procedure, you need to resolve the name conflicts by renaming the response group object in the backup pool or by using the **Import-CsRgsConfiguration** cmdlet with the –ResolveNameConflicts parameter to automatically resolve the conflict by appending a unique identifying number to the response group object.
- In general, we recommend that you perform daily backups, but if you have a high volume of changes, you might want to schedule more frequent backups. The amount of information you can lose in the event of a disaster depends on the frequency of your backups, as well as the frequency and volume of changes.
- It is possible to import response groups to a backup pool before a disaster or failover operation occurs. Importing response groups in advance reduces downtime, because the Lync Server Response Group service can be restored in the backup pool as soon as calls are routed to the backup pool.

Note:
The Response Group application cannot reach any agents homed in an inactive pool until failover is complete. During this time, the Response Group application processes calls as if those agents are unavailable.

Response Group Disaster Recovery Process

In the event of a disaster, you can recover response groups by using either of the following recovery approaches:

- Fail over to a backup pool and then fail back to the original pool.
- Fail over to a backup pool, create a new pool with a different fully qualified domain name (FQDN), and then import the response groups to the new pool.

During the failover phase of disaster recovery, the response groups reside in multiple pools: in the primary pool (which is unavailable) and in the backup pool. The response groups in both pools have the same name and the same owner (the primary pool), but they have different parents.

When you recover by creating a new pool with a different FQDN, you need to assign the new pool as the owner of the response groups when you import them. Ownership of response groups remains with the original pool unless or until you explicitly reassign ownership by using the –OverwriteOwner parameter with the **Import-CsRgsConfiguration** cmdlet.

Note:
You also need to use the –OverwriteOwner parameter if you rebuilt the pool during the recovery (that is, the Response Group database is empty), whether or not you use the same FQDN. You do not need to use the –OverwriteOwner parameter if you did not rebuild the pool, but it is permissible to use this parameter whenever you import response groups back to the primary pool.

You can define only one set of application-level Response Group configuration settings per pool. These settings include the default music-on-hold configuration, the default music-on-hold audio file, the agent ringback grace period, and the call context configuration. To view these configuration settings, run the **Get-CsRgsConfiguration** cmdlet. For details about the **Get-CsRgsConfiguration** cmdlet, see Get-CsRgsConfiguration.

You can transfer these application-level settings from one pool to another by using the **Import-CsRgsConfiguration** cmdlet with the –ReplaceExistingSettings parameter, but doing so overrides the settings in the destination pool.

Important:
This constraint about transferring settings to another pool is true only for the application-level settings and the default music-on-hold audio file. It does not apply to agent groups, queues, workflows, business hours, and holiday sets.

If you don't want to replace the application-level settings in the backup pool during a disaster and the primary pool can't be recovered, the application-level settings from the primary pool will be lost. If you need to create a new pool to replace the primary pool during recovery, either with the same FQDN or with a different FQDN, you can't recover the original application-level settings. In this case, you need to configure the new pool with these settings and include the music-on-hold audio file.

If you decide to use the **Import-CsRgsConfiguration** cmdlet to transfer application-level settings from the primary pool to the backup pool during a disaster, you can then transfer the settings from the backup pool to the new pool during recovery in the same way that you transferred them from the primary pool to the backup pool.

The following table is an overview of the steps involved in recovering response groups.

For details about performing these steps, see Response Group Disaster Recovery Procedures.

Response Group Disaster Recovery Steps

Phase	Steps	Required groups and roles
Before outage	On a routine basis, run the **Export-CsRgsConfiguration** cmdlet to create backups of all Response Group configurations in all Front End pools where Response Group application is deployed.	RTCUniversalServerAdmins CsResponseGroupAdministrator
During outage	Run the **Import-CsRgsConfiguration** cmdlet to import the backed up Lync Server Response Group service configuration from the primary pool to the backup pool. **Note:** Use the –ReplaceExistingSettings parameter if you want to replace application-level Response Group settings in the backup pool with the settings from the primary pool. If you do not transfer the application-level settings from the primary pool to the backup pool, and the primary pool can't be recovered, you will lose the settings from the primary pool.	RTCUniversalServerAdmins CsResponseGroupAdministrator
After importing	Run Response Group cmdlets with either the –ShowAll parameter (to display all response groups) or the –Owner parameter (to display only imported response groups) to verify that all response group configurations were imported to the backup pool. **Important:** If you do not use either the –ShowAll parameter or the –Owner parameter, the response groups that you imported to the backup pool will not be listed in the results returned by the cmdlets. Run the following cmdlets: • **Get-CsRgsWorkflow** • **Get-CsRgsQueue** • **Get-CsRgsAgentGroup** • **Get-CsRgsHoursOfBusiness** • **Get-CsRgsHolidaySet**	RTCUniversalServerAdmins CsResponseGroupAdministrator
After failover	• Place a test call to a response group that was imported to the backup pool and verify that the call is	N/A

	handled correctly. • All formal agents must sign in again to their formal groups on backup pool. • Manage configuration changes: Response groups in the backup pool, whether imported to the backup pool or owned by the backup pool, can be modified as usual during the outage. **Important:** You must use Lync Server Management Shell to manage the response groups that you imported to the backup pool. You cannot use Lync Server Control Panel to manage these response groups while they are in the backup pool.	
After recovery, before failback	Run the **Export-CsRgsConfiguration** cmdlet specifying the -Source parameter as the backup pool and the –Owner parameter as the primary pool to export the response groups owned by the primary pool from the backup pool.	RTCUniversalServerAdmins CsResponseGroupAdministrator
After failback	• Run the **Import-CsRgsConfiguration** cmdlet to import the response groups back to the primary pool. **Note:** If the primary pool can't be recovered and you deploy a new pool to replace it, use the –ReplaceExistingSettings parameter to transfer the application-level settings from the backup pool to the new pool. If you do not transfer the settings from the backup pool, the new pool will use the default settings. • Run the following cmdlets with either the –ShowAll parameter (to display all response groups) or the –	RTCUniversalServerAdmins CsResponseGroupAdministrator

	Owner parameter (to display only imported response groups) to verify that all response group configurations were successfully imported back to the primary pool: - **Get-CsRgsWorkflow** - **Get-CsRgsQueue** - **Get-CsRgsAgentGroup** - **Get-CsRgsHoursOfBusiness** - **Get-CsRgsHolidaySet** - Place a test call to a response group that was imported back to the primary pool and verify that the call is handled correctly. - Optionally, run the **Export-CsRgsConfiguration** cmdlet on the backup pool with the –RemoveExportedConfiguration parameter to remove the response groups owned by the primary pool from the backup pool.	

1.3.5.4.1.2 Response Group Experience During Pool Failure

Response Group Experience During Pool Failure

Planning for High Availability and Disaster Recovery > Call Management Features for High Availability and Disaster Recovery > Managing Response Groups During a Disaster >

Topic Last Modified: *2012-10-30*

This section describes in detail how response group activity is affected in the following stages:

- An outage occurs in the primary pool, but failover is not yet initiated.
- Service is failed over to the backup pool.
- Service is failed back to the primary pool.

User Experience When Outage Occurs

When a pool or site outage occurs, but the administrator has not yet initiated failover, response group activity is handled as described in the following table.

Note:

During disaster recovery, calls behave differently depending on whether the primary pool response groups were imported to the backup pool during recovery. In the following table, references to imported response groups mean that primary pool response groups were imported to the backup pool during disaster recovery mode.

Outage Occurs

Type of call or user action	During outage

Calls connected to an agent	• Regular calls remain connected. • Anonymous calls are disconnected.
In progress calls not yet connected to an agent	Calls are disconnected.
New calls	• Calls are disconnected. • If response groups were imported, calls connect to backup pool, but agents homed in primary pool are unreachable.
Agent calls on behalf of response group	Feature is disabled during this stage.
Agent sign-in and agent information	• Agent groups owned by the primary pool can be viewed on agent console but agents cannot sign in. • Agent groups owned by the backup pool can be viewed on agent console and agents can sign in. • Imported agent groups are not displayed on agent console.
Response group configuration	• Response groups owned by the primary pool can be viewed, depending on the availability of the primary pool's back-end database, but cannot be modified. • Response groups owned by the backup pool can be viewed and modified. • Imported response groups cannot be viewed with Lync Server Control Panel or the Response Group Configuration Tool, but can be configured by using Lync Server Management Shell cmdlets.

User Experience During Failover

When an administrator invokes failover to a backup pool, response group activity is handled during and after the failover as described in the following table. The first column describes the type of activity that might be taking place. The middle column describes how each activity is handled during the brief time that it takes to fail over to the backup pool. The last column describes how the activity is handled for the duration, after the failover process is complete and the backup pool is standing in for the primary pool.

Note:

During disaster recovery, calls behave differently depending on whether the primary pool response groups were imported to the backup pool during recovery. In the following table, references to imported response groups mean that primary pool response groups were imported to the backup pool during disaster recovery mode.

Failover Is Initiated

Type of call or user action	**During Failover**	**After Failover Completes**
Calls connected to an agent	• Regular calls remain connected. • Anonymous calls are disconnected.	• Regular calls remain connected. • For imported response groups, anonymous calls that have reached the backup pool remain connected.

In progress calls not yet connected to an agent	Calls are disconnected.	• If response groups were not imported, no calls are in this status. • For imported response groups, calls that have reached the backup pool remain connected.
New calls	• Calls are disconnected. • For imported response groups, calls connect to the backup pool, but agents homed in the primary pool are unreachable.	• If response groups were not imported, calls are disconnected. • For imported response groups, calls connect to the backup pool.
Agent calls on behalf of response group	Feature is disabled during this stage	• If response groups were not imported, calls fail. • For imported response groups, calls succeed.
Agent sign-in and agent information	• Agent groups owned by the primary pool can be viewed on agent console but agents cannot sign in. • Agent groups owned by the backup pool can be viewed on agent console and agents can sign in. • Imported agent groups are displayed on agent console and agents can sign in.	• Agent groups owned by the primary pool can be viewed on agent console but agents cannot sign in. • Agent groups owned by the backup pool can be viewed on agent console and agents can sign in. • Imported agent groups are displayed on agent console and agents can sign in.
Response group configuration	• Response groups owned by the primary pool can be viewed, depending on the availability of the primary pool's back-end database, but cannot be modified. • Response groups owned by the backup pool can be viewed and modified. • Imported response groups cannot be viewed with Lync Server Control Panel or the Response Group Configuration Tool, but can be configured by using Lync Server Management Shell cmdlets.	• Response groups owned by the primary pool can be viewed, depending on the availability of the back end database, but cannot be modified. • Response groups owned by the backup pool can be viewed and modified. • Imported response groups cannot be viewed with Lync Server Control Panel or the Response Group Configuration Tool, but can be configured by using Lync Server Management Shell cmdlets.

User Experience During Failback

When an administrator invokes failback to the primary pool, response group activity is handled during and after the failback as described in the following table.

Note:

During disaster recovery, calls behave differently depending on whether the primary pool response groups were imported to the backup pool during recovery. In the following table, references to imported response groups mean that primary pool response groups were imported to the backup pool during disaster recovery mode.

Call Handling in Failback

Type of call or user action	**During Failback**	**After Failback Completes**
Calls connected to an agent	• Regular calls remain connected. • If response groups were not imported, no anonymous calls are in this status. • For imported response groups, anonymous calls remain connected.	• Regular calls remain connected. • If response groups were not imported, no anonymous calls are in this status. • For imported response groups, anonymous calls remain connected.
In progress calls not yet connected to an agent	• If response groups were not imported, no calls are in this status. • For imported response groups, calls will be disconnected.	• If response groups were not imported, no calls are in this status. • For imported response groups, calls will be disconnected.
New calls	Calls connect to the primary pool, but agents homed in the primary pool are unreachable.	Calls connect to the primary pool.
Agent calls on behalf of response group	Feature is disabled during this stage.	Calls succeed.
Agent sign-in and agent information	• Agent groups owned by the primary pool can be viewed on agent console but agents cannot sign in. • Agent groups owned by the backup pool can be viewed on agent console and agents can sign in. • Imported agent groups are displayed on agent console and agents can sign in.	• Agent groups owned by the primary pool can be viewed on agent console and agents can sign in. • Agent groups owned by the backup pool can be viewed on agent console and agents can sign in. • Imported agent groups are not displayed on agent console.
Response group configuration	• Response groups owned by the primary pool can be viewed, depending on the availability of the primary pool's back-	• Response groups owned by the primary pool can be viewed and modified. • Response groups owned by the backup

	end database, but cannot be modified. • Response groups owned by the backup pool can be viewed and modified. • Imported response groups cannot be viewed with Lync Server Control Panel or the Response Group Configuration Tool, but can be configured by using Lync Server Management Shell cmdlets.	pool can be viewed and modified. • Imported response groups cannot be viewed with Lync Server Control Panel or the Response Group Configuration Tool, but can be configured by using Lync Server Management Shell cmdlets.

1.3.5.4.1.3 Response Group Disaster Recovery Procedures

Response Group Disaster Recovery Procedures

Planning for High Availability and Disaster Recovery > Call Management Features for High Availability and Disaster Recovery > Managing Response Groups During a Disaster >

Topic Last Modified: *2012-11-01*

During the failover phase of disaster recovery, the response groups reside in multiple pools: in the primary pool (which is unavailable) and in the backup pool. The response groups in both pools have the same name and the same owner (the primary pool), but they have different parents. During this time, Response Group cmdlets work a little differently. Be sure to use parameters as specified in the following procedure. For details about how cmdlets work during the failover phase, see NextHop blog article "Lync Server 2013: Recovering Response Groups During Disaster Recovery" at http://go.microsoft.com/fwlink/p/?LinkId=263957. This blog article also applies to the released version of Lync Server 2013.

Use the steps in the following procedure to prepare for and perform disaster recovery for Lync Server Response Group service.

To fail over and fail back Response Group

1. Start the Lync Server Management Shell: Click **Start**, click **All Programs**, click **Microsoft Lync Server 2013**, and then click **Lync Server Management Shell**.
2. Routinely perform backups. At the command line, type:

   ```
   Export-CsRgsConfiguration -Source "service:ApplicationServer:<primary
   ```

   For example:

   ```
   Export-CsRgsConfiguration -Source "service:ApplicationServer:primary.c
   ```

3. During an outage, after failover to the backup pool, import the response groups to the backup pool. At the command line, type:

   ```
   Import-CsRgsConfiguration -Destination "service:ApplicationServer:<bac
   ```

   If you want to replace the application-level settings in the backup pool with the settings from the primary pool, include the –ReplaceExistingSettings parameter. For example:

```
Import-CsRgsConfiguration -Destination "service:ApplicationServer:back
```

Caution:
If you do not replace the settings in the backup pool and the primary pool can't be recovered, the primary pool settings will be lost. For details, see Planning for Response Group Disaster Recovery.

4. Verify that the import was successful by displaying the imported response groups. The imported response groups are still owned by the primary pool. Do the following:
   - Display all the workflows in the backup pool that are owned by the primary pool, and verify that all the primary pool workflows are included. At the command line, type:

     ```
     Get-CsRgsWorkflow -Identity "service:ApplicationServer:<back
     ```

     For example:

     ```
     Get-CsRgsWorkflow -Identity "service:ApplicationServer:backu
     ```

   - Display all the queues in the backup pool that are owned by the primary pool, and verify that all the primary pool queues are included. At the command line, type:

     ```
     Get-CsRgsQueue -Identity "service:ApplicationServer:<backup
     ```

     For example:

     ```
     Get-CsRgsQueue -Identity "service:ApplicationServer:backup.c
     ```

   - Display all the agent groups in the backup pool that are owned by the primary pool, and verify that all the primary pool agent groups are included. At the command line, type:

     ```
     Get-CsRgsAgentGroup -Identity "service:ApplicationServer:<ba
     ```

     For example:

     ```
     Get-CsRgsAgentGroup -Identity "service:ApplicationServer:bac
     ```

   - Display all the hours of business in the backup pool that are owned by the primary pool, and verify that all the primary pool hours of business are included. At the command line, type:

     ```
     Get-CsRgsHoursOfBusiness -Identity "service:ApplicationServe
     ```

     For example:

     ```
     Get-CsRgsHoursOfBusiness -Identity "service:ApplicationServe
     ```

   - Display all the holiday sets in the backup pool that are owned by the primary pool, and verify that all the primary pool holiday sets are included. At the command line, type:

     ```
     Get-CsRgsHolidaySet -Identity "service:ApplicationServer:<ba
     ```

     For example:

     ```
     Get-CsRgsHolidaySet -Identity "service:ApplicationServer:bac
     ```

   Alternatively, you can display all the response groups in the backup pool, including the ones owned by the primary pool and the ones owned by the backup pool by using the –ShowAll parameter instead of the –Owner parameter. For example:

   ```
   Get-CsRgsWorkflow -Identity "service:ApplicationServer:<backup pool FQ
   ```

   Important:
   You must use either the –ShowAll parameter or the –Owner parameter. If you do not use either of these parameters, the response groups that you imported to the backup pool will not be listed in the results returned by the cmdlets.

5. Verify that the import was successful by placing a call to an imported

response group and verifying that the call is handled correctly.

6. Request agents who are members of formal agent groups to sign in to their agent groups in the backup pool.
7. Manage and modify the imported response groups as usual.

> **Important:**
> While the response groups are in the backup pool, you need to use Lync Server Management Shell to manage them. You cannot use Lync Server Control Panel to manage the response groups that you imported to the backup pool.

8. After the primary pool is restored and failback is complete, export the primary pool response groups that were imported to the backup pool. At the command line, type:

```
Export-CsRgsConfiguration -Source ApplicationServer:<backup pool FQDN>
```

9. Import the response groups back to the primary pool. At the command line, type:

```
Import-CsRgsConfiguration -Destination "service:ApplicationServer:<pri
```

For example:

```
Import-CsRgsConfiguration -Destination "service:ApplicationServer:prim
```

> **Note:**
> If you rebuild a pool during recovery, whether with the same or a different fully qualified domain name (FQDN), you need to use the –OverwriteOwner parameter. As a rule of thumb, you can always use the –OverwriteOwner parameter when you import response groups back to the primary pool.

If you deployed a new pool (with the same or a different FQDN) to replace the primary pool, and you want to use the application-level settings from the backup pool for the new pool, include the –ReplaceExistingSettings parameter. At the command line, type:

```
Import-CsRgsConfiguration -Destination "service:ApplicationServer:<new
```

For example:

```
Import-CsRgsConfiguration -Destination "service:ApplicationServer:newp
```

> **Important:**
> If you don't want to replace the application-level settings and default music-on-hold audio file for the new pool with the settings from the backup pool, the new pool will use the default application-level settings.

10. Verify that the import back to the primary pool was successful by displaying the imported response group configuration. Do the following:
    - Display all the workflows in the primary pool, and verify that all the imported workflows are included. At the command line, type:

      ```
      Get-CsRgsWorkflow -Identity "service:ApplicationServer:<pri
      ```

      For example:

      ```
      Get-CsRgsWorkflow -Identity "service:ApplicationServer: prim
      ```

    - Display all the queues in the primary pool, and verify that all the imported queues are included. At the command line, type:

      ```
      Get-CsRgsQueue -Identity "service:ApplicationServer:<primary
      ```

      For example:

      ```
      Get-CsRgsQueue -Identity "service:ApplicationServer:primary.
      ```

    - Display all the agent groups in the primary pool, and verify that all the imported agent groups are included. At the command line, type:

      ```
      Get-CsRgsAgentGroup -Identity "service:ApplicationServer: <p
      ```

      For example:

```
Get-CsRgsAgentGroup -Identity "service:ApplicationServer:pri
```

- Display all the hours of business in the primary pool, and verify that all the imported hours of business are included. At the command line, type:

  ```
  Get-CsRgsHoursOfBusiness -Identity "service:ApplicationServe
  ```

  For example:

  ```
  Get-CsRgsHoursOfBusiness -Identity "service:ApplicationServe
  ```

- Display all the holiday sets in the primary pool, and verify that all the imported holiday sets are included. At the command line, type:

  ```
  Get-CsRgsHolidaySet -Identity "service:ApplicationServer:<p
  ```

  For example:

  ```
  Get-CsRgsHolidaySet -Identity "service:ApplicationServer:pri
  ```

11. Verify that the import was successful by placing a call to an imported response group and verifying that the call is handled correctly.
12. Optionally, remove the response groups owned by the primary pool from the backup pool. At the command line, type:

    ```
    Export-CsRgsConfiguration -Source "service:ApplicationServer:<backup p
    ```

    For example:

    ```
    Export-CsRgsConfiguration -Source "service:ApplicationServer:backup.co
    ```

    Note:
    This step creates a new file with the exported configuration, and then removes it from the backup pool.

1.3.5.4.2 Manage Call Park During Disaster Recovery

Manage Call Park During Disaster Recovery

Planning > Planning for High Availability and Disaster Recovery > Call Management Features for High Availability and Disaster Recovery >

Topic Last Modified: *2012-09-10*

Lync Server 2013 supports Call Park in the backup pool during disaster recovery. This section describes things to consider if you want to support Call Park during an outage and what happens to parked calls during the stages of an outage.

- Planning for Call Park Disaster Recovery
- Call Park Experience During Pool Failure

1.3.5.4.2.1 Planning for Call Park Disaster Recovery

Planning for Call Park Disaster Recovery

Planning for High Availability and Disaster Recovery > Call Management Features for High Availability and Disaster Recovery > Manage Call Park During Disaster Recovery >

Topic Last Modified: *2012-10-30*

This section describes some ways to prepare the Call Park application for disaster recovery and some considerations for the disaster recovery process.

Preparing for Call Park Disaster Recovery

Keep the following in mind when preparing for and carrying out disaster recovery procedures.

- Plan for disaster recovery when you do your capacity planning. For disaster recovery capacity, each pool in a paired pool should be able to handle the workloads of the Call Park services in both pools. For details about Call Park capacity planning, see Capacity Planning for Call Park.
- During disaster recovery, users who have been redirected to the backup pool as part of the failover process use the Call Park service running in the backup pool. Therefore, support for Call Park during disaster recovery requires the Call Park application to be deployed and enabled in both the primary pool and the backup pool.
- Each pool must have a valid range of orbit numbers for users who are homed in that pool to use for parking calls.
- Always keep a separate backup copy of any customized music on hold that has been uploaded for Call Park. These files are not backed up as part of the Lync Server 2013 disaster recovery process and will be lost if the files uploaded to the pool are damaged, corrupted, or erased.

Call Park Disaster Recovery Considerations

You can define only one set of Call Park application configuration settings and one customized music-on-hold audio file per pool. These settings include the timeout threshold, music on hold, maximum call pickup attempts, and timeout URI. To view these configuration settings, run the **Get-CsCpsConfiguration** cmdlet. For details about the **Get-CsCpsConfiguration** cmdlet, see Get-CsCpsConfiguration.

During disaster recovery, Call Park uses the Call Park application in the backup pool, so settings in the primary pool are not backed up. If the primary pool can't be recovered and you deploy a new pool to replace the primary pool, the settings from the primary pool are lost, and you need to reconfigure the Call Park settings and any customized music-on-hold audio files in the new pool.

If you deploy a new pool with a different fully qualified domain name (FQDN) to replace the primary pool, you need to reassign all the Call Park orbit ranges that were associated with the primary pool to the FQDN of the new pool. To reassign orbit ranges to the new pool, you can use either Lync Server Control Panel or the **Set-CsCallParkOrbit** cmdlet. For details about the **Set-CsCallParkOrbit** cmdlet, see Set-CsCallParkOrbit.

1.3.5.4.2.2 Call Park Experience During Pool Failure

Call Park Experience During Pool Failure

Planning for High Availability and Disaster Recovery > Call Management Features for High Availability and Disaster Recovery > Manage Call Park During Disaster Recovery >

Topic Last Modified: *2012-09-10*

When a Front End pool becomes unavailable due an unplanned incident, calls that have been parked but not yet retrieved are disconnected. During failover to a backup pool, users are redirected to the backup pool and are in resiliency mode. While in resiliency mode, users cannot park calls, but they can place calls on hold and transfer them. When failover is complete, calls can again be parked and retrieved as usual. During failback, users cannot park calls until they are out of resiliency mode.

During disaster recovery, users who have been redirected to the backup pool as part of the failover process use the Call Park application that is deployed in the backup pool.

Therefore, users who are redirected to the backup pool use the call park settings that are configured for the Call Park application in the backup pool.

The following table summarizes the Call Park experience through the phases of disaster recovery.

User Experience During Disaster Recovery

Call state	When outage occurs	During failover	During failback
Call not yet parked	Call remains connected, but cannot be parked.	• During failover, call cannot be parked while users are in resiliency mode, but can be put on hold and transferred. • When failover completes, call can be parked and retrieved.	• During failback, call cannot be parked while users are in resiliency mode, but can be put on hold and transferred. • When failback completes, call can be parked and retrieved.
Call parked, but not yet retrieved	Call is disconnected.	No calls in this state.	Call remains parked.
Parked call already retrieved	Call remains connected.	Call remains connected.	Call remains connected.

1.3.5.4.3 Manage Announcements During Disaster Recovery

Manage Announcements During Disaster Recovery

Planning > Planning for High Availability and Disaster Recovery > Call Management Features for High Availability and Disaster Recovery >

Topic Last Modified: *2013-02-23*

Lync Server 2013 supports announcements for calls to unassigned numbers during outages. Restoring announcement functionality during an outage is optional. If you choose to restore announcements during an outage, you need recreate your announcement configuration in the backup pool. This section describes what you need to do if you choose to restore announcements during disaster recovery.

This section applies to unassigned number ranges that use the Announcement application. This section does not apply to unassigned number ranges that use Exchange Unified Messaging (UM) Auto Attendant.

Before an Outage

Regardless of whether you choose to use announcements during outages, you should take separate backups of any customized audio files that you configured for the Announcement application. Customized announcements are not backed up as part of the Lync Server disaster recovery process. If you do not take separate backups of the files and the files that you uploaded to the server or pool are damaged, corrupted, or erased, the files will be lost.

If you do not have backup copies of customized audio files, and the original audio files are no longer available, you can find the audio files that you configured for an Announcement application by looking in the File Store for the server or pool where you originally imported the files. You can copy all the audio files that you configured for the Announcement application from the File Store.

To copy audio files from the file store

1. At the command line, run:

   ```
   Xcopy <Source: Pool Announcement Service File Store path> <Destination
   ```

   For example:

   ```
   Xcopy "<Pool File Store Path>\X-ApplicationServer-X\AppServerFiles\RGS
   ```

   Where X-ApplicationServer-X refers to the service ID of the Application Server of the pool (for example, 1-ApplicationServer-1")

During an Outage

To use the Announcement application during an outage, you need to recreate the announcement configuration in the backup pool by performing the tasks described in this section.

> **Note:**
> We recommend that you perform these tasks after you fail over to the backup pool, because as soon as you perform step 2, the backup pool takes ownership of the unassigned number ranges.

> **Note:**
> These steps are not required for number ranges that use an Exchange UM Auto Attendant phone number.

To recreate the announcement configuration in the backup pool

1. Recreate the announcements that you deployed in the primary pool in the backup pool by doing the following:
   1.a. Import any audio files used in the primary pool to the backup pool by using the **Import-CsAnnouncementFile** cmdlet and specifying the backup pool for the Parent parameter.
   1.b. Recreate each announcement by using the **New-CsAnnouncement** cmdlet and specifying the backup pool for the Parent parameter.

   > **Note:**
   > For details about using these parameters to create announcements in the backup pool, see Create an Announcement.

2. After all announcements are recreated in the backup pool, redirect all the unassigned number ranges that use announcements in the primary pool to the recreated announcements in the backup pool.

   For each unassigned number range that uses an announcement in the primary pool, run the following:

   ```
   Set-CsUnassignedNumber -Identity "<name of number range>" -Announcemen
   ```

After the Outage

When the primary pool becomes available, you need to redirect the unassigned number ranges that you changed for the outage back to the primary pool.

> **Note:**
> These steps are not required for number ranges that use an Exchange UM Auto Attendant phone number.

To restore announcements in the primary pool

1. If you had to rebuild the primary pool during the recovery, you need to recreate the announcements in the primary pool by importing the audio files and creating announcements, just as you did in the backup pool, except that you specify the primary pool for the Parent parameter. For details, see "During an Outage" earlier in this topic.
2. For each unassigned number range that you changed for the outage, run the following:

   ```
   Set-CsUnassignedNumber [-Identity "<name of number range>"] -Announcem
   ```

3. Optionally, remove the announcements that you recreated in the backup pool. Get a list of announcements for the backup pool Announcement application. At the command line, run:

   ```
   Get-CsAnnouncement -Identity "<Service:service ID>"
   ```

   For example:

   ```
   Get-CsAnnouncement -Identity "ApplicationServer:redmond.contoso.com
   ```

   In the resulting list, locate the announcements you want to remove and copy the GUIDs. For each announcement you want to remove, run:

   ```
   Remove-CsAnnouncement -Identity "<Service:service ID/guid>"
   ```

   For example:

   ```
   Remove-CsAnnouncement -Identity "ApplicationServer:redmond.contoso.com
   ```

1.3.5.5 Configuring Persistent Chat Server for High Availability and Disaster Recovery

Configuring Persistent Chat Server for High Availability and Disaster Recovery

Microsoft Lync Server 2013 > Planning > Planning for High Availability and Disaster Recovery >

Topic Last Modified: *2012-10-01*

The Lync Server 2013, Persistent Chat Server services use a *stretched pool* configuration for disaster recovery. A stretched pool is a pool that has computers that are distributed between two physical data centers, but are within a single logical Lync Server site.

In This Section

- Required Resources
- Using Topology Builder to Configure High Availability and Disaster Recovery
- Using a Stretched Persistent Chat Server Pool for Disaster Recovery
- SQL Server Mirroring
- Setting Up SQL Server Log Shipping for the Persistent Chat Server Primary Database
- Setting Up SQL Server Log Shipping between the Primary Mirror and the Log Shipping Secondary Database

1.3.5.5.1 Required Resources

Required Resources

Planning > Planning for High Availability and Disaster Recovery > Configuring Persistent Chat Server for High Availability and Disaster Recovery >

Topic Last Modified: *2012-10-01*

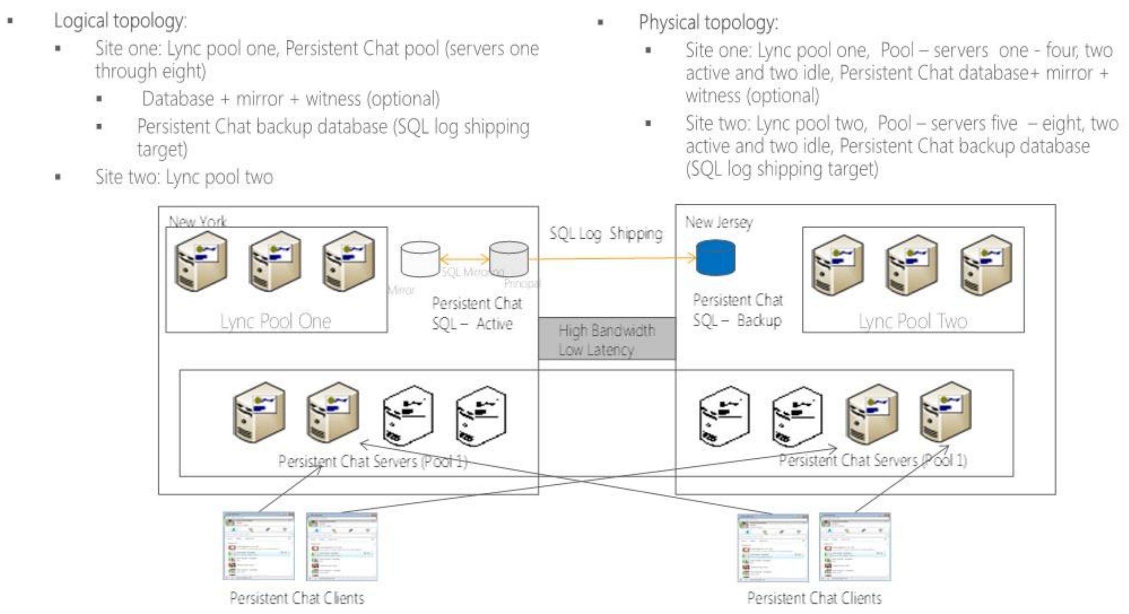
High availability and disaster recovery for Persistent Chat Server requires additional resources beyond what is typically needed for full operation. Before configuring Persistent Chat Server for high availability and disaster recovery, ensure that you have the following resources in addition to what is required for standard Persistent Chat Server operation. For additional configuration information, see Configuring Persistent Chat Server.

- One dedicated database instance located in the same physical data center in which the home front end of the Persistent Chat Server service is located. This database will serve as the SQL Server mirror for the primary Persistent Chat database. Optionally, designate an additional SQL Server to serve as the mirroring witness if you want an automated failover to the mirror database.
- One dedicated database instance located in the other physical data center. This database will serve as the SQL Server Log Shipping secondary database for the database in the primary data center.
- One dedicated database instance to serve as the SQL Server mirror for the secondary database. Optionally, designate an additional SQL Server to server as the mirroring witness. Both of these must be located in the same physical data center as the secondary database.
- If Persistent Chat Server compliance is enabled, an additional three dedicated database instances are required. Their distribution is the same as those previously outlined for the Persistent Chat database. While it is possible for the compliance database to share the same SQL Server instance as the Persistent Chat database, we recommend standalone instances for high availability and disaster recovery.
- A file share must also be created and designated for the SQL Server Log Shipping transaction logs. This share must have read/write privileges to all the SQL Server services that are running the Persistent Chat databases in both data centers. This share is not defined as part of a FileStore role.
- A file share on the secondary database server to serve as the destination folder for the SQL Server transaction logs that are copied from the primary server file share.

The following figures provide examples about how the entire Persistent Chat Server pool can be configured in the two different stretched pool topologies:

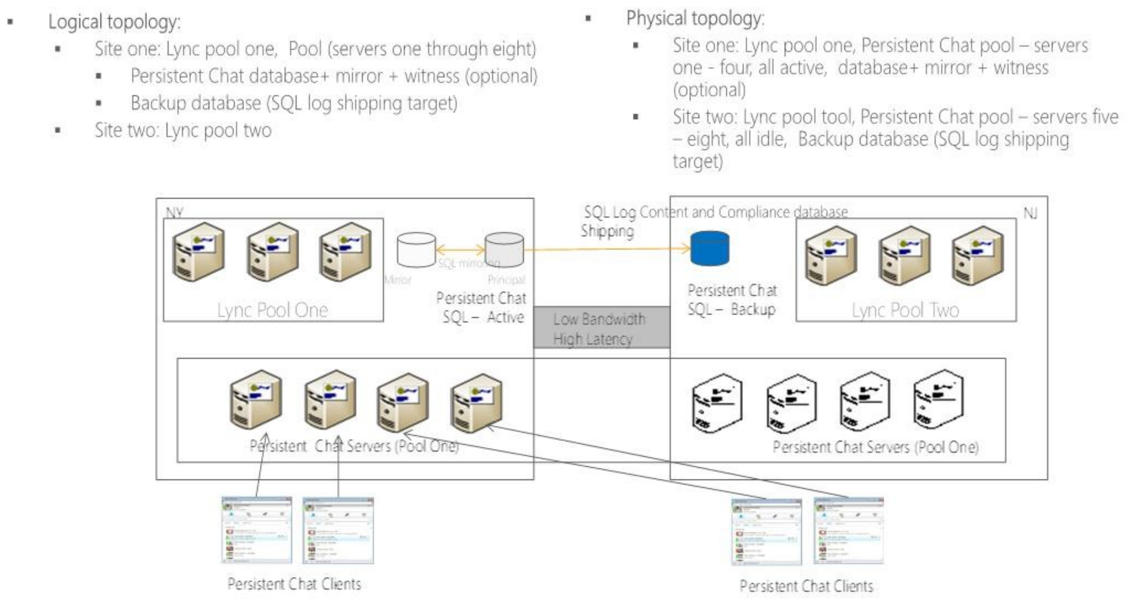
- Stretched Persistent Chat Server pool when data centers are geo-located with high bandwidth/low latency.
- Stretched Persistent Chat Server pool when data centers are geo-located with low bandwidth/high latency.

The following figure shows a stretched Persistent Chat Server pool topology where data centers are geo-located with high bandwidth/low latency.



- Logical topology:
  - Site one: Lync pool one, Persistent Chat pool (servers one through eight)
    - Database + mirror + witness (optional)
    - Persistent Chat backup database (SQL log shipping target)
  - Site two: Lync pool two
- Physical topology:
  - Site one: Lync pool one, Pool – servers one - four, two active and two idle, Persistent Chat database+ mirror + witness (optional)
  - Site two: Lync pool two, Pool – servers five – eight, two active and two idle, Persistent Chat backup database (SQL log shipping target)

The following figure shows a stretched Persistent Chat Server pool topology where data centers are geo-located with low bandwidth/high latency.



- Logical topology:
  - Site one: Lync pool one, Pool (servers one through eight)
    - Persistent Chat database+ mirror + witness (optional)
    - Backup database (SQL log shipping target)
  - Site two: Lync pool two
- Physical topology:
  - Site one: Lync pool one, Persistent Chat pool – servers one - four, all active, database+ mirror + witness (optional)
  - Site two: Lync pool tool, Persistent Chat pool – servers five – eight, all idle, Backup database (SQL log shipping target)

1.3.5.5.2 Using Topology Builder to Configure High Availability and Disaster Recovery

Using Topology Builder to Configure High Availability and Disaster Recovery

Planning > Planning for High Availability and Disaster Recovery > Configuring Persistent Chat Server for High Availability and Disaster Recovery >

Topic Last Modified: *2012-10-06*

Perform the following steps within Topology Builder to configure high availability and disaster recovery for Persistent Chat Server.

1. Add the mirror databases and the log shipping secondary database SQL Server stores.
2. Edit the Persistent Chat Server service properties to:
   2.a. Enable mirroring for the primary database.
   2.b. Add the primary mirror SQL Server store.
   2.c. Enable the SQL Server Log Shipping database.
   2.d. Add the SQL Server Log Shipping secondary SQL Server store.
   2.e. Add the SQL Server store mirror for the secondary database.
   2.f. Publish the topology.

1.3.5.5.3 Using a Stretched Persistent Chat Server Pool for Disaster Recovery

Using a Stretched Persistent Chat Server Pool for Disaster Recovery

Planning > Planning for High Availability and Disaster Recovery > Configuring Persistent Chat Server for High Availability and Disaster Recovery >

Topic Last Modified: *2012-10-06*

The disaster recovery solution for Persistent Chat Server is built on a stretched Persistent Chat Server pool. This is similar to metropolitan site resiliency in Lync Server 2010; however, there is no requirement for a stretched virtual local area network (VLAN). By stretching Persistent Chat Server pool, you essentially configure one pool in the topology logically, but you physically place the servers in the pool in two different data centers. Configure SQL Server mirroring for the database in the same way, and deploy the database and the mirror in the same data center. You need to configure a backup database in the secondary data center (with an optional mirror to provide high availability during disaster recovery). This is the backup database used for failover during disaster recovery.

For details about how to configure SQL Server mirroring for high availability, see SQL Server Mirroring. For details about failing over the database for disaster recovery, see Setting Up SQL Server Log Shipping for the Persistent Chat Server Primary Database and Setting Up SQL Server Log Shipping between the Primary Mirror and the Log Shipping Secondary Database.

1.3.5.5.4 SQL Server Mirroring

SQL Server Mirroring

Planning > Planning for High Availability and Disaster Recovery > Configuring Persistent Chat Server for High Availability and Disaster Recovery >

Topic Last Modified: *2012-09-29*

Establish the SQL Server mirroring session between the primary Persistent Chat database and its mirror. For information about how to deploy SQL Server mirroring, see Deploying SQL Mirroring for Back End Server High Availability.

1.3.5.5.5 Setting Up SQL Server Log Shipping for the Persistent Chat Server Primary Database

Setting Up SQL Server Log Shipping for the Persistent Chat Server Primary Database

Planning > Planning for High Availability and Disaster Recovery > Configuring Persistent Chat Server for High Availability and Disaster Recovery >

Topic Last Modified: *2012-11-12*

Using SQL Server Management Studio, connect to the Persistent Chat Server secondary Log Shipping database instance, and be sure that SQL Server Agent is running.

Using SQL Server Management Studio connected to the Persistent Chat primary database instance, perform the following steps:

1. Be sure that the SQL Server Agent is running.
2. Right-click the mgc database, and then click **Properties**.
3. Under **Select a page**, click **Transaction Log Shipping**.
4. Select the **Enable this as a primary database in a log shipping configuration** check box.
5. Under **Transaction log backups**, click **Backup Settings**.
6. In the **Network path to the backup folder** box, type the network path to the share that you created for the transaction log backup folder.
7. If the backup folder is located on the primary server, type the local path to the backup folder in the **If the backup folder is located on the primary server, type a local path to the folder (example: c:\backup)** box. (If the backup folder is not on the primary server, you can leave this box empty.)

   > **Important:**
   >
   > If the SQL Server service account on your primary server runs under the local system account, you must create your backup folder on the primary server and specify a local path to that folder.

8. Configure the **Delete files older than** and **Alert if no backup occurs within** parameters.
9. Look at the backup schedule listed in the **Schedule** box under **Backup job**. To customize the schedule for your installation, click **Schedule**, and adjust the SQL Server Agent schedule as required.
10. Under **Compression**, select **Use the default server setting**, and then click **OK**.
11. Under **Secondary server instances and databases**, click **Add**.
12. Click **Connect** and connect to the instance of SQL Server that you have configured as your secondary server.
13. In the **Secondary Database** box, select the **mgc** database from the list.
14. On the **Initialize Secondary database** tab, choose the option **Yes, generate a full backup of the primary database and restore it into the secondary database (and create the secondary database if it doesn't exist)**.
15. On the **Copy Files** tab, in the **Destination folder for copied files** box, type the path of the folder into which the transaction logs backups should be copied. This folder is often located on the secondary server.
16. Note the copy schedule listed in the **Schedule** box under **Copy job**. To customize the schedule for your installation, click **Schedule**, and adjust the SQL Server Agent schedule as required. This schedule should be approximately the same as the backup schedule.
17. On the **Restore** tab, under **Database state when restoring backups**, choose the **No recovery mode** option.
18. Under **Delay restoring backups at least:**, select **0 minutes**.
19. Choose an alert threshold under **Alert if no restore occurs within**.
20. Look at the restore schedule listed in the **Schedule** box under **Restore job**.

To customize the schedule for your installation, click **Schedule**, adjust the SQL Server Agent schedule as required, and click **OK**. This schedule should be approximately the same as the backup schedule.

21. On the **Database Properties** dialog box, click **OK** to begin the configuration process.

1.3.5.5.6 Setting Up SQL Server Log Shipping betw een the Primary Mirror and the Log Shipping Secondary Database

Setting Up SQL Server Log Shipping between the Primary Mirror and the Log Shipping Secondary Database

Topic Last Modified: *2013-02-21*

Perform the following steps for log shipping to continue if the primary Persistent Chat database is failed over to its mirror database.

1. Manually fail over the primary Persistent Chat database to the mirror. This is done by using the Lync Server Management Shell and the **Invoke-CsDatabaseFailover** cmdlet. For details, see "Using Lync Server Management Shell Cmdlets" in Deploying SQL Mirroring for Back End Server High Availability.
2. Using the SQL Server Management Studio, connect to the primary Persistent Chat Server mirror instance.
3. Be sure that the SQL Server Agent is running.
4. Right-click the mgc database, and then click **Properties**.
5. Under **Select a page**, click **Transaction Log Shipping**.
6. Select the **Enable this as a primary database in a log shipping configuration** check box.
7. Under **Transaction log backups**, click **Backup Settings**.
8. In the **Network path to the backup folder** box, type the network path to the share you created for the transaction log backup folder.
9. If the backup folder is located on the primary server, type the local path to the backup folder in the **If the backup folder is located on the primary server, type a local path to the folder** box. (If the backup folder is not on the primary server, you can leave this box empty.)

◆**Important:**
If the SQL Server service account on your primary server runs under the local system account, you must create your backup folder on the primary server and specify a local path to that folder.

10. Configure the **Delete files older than** and **Alert if no backup occurs within** parameters.
11. Look at the backup schedule listed in the **Schedule** box under **Backup job**. To customize the schedule for your installation, click **Schedule**, and adjust the SQL Server Agent schedule, as required.

◆**Important:**
Use the same settings that you used for the primary database.

12. Under **Compression**, select **Use the default server setting**, and click **OK**.
13. Under **Secondary server instances and databases**, click **Add**.
14. Click **Connect**, and connect to the instance of SQL Server that you have configured as your secondary server.
15. In the **Secondary Database** box, select the **mgc** database from the list.
16. On the **Initialize Secondary database** tab, select the option **No, the**

secondary database is initialized.

17. On the **Copy Files** tab, in **Destination folder for copied files**, type the path of the folder into which the transaction logs backups should be copied, and click **OK**. This folder is often located on the secondary server.
18. Open the **Script Configuration** drop-down list, and select **Script Configuration to New Query Window**.
19. In the new query window, in **Database Properties**, click **OK** to begin the configuration process.
20. Select and run the first half of the query (see step 18) up to the line: -- ****** End: Script to be run at Primary: ******.

◆**Important:**
Manually running this script is necessary because SQL Server Management Studio does not support multiple primary databases in a SQL Server Log Shipping configuration.

21. Select **Cancel** to close the Log File shipping configuration panel and to establish a working setup that correctly implements the log file shipping for both the primary and mirrored database (in case of failover).
22. Manually fail back the primary Persistent Chat database to the primary. This is done by using the Lync Server Management Shell, and the **Invoke-CsDatabaseFailover** cmdlet. For details, see "Using Lync Server Management Shell Cmdlets" in Deploying SQL Mirroring for Back End Server High Availability.

1.3.6.1 Planning for Role-Based Access Control

Planning for Role-Based Access Control

Microsoft Lync Server 2013 > Planning > Planning for Manageability and Virtualization >

Topic Last Modified: *2012-09-14*

To enable you to delegate administrative tasks while maintaining high standards for security, Lync Server 2013 offers role-based access control (RBAC). With RBAC, administrative privilege is granted by assigning users to administrative roles. Lync Server 2013 includes a rich set of built-in administrative roles, and also enables you to create new roles and specify a custom list of cmdlets for each new role. You can also add scripts of cmdlets to the allowed tasks of both predefined and custom RBAC roles.

Better Server Security and Centralization

With RBAC, access and authorization is based precisely on a user's Lync Server role. This enables use of the security practice of "least privilege," granting administrators and users only the rights that are necessary for their job.

Important:

RBAC restrictions work only on administrators working remotely, using either the Lync Server Control Panel or Lync Server Management Shell. A user sitting at a server running Lync Server is not restricted by RBAC. Therefore, physical security of your Lync Server is important to preserve RBAC restrictions.

Roles and Scope

In RBAC, a *role* is enabled to use a list of cmdlets, designed to be useful for a certain type of administrator or technician. A *scope* is the set of objects which the cmdlets defined in a role can operate on. The objects that scope affects can be either user accounts (grouped by organizational unit) or servers (grouped by site).

The following table lists the predefined roles in Lync Server, and gives a general overview of the types of tasks each can do. The fourth column shows the similar Microsoft Exchange Server role for each Lync Server role, if there is one.

Predefined Administrative Roles

Role	Tasks allowed	Underlying Active Directory group	Exchange equivalent
CsAdministrator	Can perform all administrative tasks and modify all settings, including creating roles and assigning users to roles. Can expand a deployment by adding new sites, pools, and services.	CS Administrators	Organization Management
CsUserAdministrator	Can enable and disable users for Lync Server, move users and assign existing policies to users.	CS User Administrators	Mail Recipients

	Cannot modify policies.		
CsVoiceAdministrator	Can create, configure, and manage voice-related settings and policies.	CS Voice Administrators	Not applicable
CsServerAdministrator	Can manage, monitor, and troubleshoot servers and services. Can prevent new connections to servers, stop and start services, and apply software updates. Cannot make changes with global configuration impact.	CS Server Administrators	Server Management
CsViewOnlyAdministrator	Can view the deployment, including user and server information, in order to monitor deployment health.	CS View-Only Administrators	View-Only Organization Management
CsHelpDesk	Can view the deployment, including user's properties and policies. Can run specific troubleshooting tasks. Cannot change user properties or policies, server configuration, or services.	CS HelpDesk	HelpDesk
CsArchivingAdministrator	Can modify archiving configuration and policies.	CS Archiving Administrators	Retention Management, Legal Hold
CsResponseGroupAdministrator	Can manage the configuration of the Response Group application within a site.	CS Response Group Administrators	Not applicable
CsLocationAdministrator	Lowest level of rights for Enhanced 9-1-1 (E9-1-1) management, including creating E9-1-1 locations and network identifiers, and associating these with each other. This role is always assigned with a	CS Location Administrators	Not applicable

	global scope.		
CsResponseGroupManager	Can manage specific response groups.	CS Response Group Managers	Not applicable
CsPersistentChatAdministrator	Can manage the Persistent Chat feature and specific Persistent Chat rooms.	CS Persistent Chat Administrators	Not applicable

All predefined roles shipped in Lync Server have a global scope. To follow least privilege practices, you should not assign users to roles with global scope if they are going to administer only a limited set of servers or users. To accomplish this, you can create roles which are based on an existing role, but with a more limited scope.

Creating a Scoped Role

When you create a role with limited scope (a scoped role), you specify the scope, along with the existing role it is based on and the Active Directory group to be assigned the role. The Active Directory group you specify must already be created. The following cmdlet is an example of a creating a role which has the privileges of one of the pre-defined administrative roles, but with limited scope. It creates a new role called `Site01 Server Administrators`. The role has the abilities of the predefined CsServerAdministrator role, but only for the servers located in the Site01 site. For this cmdlet to work, the Site01 site must already be defined, and a security group named `Site01 Server Administrators` must already exist.

```
New-CsAdminRole -Identity "Site01 Server Administrators" -Template CsServerAdmini
```

After this cmdlet runs, all users who are members of the `Site01 Server Administrators` group will have server administrator privileges for the servers in Site01. Additionally, any users who are later added to this security group also gain the privileges of this role. Note that both the role itself, and the security group it is assigned to are called `Site01 Server Administrators`.

The following example limits user scope instead of server scope. It creates a `Sales Users Administrator` role to administer the user accounts in the Sales organizational unit. The SalesUsersAdministrator security group must already be created for this cmdlet to work.

```
New-CsAdminRole -Identity "Sales Users Administrator " -Template CsUserAdministra
```

Creating a New Role

To create a role that has access to a set of cmdlets not in one of the predefined roles, or to a set of scripts or modules, you again start by using one of the predefined roles as a template. Note that scripts and modules that roles are to be able to run must be stored in the following locations:

- The Lync module path, which is by default C:\Program Files\Common Files \Microsoft Lync Server 2013\Modules\Lync
- The user script path, which is by default C:\Program Files\Common Files \Microsoft Lync Server 2013\AdminScripts

To make a new role, you use the **New-CsAdminRole** cmdlet. Before running **New-CsAdminRole**, you must first create the underlying security group that will be associated with this role.

The following cmdlets serve as an example of a creating a new role. They create a new role type called `MyHelpDeskScriptRole`. The new role has the abilities of the predefined CsHelpDesk role, and can additionally run the functions in a script named “testscript”.

```
New-CsAdminRole -Identity "MyHelpDeskScriptRole" -Template CsHelpDesk -ScriptModu
```

For this cmdlet to work, you must have first created the security group MyHelpDeskScriptRole.

After this cmdlet runs, you can assign users directly to this role (in which case they have global scope), or create a scoped role based on this role, as explained in Creating a Scoped Role, previously in this document.

Assigning Roles to Users

Each Lync Server role is associated with an underlying Active Directory security group. Any users who you add to the underlying group gain the abilities of that role.

The examples in the preceding sections both created a new role and assigned an existing security group to the new role. To assign an existing role to one or more users, add those users to the group associated with the role. You can add both individual users and security groups to these groups.

For example, the **CsAdministrator** role is automatically granted to the **CS Administrators** security group in Active Directory. This security group is created in Active Directory when you deploy Lync Server. To grant a user or group this privilege, you can simply add them to the **CS Administrators** group.

A user can be given multiple RBAC roles by being added to the underlying Active Directory groups that correspond to each role.

Note that when you create a role, users who are later added to the underlying Active Directory group gain the abilities of that role.

Modifying the Abilities of a Role

You can modify the list of cmdlets and scripts that a role can run. You can modify both the cmdlets and scripts that custom roles can run, but you can modify only the scripts for predefined roles. Each cmdlet you type can add, remove, or replace cmdlets or scripts.

To modify a role, use the **Set-CsAdminRole** cmdlet. The following cmdlet both removes one script from the role.

```
Set-CsAdminRole -Identity "MyHelpDeskScriptRole" -ScriptModules @{Remove="testScr
```

Planning for RBAC

For each person who is to be given any kind of administrative rights for your Lync Server deployment, consider exactly which tasks they need to perform, then assign them to roles with the least privilege and scope necessary for their job. If necessary, you can use the **Set-CsAdminRole** cmdlet to create a new role with only the cmdlets necessary for this person’s tasks.

Users who have the CsAdministrator role can create all types of roles, including roles based on CsAdministrator, and assign users to them. The best practice is to assign the CsAdministrator role to a very small set of trusted users.

1.3.6.2 Planning for Simple URLs

Planning for Simple URLs

See Also

Microsoft Lync Server 2013 > Planning > Planning for Manageability and Virtualization >

Topic Last Modified: *2013-02-21*

Simple URLs make joining meetings easier for your users, and make getting to Lync Server administrative tools easier for your administrators.

Lync Server supports three simple URLs:

- **Meet** is used as the base URL for all conferences in the site or organization. An example of a Meet simple URL is https://meet.contoso.com. A URL for a particular meeting might be https://meet.contoso.com/*username*/7322994. With the Meet simple URL, links to join meetings are easy to comprehend, and easy to communicate and distribute.
- **Dial-in** enables access to the Dial-in Conferencing Settings webpage. This page displays conference dial-in numbers with their available languages, assigned conference information (that is, for meetings that do not need to be scheduled), and in-conference DTMF controls, and supports management of personal identification number (PIN) and assigned conferencing information. The Dial-in simple URL is included in all meeting invitations so that users who want to dial in to the meeting can access the necessary phone number and PIN information. An example of the Dial-in simple URL is https://dialin.contoso.com.
- **Admin** enables quick access to the Lync Server Control Panel. From any computer within your organization's firewalls, an admin can open the Lync Server Control Panel by typing the Admin simple URL into a browser. The Admin simple URL is internal to your organization. An example of the Admin simple URL is https://admin.contoso.com

Simple URL Scope

You can configure your simple URLs to have global scope, or you can specify different simple URLs for each central site in your organization. If both a global simple URL and a site simple URL are specified, the site simple URL has precedence.

In most cases, we recommend that you set simple URLs only at the global level, so that a user's Meet simple URL does not change if they move from one site to another. The exception would be organizations that need to use different telephone numbers for dial-in users at different sites. Note that if you set one simple URL (such as the Dial-in simple URL) at a site to be a site-level simple URL, you must also set the other simple URLs at that site to be site-level as well.

You can set global simple URLs in Topology Builder. To set a simple URL at the site level, you must use the Set-CsSimpleURLConfiguration cmdlet.

Naming Your Simple URLs

There are three recommended options for naming your simple URLs. Which option you choose has implications for how you set up your DNS A records and certificates which support simple URLs. In each option, you must configure one Meet simple URL for each SIP domain in your organization.

You always need just one simple URL in your whole organization for Dial-in, and one for Admin, no matter how many SIP domains you have.

For details about the necessary DNS A records and certificates, see DNS Requirements for Simple URLs and Certificate Requirements for Internal Servers in the Planning documentation.

In Option 1, you create a new SIP domain name for each simple URL.

If you use this option, you need a separate DNS A record for each simple URL, and each Meet simple URL must be named in your certificates.

Simple URL Naming Option 1

Simple URL	Example
Meet	https://meet.contoso.com, https://meet.fabrikam.com, and so on (one for each SIP domain in your organization)
Dial-in	https://dialin.contoso.com
Admin	https://admin.contoso.com

With Option 2, simple URLs are based on the domain name lync.contoso.com. Therefore, you need only one DNS A record which enables all three types of simple URLs. This DNS A record references lync.contoso.com. Additionally, you still need separate DNS A records for other SIP domains in your organization.

Simple URL Naming Option 2

Simple URL	Example
Meet	https://lync.contoso.com/Meet, https://lync.fabrikam.com/Meet, and so on (one for each SIP domain in your organization)
Dial-in	https://lync.contoso.com/Dialin
Admin	https://lync.contoso.com/Admin

Option 3 is most useful if you have many SIP domains, and you want them to have separate Meet simple URLs but want to minimize the DNS record and certificate requirements for these simple URLs.

Simple URL Naming Option 3

Simple URL	Example
Meet	https://lync.contoso.com/contosoSIPdomain/Meet https://lync.contoso.com/fabrikamSIPdomain/Meet
Dial-in	https://lync.contoso.com/Dialin
Admin	https://lync.contoso.com/Admin

Simple URL Naming and Validation Rules

Topology Builder and the Lync Server Management Shell cmdlets enforce several validation rules for your simple URLs. You are required to set simple URLs for Meet and Dialin, but setting one for Admin is optional. Each SIP domain must have a separate Meet simple URL, but you need only one Dialin simple URL and one Admin simple URL for your whole organization.

Each simple URL in your organization must have a unique name, and cannot be a prefix of another simple URL (for example, you could not set lync.contoso.com/Meet as your Meet simple URL and lync.contoso.com/Meet/Dialin as your Dialin simple URL). Simple URL names cannot contain the FQDN of any of your pools, or any port information (for example, https://FQDN:88/meet is not allowed). All simple URLs must start with the https:// prefix.

Simple URLs can contain only alphanumeric characters (that is, a-z, A-Z, 0-9, and the period (.). If you use other characters, the simple URLs might not work as expected.

Changing Simple URLs after Deployment

If you change a simple URL after initial deployment, you must be aware of how the change impacts your DNS records and certificates for simple URLs. If the base of a simple URL changes, then you must change the DNS records and certificates as well. For example, changing from https://lync.contoso.com/Meet to https://meet.contoso.com changes the base URL from lync.contoso.com to meet.contoso.com, so you would need to change the DNS records and certificates to refer to meet.contoso.com. If you changed the simple URL from https://lync.contoso.com/Meet to https://lync.contoso.com/Meetings, the base URL of lync.contoso.com stays the same, so no DNS or certificate changes are needed.

Whenever you change a simple URL name, however, you must run **Enable-CsComputer** on each Director and Front End Server to register the change.

DNS Requirements for Simple URLs

1.3.6.3 Running Lync Server on Virtual Servers

Running Lync Server on Virtual Servers

Microsoft Lync Server 2013 > Planning > Planning for Manageability and Virtualization >

Topic Last Modified: *2012-09-10*

Lync Server 2013 supports virtualization topologies that support all Lync Server workloads, including instant messaging (IM) and presence, conferencing, Enterprise Voice, Monitoring, Archiving, and Persistent Chat. Running on virtualized servers requires Windows Server 2012 or Windows Server 2008 R2. Lync Server 2013 virtualization supports the Hyper-V virtualization platform.

Recommended Host Server Configurations

The following table shows the recommended base hardware for a host server.

Component	Recommendation
Server	Enterprise-grade server, with a minimum of two CPU sockets
CPU	Enterprise-class CPU which can support at least 24 virtual cores.
Network adapter	Two or more 1GbE or 10 GbE adapters. For best performance, we recommend using Windows Server 2012 on a host server that supports Single Root I/O Virtualization (SR-IOV).
Storage	Two or more serial advanced technology

	attachment (SATA) or serial attached SCSI (SAS) hard disk drive, 10k rpm or higher direct attach storage (DAS), or equivalent storage. RAID 1 or equivalent SSD.
Memory	At least 32 GB. Each host server should have 4 GB for the host, as well as enough memory to support each virtual server it will run, according to the amount of memory required by each server role as listed in Server Hardware Platforms.

Both the physical host servers and all virtual servers must run one of the following operating systems. Lync Server virtualization supports a mix of operating systems. For example, a host server running Windows Server 2012 that runs virtual servers that run Windows Server 2008 R2 is supported.

- Windows Server 2012. This is the recommended operation system for both host servers and virtual servers, to enable the best performance.
- Windows Server 2008 R2 with the software update described in Microsoft Knowledge Base article 981836, "Network connectivity for a Windows Server 2003-based Hyper-V virtual machine is lost temporarily in Windows Server 2008 R2," at http://go.microsoft.com/fwlink/p/?linkId=201212.

Note:
You must run this update on both the physical host server and all virtual machines, even though the Microsoft Knowledge Base article states otherwise.

Supported Topologies

You can mix physical and virtual servers in your deployment, with only the following restrictions:

- You cannot mix different types of servers within the same pool. All servers within the same pool must either be physical or virtual. For these purposes, Front End Servers and SQL Servers running the back-end database are considered to be separate, meaning that you can have virtual Front End Servers using a physical back-end database, or physical Front End Servers and a virtual back-end database. Note however that the back-end database has a real-time requirement for presence updates, which is unlike many SQL Server applications. If you run a virtual back-end database you must be aware of performance issues, especially if the host of the virtual back-end database is running other applications.
  This is the only limitation to mixing physical and virtual servers. You could have some Front End pools of physical servers and others of virtual servers. And you can deploy different types of pools and servers as either physical or virtual in any combination.
- All servers within one pool should provide about the same performance. For example, if you have virtual Front End Servers in one pool being hosted on different host servers, you should make sure each virtual Front End Server is capable of a similar level of performance.

If you are deploying a large amount of virtualized servers across different host servers, you should consider spreading out the members of one pool across different host servers. For example, in a pool of eight virtual Front End Servers, deploy four on one physical host and four on another. While this is not a true high-availability solution, it does provide some protection if a single host server fails.

Lync Server supports the use of virtual clustered storage. However, live migration (and other types of migration) of virtual servers running Lync Server is not supported. As with physical servers, Lync Server 2013 virtual servers do not support SQL clustering.

Networking Considerations

Lync Server provides real-time communications, and depends on fast and efficient networking. If a packet is delayed by as little as a few milliseconds, users might detect an audio glitch, experience a delayed call, or frozen video. To improve the network performance of your virtualized topology, you should do the following:

- The host must have at least one network adapter dedicated to the virtual machines running Lync Server roles. Sharing a network adapter with the host or with a storage area network (SAN) is not recommended.
- Note that a Lync Server workload that includes media can reach a peak network utilization of more than 500 Mbps.
- If one host server is running multiple guest virtual servers that each run Lync Server media workloads, ensure that the host network adapter can handle the traffic. To prevent bottlenecks, consider a higher speed network adapter (such as 10 GbE) or multiple network adapters using link aggregation.
- For best performance, use the Single Root I/O Virtualization (SR-IOV) capabilities of Windows Server 2012 Hyper-V. With SR-IOV, the virtual function of a physical network adapter is assigned directly to a virtual machine. This increases network throughput and reduces network latency while also reducing the host CPU overhead that is required for processing network traffic. To take advantage of SR-IOV, you must use a host server which has BIOS which supports SR-IOV, as well as use network adapters that support SR-IOV. Additionally, you must run Windows Server 2012 on both the host server and all virtual servers.
- Enable virtual LAN (VLAN) tagging on the network adapter, and implement multiple VLANs on the virtual servers to optimize network traffic.
- Implement multi-path I/O (MPIO) to your back-end database.

Managing Your Virtual Environment

We recommend you use Microsoft System Center Virtual Machine Manager (VMM) to manage your virtualized Lync Server topology.

By using VMM, you do not need to use Terminal Services or Remote Desktop Services for the virtual machine management. Additionally, by using VMM you can view and manage performance, and other components such as disk space. You can also save a virtual machine as a template for creating new instances.

VMM uses Windows PowerShell, so you can create VMM Windows PowerShell scripts that integrate with Lync Server Management Shell to manage Lync Server.

For details about VMM, see the System Center Virtual Machine Manager website at http://go.microsoft.com/fwlink/p/?linkId=202887.

Getting Started Using VMM

To get started using VMM to manage your virtualized Lync Server topology, do the following:

1. In VMM, create a new host group named `LS 2013`.
2. In the **Actions** pane, click **Add Host**.
3. If your virtual environment is part of your Active Directory domain, select that option. Otherwise, select the Windows Server-based host on a perimeter network, and click **Next**.
4. Install a VMM Agent on the host server. If the host server is on a perimeter network, you must create a security key, which must then be available to the

VMM Administrative Console.

5. Go back to the VMM Administrative Console and click **Add Host**.
6. Specify the machine name and the domain/machine name and security key, making sure that VMM can find the host, and then click **Next**.
7. After the host has been added, the four virtual machines should be available. In the VMM Administrative Console, click the **Virtual Machines** button.
8. You will now see the Virtual Machines view, with the four virtual machines running Lync Server listed.

1.3.7 Planning for Front End Servers, Instant Messaging, and Presence

Planning for Front End Servers, Instant Messaging, and Presence

Microsoft Lync Server 2013 > Planning >

Topic Last Modified: *2012-09-13*

Front End Servers provide much of the Lync Server functionality and are included in every Lync Server deployment. Instant messaging (IM) and presence are core capabilities of Lync Server and are automatically deployed and enabled in every Lync Server installation. The following sections provide more details about Front End Servers, IM and presence.

- Features and Functionality of Front End Servers, Instant Messaging, and Presence
- Defining Your Requirements for Front End Servers, Instant Messaging, and Presence
- Topologies and Components for Front End Servers, Instant Messaging, and Presence
- Technical Requirements for Front End Servers, Instant Messaging, and Presence

1.3.7.1 Features and Functionality of Front End Servers, Instant Messaging, and Presence

Features and Functionality of Front End Servers, Instant Messaging, and Presence

Microsoft Lync Server 2013 > Planning > Planning for Front End Servers, Instant Messaging, and Presence >

Topic Last Modified: *2012-09-25*

Front End Servers provide most Lync Server functionality. There are two editions available: Lync Server Enterprise Edition, which is designed primarily for larger organizations, and Lync Server Standard Edition, which is designed primarily for smaller organizations which want a smaller hardware investement and do not require high availability. Both editions support all Lync Server workloads including IM, presence, conferencing, and Enterprise Voice.

Instant messaging (IM) enables your users to communicate with each other in real time on their computers using text-based messages. Both two-party and multiparty IM sessions are supported. A participant in a two-party IM conversation can add a third participant to the conversation at any time. When this happens, the Conversation window changes to support conferencing features.

Presence provides information to users about the status of other on the network. A user’s presence status provides information to help others decide whether they should try to contact the user and whether to use instant messaging, phone, or email. Presence encourages instant communication when possible, but it also provides information about whether a user is in a meeting or out of the office, indicating that instant communication is not possible. This presence status is displayed as a presence icon in Lync and other presence-aware applications, including the Microsoft Outlook messaging and collaboration client, Microsoft SharePoint technologies, Microsoft Word, and Microsoft Excel spreadsheet software. The presence icon represents the user's current availability and willingness to communicate.

1.3.7.2 Defining Your Requirements for Front End Servers, Instant Messaging, and Presence

Defining Your Requirements for Front End Servers, Instant Messaging, and Presence

Microsoft Lync Server 2013 > Planning > Planning for Front End Servers, Instant Messaging, and Presence >

Topic Last Modified: *2013-01-11*

The main task of planning for instant messaging (IM) and presence is ensuring that you have enough Front End Servers for your users.

Enabling Communication with External Users

You can greatly increase the benefits of your investment in Lync Server by enabling your users to communicate with external users. External users can include:

- **Remote users** Your organization's own users, when they are working outside your firewalls and are using their laptops or other Lync Server devices.
- **Federated users** Users from companies you work with who also run Lync Server. To enable your users to easily contact these users, you create federated relationships with these companies.
- **Public users** Users of public IM services, such as IM services provided by the Windows Live network of Internet services, Yahoo!, and AOL, and users of providers and servers that use Extensible Messaging and Presence Protocol (XMPP), such as Google Talk.

Note:

Note that a separate license might be required for public IM connectivity with Windows Live, AOL, and Yahoo!

Important:

- As of September 1st, 2012, the Microsoft Lync Public IM Connectivity User Subscription License ("PIC USL") is no longer available for purchase for new or renewing agreements. Customers with active licenses will be able to continue to federate with Yahoo! Messenger until the service shut down date (exact date TBD, but no sooner than June 2013).
- The PIC USL is a per-user per-month subscription license that is required for Lync Server or Office Communications Server to federate with Yahoo! Messenger. Microsoft's ability to provide this service has been contingent upon support from Yahoo!, the underlying agreement for which is winding down.
- More than ever, Lync is a powerful tool for connecting across organizations and with individuals around the world. Federation

with Windows Live Messenger requires no additional user/device licenses beyond the Lync Standard CAL. Skype federation will be added to this list, enabling Lync users to reach hundreds of millions of people with IM and voice.

To enable any or all of these scenarios, you need to deploy an Edge Server to help enable secure communications between your Lync Server deployment and external users. Your organization's remote users and users at federated organizations will be able to see each other's presence and communicate using IM. For details about enabling communication with external users, see Planning for External User Access in the Planning documentation.

Archiving IM Content

Lync Server provides features you can use if your organization must follow compliance regulations. You can use Archiving to archive the content of IM messages for all users in your organization or for only certain users that you specify. For details, see Planning for Archiving in the Planning documentation.

If you also have Microsoft Exchange Server 2013 deployed, you can integrate the archiving of Exchange data with the archiving of Lync Server data, and use a single tool to search both types of archived data. For more information, see Configuring Microsoft Lync Server 2013 to Use Microsoft Exchange Server 2013 Archiving.

1.3.7.3 Topologies and Components for Front End Servers, Instant Messaging, and Presence

Topologies and Components for Front End Servers, Instant Messaging, and Presence

Microsoft Lync Server 2013 > Planning > Planning for Front End Servers, Instant Messaging, and Presence >

Topic Last Modified: *2012-11-02*

The only components required for instant messaging (IM) and presence are:

- Your organization's Front End Servers or Standard Edition servers. IM and presence capabilities are always enabled on these servers.
- A load balancer, if you have an Enterprise Edition Front End pool. For more information, see Load Balancing Requirements.

Planning for the Deployment of Front End Pools

In Lync Server 2013, Front End pool architecture has changed, and these changes affect how you should plan and maintain your Front End pools.

We recommend that all your Enterprise Edition Front End pools include at least three Front End Servers. In Lync Server, the architecture of Front End pools uses a distributed systems model, with each user's data kept on three Front End servers in the pool. For more information about this new architecture, see Topology Changes.

If you do not want to deploy three Enterprise Edition Front End Servers and want high availability and disaster recovery, we recommend you use Lync Server Standard Edition and create two pools with a paired backup relationship. This will provide the best high availability and disaster recovery solution with only two servers. For more information, on high availability and disaster recovery topologies and features, see Planning for High Availability and Disaster Recovery.

Planning for the Management of Front End Pools

For pools that contain three or more Front End Servers, follow these guidelines:

- When you start the pool for the first time, be sure to start at least three of the Front End Servers.
- When you move users to the pool for the first time, be sure at least three of the Front End Servers are running.
- If you establish a pairing relationship between this pool and another pool for disaster recovery purposes, then after establishing that relationship you must be sure this pool has three Front End Servers running simultaneously at some time to properly synchronize data with the backup pool. For more information on pool pairing and disaster recovery features, see Planning for High Availability and Disaster Recovery.

For a Front End pool to be functional, a certain number of Front End Servers in the pool need to be up and running, as shown in the table later in this section. When you plan upgrade and maintenance of a pool, you must keep this in mind. Overall, for upgrades of Front End Servers, we recommend you upgrade one server at a time. Bring one server down, apply the upgrade, then bring that server back up before upgrading another server. For detailed instructions for upgrading a Front End Server, see Upgrade or Update Front End Servers.

Total number of Front End Servers in the pool	Number of servers that must be running for pool to be functional
1-2	1
3-4	2
5-6	3
7-8	4
9-10	5
11-12	6

If the number of servers running falls below the functional level as shown in this table, the remaining servers in the pool go into survivability mode, and you will see the following message in the event log: `Local Pool Manager has been disconnected from Pool Fabric Manager. (Id: 32163)`. After five minutes, if the number of running servers is still below the threshold level, the remaining servers in the pool will stop all Lync Server services, and the following messages will be in the event log: `Pool Manager failed to connect to Fabric Pool Manager (id: 32170) Server is being shutdown because fabric pool manager could not be initialized (id: 32173)`

Changing a Front End Pool's Configuration

Whenever you add Front End Servers to a pool, or remove them from the pool, and then publish the new topology, follow these guidelines:

- After the new topology has been published, you must restart each Front End Server in the pool. Restart them one at a time.
- If the entire pool has been down during the configuration change, then run the following cmdlet after the new topology is published:

```
Reset-CsPoolRegistrarState -PoolFQDN <PoolFQDN> -ResetType ServiceReset
```

If a Front End Server fails and is unlikely to be replaced for a few days or more, remove the server from the topology. Add the new Front End Server to the topology when it is available again.

Front End Pools with Two Front End Servers

We do not recommend deploying a Front End pool that contains only two Front End Servers. If you do ever need to deploy such a pool, follow these guidelines:

- If one of the two Front End Servers goes down, you should try to bring the failed server back up as soon as you can. Similarly, if you need to upgrade one of the two servers, bring it back online as soon as the upgrade is finished.
- If for some reason you need to bring both servers down at the same time, do the following when the downtime for the pool is finished:
  - The best practice is to restart both Front End Servers at the same time.
  - If the two servers cannot be restarted at the same time, you should bring them back up in the reverse order of the order they went down.
  - If you cannot bring them back up in that order, then use the following cmdlet before bringing the pool back up:.

```
Reset -CsPoolRegistrarState -ResetType QuorumLossRecovery -Po
```

1.3.7.4 Technical Requirements for Front End Servers, Instant Messaging, and Presence

Technical Requirements for Front End Servers, Instant Messaging, and Presence

Microsoft Lync Server 2013 > Planning > Planning for Front End Servers, Instant Messaging, and Presence >

***Topic Last Modified:** 2012-09-18*

Instant messaging (IM) and presence always run on Enterprise Edition Front End pools and Standard Edition servers. For information on supported hardware, operating systems, and database software, see the following:

- Supported Hardware
- Server Software and Infrastructure Support

Supported Collocation

The Front End Server role can be collocated with Mediation Server. You can also run Monitoring and Archiving on Front End Servers. Front End Server cannot be collocated with Edge Server or Director.

1.3.8 Planning for Conferencing

Planning for Conferencing

Microsoft Lync Server 2013 > Planning >

***Topic Last Modified:** 2013-01-29*

Lync Server 2013 offers a rich set of conferencing capabilities:

- Web conferencing, which includes document collaboration, application sharing, and desktop sharing. Lync Server 2013 uses Office Web Apps and the Office Web Apps Server to handle sharing and rendering of PowerPoint presentations. For details about installing and configuring the Office Web Apps Server, see Configuring Integration with Office Web Apps Server and Lync Server 2013.
- Audio/video (A/V) conferencing, which enables users to have real-time audio or video conferences without the need for external services such as the Microsoft Live Meeting service or a third-party audio bridge.
- Dial-in conferencing, which allows users to join the audio portion of a Lync Server 2013 conference by using a public switched telephone network (PSTN) phone without requiring a third-party audio conferencing provider.
- Instant messaging (IM) conferencing, in which more than two parties communicate in a single IM session. For details about IM conferencing, see Planning for Front End Servers, Instant Messaging, and Presence.

Lync Server 2013 supports both scheduled conferences and impromptu conferences.

When you deploy Lync Server 2013, Front End Server, you can choose whether to also deploy the web conferencing, A/V conferencing, and dial-in conferencing capabilities. IM conferencing capabilities are always automatically deployed along with IM conversation capabilities on Lync Server 2013 Front End Servers.

Note:

If your deployment includes meetings organized using Office Communicator 2007 R2 clients (including the Live Meeting console or Conferencing Add-in for Microsoft Office Outlook), the meetings will have the following limitations after they are migrated to Lync Server 2013:

- Users in the meeting will not be able to use data collaboration features, including document collaboration, application sharing, and desktop sharing.
- Stability issues may arise since Office Communicator 2007 R2 clients are not supported with Lync Server 2013.

To avoid these issues, reschedule any meeting organized using Office Communicator 2007 R2 clients with Outlook 2010 or Outlook 2013 using either the Online Meeting Add-in for Lync 2010 or Online Meeting Add-in for Lync 2013.

The following sections describe what is required to deploy the various types of conferencing capabilities, including the planning process, components, hardware and software requirements, and the deployment process.

- Overview of Conferencing
- Defining Your Requirements for Conferencing
- Components and Topologies for Conferencing
- Technical Requirements for Conferencing
- Deployment Checklist for Conferencing
- Support for Large Meetings

1.3.8.1 Overview of Conferencing

Overview of Conferencing

Microsoft Lync Server 2013 > Planning > Planning for Conferencing >

Topic Last Modified: *2012-09-30*

When you deploy conferencing, you can choose to enable and use both web conferencing and A/V conferencing, or just web conferencing. Dial-in conferencing is a subset of audio conferencing and requires additional configuration.

With all forms of conferencing enabled, your users can enjoy the richest possible conferencing environment with any combination of instant messaging (IM), audio, video, desktop sharing, slide presentations, sharing attachments, and sharing applications. Conferences can be scheduled or unscheduled, and users can easily add forms of communication to a conference while it happens. For example, starting with IM, adding document collaboration, and then adding voice or video. New participants can also be added to ongoing conferences in real time.

The following topics provide an overview of the specific features and capabilities provided by web conferencing, A/V conferencing, and dial-in conferencing.

- Common Conferencing Concepts
- Web Conferencing Overview
- A/V Conferencing Overview
- Dial-In Conferencing Overview

1.3.8.1.1 Common Conferencing Concepts

Common Conferencing Concepts

Planning > Planning for Conferencing > Overview of Conferencing >

Topic Last Modified: *2012-09-19*

Several concepts are common to all types of conferencing. These are described in the following sections.

Policies and Bandwidth Management

Lync Server 2013 enables administrators to set policies for the types of meetings that users can organize. This helps you enforce your organization’s policies and control bandwidth usage. You can define a wide variety of meeting policies, and assign them to individual users and groups of users. You can also set policies that govern peer-to-peer conversations. For details about setting conferencing policies, see Conferencing Policies in the Operations documentation. For details about bandwidth management, see Overview of Call Admission Control and Configuring Video Bandwidth in Lync Server 2013.

Archiving and Compliance Features

Lync Server 2013 provides features you can use if your organization must follow compliance regulations. You can use the archiving abilities to archive content presented in meetings, and also the content of instant messaging (IM) conversations and IM conferences. For details, see Planning for Archiving in the Planning documentation. You can use compliance features of Persistent Chat Server to archive multiparty, topic-based conversations that persist over time. For details, see Planning for Persistent Chat Server in the Planning documentation.

Monitoring Feature

The Monitoring Server feature can capture call detail records (CDRs), which you can use to track which users talk to which other users using Lync Server 2013. For details about deploying and configuring monitoring, see Deploying Monitoring.

Enabling External Participation in

Conferences

You can greatly increase the benefits of your investment in Lync Server 2013 conferencing by enabling external users to also participate in conferences when invited. External users can include:

- **Remote Users** Your organization's own users, when they are working outside your firewalls and are using their laptops or other Lync Server 2013 devices.
- **Federated Users** Users from companies you work with who also run Lync Server 2013. To enable your users to easily contact these users, you create federated relationships with these companies.
- **Anonymous Users** Any other external users who are invited specifically by your users to join specific conferences. A meeting organizer in your company can send an email invitation for a conference to an external user. The email includes a link that the outside user can click to join the conference.

To enable any or all of these scenarios, you need to deploy an Edge Server to help enable secure communications between your Lync Server 2013 deployment and external users. The Lync Server 2013 solution using Edge Servers provides higher quality media than other solutions such as a virtual private network (VPN). For details, see Planning for External User Access.

Additionally, whether or not you deploy Edge Servers, you can enable users (that is, either inside or outside your organization) to dial in from standard PSTN phones to join on-premises audio conferences. This is accomplished by deploying Lync Server 2013 dial-in conferencing.

Compatibility Among Meeting Types and Client Versions

If you are going to have Lync Server 2013 interoperate with previous versions of Office Communications Server and its clients, you must be aware of the following issues:

- Users using Lync Server 2013 cannot schedule Live Meeting conferences, or modify any migrated meetings of this type.
- Users using Lync Server 2013 who need to attend Live Meeting conferences hosted on servers running Office Communications Server 2007 R2 must have the Live Meeting client installed on their computer (in addition to Lync Server 2013) to attend these meetings.
- When Live Meeting conferences are migrated to Lync Server 2013, meeting content does not migrate. If this content is needed, it must be uploaded again.

1.3.8.1.2 Web Conferencing Overview

Web Conferencing Overview

Planning > Planning for Conferencing > Overview of Conferencing >

Topic Last Modified: *2012-09-30*

With web conferencing, users can share and collaborate on documents, such as PowerPoint presentations, during their conferences. Additionally, users can share all or part of their desktops with each other in real time, making it seem as though the people in the conference were gathered around the same table in the meeting.

Whiteboard and Annotations

A whiteboard is a blank canvas that can be used for collaboration, with text, ink, drawings and images. Annotations made on whiteboards can be seen by all meeting participants. The whiteboard feature enhances collaboration by enabling meeting participants to discuss ideas, brainstorm, take notes, and so on.

Polling

The polling feature enhances collaboration by enabling presenters to quickly determine participants' preferences. During online meetings and conversations, presenters can use polling to gather anonymous responses from participants. All presenters can see the results and can either hide the results or show them to all attendees.

Application Sharing and Desktop Sharing

During a conference you can share your entire desktop, an individual application, or individual monitors in a multi-monitor environment. Aside from just viewing the content, other participants in the conference can also request control of your screen and, with the permission, interact with the content (including scrolling and editing).

Note:

Participants who are viewing the conference can also take over and start sharing content during the meeting

PowerPoint Sharing

In Lync 2010 PowerPoint presentations were viewed in one of two ways. For users running Lync 2010, PowerPoint presentations were displayed using the PowerPoint 97-2003 format and were viewed using an embedded copy of the PowerPoint viewer. For users running Lync Web App, PowerPoint presentations were converted to dynamic HTML files then viewed using a combination of those customized DHTML files and Silverlight. Although generally effective, this approach did have some limitations:

- The embedded PowerPoint Viewer (which provided the optimal viewing experience) is only available on the Windows platform.
- Many mobile devices (including some of the more popular mobile phones) do not support Silverlight.
- The PowerPoint Viewer and the DHTML/Silverlight approach do not support all of the features (such slide transitions and embedded video) that are found in the more recent editions of PowerPoint.

To help address these issues, and to improve the overall experience of users presenting or viewing PowerPoint presentations, Lync Server 2013 employs Office Web Apps and the Office Web Apps Server to handle PowerPoint presentations. Among other advantages, this new approach enables:

- Higher-resolution displays and better support for PowerPoint capabilities, such as animations, slide transitions, and embedded video.
- Additional mobile devices to access these presentations. That's because Lync Server 2013 uses standard DHTML and JavaScript to broadcast PowerPoint presentations instead of customized DHTML and Silverlight.
- Users with the appropriate privileges to scroll through a PowerPoint presentation independent of the presentation itself. For example, while Ken Myer is presenting his slide show, Pilar Ackerman can look at any slide she wants to, and without affecting Ken's presentation.

1.3.8.1.3 A/V Conferencing Overview

A/V Conferencing Overview

Planning > Planning for Conferencing > Overview of Conferencing >

Topic Last Modified: *2012-10-13*

A/V conferencing enables real-time audio and video communications between your users. When you deploy conferencing, you can choose to enable and use both web conferencing and A/V conferencing, or just web conferencing.

To plan for A/V conferencing, you need to understand the network bandwidth required by the type of conferencing media that your organization requires. This could include audio, video, and panoramic video.

Before you enable users for A/V conferencing, ensure that your network can handle the resulting load. Without sufficient network bandwidth, the user experience may be severely degraded. You can use call admission control (CAC) to manage the network bandwidth used by A/V Conferencing. This is important for restricted networks, such as limited bandwidth links between central and branch sites. For details, see Overview of Call Admission Control. For details about media bandwidth requirements, see Network Bandwidth Requirements for Media Traffic.

If you deploy audio conferencing in your network, your users will need audio devices such as headsets to participate in an audio conference. If you deploy video conferencing, you need to deploy video devices, such as webcams for users. We recommend that you use unified communications (UC) devices that are certified by Microsoft for all device types, to ensure an optimal user experience. For details about UC-certified devices, see "Phones and Devices for Lync" at http://go.microsoft.com/fwlink/p/?LinkId=263861. For either audio or video devices, device deployment, and user training are important steps for you to consider and plan for.

The following sections describe the features for audio and video conferencing, including information about managing bandwidth and selecting the appropriate clients.

Audio Conferencing Features

Lync Server 2013 provides several features that you can use to configure the audio conferencing experience for the user, including the following:

- **Audience mute** The presenter can use this setting to mute all the audio participants in the conference and put the conference in a state where non-presenters cannot unmute themselves.
- **Conferencing Entry/Exit Announcements** If you have enabled dial-in conferencing, presenters can use this setting to turn entry and exit announcements on or off to minimize distractions while a conference is in progress.
- **Adding a user by dialing out** Presenters and attendees that have been given permission, can add PSTN numbers to the conferences and have the conference dial-out to those numbers.

Video Conferencing Features

Lync Server 2013 provides several features that you can use to configure the video conferencing experience for the user, including the following:

- **Gallery View** In video conferences that have more than two people, users automatically see everyone in the conference. If the conference has more than five participants, the video of the most active participants appear in the top row and only the photo appears for the other participants. Multiparty video is turned on by default. For details about configuring or turning off multiparty video, see Configuring Video Bandwidth in Lync Server 2013.

- **Panoramic Video** If a RoundTable video conferencing device is installed in the conferencing room, this feature provides a full 360 degree view of the conference room. The panoramic video strip is only available with RoundTable devices.
- **Presenter only video mode** Presenters can configure the meeting so that only the video from the presenter is shown. This prevents distractions in large meetings when multiple video streams are available and locking to different sources. This mode also applies to video captured and provided by RoundTable devices.
- **HD video** Users can experience resolutions up to HD 1080P in two-party calls and multiparty conferences.
- **Video Spotlight** Presenters can configure the meeting so that only the video from a selected participant who is a video source is seen by the other participants in the conference. This mode also applies to video captured and provided by RoundTable devices for panoramic video.

1.3.8.1.4 Dial-In Conferencing Overview

Dial-In Conferencing Overview

Planning > Planning for Conferencing > Overview of Conferencing >

Topic Last Modified: *2012-09-30*

If your organization has users who need to attend Lync Server 2013 on-premises conferences when they are out of the office or do not have access to a computer, you can deploy dial-in conferencing so that they can join the conference by using a public switched telephone network (PSTN) phone.

Dial-in conferencing is an optional feature that you can configure when you deploy Lync Server 2013 conferencing. Although dial-in conferencing uses some of the same Lync Server 2013 components that Enterprise Voice uses, you can deploy dial-in conferencing even if you do not deploy Enterprise Voice.

Note:

If you deploy dial-in conferencing, you must deploy it in every pool where you deploy Lync Server 2013 conferencing. You do not need to assign access numbers in every pool, but you must deploy the dial-in feature in every pool. This requirement supports the recorded name feature when a user calls an access number from one pool to join a Lync Server 2013 conference in a different pool.

Conferences must be enabled for dial-in access in meeting policy. By default, conferences that are enabled for dial-in access include the following information in the conference invitation:

- A numeric conference ID that identifies the conference.
- One or more PSTN access numbers.
- A link to a Dial-in Conferencing Settings page, which contains a complete list of access numbers with their associated languages; a place to create, reset, or unblock personal identification numbers (PINs); and other information, such as dual-tone multi-frequency (DTMF) controls.

Dial-in conferencing supports both enterprise and anonymous users. Enterprise users have Active Directory Domain Services (AD DS) credentials and Lync Server 2013 accounts within their organization. Anonymous users do not have enterprise credentials within your organization. In the dial-in conferencing context, a user in a federated partner's organization who uses the PSTN to connect to a conference is treated like an anonymous user. For dial-in conferencing, unlike other contexts, federated users are not authenticated.

Enterprise users or conference leaders who join a conference that is enabled for dial-in access dial one of the conference access numbers and then are prompted to enter the conference ID. If a leader has not yet joined the meeting, users can either enter their unified communications (UC) extension (or full phone number) and PIN or wait to be admitted by a leader. The Meeting organizer can join the meeting as a leader by entering just their PIN. The Front End Server uses the combination of full phone number or extension, and PIN, to uniquely map enterprise users to their Active Directory credentials. As a result, enterprise users are authenticated and identified by name in the conference. Enterprise users can also assume a conference role predefined by the organizer.

Note:

Enterprise users who dial in from an office IP phone or from Lync Server 2013 or Lync 2010 Attendant are not prompted for their phone number because they are already authenticated.

Anonymous users who want to join a dial-in conference dial one of the conference access numbers and then they are prompted to enter the conference ID. Unauthenticated anonymous users are also prompted to record their name. The recorded name identifies unauthenticated users in the conference. Anonymous users are not admitted to the conference until at least one leader or authenticated user has joined, and they cannot be assigned a predefined role.

Note:

Enterprise users who choose not to enter their phone number and PIN are not authenticated. They are prompted to record their name and are treated as anonymous users in the conference.

At schedule time, the meeting organizer can choose to restrict access to the meeting by making the meeting closed or locked. In this case, dial-in users are requested to authenticate. If dial-in users fail or choose not to authenticate, they are transferred to the lobby. They wait in the lobby until a leader accepts or rejects them, or they time out and are disconnected. Dial-in users hear music if they are waiting to be admitted to the conference. After they are admitted to a conference, dial-in users can participate in the audio portion of the conference and can exercise dual-tone multi-frequency (DTMF) commands by using the phone keypad. Dial-in leaders can exercise DTMF commands to turn participants' ability to unmute on or off, lock or unlock the conference, admit people from the lobby, and turn entry and exit announcements on or off. Leaders can also use a DTMF command to admit everyone from the lobby, which changes the permissions of the meeting to allow anyone who subsequently joins. All dial-in participants can exercise DTMF commands to hear Help, listen to the conference roster, and mute themselves.

Dial-in participants (that is, whether or not they dial from the PSTN), hear personal announcements during the conference, such as whether they have been muted or unmuted, the meeting is being recorded, or someone is waiting in the lobby.

Note:

Participants who join the conference by clicking a link instead of dialing in do not hear personal announcements.

1.3.8.2 Defining Your Requirements for Conferencing

Defining Your Requirements for Conferencing

See Also

Microsoft Lync Server 2013 > Planning > Planning for Conferencing >

Topic Last Modified: *2012-09-30*

When you are determining which conferencing capabilities to deploy, you need to consider the features that you want available to your users and your network bandwidth capabilities. The following list of questions guides you through the conferencing planning process to determine what features of conferencing you should deploy, based on your organization's requirements.

- **Do you want to enable web conferencing, which includes document collaboration and application sharing?**

  If so, you must enable conferencing for your Front End pool in the Microsoft Lync Server 2013, Planning Tool or in Topology Builder. When you enable conferencing, you enable both web conferencing and A/V conferencing.

  Application sharing requires and uses more network bandwidth than document collaboration. Lync Server 2013 provides a throttling mechanism to control each application sharing session. By default, this is set to 1.5 KB/second for each session.

  If you do not want to enable application sharing but you do want document collaboration, you can enable conferencing and use meeting policies to disable application sharing. For details about configuring meeting policies, see Conferencing Policies.

  To enable users to share PowerPoint presentations, you need to configure Office Web Apps Server. For details about configuring Office Web Apps Server, see Configuring Integration with Office Web Apps Server and Lync Server 2013.
- **Do you want to enable A/V conferencing?**

  If so, you must enable conferencing for your Front End pool in the Lync Server 2013, Planning Tool or in Topology Builder. When you enable conferencing, you enable both web conferencing and A/V conferencing.

  A/V conferencing requires and uses more network bandwidth than web conferencing (which includes document collaboration and application sharing).

  If you do not want to enable A/V conferencing but you do want to enable web conferencing, you can enable conferencing and use meeting policies to disable A/V conferences.

  If you do want to enable audio conferences but not video conferences, you can enable A/V conferencing and use meeting policies to prevent video conferences. Alternatively, you can enable A/V conferencing and enable only certain users to start or participate in A/V conferences.

  > **Note:**
  >
  > Enterprise Voice is not required for you to use A/V conferencing. If you enable A/V conferencing, your users can add audio to their conferences if they have audio devices, even if you use a PBX for your telephone solution.
- **Do you want to enable users to join the audio portion of conferences when using a PSTN phone?**

  If so, deploy and enable dial-in conferencing. Invited users, both inside and outside your organization, can then join the audio portion of conferences by using a PSTN phone.
- **Do you want to enable external users with Lync Server 2013 clients to join the types of conferences that you have enabled?**

  If so, you should deploy Edge Servers. By allowing external participation in meetings, you maximize your investment in Lync Server 2013. For example, users with laptops with Lync Server 2013 can join conferences from wherever they are—at home, in the airport, or at customer sites.

  Additionally, with Edge Servers deployed you can create federated relationships with other organizations-such as your customers or vendors-and users from those organizations can more easily collaborate with your users.

  For details about deploying Edge Servers, see Planning for External User Access and Deploying External User Access. For details about enabling external access for Office Web Apps Server, see Publishing Office Web Apps Server Using a Reverse Proxy Server.
- **Do you want to control the clients that can join Lync Server 2013**

meetings?
If so, you should configure the meeting join page so that only the client options that you want to support are available. Each time a user clicks a link to join a scheduled meeting, Lync Server 2013 detects whether a client is already installed on the computer. It then starts the default client and opens the meeting join page, which contains links for alternate clients. The meeting join page always contains the option to use Microsoft Lync Web App. In addition to this option, you can decide whether to include links for Attendee and previous versions of Communicator. For details, see Configuring the Meeting Join Page.

Planning > Planning for Conferencing > Defining Your Requirements for Conferencing >

Topic Last Modified: *2013-01-30*

If you have chosen to enable web conferencing, you need to plan for the following:

- Access to the file store, which is used for storing web conferencing content.
- Integration with Office Web Apps Server, which is necessary in order to share PowerPoint files during a conference.

File Store

The Lync Server 2013 web conferencing service stores content shared during meetings in the file store. As part of deployment, you must specify a file share to be used as the file store for the either Standard Edition server or Enterprise Edition Front End pool. You can use an existing file share for the file store or you can specify a new file share by specifying the fully qualified domain name (FQDN) of the file server on which the file share is to be located and a folder name for the new file share. For more information, see Topology Builder – Define the File Store for the Front End. The web conferencing service encrypts the content before it stores the content in the file store.

Lync Server 2013 supports using file shares on either direct attached storage (DAS) or a storage area network (SAN), including Distributed File System (DFS) and on a redundant array of independent disks (RAID) for file stores. After the Lync Server Deployment Wizard has defined the location of the file share, Lync Server creates a folder structure within the file share similar to:

- 1-ApplicationServer-1
- 1-CentralMgmt-1
- 1-WebServices-1
  - CollabContent
  - CollabMetadata
  - DataConf

The web conferencing service then stores content such as PowerPoint slides, whiteboards, polls, and attachments in the CollabContent and CollabMetadata folders, located in the WebServices folder.

The administrator must set permissions on the file share so that RTC groups have the necessary read and write access.

⚠**Warning:**

If you encounter any errors with the permissions, open Topology Builder, download and republish the existing topology. Publishing the topology will verify the file share permissions and reset them if needed.

You can use the following settings to manage how content is stored for a meeting:

- **ContentGracePeriod**, located in Set-CsConferencingConfiguration, sets how long web conferencing content will remain on the server after the meeting has ended.
- **MaxContentStorageMb**, located in Set-CsConferencingConfiguration, sets the maximum amount of file space allowed for the storage of content during a single meeting.

MaxUploadFileSizeMb does not limit the file upload setting for Lync Web App. The file size upload limit for Lync Web App is set to approximately 30MB and is controlled by the IIS web.config file: /DataCollabWeb/Int[Ext]/Handler/web.config. To configure the file size upload limit for Lync Web App, update `maxRequestLength` and `maxAllowedContentLength` in the web.config file as shown below.

```
<system.web>
    <!--
        Since this handler is used to upload files to DMCU the request size (in k
        has to fit max allowed file size uploaded by Lync Web App client.
        The timeout has to reflect the min client bandwidth. Timeout of 600 secs
        and 512 Kbits of *client* bandwidth would result into aproximately 30 Mby
        for Lync Web App upload size limit.
    -->
      <httpRuntime maxRequestLength="500000" executionTimeout="600" />
                <security>
                <requestFiltering>
                           <requestLimits maxAllowedContentLength="524288000" />
                </requestFiltering>
                </security>
```

You must update the web.config file for each Front End Server.

Office Web Apps Server

In order to use these new capabilities administrators must install Office Web Apps Server and they must configure Lync Server 2013 to communicate with Office Web Apps Server. This documentation provides information on how to configure Lync Server 2013 to work with Office Web Apps Server. What this documentation does not provide is information about how to install Office Web Apps Server. For installation details, see the Microsoft Office Web Apps Deployment website at http://go.microsoft.com/fwlink/p/?linkid=257525. That guide includes complete prerequisite information for Office Web Apps Server. Note that Office Web Apps Server should be installed on a stand-alone computer that is not running Lync Server, SQL Server, or any other server application. (You must not have any version of Office installed on that computer.) Any computer used to run Office Web Apps Server must also have a specific set of software installed (including .NET Framework 4.5 and Windows PowerShell 3.0). These requirements, along with information about configuring certificates and Internet Information Services (IIS), are discussed in detail in the Microsoft Office Web Apps Deployment website at http://go.microsoft.com/fwlink/p/?linkid=257525.

A/V Conferencing Requirements

See Also

Planning > Planning for Conferencing > Defining Your Requirements for Conferencing >

Topic Last Modified: *2012-09-30*

Lync Server 2013 infrastructure requirements for conferencing are the same as for deployment of Lync Server 2013. For details, see Determining Your Infrastructure Requirements in the Planning documentation.

It is important that you have the necessary Media bandwidth to handle media traffic generated by conferencing. For details that you can use to calculate your needed bandwidth, see Network Bandwidth Requirements for Media Traffic. For details about limiting the bandwidth, see Creating or Modifying Bandwidth Policy Profiles. For details about infrastructure requirements, see Network Infrastructure Requirements.

In order to use the conferencing features, Lync Server 2013 requires that certain ports are open. For details about Port Requirements, see Ports and Protocols for Internal Servers. For details about configuring ports, see Configuring Port Ranges for Your Conferencing, Application, and Mediation Servers.

A/V Conferencing Overview
Deployment Checklist for A/V Conferencing

1.3.8.2.3 Dial-In Conferencing Requirements

Dial-In Conferencing Requirements

See Also

Planning > Planning for Conferencing > Defining Your Requirements for Conferencing >

Topic Last Modified: *2012-09-30*

Before you start the Lync Server 2013 deployment process you need to plan for the following:

- The configuration to use for connecting to the public switched telephone network (PSTN)
- Your strategy for assigning dial-in conferencing regions to dial-in access numbers
- Your strategy for creating conference directories

Planning for Dial-in PSTN Connectivity

Dial-in conferencing requires at least one Mediation Server and at least one PSTN gateway.

You can deploy a Mediation Server in a central site or in a branch site. In a central site, you can collocate a Mediation Server on a Front End pool or Standard Edition server, or you can deploy it on a stand-alone server or pool. In a branch site, you can deploy a Mediation Server on a stand-alone server or as a component of the Survivable Branch Appliance.

You can deploy a PSTN gateway in a central site or in a branch site. In a branch site, the PSTN gateway can be stand-alone or a component of the Survivable Branch Appliance.

Note:

Dial-in conferencing does not use media bypass because A/V Conferencing Server do not support media bypass.

For details about planning your configuration for Mediation Server and PSTN gateways for dial-in conferencing, see Components and Topologies for Mediation Server in the Planning documentation.

Planning for Dial-in Conferencing Regions

During dial-in configuration, you create dial plans and dial-in conferencing access numbers. Dial plans are sets of normalization rules that specify the number and pattern of digits in a phone number and translate the phone number into the standard E.164 format for call routing. Dial-in conferencing access numbers are the numbers participants call to join a conference.

Every dial-in conferencing access number must be associated with at least one dial plan. Dial-in conferencing regions associate a dial-in conferencing access number with its dial plans. When you set up a dial plan, you specify the dial-in conferencing region that applies to the dial plan. When you create the dial-in access number, you select the regions that associate the access number with the appropriate dial plans.

When you create a dial plan, you specify the scope of the dial plan: user scope, pool scope, or site scope. Every user is assigned the dial plan from the narrowest scope that applies to the user. For example, a user is assigned a user-level dial plan, if one applies. If a user-level dial plan does not apply, the user is assigned a pool-level dial plan. If a pool-level dial plan does not apply, the user is assigned a site-level dial plan. If a site-level dial plan does not apply, the user is assigned the global dial plan.

Before you configure the dial plans, is it important to plan how you want to name and use regions. The following considerations apply to dial-in conferencing regions:

- A region is typically a geographical area that is associated with an office or group of offices.
- Languages are associated with dial-in access numbers. If you support geographical areas that have multiple languages, you should decide how you want to define regions to support the multiple languages. For example, you might define multiple regions based on a combination of geography and language, or you might define a single region based on geography and have a different dial-in access numbers for each language.
- When a user schedules a meeting, by default the meeting uses the region specified by that user's dial plan.
- By default, the all of the dial-in access numbers for the region are included in the meeting invitation.
- It is important to name regions so that they are clearly recognizable. The user can use the names of the regions to change a meeting's region so that different access numbers are included in the invitation. (When users use Outlook to schedule a meeting, the user uses the Online Meeting Add-in for Lync 2013 to change the region).
- Regions should be designed so that any invitee who wants to dial into a

conference can see a local access number in the conference invitation.

- You can configure the order in which access numbers within a region appear on the Dial-in Conferencing Settings page (and, therefore, the order in which they appear in the conference invitation) by using Lync Server Management Shell cmdlets.
- Any user from any location can call any dial-in access number to join a conference.

Planning for Conference Directories

Conference directories maintain a mapping between the alphanumeric meeting ID that a participant uses to join a conference when using Lync 2013, and the numeric-only conference ID that a dial-in conferencing participant uses to join the conference. The format of the conference ID is as follows:

```
      <housekeeping digit (1 digit)><conference directory (usually 1-2 digits)><c
```

Creating multiple conference directories will ensure that conference IDs will stay short until a significant amount of conferences have been created. In an organization with a typical number of conferences per user, we recommend that you create one conference directory for every 999 users in the pool. Using this guideline the conference IDs can generally be kept small. However, once the number of conference directories (across the pools) exceed 9, the Conference ID number will grow to support additional conferences.

1.3.8.3 Components and Topologies for Conferencing

Components and Topologies for Conferencing

Microsoft Lync Server 2013 > Planning > Planning for Conferencing >

Topic Last Modified: *2013-02-04*

When you select conferencing in Topology Builder, conferencing is deployed as part of the Front End Server or Standard Edition server. Dial-in conferencing and PowerPoint sharing requires additional components and configuration. The following sections describe the supported components and topologies for web conferencing, A/V conferencing, and dial-in conferencing.

Supported Components

The only components web conferencing and A/V conferencing require are your organization's Front End Servers or Standard Edition servers. For a list of hardware and software requirements for the Front End Servers and Standard Edition servers, see Supported Hardware and Server Software and Infrastructure Support.

Lync Server 2013 uses Office Web Apps and the Office Web Apps Server to handle sharing and rendering of PowerPoint presentations. For details about installing and configuring the Office Web Apps Server, see Configuring Integration with Office Web Apps Server and Lync Server 2013.

In addition to the requirements for web conferencing and A/V conferencing, dial-in conferencing uses the following Lync Server 2013 components:

- **Application service** Application service provides a platform for deploying, hosting, and managing unified communications (UC) applications. Dial-in conferencing uses two UC applications that require Application service: Conferencing Attendant and Conferencing Announcement. Application service is installed and activated by default on every Front End Server in a Front End pool and on every Standard Edition server when you deploy a Conferencing workload and select the dial-in conferencing option.
- **Conferencing Attendant application** Conferencing Attendant application is a unified communications application that accepts public switched telephone network (PSTN) calls, plays prompts, and joins the calls to an A/V conference. Conferencing Attendant application is installed and activated by default when you deploy a Conferencing workload and select the dial-in conferencing option.
- **Conferencing Announcement application** Conferencing Announcement application is a unified communications application that plays tones and prompts to PSTN participants on certain actions, such as when participants join or leave a conference, participants are muted or unmuted, someone enters the conference lobby, or the conference is locked or unlocked. Conferencing Announcement application also supports dual-tone multifrequency (DTMF) commands from the phone keypad. Conferencing Announcement application is automatically installed and activated by default when you deploy a Conferencing workload and select the dial-in conferencing option.
- **Dial-in Conferencing Settings page** The Dial-in Conferencing Settings page displays conference dial-in numbers with their available languages, assigned conference information (that is, for meetings that do not need to be scheduled), and in-conference DTMF controls, and supports management of personal identification number (PIN) and assigned conferencing information. The Dial-in Conferencing Settings page is automatically installed as part of Web Services.
- **Lync Server 2013, Mediation Server and PSTN gateway** Dial-in conferencing requires a Mediation Server to translate signaling (and media, in some configurations) between Lync Server 2013 and the PSTN gateway, and a PSTN gateway to translate signaling and media between the Mediation Server and the PSTN gateway. For dial-in conferencing, you must deploy at least one Mediation Server and at least one of the following:
  - PSTN gateway
  - IP-PBX
  - Session Border Controller (SBC) (for an Internet telephony service provider to which you connect by configuring a SIP trunk)

  Note:

  If you are also deploying Enterprise Voice, Mediation Server and PSTN gateways are part of the Enterprise Voice deployment. If you are not deploying Enterprise Voice, you need to deploy at least one Mediation Server and at least one PSTN gateway, IP-PBX, or SBC for dial-in conferencing.
- **File store** File store is used for recorded name audio files. File Store is a standard component in every Enterprise Edition or Standard Edition deployment.
- **User store** User store is used to store user Lync Server 2013 PINs. PINs are hashed. The User store is a standard component in every Enterprise Edition or Standard Edition deployment.
- **Lync Server Control Panel** Some dial-in settings can be configured by using Lync Server Control Panel.
- **Lync Server Management Shell** All dial-in settings can be configured by using Lync Server Management Shell cmdlets. Lync Server Management Shell cmdlets are available for deploying, configuring, running, monitoring, and troubleshooting Conferencing Attendant application and Conferencing Announcement application. For details about specific cmdlets, see Lync Server Management Shell documentation.

Supported Topologies

In Lync Server 2013, the server running conferencing services is always collocated with the Front End Servers or Standard Edition servers. During your initial deployment, Topology Builder gives you the option to include conferencing in your topology. You can also use Topology Builder to add conferencing to an existing deployment. For details, see Defining and Configuring the Topology.

Dial in Conferencing Toplogies

You can deploy dial-in conferencing in the following topologies and configurations:

- Lync Server 2013 Standard Edition
- Lync Server 2013 Enterprise Edition
- With or without Enterprise Voice

You can deploy Application service, Conferencing Attendant application, and Conferencing Announcement application in a central site, but not in a branch site.

Note:

If you deploy dial-in conferencing, you must deploy it in every pool where you deploy Lync Server 2013 conferencing. You do not need to assign access numbers in every pool, but you must deploy the dial-in conferencing feature in every pool. This requirement supports the recorded name feature when a user calls an access number from one pool to join a Lync Server 2013 conference in a different pool.

Supported Topologies for Lync Server 2013 and Office Web Apps

Lync Server 2013 provides the following ways to configure Office Web Apps Server. Depending on your needs you can:

- **Install both Lync Server 2013 and Office Web Apps Server on-premises behind your organization’s firewall, and in the same network zone.** With this topology, external access to Office Web Apps Server will be provided through your reverse proxy server. Both Lync Server 2013 and Office Web Apps Server (or an Office Web Apps Server farm) are installed on-premises and behind your organization's firewall. Ideally, you should install Office Web Apps Server in the same network zone as Lync Server.
  External Lync clients can connect to Lync Server 2013 and to Office Web Apps Server by using a reverse proxy server, which is a server that takes requests from the Internet and forwards them to the internal network. (Internal clients do not need to use the reverse proxy server because they can connect to Office Web Apps Server directly.) This topology works best if you want to use a dedicated Office Web Apps Server farm that is only used by Lync Server 2013.
- **Using an externally deployed Office Web Apps Server**
  In this topology, Lync Server 2013 is deployed on-premises, and uses an Office Web Apps Server that is deployed outside of Lync Server network zone. This may happen when Office Web Apps Server is shared across multiple applications in the corporation and is deployed in a network requiring Lync Server to use the external interface of Office Web Apps Server and vice versa. You do not need to install a reverse proxy server; instead, all the requests from the Office Web Apps Server to Lync Server 2013 are routed through your Edge Server. Both your internal and your external Lync clients connect to Office Web Apps Server using the external URL.
  If the Office Web Apps Server is deployed outside your internal firewall, then select the option **Office Web Apps Server is deployed in an external network (that is, perimeter/Internet)** in Topology Builder. For more details see Configuring Integration with Office Web Apps Server and Lync Server 2013.

Regardless of the topology you select, it is critical that the correct firewall ports be opened. You must make sure that DNS names, IP addresses, and ports are not blocked by firewalls on the Office Web Apps Server, the load balancer, or Lync Server.

Note:
Another option for providing external access to Office Web Apps Server is to deploy the server in the perimeter network. If you elect to do this, keep in mind that Office Web Apps Server setup requires the server computer to be a member of your Active Directory domain. Unless your network policy allows computers in the perimeter network to be Active Directory domain members, it is recommended that you do not install Office Web Apps Server in the perimeter network. Instead, you should install Office Web Apps Server in the internal network and provide external user access through your reverse proxy server.

1.3.8.4 Technical Requirements for Conferencing

Technical Requirements for Conferencing

Microsoft Lync Server 2013 > Planning > Planning for Conferencing >

Topic Last Modified: *2012-09-11*

For Lync Server 2013, dial-in conferencing, A/V conferencing, instant messaging (IM) conferencing and web conferencing capabilities always run on Front End Servers.

This section details the hardware and software requirements for these servers, along with the supported collocation.

Dial-in conferencing is a feature that includes a variety of components. Some of the components are specific to dial-in conferencing and some are Enterprise Voice components. This section describes the requirements for the components that are specific to dial-in conferencing. For details about Mediation Server and public switched telephone network (PSTN) gateway requirements, see Mediation Server Component and Components and Topologies for Mediation Server in the Planning documentation.

Hardware Requirements

Because web conferencing and A/V conferencing are collocated with the Front End Server, the server hardware requirements are the same as for the Front End Servers. For details about hardware requirements, see Server Hardware Platforms in the Supportability documentation. The following components required for dial-in conferencing also have the same hardware requirements as Front End Servers:

- Application service
- Conferencing Attendant application
- Conferencing Announcement application

The hardware requirements for Front End Server are the same as for many other server roles in Lync Server 2013 are outlined in the following table.

Software Requirements

Because web conferencing and A/V conferencing are collocated with the Front End Server, the server software requirements are the same as for the Front End Servers. For details about software requirements, see Server and Tools Operating System Support in the Supportability documentation.

For web conferencing, Lync Server 2013 also requires Office Web Apps and the Office Web Apps Server (formerly known as WAC Server) to handle PowerPoint presentations. For details, see Configuring Integration with Office Web Apps Server and Lync Server 2013.

For dial-in conferencing, Application service, Conferencing Attendant application, and Conferencing Announcement application have the same operating system requirements as Front End Servers. For details about software requirements, see Server and Tools Operating System Support in the Supportability documentation.

Conferencing Attendant application and Conferencing Announcement application require that Windows Media Format Runtime is installed on Front End Servers. The Windows Media Format Runtime is required to play Windows Media audio (WMA) files that are used for music on hold, recorded names, and prompts. Except for Windows Server 2012, the Windows Media Format Runtime is installed automatically as part of the Windows Desktop Experience when you run Setup, but you might need to restart the computer. Therefore, we recommend that you install as part of the Windows Desktop Experience, which includes Windows Media Format Runtime before you run Setup. Windows Server 2012 requires Microsoft Media Foundation.

Port Requirements for dial-in conferencing

The following table describes the ports that are used by dial-in conferencing. If you use a load balancer, ensure that the load balancer is configured for the ports used by any applications that will run in the pool.

These ports are default settings that you can change by using the **Set-CsApplicationServer** cmdlet. For details about this cmdlet, see the Lync Server Management Shell documentation.

Note:
All instances of the same application in a pool use the same SIP listening port.

Ports used by dial-in conferencing

Port number	Description
5072	Used by Conferencing Attendant application for SIP listening requests
5073	Used by Conferencing Announcement application for SIP listening requests

Supported Clients for Dial-In Conferencing

You can use the following client to schedule on-premises conferences that support dial-in access:

- Online Meeting Add-in for Lync 2013 (installed automatically when you install Lync 2013 or Attendee)

Dial-in Conferencing Settings page Requirements

The Dial-in Conferencing Settings page supports the combinations of operating systems and web browsers described in the following table.

Important:
The Dial-in Conferencing Settings page is not supported on 64-bit browsers.

Note:
32-bit and 64-bit versions of the operating systems are supported.

Supported Operating Systems and Web Browsers

Operating system	Web browser
Windows 7	Internet Explorer 9 Internet Explorer 8 Internet Explorer 7 Firefox 9.x
Windows Vista with Service Pack 2	Internet Explorer 9 Internet Explorer 8 Internet Explorer 7 Firefox 9.x
Windows XP with Service Pack 2 (SP2) or latest service pack	Internet Explorer 9 Internet Explorer 8 Internet Explorer 7 Firefox 9.x
Windows Server 2008 R2	Internet Explorer 9 Internet Explorer 8 Internet Explorer 7
Windows Server 2008 with SP2	Internet Explorer 9 Internet Explorer 8 Internet Explorer 7
Windows Server 2003 (except on Intel Architecture 64-bit [IA-64])	Internet Explorer 9 Internet Explorer 8 Internet Explorer 7
Mac OS 10.4.8 and later versions (Intel based)	Firefox 3.x Safari 5.x Safari 4.x

Audio File Requirements for dial-in conferencing

Lync Server 2013 does not support customization of voice prompts and music for dial-in conferencing. However, if you have a strong business need that requires you to change the default audio files, see Microsoft Knowledge Base article 961177, "How to customize voice prompts or music files for dial-in audio conferencing in Microsoft Office Communications Server 2007 R2," available at http://go.microsoft.com/fwlink/p/?linkid=3052&kbid=961177.

Conferencing Attendant application and Conferencing Announcement application have the following requirements for music on hold, recorded name, and audio prompt files:

- Windows Media Audio (WMA) file format
- 16-bit mono
- 48 kbps 2-pass CBR (constant bit rate)
- Speech level at -24DB

User Requirements for Dial-In Conferencing

Dial-in conferencing users must have a unique phone number or extension assigned to their account. This requirement supports authentication during dial-in conferencing. Enterprise users (that is, users who have Active Directory Domain Services (AD DS) credentials and Lync Server accounts within your organization) enter their phone number (or extension) and a personal identification number (PIN) to dial in to conferences as an authenticated user.

1.3.8.5 Deployment Checklist for Conferencing

Deployment Checklist for Conferencing

Microsoft Lync Server 2013 > Planning > Planning for Conferencing >

Topic Last Modified: *2012-09-30*

The following topics provide a checklist for deploying and configuring web conferencing, A/V conferencing, and dial-in conferencing.

- Deployment Checklist for Web Conferencing
- Deployment Checklist for A/V Conferencing
- Deployment Checklist for Dial-In Conferencing

1.3.8.5.1 Deployment Checklist for Web Conferencing

Deployment Checklist for Web Conferencing

Planning > Planning for Conferencing > Deployment Checklist for Conferencing >

Topic Last Modified: *2012-09-30*

As with deployment of your other Lync Server 2013 components, deployment of web conferencing requires that you use Topology Builder to create and publish a topology that incorporates conferencing.

Deployment Sequence

You can deploy conferencing at the same time that you deploy your initial topology or after you have deployed at least one Front End pool or Standard Edition server.

Conferencing Deployment Process

The following table provides an overview of the steps required to deploy conferencing into an existing topology.

Phase	Steps	Roles and group memberships	Documentation
Install prerequisite hardware and software	Conferencing runs on Front End Servers in a Front End pool and Standard Edition servers. It has no additional hardware or software requirements beyond what is required to install those servers. **Note:** Lync Server 2013 uses Office Web Apps and the Office Web Apps Server to handle sharing and rendering of PowerPoint presentations. For information about installing and configuring the Office Web Apps Server, see Configuring Integration with Office Web Apps Server and Lync Server 2013.	Domain user who is a member of the local Administrators group	Supported Hardware in the Supportability documentation Server Software and Infrastructure Support in the Supportability documentation Determining Your System Requirements in the Planning documentation. Technical Requirements for Archiving in the Planning documentation.
Create the appropriate internal topology to support conferencing	Run Topology Builder to add conferencing to the topology, and then publish the topology.	To define a topology, an account that is a member of the local Users group To publish the topology, an account that is a member of the Domain Admins group and RTCUniversalServerAdmins group, and that has full control permissions (read/write/modify) on the file share to be used for the Lync Server 2013 file store (so that Topology Builder can configure the required DACLs)	Define and Configure a Topology in Topology Builder in the Deployment documentation.
Configure conferencing policies and support	Use the Lync Server 2013 Control Panel or Lync Server	RTCUniversalServerAdmins group (Windows	Conferencing Policies in the Operations documentation.

	Management Shell to configure conferencing settings.	PowerShell only) or assign users to the [] or CSAdministrator role	

Lync Server 2013 now includes the **MaxUploadFileSizeMb** setting, which limits the size of files that can be uploaded during a meeting. The default value for this setting is 500 MB. You can adjust **MaxUploadFileSizeMb** using the **Set-CsConferencingConfiguration** cmdlet.

MaxUploadFileSizeMb does not limit the file upload setting for Lync Web App. The file size upload limit for Lync Web App is set to approximately 30MB and is controlled by the IIS web.config file: /DataCollabWeb/Int[Ext]/Handler/web.config. To configure the file size upload limit for Lync Web App, update `maxRequestLength` and `maxAllowedContentLength` in the web.config file as shown below.

```
<system.web>
    <!--
        Since this handler is used to upload files to DMCU the request size (in k
        has to fit max allowed file size uploaded by LWA client.
        The timeout has to reflect the min client bandwidth. Timeout of 600 secs
        and 512 Kbits of *client* bandwidth would result into aproximately 30 Mby
        for LWA upload size limit.
    -->
      <httpRuntime maxRequestLength="500000" executionTimeout="600" />
                <security>
                <requestFiltering>
                           <requestLimits maxAllowedContentLength="524288000" />
                </requestFiltering>
                </security>
```

You must update the web.config file for each Front End Server.

1.3.8.5.2 Deployment Checklist for A/V Conferencing

Deployment Checklist for A/V Conferencing

See Also

Planning > Planning for Conferencing > Deployment Checklist for Conferencing >

Topic Last Modified: *2012-09-30*

As with deployment of your other Lync Server 2013 components, deployment of A/V conferencing requires that you use Topology Builder to create and publish a topology that incorporates conferencing.

Deployment Sequence

You can deploy conferencing at the same time that you deploy your initial topology or after you have deployed at least one Front End pool or Standard Edition server.

Conferencing Deployment Process

The following table provides an overview of the steps required to deploy conferencing into an existing topology.

Phase	Steps	Roles and group memberships	Documentation
Install prerequisite hardware and software	Conferencing runs on Front End Servers of a Front End pool and Standard Edition servers. It has no additional hardware or software requirements beyond what is required to install those servers. **Note:** Lync Server 2013 uses Office Web Apps and the Office Web Apps Server to handle sharing and rendering of PowerPoint presentations. For details about installing and configuring the Office Web Apps Server, see Configuring Integration with Office Web Apps Server and Lync Server 2013.	Domain user who is a member of the local Administrators group	Supported Hardware in the Supportability documentation Server Software and Infrastructure Support in the Supportability documentation Determining Your System Requirements in the Planning documentation. Technical Requirements for Archiving in the Planning documentation.
Create the appropriate internal topology to support conferencing	Run Topology Builder to add conferencing to the topology, and then publish the topology.	To define a topology, an account that is a member of the local Users group To publish the topology, an account that is a member of the Domain Admins group and RTCUniversalServerAdmins group, and that has full control permissions (read/write/modify) on the file share to be used for the Lync Server 2013 file store (so that Topology Builder can configure the required DACLs)	Define and Configure a Topology in Topology Builder in the Deployment documentation.
Configure conferencing policies and support	Use the Lync Server 2013 Control Panel or Lync Server Management Shell to configure conferencing settings. 1.3.8.5.3 Deployment Checklist for Dial-In Conferencing

Deployment Checklist for Dial-In Conferencing

Planning > Planning for Conferencing > Deployment Checklist for Conferencing >

Topic Last Modified: *2013-02-25*

The components required for dial-in conferencing are deployed when you deploy the conferencing workload. Before you can configure dial-in conferencing, you need to deploy either Enterprise Voice or a Mediation Server and a public switched telephone network (PSTN) gateway.

All the steps in the following table must be performed before users can dial in from the PSTN to join an audio/video conference.

Note:
If you are migrating from Office Communications Server 2007 R2, you must apply the latest updates to your Office Communications Server 2007 R2 environment before deploying dial-in conferencing.

Dial-in Conferencing Deployment Process

Phase	Steps	Permissions	Deployment documentation
Create a topology that includes the Conferencing workload, including a Mediation Server and PSTN gateway, and deploy the Front End pool or Standard Edition server	1. Run Topology Builder to configure your topology. While configuring the topology, select the dial-in conferencing option. 2. Publish the topology and deploy the Front End pool or Standard Edition server. 3. If necessary, create a stand-alone Mediation Server and associate it with a PSTN gateway. **Note:** This step is required only if you do not deploy Enterprise Voice and do not	Domain Admins RTCUniversalServerAdmins Administrator	- Deploying Lync Server 2013 - To create a stand-alone Mediation Server pool: Deploying Mediation Servers and Defining Peers

	collocate the Mediation Server with the Enterprise Edition Front End Server or Standard Edition server. If you deploy Enterprise Voice, you install and configure Mediation Servers and PSTN gateways as part of the Enterprise Voice deployment. If you collocate the Mediation Server, you install and configure the Mediation Server as part of the Front End pool or Standard Edition server deployment.		
Configure dial plans	A dial plan is a set of phone number normalization rules that translate phone numbers dialed from a specific location to a single standard (E.164) format for purposes of phone authorization and call routing. The same phone number dialed from different locations can, based on the respective dial plans, resolve to different E.164 numbers, as appropriate to each location. If you deploy Enterprise Voice, you set up dial plans as part of that deployment, and you need to make sure that the dial plans also accommodate dial-in conferencing. If you do not deploy Enterprise Voice, you need to set up dial plans for dial-in conferencing. Use the Lync Server 2013 Control Panel or Lync Server Management Shell to set up dial plans as follows:	RTCUniversalServerAdmins CsVoiceAdministrator CsServerAdministrator CsAdministrator	Configure Dial Plans for Dial-in Conferencing

	1. Create one or more dial plans for routing dial-in access phone numbers. 2. Assign a default dial plan to each pool. Set the **Dial-in conferencing region** to the geographic location to which the dial plan applies. The region associates the dial plan with dial-in access numbers.		
Make sure that dial plans are assigned regions	Run the **Get-CsDialPlan** and **Set-CsDialPlan** cmdlets to make sure that all dial plans have a region assigned.	RTCUniversalServerAdmins CsVoiceAdministrator CsServerAdministrator CsAdministrator	Make Sure Dial Plans Have Assigned Regions
(Optional) Verify or modify user personal identification number (PIN) requirements	Use Lync Server 2013 Control Panel or Lync Server Management Shell to view or modify the Conferencing **PIN Policy**. You can specify minimum PIN length, maximum number of logon attempts, PIN expiration, and whether common patterns are allowable.	RTCUniversalServerAdmins CsServerAdministrator CsAdministrator	(Optional) Verify PIN Policy Settings
Configure conferencing policy to support dial-in conferencing	Use Lync Server 2013 Control Panel or Lync Server Management Shell to configure **Conferencing Policy** settings. Specify whether: • PSTN conference dial-in is enabled. • Users can invite anonymous participants. • Unauthenticated users can join a conference by using dial-out phoning. With dial-out phoning,	RTCUniversalServerAdmins CsServerAdministrator CsAdministrator	Configure Conferencing Policy for Dial-in

	the conference server calls the user, and the user answers the phone to join the conference.		
Configure dial-in access numbers	Use Lync Server 2013 Control Panel or Lync Server Management Shell to set up dial-in access numbers that users call to dial in to a conference, and specify the regions that associate the access number with the appropriate dial plans. The first three access numbers for the region specified by the organizer's dial plan are included in the conference invitation. All access numbers are available on the Dial-in Conferencing Settings page. 📝**Note:** After you create dial-in access numbers, you can use the **Set-CsDialInConferencingAccessNumber** cmdlet to modify the display name of the Active Directory contact objects so that users can more easily identify the correct access number.	RTCUniversalServerAdmins CsServerAdministrator CsAdministrator	Configure Dial-in Conferencing Access Numbers
(Optional) Verify dial-in conferencing settings	Use the **Get-CsDialinConferencingAccessNumber** cmdlet to search for dial plans that have a dial-in conferencing region that is not used by any access number and for access numbers that have no region assigned.	RTCUniversalServerAdmins CsServerAdministrator CsAdministrator CsViewOnlyAdministrator CsHelpDesk	(Optional) Verify Dial-in Conferencing Settings
(Optional) Modify key mapping of DTMF commands	Use the **Set-CsDialinConferencingDtmfConfiguration** cmdlet to modify the keys used for dual-tone multifrequency (DTMF) commands, which participants can use to control conference settings (such as mute and unmute or lock and unlock).	RTCUniversalServerAdmins CsServerAdministrator CsAdministrator	(Optional) Modify Key Mapping for DTMF Commands

(Optional) Modify conference join and leave announcement behavior	Use the **Set-CsDialinConferencingConfiguration** to change how announcements work when participants join and leave conferences.	RTCUniversalServerAdmins CsServerAdministrator CsAdministrator	(Optional) Enable and Disable Conference Join and Leave Announcements
(Optional) Verify dial-in conferencing	Use the **Test-CsDialInConferencing** cmdlet to test that the access numbers for the specified pool work correctly.	RTCUniversalServerAdmins CsServerAdministrator CsAdministrator	(Optional) Verify Dial-in Conferencing
Deploy the Online Meeting Add-in for Lync 2013	Deploy the Online Meeting Add-in for Lync 2013 so that users can schedule conferences that support dial-in conferencing. The Online Meeting Add-in for Lync 2013 is installed automatically when you install Lync 2013.	Administrators	Deploy the Online Meeting Add-in for Lync 2013
Configure user account settings	Use Lync Server 2013 Control Panel or Lync Server Management Shell to configure the telephony **Line URI** as a unique, normalized phone number (for example, tel:+14255550200).	RTCUniversalServerAdmins CsAdministrator CsUserAdministrator	Configure User Account Settings
(Optional) Welcome users to dial-in conferencing and set the initial PIN	Use the **Set-CsPinSendCAWelcomeMail** script to set users' initial PINs and send a welcome email that contains the initial PIN and a link to the Dial-in Conferencing Settings page.	RTCUniversalServerAdmins	(Optional) Welcome Users to Dial-in Conferencing

1.3.8.6 Support for Large Meetings

Support for Large Meetings

Microsoft Lync Server 2013 > Planning > Planning for Conferencing >

Topic Last Modified: *2012-10-01*

Lync Server 2013 can support meetings with up to 1000 participants using audio/video (A/V) conferencing, including sharing PowerPoint presentations. This support requires a dedicated pool configured to support large meetings and managed in a way that ensures hosting of only a single large meeting at a time.

This section describes how to support large meetings using a dedicated Lync Server 2013 pool. It describes scalability considerations and the implementation requirements for a dedicated pool, including topology, hardware, software, and configuration requirements. It also provides a set of best practice recommendations for supporting large meetings, a summary of the test methods and results of server scalability testing conducted by the Lync Server engineering team, and the answers to frequently asked questions about support for large meetings.

- Overview of Lync Server 2013 Conferencing Scalability
- Supporting Large Meetings Using Lync Server 2013
- Lync Server 2013 Large Meeting Support FAQ

1.3.8.6.1 Overview of Lync Server 2013 Conferencing Scalability

Overview of Lync Server 2013 Conferencing Scalability

Planning > Planning for Conferencing > Support for Large Meetings >

Topic Last Modified: *2012-10-01*

The maximum size of a conference hosted on Lync Server 2013 in a shared pool (that is, a pool that hosts all Lync Server 2013 workloads including instant messaging (IM) and presence, conferencing, and Enterprise Voice) is 250 users.

Before we discuss using Lync Server to support larger meetings, let’s look at the scalability testing methodology we use and how we determine the 250-user model for shared pool testing.

- Scalability Testing
- The Conferencing User Model
- Conferencing Load Distribution

1.3.8.6.1.1 Scalability Testing

Scalability Testing

Planning for Conferencing > Support for Large Meetings > Overview of Lync Server 2013 Conferencing Scalability >

Topic Last Modified: *2012-10-01*

Lync Server 2013 provides the server infrastructure for all Lync Server real-time communications, including instant messaging (IM) and presence, conferencing, and Enterprise Voice. This includes any features that use the hardware resources of a Lync Server 2013 pool and, therefore, affect performance and scale. All organizations do not use all features equally.

For example, some organizations might use video in conferences very heavily while others might have little or no video usage. Some organizations prefer PowerPoint slide sharing to application sharing, while others prefer the opposite. Those organizations that deploy Enterprise Voice might or might not use the Response Group application heavily. Most organizations deploy Monitoring Servers, but not many of them deploy Archiving Servers. Additionally, organizations do not all have the same infrastructures, including hardware capacities, network capacities, and the number of pools and size of pools deployed. The diversity of features and infrastructures poses a challenge to scalability testing – it is not possible to simulate all possible combinations of features and infrastructures.

To determine scalability support for Lync Server, we conduct testing by using all Lync Server features concurrently, based on an average usage model (user model). To determine an appropriate user model for Lync Server workloads, we analyze many data points, including customer surveys, feedback from the Microsoft customer experience improvement program, Lync Server usage data from the internal IT department at Microsoft, and data mined from our Live Meeting Service. In many cases, the user model has a bias towards heavier loads to provide a comfortable margin for usage within an organization.

In our scalability tests, we set up Lync Server 2013 pools according to the recommended hardware and software specifications, including infrastructure components, such as Active Directory Domain Services (AD DS), hardware load balancers, and firewalls. We set up Lync Server environments as closely as possible to typical real-world environments. We then use the Lync Server 2013 Stress and Performance Tool to simulate Lync Server 2013 loads (based on our user model). .

We do multiple iterations of scalability tests (including multiple three-week test runs). We use the results of all tests to help with performance tuning and to verify support for the scalability numbers in our user model.

1.3.8.6.1.2 The Conferencing User Model

The Conferencing User Model

Planning for Conferencing > Support for Large Meetings > Overview of Lync Server 2013 Conferencing Scalability >

Topic Last Modified: *2012-10-22*

A critical part of the Lync Server conferencing user model is meeting size. After collecting data from the multiple data points (as described in the previous section), we determined the following:

- Most meetings are actually small collaborative meetings with an average of four to six participants
- Approximately 80 percent of meetings have fewer than 20 participants.
- 99.98 percent of meetings have fewer than 100 participants.

In addition to meeting size, the conferencing user model also takes into account a variety of factors, such as:

- **Concurrent meetings** How many users are expected to be in meetings at the same time?
- **Media mix** What types of media are available and expected to be used by users in meetings?
- **User types** Are users internal users, remote users, federated users, or anonymous users?
- **Meeting ramp up time** How long does it take for all users of a meeting to join a meeting?

For details about the user model, see Lync Server 2013 User Models.

To determine the number of meetings and users to use for testing, we did the following:

- Took the total number of users in an organization (for example, 80,000 users) and multiplied it by the meeting concurrency rate (for example, 5% of all users) to determine the total number of users expected to be in meetings at the same time (in this example, 4000 users).
- Divided the total number of users by the number of Lync Server 2013, Front End Servers in the deployment (for example, 8 servers) to determine the estimated number of meeting participants per Front End Server (in this example, 500 users per Front End Server).
- Divided the number of users per Front End Server by the average meeting size (for example, 4 users) to determine the estimated average number of meetings per Front End Server (in this example, 125 meetings per Front End

Server).
- To get the per media load on each Front End Server, we estimated the media mix. For example, assuming that 75% of the meetings require more than just audio support and 50% of those meetings require application sharing, an average of 47 meetings and 188 users connect concurrently to each Front End Server for application sharing.
- Tested a variety of meeting sizes (based our user model of up to 250 users in a shared pool) to ensure server scalability.

1.3.8.6.1.3 Conferencing Load Distribution

Conferencing Load Distribution

Planning for Conferencing > Support for Large Meetings > Overview of Lync Server 2013 Conferencing Scalability >

Topic Last Modified: *2012-10-22*

Unlike some other dedicated conferencing solutions, Lync Server architecture is a shared-hardware model. This means that the same hardware is shared by many software components, each of which supports different real-time communications. Each type of real-time communications places specific loads on the servers. For example, the Front End Server can run the Session Initiation Protocol (SIP) routing components, web applications (such as Address Book search), Web Conferencing service, A/V Conferencing service, Enterprise Voice applications (for example, Conferencing Attendant application and Response Group application), and Mediation Server. A set of databases on the Front End Server also provide storage and processing for user, contact, presence, conferencing, and voice routing data. With this hardware sharing, components, services, and processes compete for CPU and memory resources, so non-conferencing workloads have a direct impact on server scaling.

Compared to other hardware port-based conferencing solutions, Lync Server conferencing architecture is a no-reservation model. When a user schedules a meeting, Lync Server creates a record in the conferencing database, which stores conferencing data, but does not reserve any hardware resources for the scheduled meeting ahead of time. Instead, Lync Server has built-in load balancing logic to dynamically allocate conferencing resources on Front End Servers in a way that distributes loads equally across all Front End Servers in the pool. This effectively provisions and utilizes hardware resources, but makes it challenging to support very large meetings (especially without appropriate planning). For example, when a Lync Server 2013 pool is running close to its top capacity, each Front End Server might host approximately 125 average-size meetings. Adding another small meeting would not be a problem, but adding a meeting for 1000 users would be a problem because the Front End Servers would probably not be able to support such a large meeting at the same time as the other 125 meetings.

1.3.8.6.2 Supporting Large Meetings Using Lync Server 2013

Supporting Large Meetings Using Lync Server 2013

Planning > Planning for Conferencing > Support for Large Meetings >

Topic Last Modified: *2012-10-03*

Large meetings do not follow the test model described in the previous section because they have the following characteristics:

- The meeting format is a one-to-many presentation.
- One or a few users are presenters, and everyone else participates only as attendees.

- PowerPoint presentation sharing is the main data collaboration activity.
- Audio is required and video may also be used.
- A dedicated person, generally either the meeting organizer or an assistant to the organizer sets up the meeting well in advance.
- Dedicated staff (not the presenters) runs the meeting, including connecting to an online meeting, verifying that audio, video, and slide sharing work, managing lobby and user roles, muting and unmuting participants, taking questions, and managing recordings, as appropriate.

Supporting large meetings of up to 1000 users requires addressing the issues related to both the shared hardware model and the no-reservation model.

To have sufficient CPU and memory resources for meetings of up to 1000 users, the hosting Front End Servers should not host any other instant messaging (IM) and presence or Enterprise Voice workloads. It should also not host any other meetings, regardless of the size of the other meetings. This means that hosting meetings of up to 1000 users requires setting up a separate Lync Server pool that is dedicated to hosting large meetings of up to 1000 users.

A Lync Server pool that is dedicated to hosting large meetings should host one and only one meeting of up to 1000 users at the same time, so meeting times need to be reserved in advance via an out of band scheduling process to ensure dedicated support from the Front End Servers. To support more than one large meeting at the same time, we recommend setting up multiple dedicated large-meeting pools.

We recommend that a dedicated person run and monitor the online portion of a large meeting. This person might be the organizer, delegate of the organizer or presenter, or a member of the dedicated large meeting support team, depending on the organization’s preferences.

In the following sections, we describe how to implement a dedicated pool for large meetings, including best practices for using Lync Server 2013 to support large meeting scenarios.

- Setting Up Support for Large Meetings
- Managing Large Meetings

1.3.8.6.2.1 Setting Up Support for Large Meetings

Setting Up Support for Large Meetings

Planning for Conferencing > Support for Large Meetings > Supporting Large Meetings Using Lync Server 2013 >

Topic Last Modified: *2012-10-05*

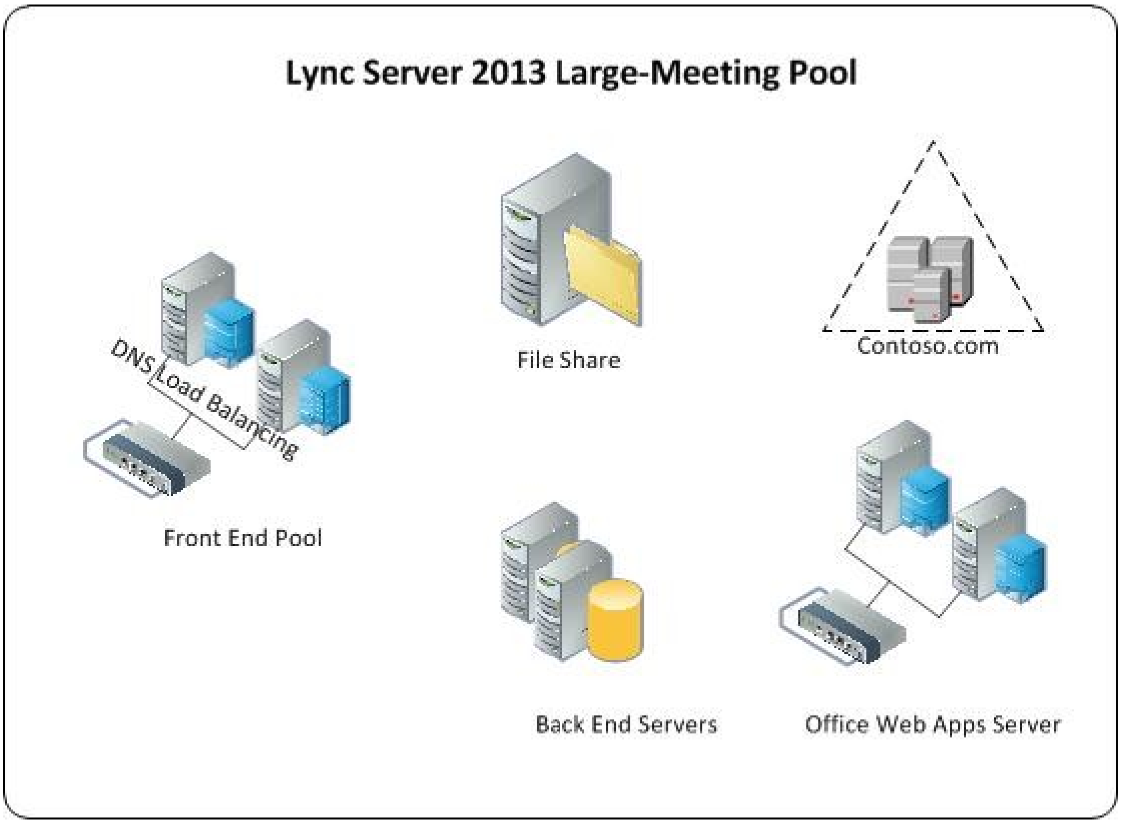
Supporting large meetings of up to 1000 users requires creating an appropriate topology, meeting hardware and software prerequisites, and configuring the environment appropriately.

Topology Requirements

A single large meeting requires at least one Front End Server and one Back End Server. However, to provide high availability, we recommend a two Front End Server pool with mirrored Back End Servers.

The user who hosts the large meetings must have their user account homed in this pool. However, we do not recommend that you host other user accounts in this pool. Instead, use it only for the large meetings. The best practice is to create a special user account in this pool to be used only to host large meetings. Managing a pool with exactly two Front End Servers requires some special considerations. For more information, see Topologies and Components for Front End Servers, Instant Messaging, and Presence.

Additionally, if you want to optionally provide disaster recovery backup and failover for the pool used for large meetings, you can pair it with a similarly set up dedicated pool in a different data. For details, see Planning for High Availability and Disaster Recovery.



Additional notes about the topology include:

- A file share is required for storing meeting content and, if Archiving Server is deployed and enabled, for storing the archiving files. The file share can be dedicated to the pool or can be the same file share used by another pool at the site in which the pool is deployed. For details about configuring the file share, see Configure File Storage.
- A Office Web Apps Server is required for enabling the PowerPoint presentation functionality in large meetings. The Office Web Apps Server can be dedicated to the large meeting pool or, it can be the same Office Web Apps Server used by other pools at the site in which the dedicated pool is deployed.
- Load balancing of the Front End Servers requires hardware load balancing for the HTTP traffic (such as meeting content download). DNS load balancing is recommended for SIP traffic. For details see Load Balancing Requirements.
- If you want to use Monitoring Server for the dedicated large-meeting pool, we recommend using the Monitoring Server and its database that are shared across all of the Front End Server pools in your Lync Server deployment.

Hardware and Software Requirements

The hardware requirements for servers in a dedicated large-meeting pool are the same as for your other Lync Server 2013 servers. For details about hardware requirements, see

"Server Hardware Platforms.

Servers in a dedicated large-meeting pool must meet all Lync Server 2013 software requirements. For details about software requirements, please see the following documentation:

- Server and Tools Operating System Support
- Database Software Support
- Additional Software Requirements

Additionally, both Lync Server 2013 and all Lync Server 2013 clients must have the latest updates.

Configuration Requirements

We recommend creating a new conferencing policy specifically for large meetings, and then assigning the conferencing policy to the users who are homed on the dedicated large-meeting pool. Configure the conferencing policy using the following settings:

- Set the **MaxMeetingSize** option to **1000**. (The default is **250**.)
- Set the **AllowLargeMeetings** option to **True**.
- Set the **EnableAppDesktopSharing** option to **None**.
- Set the **AllowUserToScheduleMeetingsWithAppSharing** option to **False**.
- Set the **AllowSharedNotes** option to **False**.
- Set the **AllowAnnotations** option to **False**.
- Set the **DisablePowerPointAnnotations** option to **True**.
- Set the **AllowMultiview** option to **False**.
- Set the **EnableMultiviewJoin** option to **False**.

Note:

The support for 1000 user large meetings in Lync Server 2013 requires the **AllowLargeMeetings** setting in the conferencing policy for the meeting scheduler to be set to true. When this setting is set to true, the Lync experience will be optimized for extra large meetings when users joins such meeting. Specifically, in a large meeting, Lync will not show the initial or update of the full meeting participant list, which is a performance bottleneck for both the client and Lync Server 2013. Instead, Lync will only show information about the user and the list of presenters of the meeting. Lync will still properly shows total number of participants available in the large meetings.

Except for the **Maximum meeting size** setting, all the other conferencing policy settings specified here are required in order to disable conferencing capabilities that are not necessary in large meetings.

Additionally, you need to configure the dedicated large-meeting pool so that each Lync Server 2013 user that is homed on the pool and responsible for managing the meeting schedule has the appropriate permissions. To do this, do the following:

- Set the **Designate as presenter** option to **None**. Typically, one or just a few users of all the participants of a large meeting are presenters, so participants should not be automatically admitted to large meetings as presenters. Instead, the presenters should be explicitly designated at meeting scheduling time, or be explicitly promoted during the large meeting.
- Make sure that the **Assigned conference type by default** check box is not selected. This setting controls whether the Online Meeting Add-in for Lync 2013 always schedules conferences using the organizer’s assigned conference, which means that scheduled meetings have the same join URL and audio information. In small group collaboration scenarios, having such assigned conference type works well because everyone has their own individual assigned conference, and the constant join URL and audio information helps to facilitate faster meeting joining. However, in the large-meeting scenario, the large meeting support staff schedules the large

meetings using a single set of user credentials, and then provides join URLs and audio information to the meeting requesters. In this case, using a different URL to join each meeting works better.
- Ensure that the **Admit anonymous users by default** check box is not selected, unless it is required. This setting affects the default meeting access type scheduled by the Online Meeting Add-in for Lync 2013 when not using an assigned conference. The appropriate option for this setting depends on your organization’s needs. If most large meetings for your organization are internal meetings, do not select this option. If most large meetings require that external users be able to join, select this option.

1.3.8.6.2.2 Managing Large Meetings

Managing Large Meetings

Planning for Conferencing > Support for Large Meetings > Supporting Large Meetings Using Lync Server 2013 >

Topic Last Modified: *2012-10-01*

After setting up a dedicated pool for large conferences, you can take steps to help ensure that large meetings hosted in the pool provide the best user experience. The topics in this section provide details about how to organize and manage large meetings.

- Dedicated Organizers
- Separate Large-Meeting Calendar
- Large-Meeting Scheduling Process
- Scheduling Details
- Running Large Meetings

Dedicated Organizers

Support for Large Meetings > Supporting Large Meetings Using Lync Server 2013 > Managing Large Meetings >

Topic Last Modified: *2012-10-01*

To minimize the real-time communications traffic in the large-meeting pool, we do not recommend hosting users who regularly sign in using Lync clients and participate in instant messaging (IM), presence, conferencing, and voice sessions. Instead, we recommend doing one of the following:

- Create one or more dedicated user accounts just for scheduling large meetings, or
- Home the user accounts of the staff responsible for scheduling large meetings on a large-meeting pool.

In either case, the user accounts that are homed on the large-meeting pool should not be used to regularly sign in to Lync, other than to schedule meetings.

Separate Large-Meeting Calendar

Support for Large Meetings > Supporting Large Meetings Using Lync Server 2013 > Managing Large Meetings >

Topic Last Modified: *2012-10-01*

For each large-meeting pool, you should maintain a separate a calendar of large meetings scheduled on that pool. For example, you can home a single user account on the large-meeting pool and use Outlook with Exchange and Online Meeting Add-in for Lync 2013 to maintain a separate calendar. If you use multiple user accounts to enable a support staff to create large meetings, you can set up a separate calendar that aggregates all large meetings created by the members of the support staff.

Maintaining a separate large meeting calendar helps to prevent conflicts and ensure that only one large meeting is active at any time.

Large-Meeting Scheduling Process

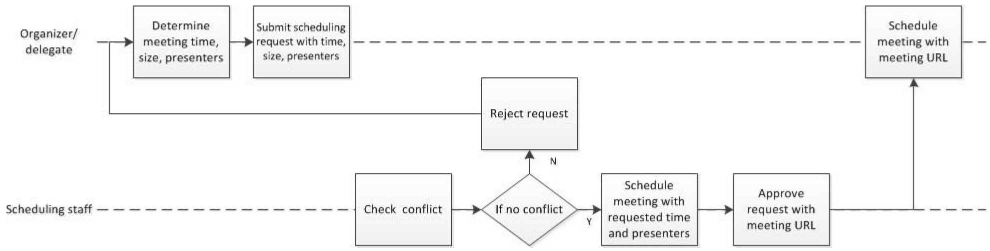
Support for Large Meetings > Supporting Large Meetings Using Lync Server 2013 > Managing Large Meetings >

***Topic Last Modified:** 2012-10-22*

Because only one large meeting at a time is supported on the dedicated large meeting pool, we recommend implementing a large meeting scheduling process to help prevent large meeting conflicts. The purpose of such the scheduling process is to facilitate setting up large meetings. Such capability is not provided directly by Lync Server or Lync Server clients. One way to implement such a process is to use your organization’s support team’s ticketing system, if available.

For organizers of large meetings, scheduling a large meeting involves completing the following steps:

1. The meeting organizer or delegate determines the time, duration, and size of an upcoming meeting, in addition to the list of presenters. If the anticipated meeting size exceeds 250 users or to ensure the best user experience for a meeting of fewer than 250 users, the organizer or the delegate submits a request for a large meeting.
2. The scheduling staff checks to see whether the requested date and time is available. Since we support only a single large meeting on the dedicated pool at a time, the scheduling staff needs to check the large-meeting calendar to determine whether there is another meeting scheduled for the requested date and time. If the requested time is available, the staff approves the meeting request.
3. If the request is approved, the scheduling staff (using credentials on the dedicated pool) uses Online Meeting Add-in for Lync 2013 with Outlook to set up a meeting on the dedicated large-meeting pool. The URL to be used to join the meeting is provided to the requester as part of the approval notice.
4. The meeting organizer or delegate uses Outlook to schedule the upcoming meeting, adding the URL for joining the meeting to the meeting invitation. The meeting organizer or delegate then specifies the users to be invited and sends out the meeting invitation.
   The following figure illustrates a typical request and approval workflow for scheduling large meetings.



Organizer/ delegate
Determine meeting time, size, presenters
Submit scheduling request with time, size, presenters
Schedule meeting with meeting URL
Reject request
N
Scheduling staff
Check conflict
If no conflict
Y
Schedule meeting with requested time and presenters
Approve request with meeting URL

Scheduling Details

Support for Large Meetings > Supporting Large Meetings Using Lync Server 2013 > Managing Large Meetings >

Topic Last Modified: *2012-10-04*

After checking to ensure that no other meeting is scheduled at the requested time, the large meeting support staff that handles the request schedules the meeting on the large-meeting pool. Use the Online Meeting Add-in for Lync that is installed with the Lync Server 2013 client to perform this task, using the credentials of a user enabled for Lync Server in the dedicated large-meeting pool.

To ensure the best user experience, it is important to schedule the large meeting with the right access levels and meeting settings that are appropriate to the meeting organizer's needs. We recommend the following scheduling settings configured in Lync Meeting options:

- Use a new meeting space for each large meeting instead of reusing the dedicated meeting space.
- Specify the meeting access level as follows:
  - If at least one invitee is external to the organization, set the meeting access type to **Anyone (no restrictions**. This enables you to avoid having to manage a potentially large lobby when the meeting is in progress.
  - If the meeting is an internal-only meeting, set the meeting access type to **Anyone from my organization**.

> **Note:**
> Avoid setting the meeting access type to **People I invite from my company** because when you use this setting, organizers must add all user email addresses to the invitee list and you cannot invite a distribution group.
> Avoid setting the meeting access type to **Only me, the meeting organizer** because this setting requires that every meeting participant, including presenters, must be put in the lobby at meeting run time. The person responsible for running the large meeting must then constantly monitor the lobby roster and admit new users who are in the lobby.

- Allow users who dial-in from phones to enter the meeting automatically by checking the **Callers get in directly** setting.
- Explicitly invite the following users:
  - Meeting organizer and delegate (requester)
  - The list of presenters provided by a meeting requester

> **Note:**
> If the meeting access type is set to **People I choose**, you need to explicitly add each participant of a large meeting as an invitee of the meeting.

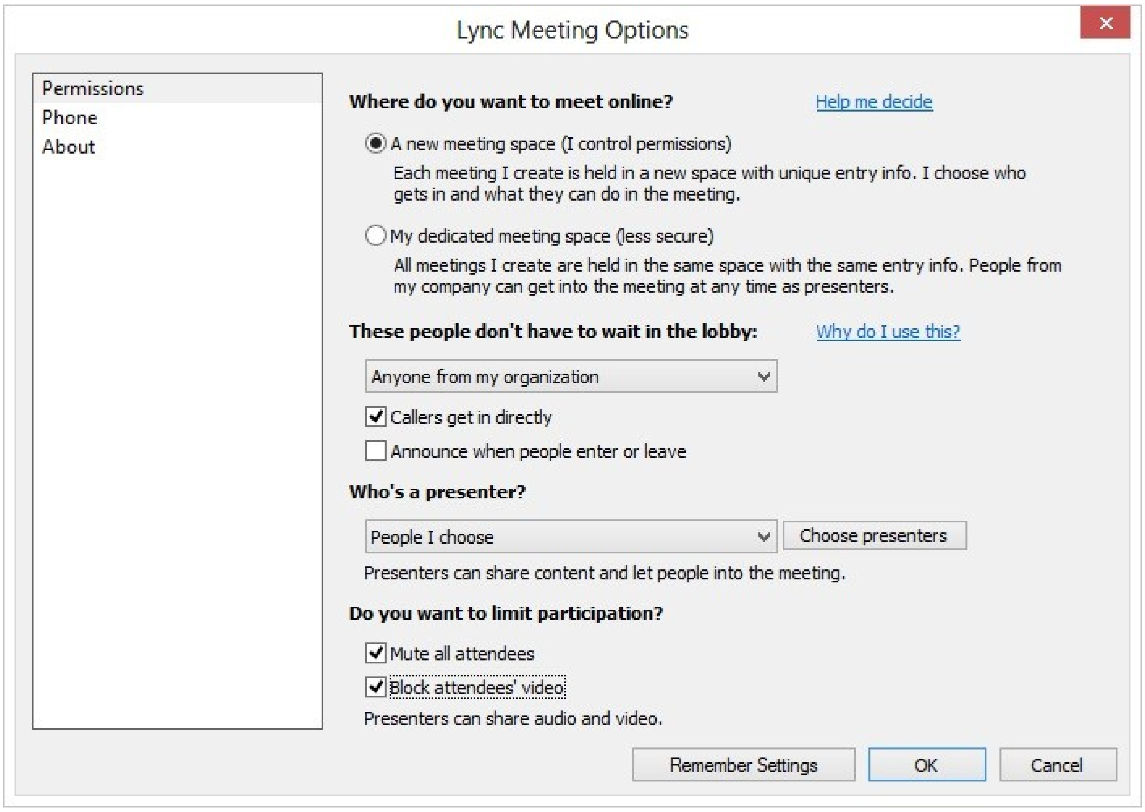
- Explicitly manage presenters, instead of setting the presenter option to one of the auto-promote values. Be sure to add the following users as presenters:
  - Meeting organizer and delegate (requester)
  - The list of presenters provided by large meeting requesters

> **Note:**
> By explicitly managing presenters, you can control the number of presenters, so that you can limit presenters to a small enough number to make it possible to have an effective large meeting. If the majority of meeting participants have the attendee role, it helps reduce the chance of people accidentally taking control of the presentation, deleting a PowerPoint presentation, muting/unmuting presenters, and other disruptions to the meeting.

- Check the **Mute all attendees** setting to make sure that only presenters can broadcast audio into the meeting.

- Check the **Block attendees' video** setting to make sure only presenters can broadcast video into the meeting.

The following figure shows the recommended settings for the Online Meeting Add-in for Lync.



Lync Meeting Options

Where do you want to meet online?

● A new meeting space (I control permissions)

Each meeting I create is held in a new space with unique entry info. I choose who gets in and what they can do in the meeting.

○ My dedicated meeting space (less secure)

All meetings I create are held in the same space with the same entry info. People from my company can get into the meeting at any time as presenters.

These people don't have to wait in the lobby:

Anyone from my organization

☑ Callers get in directly

□ Announce when people enter or leave

Who's a presenter?

People I choose

Presenters can share content and let people into the meeting.

Do you want to limit participation?

☑ Mute all attendees

☑ Block attendees' video

Presenters can share audio and video.

Running Large Meetings

Support for Large Meetings > Supporting Large Meetings Using Lync Server 2013 > Managing Large Meetings >

Topic Last Modified: *2012-10-01*

With serveral hundred to a thousand users in a meeting, it is a good pratice to have a dedicated person moderate the online session of a large meeting. This dedicated person can be a delegate of the meeting organizer or a member of the organization's large-meeting support staff. It is important to add the dedicated meeting moderator as a presenter at the time that the meeting is scheduled, although it is possible to promote an online meeting attendee to the presenter role while the meeting is in progress.

The meeting moderator can use all presenter functionalities of Lync Server 2013 clients to manage the large meeting. Those functionalities include:

1. Monitoring the lobby and admitting or rejecting users in the lobby.
2. Removing any users from the meeting who should not be in the meeting.
3. Changing meeting access types.
4. Changing participant roles.
5. Inviting additional participants during the meeting using Lync drag and drop functionality, phone dial out, or e-mail.
6. Muting and unmuting the audience or individidual users.
7. Managing meeting content, including uploading content, deleting content,

and switching active content.

1.3.8.6.3 Lync Server 2013 Large Meeting Support FAQ

Lync Server 2013 Large Meeting Support FAQ

Planning > Planning for Conferencing > Support for Large Meetings >

Topic Last Modified: *2012-10-22*

The following sections provide answers to common questions for creating and running large meetings.

Q: How many users can participate in a large meeting?

The Lync Server user model specifies limits of 250 users in a shared pool or 1000 users in a pool dedicated to large meetings, but these numbers only represent the number of users we tested and only for the specific set of hardware that we used in our testing. Based on our testing, we recommend those limits for maximum sizes. However, you control the actual number of participants allowed in meetings in your organization by configuring one or more conferencing policies (which you configure using Windows PowerShell cmdlets in the Lync Server Management Shell or using the Lync Server Control Panel). The number that you specify in a conferencing policy can be any 32-bit whole number between 1 and 4,294,967,295, but the recommended size is between 2 and 250 participants, inclusive; and the default value is 250.

Q: How many meetings or other workloads can I have in a pool that is dedicated to large meetings?

To ensure the best user experience in large meetings of up to 1000 participants, we recommend hosting only a single large meeting at a time on a pool that is dedicated to large meetings. We also recommend not allowing any other workloads to run on that pool when the large meeting is in progress.

Q: Should the organizers of large meeting be homed on the dedicated pool?

No. We recommend not homing any users other than the dedicated staff that manages scheduling of large meetings on the dedicated pool. This prevents other real-time communications traffic from causing problems with large meetings that are hosted in the pool. You should schedule large meetings on the dedicated pool using a user account of the large meeting scheduling staff. You should add the user account of the meeting organizer (the user who requests a large meeting) as a presenter for the large meeting.

Q: What media modalities can I use in a large meeting?

Large meetings with up to 1000 users can include audio, video, PowerPoint sharing, whiteboards, and presence polling.

Q: Can I use group instant messaging (IM) in large meetings?

Yes. However, large numbers of instant messages, especially when sent by a large number of meeting participants, can affect the user experience due to problems with fast text scrolling in the IM window. Delivering a large amount of instant messages to up to 1000 users can also introduce significant server loads, which can affect performance. Generally, IM is only required for questions and answers (Q&As).

Can users join large meetings by dialing in from a phone?

Yes. If the Lync Server 2013 pool is properly deployed and enabled for dial-in conferencing, users will be able to join the large meetings by dialing in. Our testing has shown that up to 15% of the 1000 users can join the large meeting over a 10 minute period.

Q: Can I host large meetings in a virtual topology?

We have not tested large meetings in a virtual topology, so we do not support the use of virtual machines to host a dedicated pool for large meetings.

1.3.9 Planning for External User Access

Planning for External User Access

Microsoft Lync Server 2013 > Planning >

Topic Last Modified: *2013-01-19*

Communications in most organizations involve services and users that are not inside your internal network. These services and users include employees who are temporarily or permanently offsite, employees of customer or partner organizations, people who use public instant messaging (IM) services, and potential customers, partners and anonymous users whom you invite to meetings and presentations. In this documentation, these people are collectively referred to as *external users*.

With Microsoft Lync Server 2013, users in your organization can use IM and presence to communicate with external users, and they can participate in audio/video (A/V) conferencing and web conferencing with your offsite employees and other types of external users. You can also support external access from mobile devices and over Enterprise Voice. External users who are not members of your organization can participate in Lync Server 2013 meetings, allowing anonymous attendees.

To support communications across your organization’s firewall, you deploy Lync Server 2013 Edge Server in your perimeter network (also known as DMZ, demilitarized zone, and screened subnet). The Edge Server controls how users outside the firewall can connect to your internal Lync Server 2013 deployment. It also controls communications with external users that originate within the firewall.

Depending on your requirements, you can deploy one or more Edge Servers in one or more locations. This section describes scenarios for external user access in Lync Server 2013, and it explains how to plan your edge and reverse proxy topology.

Note:

Although you need an Edge Server to support Enterprise Voice and external user access, this section focuses on support for IM, presence, A/V conferencing, federation, web conferencing, and Lync Mobile. For details about support for Enterprise Voice, see Planning for Enterprise Voice in the Planning documentation.

- Scenarios for External User Access

1.3.9.1 Changes in Lync Server 2013 That Affect Edge Server Planning

Changes in Lync Server 2013 That Affect Edge Server Planning

Microsoft Lync Server 2013 > Planning > Planning for External User Access >

Topic Last Modified: *2012-10-22*

Lync Server 2013 introduces new features that extend the features and communications methods for your users. Also, Lync Server 2013 introduces changes to existing services to better integrate and extend the services that are available to your organization. Following is a summary of changes that may affect your planning and deployment of Lync Server 2013 Edge Server services.

Support for IPv6 Addressing

Lync Server 2013 supports IPv6 addressing for all Edge Server services. If you have provided IPv6 addresses for the interfaces through configuration in Windows Server, you can use IPv6 addresses in your Edge Server configuration through the IP address configuration in Topology Builder. Additionally, the extensible messaging and presence protocol (XMPP) supports IPv6. No additional configuration is required. If IPv6 is configured in the topology, XMPP will use IPv6 (where required).

An added requirement to support IPv6 in Lync Server 2013 is to create domain name system records for records that must be discovered and resolved to an IPv6 address. IPv6 DNS uses host records that are defined as **AAAA** and called “quad-A”. Other record types are consistent with their IPv4 counterparts.

Support for Extensible Messaging and

Presence Protocol (XMPP) Deployment

Edge Server introduces a fully integrated XMPP proxy (deployed on the Edge Servers) and an XMPP gateway (deployed on your Front End Servers). You can deploy XMPP federation as an optional component. By adding and configuring the XMPP proxy and XMPP gateway, you can enable your Microsoft Lync 2013 users to add contacts from XMPP-based partners for instant messaging (IM) and presence.

Note:

Currently, the XMPP services in Edge Server only provide IM and presence between Lync Server clients and XMPP-based contacts. Additionally, XMPP is hosted in only one site.

Important:

The XMPP capability of Lync Server 2013 is tested and supported by Microsoft for instant messaging federation with Google Talk. For any other XMPP systems contact the third-party vendor to verify that they support federation with Lync Server 2013, and for any deployment or troubleshooting recommendations.

Support for Rolling Audio/Video Authentication and Server to Server Authentication Certificates

A certificate is used to generate tokens that are issued to clients and other consumers of the A/V Authentication service and for server to server authentication. The Audio/Video Authentication certificate is of type *AudioVideoAuthentication* and the Server to Server Authentication certificate is of type *OAuthTokenIssuer*.

For Audio/Video Authentication, tokens are used to authenticate port allocation requests, and the tokens are cached for up to 8 hours – the default lifetime of the token. Under normal operation, this is a very reliable method to create and distribute authentication material to the A/V consumers. However, certificates have a finite lifetime and expire on a predefined date and time (based on creation date and the policies enforced at the certification authority that created the certificate, typically 2 years for this type of certificate). When the certificate expires, any tokens created by the expired certificate and cached by consumers become not valid. Any attempts to use a token created with an expired certificate would result in failed Media Relay allocations and any current Audio/Video sessions will fail. The client would need to acquire a new token created by a valid certificate to resume normal Audio and Video functionality.

Server to Server Authentication is managed by a global certificate that is requested and applied to all servers in the deployment. The certificate is responsible for authenticating servers in Lync Server 2013 as well as authenticating to Exchange 2013 and Microsoft SharePoint Server 2013. For more information on how Server to Server Authentication works, see Managing Server-to-Server Authentication (Oauth) and Partner Applications. One very important difference between the Audio/Video Authentication process and the Server to Server Authentication process is the lifetime of the authentication, or tokens. For Audio/Video Authentication, the authentication expires after eight hours. Server-to-Server Authentication has a lifetime of 24 hours. You must plan accordingly for each of the certificate types.

New for Lync Server 2013 is the ability to stage a replacement Audio/Video Authentication certificate and Server to Server Authentication certificate in advance of the expiration of the current certificate. The new certificate is then used for generating new tokens or new authentication requests. but retains the old certificate for verifying the current sessions and authentications.. What this accomplishes is to effectively prevent nearly all failures due to token and certificate expirations. For details of this feature and how to configure it, see Staging AV and OAuth Certificates Using -Roll in Set-CsCertificate

Reduced Reliance on Cookie-based Affinity

In previous versions of Lync Server and Office Communications Server, cookie-based affinity was used by the Web services to ensure that the client and Web services session state was maintained. Lync Server 2013 Web services use a built in affinity mechanism that eliminates most of the requirements for cookie-based affinity.

⚠**Warning:**

The Microsoft Lync 2010 Mobile client must still use cookie-based affinity and will require configuration of cookie-based affinity until you have migrated all clients to the upcoming Microsoft Lync Mobile client (Date of release not yet determined).

For details about cookie-based affinity in Lync Server 2013, see Components Required for External User Access.

AutoDiscover Enhancements

The autodiscover feature in Lync Server 2013 enables clients to locate additional features that are made available for communication. Autodiscover was first introduced in the cumulative update for Lync Server 2010: November 2011 for Mobility and Microsoft Lync 2010 Mobile. The autodiscover feature (also known by the DNS record names LyncDiscover and LyncDiscoverInternal) allows clients to locate and use mobility services (for Microsoft Lync 2010 Mobile clients), the Microsoft Lync Web App, and the Lync Web scheduler, as well as communications with Microsoft Exchange Server and SharePoint Server. Autodiscover is installed as normal part of the setup and deployment of your infrastructure and Lync Server 2013 servers. The Topology Builder and Lync Server Deployment Wizard eliminate most of the configuration tasks that were required in cumulative update for Lync Server 2010: November 2011.

Services for Mobile Clients

Introduced in the cumulative update for Lync Server 2010: November 2011, mobility services in Lync Server 2013 enable mobile phones running Lync Mobile and tablet devices using supported Apple iOS, Android, Windows Phone, or Nokia mobile devices to perform activities such as sending and receiving instant messages, viewing contacts, and viewing presence. In addition, mobile devices support some Enterprise Voice features, such as click to join a conference, Call via Work, single number reach, voice mail, and missed call notification.

Note:

The mobility services use the reverse proxy and published services that are deployed on your Front End Servers. No changes are required to Edge Servers. Minimally you need outbound SIP/TCP/5061from the server running the Lync Server Access Edge service.

Director Role is Optional

The role of the Director server in the Lync Server 2013 topology has not changed. It still hosts web services, preauthenticates incoming user requests, and directs external users to their home pool. By changing the Director from a recommended role to an optional role, Microsoft does not intend to diminish the value of the Director. The intention is to reduce server count and other hardware requirements (for example, hardware load balancers for the Director) without compromising features and functionality. Because the Front End Servers can do the same job as the Director with no impact to services provided, you can deploy Directors if you choose to. You can safely exclude the Director with confidence that the Front End Servers will provide the same services in place of a Director.

1.3.9.2 System Requirements for External User Access Components

System Requirements for External User Access Components

Microsoft Lync Server 2013 > Planning > Planning for External User Access >

Topic Last Modified: *2013-01-17*

System requirements for edge components include hardware, software, and collocation requirements for Edge Servers, reverse proxy servers and optional Directors that you plan to deploy.

- Components Required for External User Access
- Configuration Requirements for Reverse Proxy
- Hardware Load Balancer Requirements
- Hardware and Software Requirements for Edge Components
- Supported Server Collocation for Edge Components

1.3.9.2.1 Components Required for External User Access

Components Required for External User Access

See Also

Planning > Planning for External User Access > System Requirements for External User Access Components >

Topic Last Modified: *2013-01-17*

Most Edge components are deployed in a perimeter network. The following components make up the edge topology of the perimeter network. Except where noted, the components are part of the Scenarios for External User Access and are in the perimeter network. Edge components include the following:

- Edge Servers
- Reverse proxies
- Firewalls
- Directors (optional, and logically located on the internal network)
- Load balancing for Scaled Edge Topologies (either DNS load balancing or a hardware load balancer)

Important:
Using DNS load balancing on one interface and hardware load balancing on the other is not supported. You must use hardware load balancing for both interfaces or DNS load balancing for both.

Edge Servers

The Edge Servers send and receive network traffic for the services offered by internal deployment by external users. The Edge Server runs the following services:

- **Access Edge service** The Access Edge service provides a single, trusted connection point for both outbound and inbound Session Initiation Protocol

(SIP) traffic.

- **Web Conferencing Edge service** The Web Conferencing Edge service enables external users to join meetings that are hosted on your internal Lync Server 2013 deployment.
- **A/V Edge service** The A/V Edge service makes audio, video, application sharing, and file transfer available to external users. Your users can add audio and video to meetings that include external participants, and they can communicate using audio and/or video directly with an external user in point-to-point sessions. The A/V Edge service also provides support for desktop sharing and file transfer.
- **XMPP Proxy service** The XMPP Proxy service accepts and sends extensible messaging and presence protocol (XMPP) messages to and from configured XMPP Federated partners.

Authorized external users can access the Edge Servers in order to connect to your internal Lync Server 2013 deployment, but the Edge Servers do not provide a means for any other access to the internal network.

Reverse Proxy

The reverse proxy is required for the following:

- To allow users to connect to meetings or dial-in conferences using simple URLs
- To enable external users to download meeting content
- To enable external users to expand distribution groups
- To allow the user to obtain a user-based certificate for client certificate based authentication
- To enable remote users to download files from the Address Book Server or to submit queries to the Address Book Web Query service
- To enable remote users to obtain updates to client and device software
- To enable mobile devices to automatically discover Front End Servers offering mobility services
- To enable push notifications to mobile devices from the Office 365 or Apple push notification services

For additional information related to reverse proxies and the requirements that reverse proxies must meet, see the details in Configuration Requirements for Reverse Proxy.

Note:

External users do not need a virtual private network (VPN) connection to your organization in order to participate in communications using Lync Server 2013. If you have implemented VPN technology in your organization and your users use the VPN for Lync, media traffic (such as video conferencing) can be adversely affected. You should consider providing a means for media traffic to connect to the AV Edge service directly and bypass the VPN. For details, see the NextHop Blog article, “Enabling Lync Media to Bypass a VPN Tunnel,” at http://go.microsoft.com/fwlink/p/?LinkId=256532.

Firewall

You can deploy your edge topology with only an external firewall or both external and internal firewalls. The scenario architectures include two firewalls. Using two firewalls is the recommended approach because it ensures strict routing from one network edge to the other, and it protects your internal deployment behind two levels of firewall.

Director

A Director is a separate, optional server role in Lync Server 2013 that does not home user accounts, or provide presence or conferencing services. It serves as an internal next hop server to which an Edge Server routes inbound SIP traffic destined for internal servers. The Director preauthenticates inbound requests and redirects them to the user's home pool or server. By preauthenticating at the Director, you can drop requests from user accounts that are unknown to the deployment.

A Director helps insulate Standard Edition servers and Front End Servers in Enterprise Edition Front End pools from malicious traffic such as denial-of-service (DoS) attacks. If the network is flooded with invalid external traffic in such an attack, the traffic ends at the Director. For details about the use of Directors, see Scenarios for the Director.

Hardware Load Balancer Requirements

1.3.9.2.2 Configuration Requirements for Reverse Proxy

Configuration Requirements for Reverse Proxy

Planning > Planning for External User Access > System Requirements for External User Access Components >

Topic Last Modified: *2013-03-05*

Lync Server 2013 imposes a few requirements on communications from the external client that are then passed on to the external Web services hosted on the Director, Director pool, Front End Server or Front End pool. The reverse proxy is also responsible for publishing the Office Web Apps Server, if you are offering conferencing to your users.

> **Note:**
>
> Lync Server 2013 does not specify a particular reverse proxy that you must use. Lync Server 2013 only defines operational requirements that the reverse proxy must be able to do. Typically, the reverse proxy that you already have deployed in your infrastructure may be able to meet the requirements.

Reverse Proxy Requirements

The functional operations that Lync Server 2013 expect a reverse proxy to perform are:

- Use secure socket layer (SSL) and transport layer security (TLS) implemented by using certificates acquired from a public certification authority to connect to the published external Web services of the Director, Director pool, Front End Server or Front End pool. The Director and the Front End Server can be in a load-balanced pool by using hardware load balancers.
- Able to publish internal Web sites using certificates for encryption, or publish them over an unencrypted means, if needed.
- Able to publish an internally hosted web site externally by using a fully qualified domain name (FQDN).
- Able to publish all contents of the hosted web site. By default, you can use the **/*** directive, which is recognized by most web servers to mean "Publish all content on the web server." You can also modify the directive—for example, **/Uwca/***, which means "Publish all content under the virtual directory Ucwa."
- Must be configurable to require Secure Sockets Layer (SSL) and/or Transport Layer Security (TLS) connections with clients that request content from a published website.
- Must accept certificates with subject alternative name (SAN) entries.
- Must be able to allow binding of a certificate to a listener or interface through which the external web services FQDN will resolve. Listener configurations are preferable to interfaces. Many listeners can be configured on a single

interface.

- Must allow for the configuration of host header handling. Often, the original host header sent by the requesting client must be passed transparently, instead of being modified by the reverse proxy.
- Bridging of SSL and TLS traffic from one externally defined port (for example, TCP 443) to another defined port (for example, TCP 4443). The reverse proxy may decrypt the packet on receipt and then reencrypt the packet on sending.
- Bridging of unencrypted TCP traffic from one port (for example, TCP 80) to another (for example, TCP 8080).
- Allow configuration of, or accept, NTLM authentication, No authentication and Pass-through authentication.

1.3.9.2.3 Hardware Load Balancer Requirements

Hardware Load Balancer Requirements

Planning > Network Planning for Lync Server > Load Balancing Requirements >

Topic Last Modified: *2012-10-22*

The Lync Server 2013 scaled consolidated Edge topology is optimized for DNS load balancing for new deployments federating primarily with other organizations using Lync Server. If high availability is required for any of the following scenarios, a hardware load balancer must be used on Edge Server pools for the following:

- Federation with organizations using Office Communications Server 2007 R2 or Office Communications Server 2007
- Exchange UM for remote users using Exchange UM prior to Exchange 2010 with SP1
- Connectivity to public IM users

Important:

Using DNS load balancing on one interface and hardware load balancing on the other is not supported. You must use hardware load balancing for both interfaces or DNS load balancing for both.

Note:

If you are using a hardware load balancer, the load balancer deployed for connections with the internal network must be configured to load balance only the traffic to servers running the Access Edge service and the A/V Edge service. It cannot load balance the traffic to the internal Web Conferencing Edge service or the internal XMPP Proxy service.

Note:

The direct server return (DSR) NAT is not supported with Lync Server 2013.

To determine whether your hardware load balancer supports the necessary features required by Lync Server 2013, see "Lync Server 2010 Load Balancer Partners" at http://go.microsoft.com/fwlink/p/?linkId=202452.

Hardware Load Balancer Requirements for Edge Servers Running the A/V Edge Service

Following are the hardware load balancer requirements for Edge Servers running the A/V Edge service:

- Turn off TCP nagling for both internal and external ports 443. Nagling is the process of combining several small packets into a single, larger packet for more efficient transmission.

- Turn off TCP nagling for external port range 50,000 – 59,999.
- Do not use NAT on the internal or external firewall.
- The edge internal interface must be on a different network than the Edge Server external interface and routing between them must be disabled.
- The external interface of the Edge Server running the A/V Edge Service must use publically routable IP addresses and no NAT or port translation on any of the edge external IP addresses.

Hardware Load Balancer Requirements

Cookie-based affinity requirements are greatly reduced in Lync Server 2013 for Web services. If you are deploying Lync Server 2013 and will not retain any Lync Server 2010 Front End Servers or Front End pools, you do not need cookie-based persistence. However, if you will temporarily or permanently retain any Lync Server 2010 Front End Servers or Front End pools, you still use cookie-based persistence as it is deployed and configured for Lync Server 2010.

Note:

If you decide to use cookie-based affinity even though your deployment does not require it, there is no negative impact to doing so.

For deployments that **will not use** cookie-based affinity:

- On the reverse proxy publishing rule for port 4443, set **Forward host header** to True. This will ensure that the original URL is forwarded.

For deployments that **will use** cookie-based affinity:

- On the reverse proxy publishing rule for port 4443, set **Forward host header** to True. This will ensure that the original URL is forwarded.
- Hardware load balancer cookie MUST NOT be marked httpOnly
- Hardware load balancer cookie MUST NOT have an expiration time
- Hardware load balancer cookie MUST be named **MS-WSMAN** (This is the value that the Web services expect, and cannot be changed)
- Hardware load balancer cookie MUST be set in every HTTP response for which the incoming HTTP request did not have a cookie, regardless of whether a previous HTTP response on that same TCP connection had already obtained a cookie. If the load balancer optimizes cookie insert to only occur once per TCP connection, that optimization MUST NOT be used

Note:

Typical hardware load balancer configurations use source-address affinity and a 20 min. TCP session lifetime, which is fine for Lync Server and Lync 2013 clients because session state is maintained through client usage and/or and application interaction.

If you are deploying mobile devices, your hardware load balancer must be able to load balance individual request within a TCP session (in effect, you must be able to load balance an individual request based on the target IP address).

⚠**Warning:**

F5 hardware load balancers have a feature called OneConnect that ensures each request within a TCP connection is individually load balanced. If you are deploying mobile devices, ensure your hardware load balancer vendor supports the same functionality. The latest Apple iOS mobile apps require Transport Layer Security (TLS) version 1.2. F5 provides specific settings for this.
For details on third party hardware load balancers, see http://go.microsoft.com/fwlink/p/?linkId=230700

Following are the hardware load balancer requirements for Director and Front End pool Web Services:

- For internal Web Services VIPs, set Source_addr persistence (internal port 80, 443) on the hardware load balancer. For Lync Server 2013, Source_addr persistence means that multiple connections coming from a single IP address are always sent to one server to maintain session state.
- Use TCP idle timeout of 1800 seconds.
- On the firewall between the reverse proxy and the next hop pool's hardware load balancer, create a rule to allow https: traffic on port 4443, from the reverse proxy to the hardware load balancer. The hardware load balancer must be configured to listen on ports 80, 443, and 4443.

Summary of Hardware Load Balancer Affinity Requirements

Client/user location	External web services FQDN affinity requirements	Internal web services FQDN affinity requirements
Lync Web App (internal and external users) Mobile device (internal and external users)	No affinity	Source address affinity
Lync Web App (external users only) Mobile device (internal and external users)	No affinity	Source address affinity
Lync Web App (internal users only) Mobile device (not deployed)	No affinity	Source address affinity

Port Monitoring for Hardware Load Balancers

You define port monitoring on the hardware load balancers to determine when specific services are no longer available due to hardware or communications failure. For example, if the Front End Server service (RTCSRV) stops because the Front End Server or Front End pool fails, the HLB monitoring should also stop receiving traffic on the Web Services. You implement port monitoring on the HLB to monitor the following:

Front End Server User Pool – HLB Internal Interface

Virtual IP/Port	Node Port	Node Machine/ Monitor	Persistence Profile	Notes
<pool>web-int_mco_443_vs 443	443	Front End 5061	Source	HTTPS
<pool>web-int_mco_80_vs 80	80	Front End 5061	Source	HTTP

Front End Server User Pool – HLB External Interface

Virtual IP/Port	Node Port	Node Machine/ Monitor	Persistence Profile	Notes
<pool>web_mco _443_vs 443	4443	Front End 5061	None	HTTPS
<pool>web_mco _80_vs 80	8080	Front End 5061	None	HTTP

1.3.9.2.4 Hardware and Software Requirements for Edge Components

Hardware and Software Requirements for Edge Components

Planning > Planning for External User Access > System Requirements for External User Access Components >

Topic Last Modified: *2013-02-21*

The hardware and software requirements for edge components include those for the Microsoft Lync Server 2013 communications software components, including Edge Servers and the optional Directors, as well as those for other components, including reverse proxy servers, firewalls, and load balancers to be deployed the perimeter network to support external user access. For details about the components required to support external user access and supported topologies, see Components Required for External User Access.

Hardware and Software Requirements for Edge Servers

The operating system requirements for Edge Servers are the same as for the other Lync Server 2013 roles: the 64-bit edition of the Windows Server 2008 R2 SP1 or Windows Server 2012.

The following table shows the hardware requirements for Edge Servers.

Hardware System Requirements for Edge Servers

Hardware component	Minimum requirement
CPU	One of the following: • 64-bit dual processor, quad-core, 2.0 GHz or higher • 64-bit 4-way processor, dual-core, 2.0 GHz or higher
Memory	12 GB recommended
Disk	• One of the following: • 10K RPM hard disk drive (HDD) • High-performance solid state drive (SSD) with performance equal to or better than 10K RPM HDD • 2x RAID 10 (striped and mirrored) 15K

	RPM disk set
Network	Two interfaces required, either one 2-port 1 Gbps NIC or two 1-port 1 Gbps NICs.

Lync Server 2013 is available only in 64-bit, therefore each Edge Server requires one of the following operating systems.

- Windows Server 2008 R2 Enterprise Edition with SP1 operating system, or Windows Server 2008 R2 Standard Edition with SP1 operating system.
- Windows Server 2012 Enterprise or Datacenter operating system.

Directors are internal components and installed as part of the internal network prior to deployment of Edge Servers. For hardware and software requirements for Directors, see Hardware and Software Requirements for the Director.

Lync Server 2013 Edge Servers require the installation of additional programs and updates. The requirements for additional software on Edge Servers are listed here.

- Each server running Lync Server 2013 must have the correct release of Windows PowerShell 3.0 installed. For details, see Installing Windows PowerShell 3.0.
- Lync Server requires Microsoft .NET Framework 4.5. For Lync Server 2013 installed on Windows Server 2008 R2, you must manually install the 64-bit edition of Microsoft .NET Framework 4.5 on the server prior to installing Lync Server 2013. To manually install it, download the Microsoft .NET 4.5 Framework from the Microsoft Download Center at http://go.microsoft.com/fwlink/p/?LinkId=268529
- **Windows Identity Foundation** in Lync Server 2013 requires the installation of Windows Identity Foundation in order to support server to server authentication scenarios. Windows Server 2008 R2 and Windows Server 2012 require different procedures to install the Windows Identify Foundation. Select your server operating system from the following list:
  - Windows Server 2008 R2   For Windows Server 2008 R2, you check to see if it has already been installed on your computer. To do this, go to **Add/ Remove Programs**, **View Installed Updates**, and look under **Windows** for the entry **Windows Identity Foundation (KB974405)**. For details about installing Windows Identity Foundation, see http://go.microsoft.com/fwlink/?LinkId=285258.
  - Windows Server 2012   For Windows Server 2012, you use **Server Manager** to install the Windows Identity Foundation. In the Server Manager **Add Roles and Features Wizard**, select **Features**. Select **Windows Identity Foundation 3.5** from the list. Click **Next**, then click **Install**.

1.3.9.2.5 Supported Server Collocation for Edge Components

Supported Server Collocation for Edge Components

Planning > Planning for External User Access > System Requirements for External User Access Components >

Topic Last Modified: *2012-09-08*

The Access Edge service, Web Conferencing Edge service, A/V Edge service and XMPP Proxy service are collocated on the Edge Servers. The following servers provide functions needed for external user access and must be deployed as dedicated servers:

- Edge Server
- Director (Optional)
- Reverse proxy

Important:
The reverse proxy does not need to be dedicated to serving only Lync Server 2013. For example, you can provide services to publish the Lync Server Web services, and concurrently provide a published Web site for another Web site that has no bearing on Lync Server at all. If you already have a reverse proxy server in the perimeter network to support other services, you can use it for Lync Server 2013.

1.3.9.3 Overview of External User Access

Overview of External User Access

Microsoft Lync Server 2013 > Planning > Planning for External User Access >

Topic Last Modified: *2012-10-13*

In this documentation, we use the term *external user* to define a large category of users who communicate with your Lync Server 2013 and Lync 2013 users from outside the firewall. External users that you can authorize to communicate Lync Server 2013 with internal users (that is, users who sign in to Lync Server from inside the firewall) can include the following:

- **Remote users** Users of your organization who sign in to Lync Server from outside the firewall (for example, business travelers and telecommuters) by using a virtual private network (VPN), Microsoft Direct Access (a feature of Windows Server 2008 R2 and Windows Server 2012), clients using transport layer security connection (TLS)), or the Lync Web App by using a browser.
- **Federated users** Users who have an account with a trusted customer or partner organization, such as Lync Server 2010, Lync Server 2013 or Office Communications Server 2007 R2. Federated users can also be members of defined partner organizations using extensible messaging and presence protocol (XMPP) by way of the XMPP proxy on the Edge Server and XMPP gateway on the Front End Server or pool. A defined trust relationship, called a federation, is not related to or dependent upon an Active Directory Domain Services (AD DS) trust relationship.
- **Public Instant Messaging Connectivity users** Contacts that your users establish through public instant messaging connectivity services (Windows Live, Yahoo! and AOL).
- **Mobile users** Users that are members of your organization that use a smart phone or tablet running a Lync Mobile client sign in to your internal deployment and are able to communicate with the other classes of users. The mobile user uses mobility services that are published through the reverse proxy to access the internal deployment. For details on features and capabilities available to Lync Mobile , see the Mobile Client Comparison Tables at http://go.microsoft.com/fwlink/p/?LinkID=234777.
- **Anonymous users** Users who do not have a user account in your organization's Active Directory Domain Services (AD DS) or in a supported federated domain, but who have received invitations to participate remotely in an on-premises conference.

Your edge deployment provides external access for the following types of communication:

- **IM and presence** Authorized external users can participate in IM conversations and conferences, and they can get information about one another’s presence status. Users of public IM service providers can participate in IM conversations with individual Lync Server users in your organization and access presence information, but they cannot participate in IM multiparty conferences using Lync Server. It is strictly peer-to-peer communication. File transfer is not supported for users of public IM service providers, and audio/video in peer-to-peer communications is supported for Windows Messenger 2011 users, but not other users of public IM service providers.

Both SIP and XMPP protocols are supported. To provide services for XMPP, see Scenarios for Federation, Public Instant Messaging Connectivity, and XMPP Federation.

- **Web conferencing** Authorized external users can participate in conferences that are hosted on your Lync Server deployment. Remote users, federated users, and anonymous users can be enabled for participation in web conferencing, but public IM users cannot participate in conferences. Depending on the options that you select, web conferencing-enabled users can participate in desktop and application sharing and can act as meeting organizers or presenters.
- **A/V conferencing** Authorized external users can participate in audio and video conferences that your Lync Server deployment hosts. Audio/video in peer-to-peer communications is supported for Windows Messenger 2011 users, but not for other users of public IM service providers.

In order to control communications, you can configure one or more policies that define how users inside and outside your organization communicate with each other. You can also configure settings and apply policies for individual internal users or for specific types of external users to control communications with external users.

Lync Server 2013 roles that are used to provide external access:

Edge Server The Edge Server is a server or a pool of servers that run the services that allow external access to IM and presence, conferencing, audio/video, and other media (for example, file transfer) services. Optionally, you can configure the Edge Server to federate with other Lync Server or Office Communications Server 2007 R2 deployments, and other XMPP deployments. The optional public IM connectivity feature is enabled and configured through the Edge Server.

Director The Director is an optional server or server pool running the Lync Server 2013 Director role that pre-authenticates user requests and routes requests to the users' home Front End Server or Front End pool, but does not home any user accounts.

Reverse Proxy A reverse proxy is a general term for specialized servers that publish resources available on the internal network and retrieve information for clients from the published resource. Lync Server 2013 uses the reverse proxy to publish a number of features, such as conferencing meetings, conference join locations, the address book, distribution list expansion, downloading meeting content, device updates, Mobility services, and more. Any reverse proxy that can meet the requirements for publishing the necessary resource locations can be used. Microsoft Forefront Threat Management Gateway (TMG) 2010 is used as an example for the purposes of illustrating the publishing rules necessary, but Forefront TMG 2010 is not required.

Important:

Lync Server 2013 supports both IPv4 and IPv6. Windows Server 2008 R2 and Windows Server 2012 uses a dual stack that can use both IPv4 and IPv6 concurrently. This is important because of the transitional nature of a deployment moving from IPv4 to IPv6. IPv4 can be supported in some areas, where in other areas of the deployment, IPv6 can be used. This is especially important where the Internet and internal deployments are concerned. External clients must communicate through the reverse proxy to use services such as mobility, meetings, address book download, and others. Currently, Forefront Threat Management Gateway 2010 and Internet Security and Acceleration Server 2006 do not support IPv6 addressing, regardless of the operating system version that they are deployed on. You must plan accordingly in relation to your use of IPv6 and IPv4 as they relate to external clients.

1.3.9.4 Understanding Autodiscover

Understanding Autodiscover

Microsoft Lync Server 2013 > Planning > Planning for External User Access >

Topic Last Modified: *2013-03-05*

The Lync Server 2013 Autodiscover Service is a feature that was originally introduced in Microsoft Lync Server 2010 as part of the Cumulative Update for Lync Server 2010: November 2011. In addition to fixes, this cumulative update delivered support for Lync Mobile and Lync 2013 clients.

In Lync Server 2013, the Autodiscover Service is an integral part of the operation of external and internal mobile clients, and Autodiscover is also extended to new clients, such as the recently introduced Lync Windows Store app for Windows 8. Autodiscover is also used by the Lync 2013 desktop clients. Autodiscover is recognized in Lync Server by the required domain name system (DNS) records **lyncdiscover.<domain>** and **lyncdiscoverinternal.<domain>**. Additionally, newer versions of the Lync 2010 and Lync 2013 desktop client prefer Autodiscover over the domain name system (DNS) SRV records, using DNS SRV records only if lyncdiscover.<domain> or lyncdiscoverinternal.<domain> does not respond or does not resolve. The Lync Windows Store app for Windows 8 and Lync Mobile uses Autodiscover exclusively and will not refer to the traditional DNS SRV records.

In Lync Server 2013, Autodiscover is expanded to communicate to the client which elements, features, and communication methods are available to the client. The information is communicated through a request that is sent from the client, and the Lync Server web services responds with a clearly defined response that names what is available to the client, and how to contact those features in the format of the Autodiscover Response document.

The best way to understand the Autodiscover response document, including how the web services communicate features to clients through this document, is to dissect and define each line in a typical response from the Lync web service Autodiscover response document.

> **Note:**
>
> In the details that follow, the user has already authenticated to the home server by responding to an authentication request.

> **Note:**
>
> The Lync Autodiscover Web Service is defined in the **Microsoft Office Protocols** in the **Open Specifications** section of the **Microsoft Developer Network** (MSDN) library. For details, see the full specification document, "Lync Autodiscover Web Service Protocol," at: http://go.microsoft.com/fwlink/?LinkId=273839. For details about authentication, see "OC Authentication Web Service Protocol" at http://go.microsoft.com/fwlink/?LinkId=279015.

The Lync Server Web Service Autodiscover Response

The response returned when the Autodiscover request is sent is the same for an internal or an external client. Some parameters that are location–aware may change. If a client request is received, but the actual pool is other than the one that has been contacted, the user’s home pool will be set for that user. A colleague whose user account is on a different pool, but logging in from the same office, would get a slightly different response. The response indicates the correct Front End Server or Front End pool for that user.

An example of an Autodiscover Response document:

```
<AutodiscoverResponse xmlns:xsd="http://www.w3.org/2001/XMLSchema" xmlns:xsi="htt
   <User>
      <SipServerInternalAccess fqdn="pool01.contoso.com" port="5061"/>
      <SipClientInternalAccess fqdn=" pool01.contoso.com" port="443"/>
      <SipServerExternalAccess fqdn="sip.contoso.com" port="5061"/>
      <SipClientExternalAccess fqdn="sip.contoso.com " port="443"/>
      <Link token ="External/Autodiscover" href="https://webexternal.contoso.com/
      <Link token="Internal/Autodiscover" href="https://webinternal.contoso.net/A
      <Link token="External/AuthBroker" href="https://webexternal.contoso.com/Rea
      <Link token="Internal/AuthBroker" href="https://webinternal.contoso.net/Rea
      <Link token="External/WebScheduler" href="https://webexternal.contoso.com/S
      <Link token="Internal/WebScheduler" href="https://webinternal.contoso.net/S
      <Link token="External/Mcx" href="https://webexternal.contoso.com/Mcx/McxSer
      <Link token="Internal/Mcx" href="https://webexternal.contoso.net/Mcx/McxSer
      <Link token="External/Ucwa" href="https://webexternal.contoso.com/ucwa/v1/a
      <Link token="Internal/Ucwa" href="https://webinternal.contoso.net/ucwa/v1/a
      <Link token="Ucwa" href="https://webexternal.contoso.com/ucwa/v1/applicatio
      <Link token="External/XFrame" href="https://webexternal.contoso.com/Autodis
      <Link token="Internal/XFrame" href="https://webinternal.contoso.net/Autodis
      <Link token="XFrame" href="https://webexternal.contoso.com/Autodiscover/XFr
      <Link token="Self" href="https://webexternal.contoso.net/Autodiscover/Autod
   </User>
</AutodiscoverResponse>
```

Autodiscover Response Document Details

The Autodiscover Response document can be in one of two formats. The default format is a JavaScript Object Notation (JSON). The other format is extensible markup language (XML) document. The XML is used for this example. The request and response are predictable because the document has a defined schema that determines the format. The line in the document that describes the schema used is the first line in the request or response:

```
<AutodiscoverResponse xmlns:xsd="http://www.w3.org/2001/XMLSchema" xmlns:xsi="htt
```

The definition of **AccessLocation=”External”** indicates that the request was made from an external user.

```
<SipServerInternalAccess fqdn="pool01.contoso.com" port="5061"/>
```

```
<SipServerExternalAccess fqdn="sip.contoso.com" port="5061"/>
```

SipServerInternalAccess and SipServerExternalAccess are currently not used. These entries are reserved for future use.

```
<SipClientInternalAccess fqdn=" pool01.contoso.com" port="443"/>
```

```
<SipClientExternalAccess fqdn="sip.contoso.com " port="443"/>
```

SipClientInternalAccess and SipClientExternalAccess describe the fully qualified domain name and port that an internal or external client will use to access the defined SIP Server. The Lync desktop client and the Lync Windows Store app use these entries, based on their location (internal or external) to find the Director or Front End Server.

```
<Link token="Internal/Autodiscover" href="https://webinternal.contoso.net/Autodis
```

```
<Link token ="External/Autodiscover" href="https://webexternal.contoso.com/Autodi
```

The `Autodiscover` references contain the service entry points for the Autodiscover service. The token attribute contains the name of the service, and the href is a URL that defines for the client where the service can be found. Clients on an external network use the `External/Autodiscover`. The Autodiscover service is installed as part of the deployment process. `Internal/Autodiscover` is not currently used, and is reserved for future use.

```
<Link token="Internal/AuthBroker" href="https://webinternal.contoso.net/Reach/sip
```

```
<Link token="External/AuthBroker" href="https://webexternal.contoso.com/Reach/sip
```

The `AuthBroker` references contain the service entry points for the internal and the external authentication broker service, in this case, sip.svc. The token attribute contains the name of the service, and the href is a URL that defines for the client where the service can be found. Clients on the internal network with use `Internal/AuthBroker`. Clients on an external network use the `External/AuthBroker`. The AuthBroker service is installed as part of the deployment process of your internal Lync Server 2013 deployment web services.

```
<Link token="Internal/WebScheduler" href="https://webinternal.contoso.net/Schedul
```

```
<Link token="External/WebScheduler" href="https://webexternal.contoso.com/Schedul
```

The `WebScheduler` token references the URLs for client access to the web-based scheduling for Lync Server conferences. Currently, on the `External/WebScheduler` is used. The WebScheduler is installed as part of the deployment process of your internal Lync Server 2013 deployment web services.

```
<Link token="Internal/Mcx" href="https://webexternal.contoso.net/Mcx/McxService.s
```

```
<Link token="External/Mcx" href="https://webexternal.contoso.com/Mcx/McxService.s
```

`Internal/Mcx` and `External/Mcx` are the locations of the Mobility services, introduced in Cumulative Update for Lync Server 2010: November 2011. These references will continue to be used by Lync 2010 Mobile on all supported devices. The Mcx service is installed as part of the deployment process of your internal Lync Server 2013 deployment web services.

```
<Link token="Internal/Ucwa" href="https://webinternal.contoso.net/ucwa/v1/applica
```

```
<Link token="External/Ucwa" href="https://webexternal.contoso.com/ucwa/v1/applica
```

```
<Link token="Ucwa" href="https://webexternal.contoso.com/ucwa/v1/applications"/>
```

Internal/Ucwa, **External/Ucwa** and **Ucwa** provide a means for clients to access the Unified Communications Web Application Programming Interface (UCWA API, or simply UCWA). `Internal/Ucwa` and `External/Ucwa` virtual directories are access points reserved for future feature enhancement, and are not used. The `Ucwa` virtual directory is used for Microsoft Lync Mobile (introduced with Lync Server 2013) on all supported devices. The UCWA service is installed as part of the deployment process of your internal Lync Server 2013 deployment web services.

```
<Link token="Internal/XFrame" href="https://webinternal.contoso.net/Autodiscover/
```

```
<Link token="External/XFrame" href="https://webexternal.contoso.com/Autodiscover/
```

```
<Link token="XFrame" href="https://webexternal.contoso.com/Autodiscover/XFrame/XF
```

`Internal/XFrame`, **External/XFrame** and **XFrame** provide access for UCWA-based server applications. XFrame is installed as part of the deployment process of your internal Lync Server 2013 deployment web services.

```
<Link token="Self" href="https://webexternal.contoso.net/Autodiscover/Autodiscove
```

The `Self` token refers to information specific to the client (user response type) that is making the request. The client that made this request was external, and this Autodiscover reference is to the user portion of the Autodiscover service.

1.3.9.5 Choosing a Topology

Choosing a Topology

Microsoft Lync Server 2013 > Planning > Planning for External User Access >

Topic Last Modified: *2013-02-21*

When you choose a topology, you can use one the following supported topology options:

> **Note:**
> Unless otherwise noted, if you have experience with Microsoft Lync Server 2010, you will find the guidance here is largely unchanged.

- Single Consolidated Edge with Private IP Addresses and NAT
- Single Consolidated Edge with Public IP Addresses
- Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT
- Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses
- Scaled Consolidated Edge with Hardware Load Balancers

> **Important:**
> The internal Edge interface and external Edge interface must use the same type of load balancing. You cannot use DNS load balancing on one Edge interface and hardware load balancing on the other Edge interface.

The following table summarizes the functionality available with the supported Microsoft Lync Server 2013 topologies. The column headings indicate the functionality available for a given Edge configuration option. Using the Scaled Edge (DNS load balanced) option as an example, you can see that it supports high availability, can use non-routable private IP addresses (with NAT) or routable public IP addresses assigned to the Edge external interfaces, and reduces cost because a hardware load balancer is not required.

Edge failover scenarios supported with DNS Load Balancing are Lync-to-Lync point-to-point sessions, Lync conferencing sessions, Lync-to-PSTN sessions and Office 365. Edge failover scenarios that do not benefit from DNS Load Balancing are failover for remote user Exchange Unified Messaging (UM) (prior to Exchange 2010 SP1), public instant messaging (IM) connectivity, and federation with servers running Office Communications Server.

Summary of Edge Server Topology Options

Topology	High availability	Additional DNS A records required for external Edge Server in the Edge pool	Edge Failover for Lync-to-Lync sessions	Edge Failover for Lync-to-Lync EUM/PIC/OCS Federation sessions
Single Edge using NAT	No	No	No	No
Single Edge using Public IP	No	No	No	No
Scaled Edge (DNS Load Balanced) using NAT	Yes	Yes	Yes	*

Scaled Edge (DNS Load Balanced) using Public IP	Yes	Yes	Yes	*
Scaled Edge Hardware load balanced)	Yes	No (one DNS A record per VIP)	Yes	Yes

***** Failover for public instant messaging (IM) connectivity, and federation with servers running Office Communications Server is not available with DNS load balancing. Exchange UM (remote user) failover using DNS load balancing requires Exchange Server 2010 SP1 or newer.

> **Note:**
>
> Single Edge and Scaled Edge (DNS load balanced) topologies can use:
>
> - Routable public IP addresses
> - Non-routable private IP address if symmetric network address translation (NAT) is used
>
> > **Note:**
> >
> > If you use public IP address or private IP address with NAT, you will still use the same number of IP addresses based on your configuration choice in Topology Builder. You can configure the Edge Server to use a single IP address with distinct ports per service, or use distinct IP addresses per service, but use the same port (by default, TCP 443).
>
> If you decide to use non-routable private IP addresses with NAT:
>
> - You must use routable private IP addresses on all three external interfaces
> - You must configure symmetric NAT for incoming and outgoing traffic
>
> Scaled Edge (hardware load balanced) topology must use public IP addresses.

Lync Server 2013 supports placing Access, Web Conferencing, and A/V Edge external interfaces behind a router or firewall that performs network address translation (NAT) for both single and scaled consolidated Edge Server topologies.

Using NAT for all Edge external interfaces requires the use of DNS load balancing. When compared to using hardware load balancers, using DNS load balancing without NAT allows you to reduce the number of public IP address per Edge Server in an Edge pool as described in the following list:

- Lync Server 2013 Scaled Consolidated Edge (DNS load balanced) Requires three public IP addresses for each Edge Server in an Edge pool.
- Lync Server 2013 Scaled Consolidated Edge (hardware load balanced) Requires three public IP address for load balancer virtual IP addresses (one time requirement that does not increment as more Edge Servers are added to the pool) plus three public IP addresses per Edge Server in a pool.

IP Address Requirements for Scaled Consolidated Edge (IP Address per role)

Number of Edge Servers per pool	Number of required IP addresses Lync Server 2013 (DNS load balanced)	Number of required IP addresses Lync Server 2013 (hardware load balanced)
2	6	3 (1 per VIP) + 6
3	9	3 (1 per VIP) + 9
4	12	3 (1 per VIP) + 12

5	15	3 (1 per VIP) + 15

IP Address Requirements for Scaled Consolidated Edge (Single IP address for all roles)

Number of Edge Servers per pool	Number of required IP addresses Lync Server 2013 (DNS load balanced)	Number of required IP addresses Lync Server 2013 (hardware load balanced)
2	2	1 (1 per VIP) + 2
3	3	1 (1 per VIP) + 3
4	4	1 (1 per VIP) + 4
5	5	1 (1 per VIP) + 5

The primary decision points for topology selection are high availability and load balancing. The requirement for high availability can influence the load balancing decision.

- **High availability** If you need high availability, deploy at least two Edge Servers in a pool. A single Edge pool will support up to twelve Edge Servers. If more capacity is required, you can deploy multiple Edge pools. As a general rule, 10% of a given user base will need external access.

  Important:
  Topology Builder will allow you to configure up to twenty Edge Servers in a single Edge pool. The tested and supported maximum number of Edge Servers in a pool is twelve and Topology Builder allowing for a number larger than twelve should not be construed as implied support for more than twelve Edge Servers in a single Edge pool.

- **Hardware load balancing** Hardware load balancing is supported for load balancing Lync Server 2013 Edge Servers when using publicly routable IP addresses for the Edge external interfaces. For example, you would use this approach in situations where failover is required for any of the following applications:
  - Public IM connectivity
  - Federation with companies running Microsoft Office Communications Server 2007 or Microsoft Office Communications Server 2007 R2
  - External access to Exchange 2007 Unified Messaging (UM) or Exchange 2010 UM

    Important:
    DNS load balancing for Exchange 2010 SP1 and newer is supported for Exchange UM.

  These three applications will continue to operate, but they are not DNS load balancing aware and will only connect to the first Edge Server in the pool. If that server is unavailable, the connection will fail. For example, if multiple Edge Servers are deployed in a pool to handle the federated traffic load, only one access proxy actually receives traffic while the others are idle.

Important:
Using DNS load balancing is recommended if you are federating with companies using Lync Server 2010 and Microsoft Office 365. Be aware that there are significant performance impacts if most of your federated partners are using Office Communications Server 2007 or Office Communications Server 2007 R2.

1.3.9.6 Data Collection

Data Collection

Microsoft Lync Server 2013 > Planning > Planning for External User Access >

Topic Last Modified: *2012-09-08*

In Microsoft Lync Server 2013 communications software, you can run the Microsoft Lync Server 2013, Planning Tool without documenting your existing and proposed IP addresses and Edge Server fully qualified domain names (FQDNs), but it is significantly harder to do so without causing configuration errors. For example, if coexistence is required for a period of time, a common mistake is to reuse FQDNs from an existing Edge deployment for your Lync Server 2013 Edge deployment. By having the existing and proposed IP addresses and FQDNs written down in a spreadsheet, table, or other visual form, you help prevent setup problems during installation.

> ⚠**Warning:**
>
> If you have used previous versions of the Planning Tool, you may have used the tool to create your topology and the exported the topology document for use in Topology Builder to publish your topology. The ability to export the topology was removed from Planning Tool. Using a previous version of the Planning Tool to create a topology document for Lync Server 2013 is strongly discouraged, and will produce unexpected results.

Therefore, the recommended approach is to use the following data collection template, which corresponds to your Edge topology, to gather the various FQDN and IP addresses that you will need to enter into the Planning Tool. By documenting the current and proposed configuration, you can put the values in the proper context for your production environment. And, you are forced to think about how you will configure coexistence and features such as simple URLs, file shares, and load balancing.

To successfully deploy Microsoft Lync Server 2013, you need to understand the interaction of and reliance on the individual components. By collecting data from your existing network and server infrastructure, and applying the planning guidance in these sections, you can integrate Lync Server 2013 Edge Server components into your infrastructure.

Introduced in Choosing a Topology, there are three main architectures with two variations, for a total of five possible deployment scenarios. One of these scenarios will be the starting point for your data collection. The IP addresses, server names, and domain names are examples that coincide with the matching certificate, firewall, and DNS diagrams that detail the information required for a complete planning solution. The diagrams and filling in your required certificate, DNS and firewall values is especially important in cross-team communications where the management of the certification authority, firewall configuration and DNS is managed by teams other than the team that plans the deployment. The diagrams provide information on required components that can be used to communicate these requirements for cross-team collaboration.

The provided diagrams are intentionally generic, but allow for the collection of all pertinent data that would be necessary for communication of requirements in a cross team scenario where networking, firewall, certificate creation and management, server deployment, and server management are handled by different groups. Having the required details for configuration of networking, firewalls, ports and protocols, certificates, and servers is invaluable when the deployment of Lync Server is underway.

1.3.9.7 Determine DNS Requirements

Determine DNS Requirements

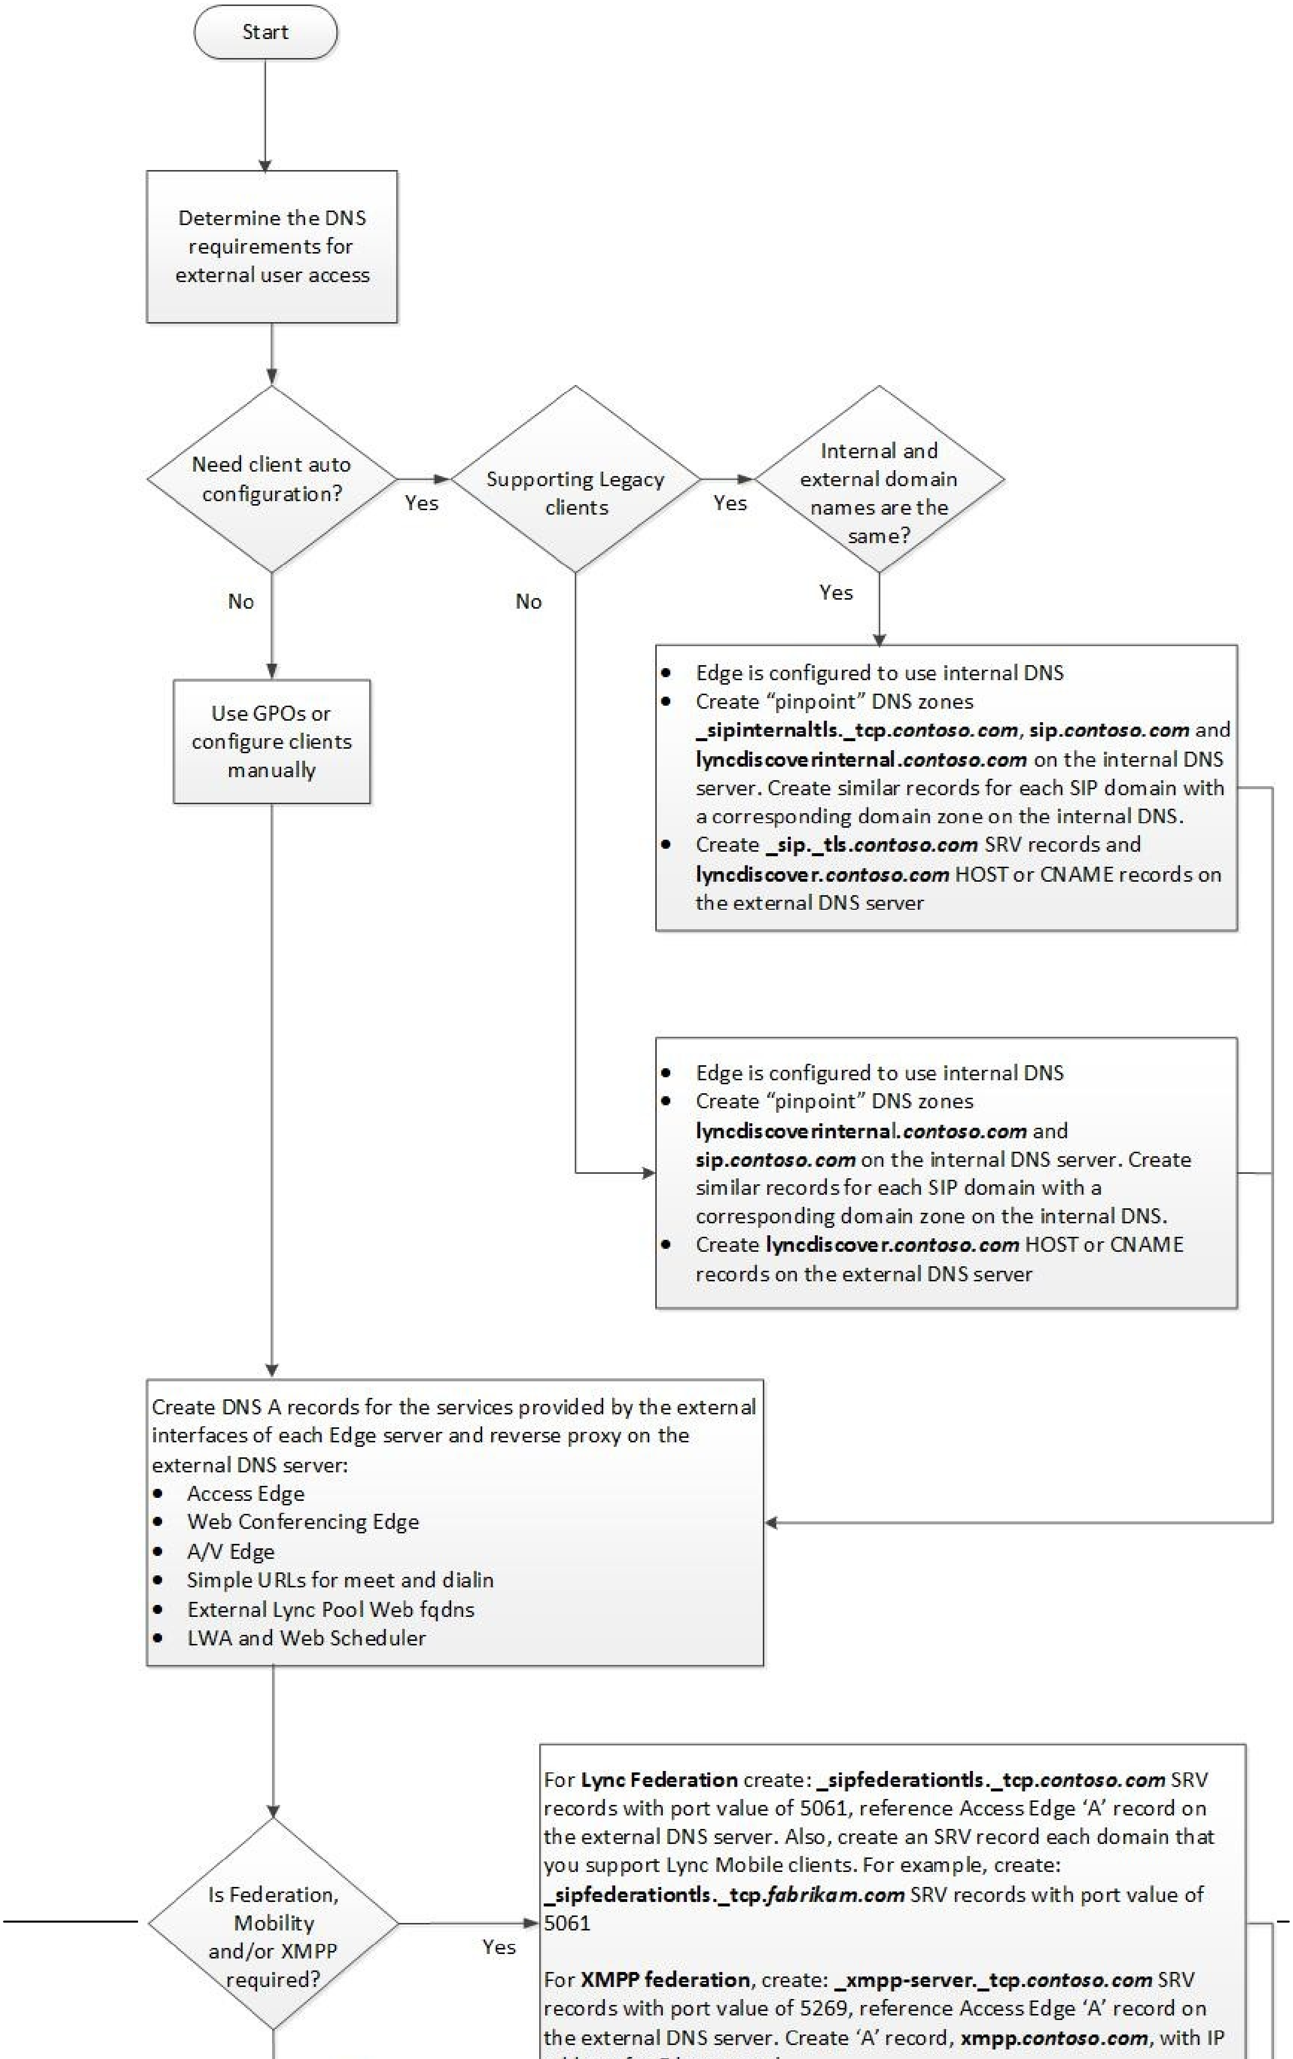
Planning > Network Planning for Lync Server > Domain Name System (DNS) Requirements >

Topic Last Modified: *2013-02-22*

Use the following flow chart to determine Domain Name System (DNS) requirements. Changes for the Cumulative Updates for Lync Server 2013: February 2013 are noted where they apply.

Important:

Microsoft Lync Server 2013 supports the use of IPv6 addressing. To use IPv6 addresses, you must also provide support for IPv6 DNS and configure DNS host AAAA (known as “quad-A”) records. In deployments where both IPv4 and IPv6 are being used, it is best to configure and maintain both host A records for IPv4 and host AAAA for IPv6. Even if your deployment has transitioned fully to IPv6, IPv4 DNS host records may still be required when external users are still using IPv4.



Start
Determine the DNS requirements for external user access
Need client auto configuration?
Yes
No
Supporting Legacy clients
Yes
No
Internal and external domain names are the same?
Yes
Use GPOs or configure clients manually
Is Federation, Mobility and/or XMPP required?
Yes

- Edge is configured to use internal DNS
- Create "pinpoint" DNS zones **_sipinternaltls._tcp.contoso.com**, **sip.contoso.com** and **lyncdiscoverinternal.contoso.com** on the internal DNS server. Create similar records for each SIP domain with a corresponding domain zone on the internal DNS.
- Create **_sip._tls.contoso.com** SRV records and **lyncdiscover.contoso.com** HOST or CNAME records on the external DNS server

- Edge is configured to use internal DNS
- Create "pinpoint" DNS zones **lyncdiscoverinternal.contoso.com** and **sip.contoso.com** on the internal DNS server. Create similar records for each SIP domain with a corresponding domain zone on the internal DNS.
- Create **lyncdiscover.contoso.com** HOST or CNAME records on the external DNS server

Create DNS A records for the services provided by the external interfaces of each Edge server and reverse proxy on the external DNS server:

- Access Edge
- Web Conferencing Edge
- A/V Edge
- Simple URLs for meet and dialin
- External Lync Pool Web fqdns
- LWA and Web Scheduler

For **Lync Federation** create: **_sipfederationtls._tcp.contoso.com** SRV records with port value of 5061, reference Access Edge 'A' record on the external DNS server. Also, create an SRV record each domain that you support Lync Mobile clients. For example, create: **_sipfederationtls._tcp.fabrikam.com** SRV records with port value of 5061

For **XMPP federation**, create: **_xmpp-server._tcp.contoso.com** SRV records with port value of 5269, reference Access Edge 'A' record on the external DNS server. Create 'A' record, **xmpp.contoso.com**, with IP

Important:

By default the computer name of a computer that is not joined to a domain is a host name, not a fully qualified domain name (FQDN). Topology Builder uses FQDNs, not host names. So, you must configure a DNS suffix on the name of the computer to be deployed as an Edge Server that is not joined to a domain. **Use only standard characters** (including A–Z, a–z, 0–9, and hyphens) when assigning FQDNs of your Lync Servers, Edge Servers, and pools. Do not use Unicode characters or underscores. Nonstandard characters in an FQDN are often not supported by external DNS and public CAs (that is, when the FQDN must be assigned to the SN in the certificate). For additional details, see Configure DNS Host Records

How Lync Clients Locate Services

Microsoft Lync 2010, Lync 2013, and Lync Mobile are similar in how the client finds and accesses services in Lync Server 2013. The notable exception is the Lync Windows Store app that uses a different service location process. This section details two scenarios of how the clients locate services, first the traditional method using a series of SRV and A host records, second using only the Autodiscover service records. Cumulative updates to the desktop clients change the DNS location process from Lync Server 2010 For all clients, the DNS query process continues until a successful query is returned, or the list of possible DNS records is exhausted, and the final error is returned to the client.

For all clients **except** for the Lync Windows Store app During DNS lookup, SRV records are queried and returned to the client in the following order:

1. lyncdiscoverinternal.<*domain*>   A (host) record for the Autodiscover service on the internal Web services
2. lyncdiscover.<*domain*>   A (host) record for the Autodiscover service on the external Web services
3. _sipinternaltls._tcp.<*domain*>   SRV (service locator) record for internal TLS connections
4. _sipinternal._tcp.<*domain*>   SRV (service locator) record for internal TCP connections (performed only if TCP is allowed)
5. _sip._tls.<*domain*>   SRV (service locator) record for external TLS connections
6. sipinternal.<*domain*>   A (host) record for the Front End pool or Director, resolvable only on the internal network
7. sip.<*domain*>   A (host) record for the Front End pool or Director on the internal network, or the Access Edge service when the client is external
8. sipexternal.<*domain*>   A (host) record for the Access Edge service when the client is external

The Lync Windows Store app changes the process completely because it uses two records:

1. lyncdiscoverinternal.<*domain*>   A (host) record for the Autodiscover service on the internal Web services
2. lyncdiscover.<*domain*>   A (host) record for the Autodiscover service on the external Web services

There is no fallback to the other record types.

The difference between the methods used for newer clients as compared to older clients is that the Autodiscover service is becoming the preferred method to locate all services.

When a connection is successful, the Autodiscover Service returns all the Web Services URLs for the user's home pool, including the Mobility Service (known as Mcx by the virtual directory created for the service in IIS), Microsoft Lync Web App and Web scheduler URLs. However, both the internal Mobility Service URL and the external Mobility Service URL is associated with the external Web Services FQDN. Therefore, regardless of whether a mobile device is internal or external to the network, the device always connects to the Mobility Service externally through the reverse proxy.

If the Cumulative Updates for Lync Server 2013: February 2013 has been installed, the Autodiscover Service also returns references to Internal/UCWA, External/UCWA and UCWA. These entries refer to the Unified Communications Web API (UCWA) web component. Currently, only the entry UCWA is used and provides a reference to a URL for the web component. UCWA is used by Lync 2013 Mobile clients instead of the Mcx Mobility Service used by the Lync 2010 Mobile clients.

Note:

When creating SRV records, it is important to remember that they must point to a DNS A and AAAA (if you are using IPv6 addressing) record in the same domain in which the DNS SRV record is created. For example, if the SRV record is in contoso.com, the A and AAAA (if you are using IPv6 addressing) record it points to cannot be in fabrikam.com.

Tip:

The default configuration is to direct all mobile client traffic through the external site. You can modify settings to return only the internal URL, if this is more preferable for your requirements. With this configuration, users can use Lync mobile applications on their mobile devices only when they are inside the corporate network. To define this configuration, you use the **Set-CsMcxConfiguration** cmdlet.

Note:

Although mobile applications can also connect to other Lync Server 2013 services, such as Address Book Service, internal mobile application web requests go to the external web FQDN only for the Mobility Service. Other service requests, such as Address Book requests, do not require this configuration.

Mobile devices support manual discovery of services. In this case, each user must configure the mobile device settings with the full internal and external Autodiscover Service URIs, including the protocol and path, as follows:

- https://<*ExtPoolFQDN*>/Autodiscover/autodiscoverservice.svc/Root for external access
- https://<*IntPoolFQDN*>/AutoDiscover/AutoDiscover.svc/Root for internal access

We recommend that you use automatic discovery, rather than manual discovery. However, manual settings can be useful for troubleshooting mobile device connectivity issues.

Configuring Split-Brain DNS with Lync Server

Split-brain DNS is known by a number of names, for example, split DNS or split-horizon DNS. Simply, it describes a DNS configuration where there are two DNS zones with the same namespace – but one DNS zone services internal-only requests, and the other DNS zone services external-only requests. However, many of the DNS SRV and A records contained in the internal DNS will not be contained in the external DNS, and the reverse is also true. In cases where the same DNS record exists in both the internal and external DNS (for example, www.contoso.com), the IP address returned will be different based on where (internal or external) the query was initiated.

Important:

Currently, Split-Brain DNS is not supported for the mobility, or more specifically, the LyncDiscover and LyncDiscoverInternal DNS records. LyncDiscover must be defined on an external DNS server and LyncDiscoverInternal must be defined on an internal DNS server.

For the purposes of these topics, the term split-brain DNS will be used.

If you are configuring split-brain DNS, the following internal and external zone contain a summary of the types of DNS records required in each zone. For details, see Scenarios for External User Access.

Internal DNS:

- Contains a DNS zone called contoso.com for which it is authoritative
- The internal contoso.com zone contains:
  - DNS A and AAAA (if you are using IPv6 addressing) and SRV records for internal Lync Server 2013 client autoconfiguration (optional)
  - DNS A and AAAA (if you are using IPv6 addressing) or CNAME records for automatic discovery of Lync Server 2013 Web Services (optional)
  - DNS A and AAAA (if you are using IPv6 addressing) records for Front End pool name, Director or Director pool name, and all internal servers running Lync Server 2013 in the corporate network
  - DNS A and AAAA (if you are using IPv6 addressing) records for the Edge internal interface of each Lync Server 2013, Edge Server in the perimeter network
  - DNS A and AAAA (if you are using IPv6 addressing) records for the internal interface of each reverse proxy server in the perimeter network (optional for management of reverse proxy)
  - All Lync Server 2013 Edge Server internal edge interfaces in the perimeter network use the internal DNS zone for resolving queries to contoso.com
  - All servers running Lync Server 2013 and clients running Lync 2013 in the corporate network point to the internal DNS servers for resolving queries to contoso.com, or use of HOSTS file on each Edge server and list A and AAAA (if you are using IPv6 addressing) records for next hop server, specifically the Director or Director VIP, Front End pool VIP, or Standard Edition server

External DNS:

- Contains a DNS zone called contoso.com for which it is authoritative
- The external contoso.com zone contains:
  - DNS A and AAAA (if you are using IPv6 addressing) and SRV records for Lync Server 2013 client autoconfiguration (optional)
  - DNS A and AAAA (if you are using IPv6 addressing) or CNAME records for automatic discovery of Lync Server 2013 Web Services for use with mobility
  - DNS A and AAAA (if you are using IPv6 addressing) and SRV records for the Edge external interface of each Lync Server 2013, Edge Server or hardware load balancer virtual IP (VIP) in the perimeter network
  - DNS A and AAAA (if you are using IPv6 addressing) records for the external interface of the reverse proxy server or VIP for a pool of reverse proxy servers in the perimeter network

Automatic Configuration without Split-Brain DNS

Using split-brain DNS, a Lync Server 2013 user that signs in internally can take advantage of automatic configuration if the internal DNS zone contains a _sipinternaltls._tcp SRV record for each SIP domain in use. However, if you do not use split-brain DNS, internal automatic configuration of clients running Lync will not work unless one of the workarounds described in later in this section is implemented. This is because Lync Server 2013 requires the user's SIP URI to match the domain of the Front End pool designated for automatic configuration. This was also the case with earlier versions of Communicator.

For example, if you have two SIP domains in use, the following DNS service (SRV) records would be required:

- If a user signs in as bob@contoso.com the following SRV record will work for automatic configuration because the user's SIP domain (contoso.com) matches the domain of automatic configuration Front End pool):

_sipinternaltls._tcp.contoso.com. 86400 IN SRV 0 0 5061 pool01.contoso.com

- If a user signs in as alice@fabrikam.com the following DNS SRV record will work for automatic configuration of the second SIP domain.
  _sipinternaltls._tcp.fabrikam.com. 86400 IN SRV 0 0 5061 pool01.fabrikam.com

For comparison, if a user signs in as tim@litwareinc.com the following DNS SRV record will not work for automatic configuration, because the client's SIP domain (litwareinc.com) does not match the domain that the pool is in (fabrikam.com):

_sipinternaltls._tcp.litwareinc.com. 86400 IN SRV 0 0 5061 pool01.fabrikam.com

If automatic configuration is required for clients running Lync, select one of the following options:

- **Group Policy Objects** Use Group Policy objects (GPOs) to populate the correct server values.

  Note:
  This option does not enable automatic configuration, but it does automate the process of manual configuration, so if this approach is used, the SRV records associated with automatic configuration are not required.

- **Matching internal zone** Create a zone in the internal DNS that matches the external DNS zone (for example, contoso.com) and create DNS A and AAAA (if you are using IPv6 addressing) records corresponding to the Lync Server 2013 pool used for automatic configuration. For example, if a user is homed on pool01.contoso.net but signs into Lync as bob@contoso.com, create an internal DNS zone called contoso.com and inside it, create a DNS A and AAAA (if IPv6 addressing is used) record for pool01.contoso.com.
- **Pin-point internal zone** If you are creating an entire zone in the internal DNS is not an option, you can create pin-point (that is, dedicated) zones that correspond to the SRV records that are required for automatic configuration, and populate those zones using dnscmd.exe. Dnscmd.exe is required because the DNS user interface does not support creation of pin-point zones. For example, if the SIP domain is contoso.com and you have a Front End pool called pool01 that contains two Front End Servers, you need the following pin-point zones and A records in your internal DNS:

```
dnscmd . /zoneadd _sipinternaltls._tcp.contoso.com. /dsprimary
dnscmd . /recordadd _sipinternaltls._tcp.contoso.com. @ SRV 0 0 5061 po
dnscmd . /zoneadd pool01.contoso.com. /dsprimary
dnscmd . /recordadd pool01.contoso.com. @ A 192.168.10.90
dnscmd . /recordadd pool01.contoso.com. @ AAAA <IPv6 address>
dnscmd . /recordadd pool01.contoso.com. @ A 192.168.10.91
dnscmd . /recordadd pool01.contoso.com. @ AAAA <IPv6 address>
```

  If your environment contains a second SIP domain (for example, fabrikam.com), you need the following pin-point zones and A records in your internal DNS:

```
dnscmd . /zoneadd _sipinternaltls._tcp.fabrikam.com. /dsprimary
dnscmd . /recordadd _sipinternaltls._tcp.fabrikam.com. @ SRV 0 0 5061 p
dnscmd . /zoneadd pool01.fabrikam.com. /dsprimary
dnscmd . /recordadd pool01.fabrikam.com. @ A 192.168.10.90
dnscmd . /recordadd pool01.contoso.com. @ AAAA <IPv6 address>
dnscmd . /recordadd pool01.fabrikam.com. @ A 192.168.10.91
dnscmd . /recordadd pool01.contoso.com. @ AAAA <IPv6 address>
```

Note:
The Front End pool FQDN appears twice, but with two different IP addresses. This is because DNS load balancing is used, but if hardware load balancing is used, there would be only a single Front End pool entry. Also, the Front End pool FQDN values change between the contoso.com example and the fabrikam.com example, but the IP addresses remain the same. This is because users signing in from either SIP domain, use the same Front End pool for automatic configuration.

For details, see the DMTF blog article, "Communicator Automatic Configuration and Split-Brain DNS," at http://go.microsoft.com/fwlink/p/?linkId=200707.

Note:
The content of each blog and its URL are subject to change without notice.

Configuring the domain name system (DNS) for Disaster Recovery

To configure DNS to redirect Lync Server 2013 Web traffic to your disaster recovery and failover sites, you must be using a DNS provider that supports GeoDNS. You can set up your DNS records for Web to support disaster recovery, so that features that use Web services continue even if one entire Front End pool goes down. This disaster recovery feature supports the Autodiscover (Lyncdiscover URL), Meet and Dial-In simple URLs.

You define and configure additional DNS host (A and AAAA if using IPv6) records for internal and external resolution of Web services at your GeoDNS provider. The following details assume paired pools, geographically dispersed, and GeoDNS supported by your provider with either round-robin DNS, or configured to use Pool1 as primary, and fail over to Pool2 in the event of communications loss or hardware failure.

GeoDNS record (example)	Pool records (example)	CNAME records (example)	DNS settings (select one option)
Meet-int.geolb.contoso.com	Pool1InternalWebFQDN.contoso.com Pool2InternalWebFQDN.contoso.com	Meet.contoso.com alias to Pool1InternalWebFQDN.contoso.com Meet.contoso.com alias to Pool2InternalWebFQDN.contoso.com	Round Robin between pools Use primary, connect to secondary if failure
Meet-ext.geolb.contoso.com	Pool1ExternalWebFQDN.contoso.com Pool2ExternalWebFQDN.contoso.com	Meet.contoso.com alias to Pool1ExternalWebFQDN.contoso.com Meet.contoso.com alias to Pool2ExternalWebFQDN.contoso.com	Round Robin between pools Use primary, connect to secondary if failure
Dialin-int.geolb.contoso.com	Pool1InternalWebFQDN.contoso.com Pool2InternalWebFQDN.contoso.com	Dialin.contoso.com alias to Pool1InternalWebFQDN.contoso.com Dialin.contoso.com alias to Pool2InternalWebFQDN.contoso.com	Round Robin between pools Use primary, connect to secondary if failure
Dialin-ext.geolb.contoso.com	Pool1ExternalWebFQDN.contoso.com Pool2ExternalWebFQDN.contoso.com	Dialin.contoso.com alias to Pool1ExternalWebFQDN.contoso.com	Round Robin between pools Use primary, connect to secondary if failure

		Dialin.contoso.com alias to Pool2ExternalWebFQDN.contoso.com	
Lyncdiscoverint-int.geolb.contoso.com	Pool1InternalWebFQDN.contoso.com Pool2InternalWebFQDN.contoso.com	Lyncdiscoverinternal.contoso.com alias to Pool1InternalWebFQDN.contoso.com Lyncdiscoverinternal.contoso.com alias to Pool2InternalWebFQDN.contoso.com	Round Robin between pools Use primary, connect to secondary if failure

Scheduler-ext.geolb.contoso.com	Pool1ExternalWebFQDN.contoso.com Pool2ExternalWebFQDN.contoso.com	Scheduler.contoso.com alias to Pool1ExternalWebFQDN.contoso.com Scheduler.contoso.com alias to Pool2ExternalWebFQDN.contoso.com	Round Robin between pools Use primary, connect to secondary if failure

DNS Load Balancing

DNS load balancing is typically implemented at the application level. The application (for example, a client running Lync), tries to connect to a server in a pool by connecting to one of the IP addresses returned from the DNS A and AAAA (if IPv6 addressing is used) record query for the pool fully qualified domain name (FQDN).

For example, if there are three front end servers in a pool named pool01.contoso.com, the following will happen:

- Clients running Lync query DNS for pool01.contoso.com. The query returns three IP addresses and caches them as follows (not necessarily in this order):
  pool01.contoso.com   192.168.10.90
  pool01.contoso.com   192.168.10.91

pool01.contoso.com 192.168.10.92

- The client attempts to establish a Transmission Control Protocol (TCP) connection to one of the IP addresses. If that fails, the client tries the next IP address in the cache.
- If the TCP connection succeeds, the client negotiates TLS to connect to the primary registrar on pool01.contoso.com.
- If the client tries all cached entries without a successful connection, the user is notified that no servers running Lync Server 2013 are available at the moment.

Note:

DNS-based load balancing is different from DNS round robin (DNS RR) which typically refers to load balancing by relying on DNS to provide a different order of IP addresses corresponding to the servers in a pool. Typically DNS RR only enables load distribution, but does not enable failover. For example, if the connection to the one IP address returned by the DNS A and AAAA (if you are using IPv6 addressing) query fails, the connection fails. Therefore, DNS round robin by itself is less reliable than DNS-based load balancing. You can use DNS round robin in conjunction with DNS load balancing.

DNS load balancing is used for the following:

- Load balancing server-to-server SIP to the Edge Servers
- Load balancing Unified Communications Application Services (UCAS) applications such as Conferencing Auto Attendant, Response Group, and Call Park
- Preventing new connections to UCAS applications (also known as "draining")
- Load balancing all client-to-server traffic between clients and Edge Servers

DNS load balancing cannot be used for the following:

- Client-to-server web traffic to Director or Front End Servers

DNS load balancing and federated traffic:

If multiple DNS records are returned by a DNS SRV query, the Access Edge service always picks the DNS SRV record with the lowest numeric priority and highest numeric weight. The Internet Engineering Task Force document "A DNS RR for specifying the location of services (DNS SRV)" http://www.ietf.org/rfc/rfc2782.txt specifies that if there are multiple DNS SRV records defined, priority is first used, then weight. For example DNS SRV record A has a weight of 20 and a priority of 40 and DNS SRV record B has a weight of 10 and priority of 50. DNS SRV record A with priority 40 will be selected. The following rules apply to DNS SRV record selection:

- Priority is considered first. A client MUST attempt to contact the target host defined by the DNS SRV record with the lowest numbered priority it can reach. Targets with the same priority SHOULD be tried in an order defined by the weight field.
- The weight field specifies a relative weight for entries with the same priority. Larger weights SHOULD be given a proportionately higher probability of being selected. DNS administrators SHOULD use Weight 0 when there isn't any server selection to do. In the presence of records containing weights greater than 0, records with weight 0 should have a very small chance of being selected.

If multiple DNS SRV records with equal priority and weight are returned, the Access Edge service will select the SRV record that was received first from the DNS server.

1.3.9.8 Determine External A/V Firewall and Port Requirements

Determine External A/V Firewall and Port Requirements

Microsoft Lync Server 2013 > Planning > Planning for External User Access >

Topic Last Modified: *2012-10-29*

Audio/Video (A/V) communication can be a complex. Because of the nature of protocols used in A/V and how clients and servers use the protocols, a special section is warranted to explain the differences between client and server versions.

Use the following A/V Firewall and Port table to determine firewall requirements and which ports to open. Then, review the network address translation (NAT) terminology because NAT can be implemented in many different ways. For a detailed example of firewall port settings, see the reference architectures in Scenarios for External User Access.

General Protocol Usage for UDP and TCP in Audio/Video and Media Traffic

Audio/Video Transport	Usage
UDP	Preferred transport layer protocol for audio and video
TCP	Fallback transport layer protocol for audio and video Required transport layer protocol for application sharing to Office Communications Server 2007 R2, Lync Server 2010 and Lync Server 2013 Required transport layer protocol for file transfer to Lync Server 2010 and Lync Server 2013

External A/V Firewall Port Requirements for External User Access

The firewall port requirements for external (and internal) SIP and conferencing interfaces are consistent, regardless of the version of your client or the version of the federation partner.

The same is not true for the Audio/Video Edge external interface. For federation with Office Communications Server 2007, the A/V Edge service requires that external firewall rules allow RTP/TCP and RTP/UDP traffic in the 50,000 through 59,999 port range to flow in both directions. The previous table assumes that Lync Server 2013 is the primary federation partner and it is being configured to communicate with one of the other federation partner types listed.

Configuring the Audio/Video port range of 50,000-59,999 must take into account that the port range will contain the source ports for communications to federation partners. In detail, consider that a communication is initiated from a federation partner. The communication from the A/V Edge service ports in the 50,000-59,999 range will connect to the expected port TCP 443 of the partner’s A/V Edge service. Conversely, inbound traffic to your A/V Edge service port TCP 443 will have a source port in the range of 50,000-59,999.

Different firewalls and policies for firewall administration may require only destination rules to be configured, or they may require both source and destination to be configured. If your requirements are for destination ports only, the Audio/Video requirements are:

Source IP	Destination IP	Destination Port
A/V Edge service interface	Any	TCP 443
A/V Edge service interface	Any	UDP 3478
Any	A/V Edge service interface	TCP 443
Any	A/V Edge service interface	UDP 3478

If your policies require both inbound and outbound firewall rule definitions, the Audio/ Video requirements are:

Source IP	Destination IP	Source Port	Destination Port
A/V Edge service interface	Any	TCP 50,000-59,999	TCP 443
A/V Edge service interface	Any	UDP 3478	UDP 3478
Any	A/V Edge service interface	Any	TCP 443
Any	A/V Edge service interface	Any	UDP 3478

Important:

Microsoft Office Communications Server 2007 requires a slightly different configuration. The TCP and UDP port range of 50,000-59,999 must be open inbound and outbound. This requirement is only for Office Communicator 2007. Office Communications Server 2007 R2, Lync Server 2010 and Lync Server 2013 only require TCP range 50,000-59,999 open outbound.

NAT Requirements for External User Access

NAT has typically been a routing function, but newer devices such as firewalls and even hardware load balancers can be configured for NAT. Rather than focusing on which device is performing NAT, this topic describes the required NAT behavior instead.

Lync Server 2013 communications software does not support NAT for traffic to or from the Edge internal interface, but for the Edge external interface, the following NAT behavior is required.

Important:

You must configure symmetric NAT for incoming and outgoing traffic. Symmetric NAT is the NAT technology described in this topic.

This documentation uses the acronyms ChangeDST and ChangeSRC in tables and drawings to define the following required behavior:

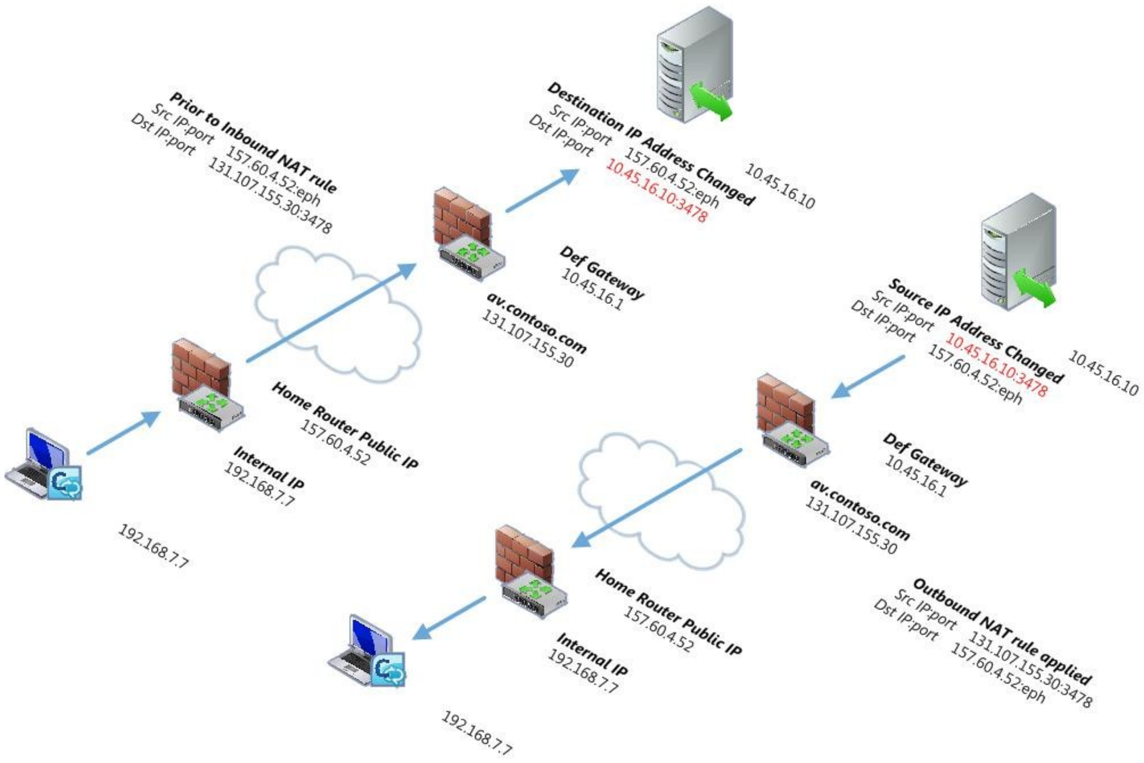
- **ChangeDST** The process of changing the destination IP address on packets destined for the network that is using NAT. This is also known as transparency, port forwarding, destination NAT mode, or half-NAT mode.
- **ChangeSRC** the process of changing the source IP address on packets leaving the network that is using NAT. This is also known as proxy, secure

NAT, stateful NAT, source NAT or full-NAT mode.

Regardless of the naming convention used, the NAT behavior required for the external interface of the Edge Server is as follows:

- For traffic from the Internet to the Edge external interface:
  - Change the destination IP address of the incoming packet from the Edge external interface public IP address to the translated IP address of the Edge external interface.
  - Leave the source IP address intact so that there is a return route for the traffic.
- For traffic from the Edge external interface to the Internet:
  - Change the source IP address of the packet leaving the Edge external interface, from the translated IP address to the public IP address of the Edge external interface so that the internal Edge IP address is not exposed and because it is a non-routable IP address.
  - Leave the destination IP address intact on the outgoing packets.

The following figure shows the distinction between changing the destination IP address (ChangeDST) for inbound traffic and changing the source IP Address (ChangeSRC) for outbound traffic using the A/V edge as an example.



Prior to Inbound NAT rule
Src IP:port 157.60.4.52:eph

Dst IP:port 157.60.4.52:eph
192.168.7.7

The key points are:

- Traffic that is inbound to the server running the A/V Edge service, the source IP address does not change but the destination IP address changes from 131.107.155.30 to the translated IP address of 10.45.16.10.
- Traffic that is outbound from the server running the A/V Edge service back to the workstation, the source IP address changes from the server's public IP address to the public IP address of the server running the A/V Edge service. The destination IP remains the workstation's public IP address. After the packet leaves the first NAT device outbound, the rule on the NAT device changes the source IP address of the server running the A/V Edge service

external interface IP address (10.45.16.10) to its public IP address (131.107.155.30).

1.3.9.9 Plan for Edge Server Certificates

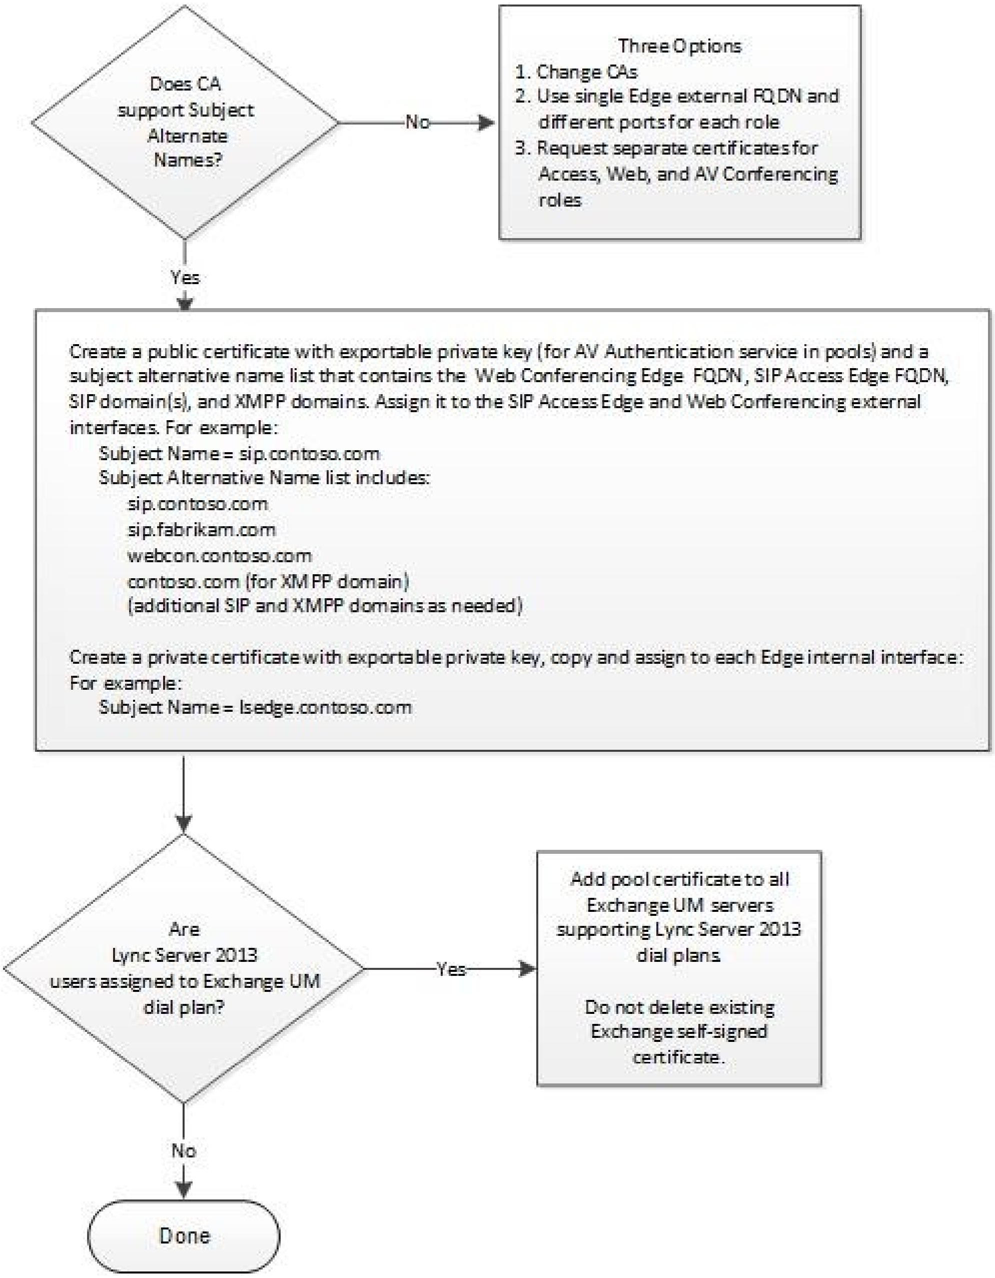
Plan for Edge Server Certificates

See Also

Microsoft Lync Server 2013 > Planning > Planning for External User Access >

Topic Last Modified: *2012-11-05*

Certificate creation for Edge is simplified in Lync Server 2013.



Does CA support Subject Alternate Names?
No
Three Options
1. Change CAs
2. Use single Edge external FQDN and different ports for each role
3. Request separate certificates for Access, Web, and AV Conferencing roles
Yes
Create a public certificate with exportable private key (for AV Authentication service in pools) and a subject alternative name list that contains the Web Conferencing Edge FQDN, SIP Access Edge FQDN, SIP domain(s), and XMPP domains. Assign it to the SIP Access Edge and Web Conferencing external interfaces. For example:
Subject Name = sip.contoso.com
Subject Alternative Name list includes:
sip.contoso.com
sip.fabrikam.com
webcon.contoso.com
contoso.com (for XMPP domain)
(additional SIP and XMPP domains as needed)
Create a private certificate with exportable private key, copy and assign to each Edge internal interface:
For example:
Subject Name = lsedge.contoso.com
Are Lync Server 2013 users assigned to Exchange UM dial plan?
Yes
Add pool certificate to all Exchange UM servers supporting Lync Server 2013 dial plans
Do not delete existing Exchange self-signed certificate.
No
Done

Create a single public certificate, ensure that you have an exportable private key defined for the certificate, and assign it to the following Edge Server external interfaces using the certificate wizard:

Important:

Wildcard certificates are not supported in Lync Server, except where used to summarize the Simple URLs through the reverse proxy. You must define distinct subject alternate names (SANs) for each SIP domain name, Web Conferencing Edge service, A/V Edge service and XMPP domain offered by your deployment.

Note:

Introduced in Lync Server 2013, staging Audio/Video Authentication certificates in advance of the expiration time of the current certificate requires some additional planning. Instead of one certificate with multiple purposes for the external Edge interface, you will require two certificates, one assigned to the Access Edge service and Web Conferencing Edge service, and one certificate for the A/V Edge service. For additional details, see Staging AV and OAuth Certificates Using -Roll in Set-CsCertificate

Important:

In the event of a pool of Edge Servers, you export the certificate with the private key to each Edge Server and assign the certificate to each Edge Server service. Do the same for the internal Edge Server certificate, exporting the certificate with the private key and assigning to each internal Edge interface.

- Ensure that you have an exportable private key assigned for the certificate
- Access Edge service (referred to as **SIP Access Edge External** in the certificate wizard)
- Web Conferencing Edge service (referred to as **Web Conferencing Edge External** in the certificate wizard)
- A/V Authentication service (referred to as **A/V Edge External** in the certificate wizard)

Create a single internal certificate with exportable private key, copy and assign it to each of the Edge Server internal interfaces:

- Edge Server (referred to as **Edge Internal** in the certificate wizard)

Important:

It is possible to use separate and distinct certificates for each Edge Server service. A good reason to choose separate certificates is if you want to use the new rolling certificate feature for the A/V Edge service certificate. In the case of this feature, decoupling the A/V Edge service certificate from the Access Edge service and Web Conferencing Edge service is recommended. If you choose to request, acquire and assign separate certificates for each service, you must request that the private key be exportable for the A/V Edge service (again, this is in actuality the A/V Authentication service) and assign the same certificate to the A/V Edge External interface on each Edge Server.

Staging AV and OAuth Certificates Using -Roll in Set-CsCertificate

Concepts

Changes in Lync Server 2013 That Affect Edge Server Planning

1.3.9.10 Scenarios for External User Access

Scenarios for External User Access

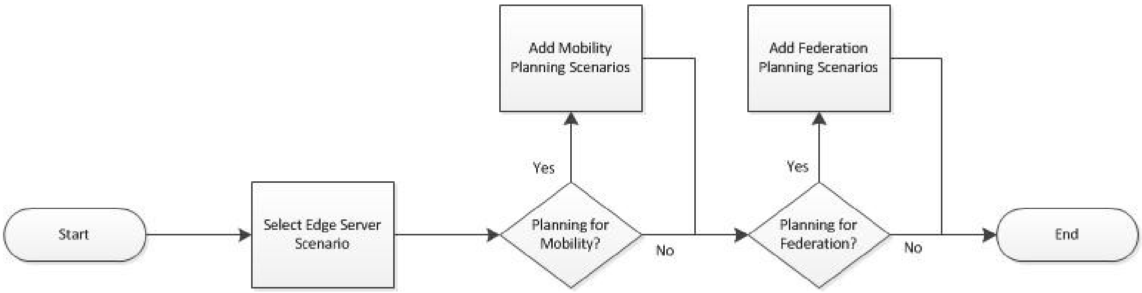
Microsoft Lync Server 2013 > Planning > Planning for External User Access >

Topic Last Modified: *2012-09-08*

Providing external user access for Lync Server 2013 requires that you deploy at least one Edge Server and one reverse proxy in your perimeter network. Optionally, you may deploy a Director or Director pool in your internal network.

If you need greater capacity than a single Edge Server can provide, or if you need high availability for your Edge Server deployment, you can configure load balancing and deploy multiple Edge Servers in a load balanced pool. If your organization has multiple data centers, you can have Edge Server or Edge pool deployments at more than one location. However, only one of the Edge Server deployments can be designated as the federation route.

This section defines the scenarios for Edge Server deployments and maps the planning sections to the possible scenarios. For example, if your deployment requires high availability, federation with extensible messaging and presence (XMPP) contacts, and Lync mobility, you would select the matching entries in the following table that would satisfy these requirements and use the referenced planning sections to define your deployment, as illustrated in the following flowchart.



Start
Select Edge Server Scenario
Planning for Mobility?
Yes
Add Mobility Planning Scenarios
No
Planning for Federation?
Yes
Add Federation Planning Scenarios
No
End

By using this process, you can plan for and document the configuration of all potential features that you intend to deploy for your users. However, you can add federation and mobility services after you have deployed the Edge Server and have confirmed the correct operation before adding other features. The process of adding features to an existing Edge Server deployment is covered in the Deployment section. For details on deployment, see Deploying External User Access By including planning for these features during the initial planning process, you can prepare for the DNS, firewall, and certificate requirements for the added features, which enables you to acquire the certificates and configure DNS and port/protocol requirements in advance.

Tip:

If you are planning to install the Edge Servers and reverse proxy and then add features later (for example, federation and mobility), determine what certificates you will require for all services after deployment. Planning for and acquiring the certificates for all features in advance, initially deployed or not, saves you from having to order new certificates to satisfy the requirements of federation (that is, on the Edge Servers) or the reverse proxy (that is, for mobility services).

Note:

All edge services run on each Edge Server. Services cannot be split between two different Edge Servers. If you deploy an Edge pool for scalability, all edge services are deployed on each Edge Server in the pool. XMPP federation, Office Communications Server, and Lync Server federation, public IM connectivity and client mobility are additional services that can be deployed after you have deployed your first Edge Server or Edge pool. Mobility services is a feature that uses the reverse proxy. Installation of mobility services will not add features to your Edge Servers, but will require reconfiguration of your reverse proxy. The **Installation goal** column that lists these features provides planning guidance in the associated column under **Edge Server planning section or sections** for concurrently planning these features to be deployed when the Edge Servers are installed and configured.

Identifying and Mapping Your Deployment Goals

Installation goal	Edge Server planning documentation
You have decided that a single server is sufficient for Edge services in your infrastructure. You also intend to use private IP addresses for the Edge server external interfaces with NAT to the Internet.	Single Consolidated Edge with Private IP Addresses and NAT

Use this planning section if you are deploying a single Edge Server in your perimeter. You will deploy an Edge Server with private IP addresses assigned to the Edge Server and will use NAT to provide the public IP addresses for the external users on the Internet.	
You have decided that a single server is sufficient for Edge services in your infrastructure. You also intend to use public IP addresses for the Edge server external interfaces to the Internet. Use this planning section if you are deploying a single Edge Server in your perimeter. You will deploy an Edge Server with public IP addresses assigned to the Edge Server. Instead of NAT, you will use routing in this scenario. The actual public IP address of the Edge Server are made available for external user connections.	Single Consolidated Edge with Public IP Addresses
You have decided that high availability of the Edge services is important to your users and you will deploy two or more Edge Servers in this pool. You also intend to use private IP addresses for the Edge Server external interfaces with NAT to the Internet. Use this planning section if you are deploying a pool of Edge Servers in your perimeter. You will deploy the Edge Servers with private IP addresses assigned to the Edge Server, using DNS load balancing to distribute communication across the pool. You will use NAT to provide the public IP addresses for the external users on the Internet.	Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT
You have decided that high availability of the Edge services is important to your users and you will deploy two or more Edge Servers in this pool. You also intend to use public IP addresses for the Edge Server external interfaces to the Internet. Use this planning section if you are deploying a pool of Edge Servers in your perimeter. You will deploy the Edge Servers with public IP addresses assigned to the Edge Server, using DNS load balancing to distribute communication across the pool. Instead of NAT, you will use routing to provide the public IP addresses for the external users on the Internet.	Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses
You have decided that high availability of the Edge services is important to your users and you will deploy two or more Edge	Scaled Consolidated Edge with Hardware Load Balancers

Servers in this pool using a hardware load balancer. Use this planning section if you are deploying a pool of Edge Servers in your perimeter. You will deploy the Edge Servers with public IP addresses assigned to the Edge Server, using hardware load balancers to distribute communication across the pool. Instead of NAT, you will use routing to provide the public IP addresses for the external users on the Internet.	
The federation scenarios allow you to plan for the feature that will extend the types of partners that your users can communicate with. • Lync Server federation • Office Communications Server federation • Public IM connectivity • XMPP federation	Planning for Federation Scenarios • Planning for Lync Server and Office Communications Server Federation • Planning for Public Instant Messaging Connectivity • Planning for Extensible Messaging and Presence Protocol (XMPP) Federation
Mobility services are offered through the reverse proxy. Services that enable mobility for external users are deployed on the Front End Server or Front End pool. You create or modify existing publishing rules on the reverse proxy to enable mobility services for your external users.	Planning for Mobility

Tip:

In the following Scenarios sections are reference architectures, example DNS, port/protocol definitions, and certificate requirements. Also included are diagrams for your DNS, port/protocol definitions and certificate needs. The diagrams will provide a template for you to fill in and distribute to other teams (for example, your organization's Network Team, Public Key Infrastructure Team, and Server Deployment Team). The goal of the diagrams is to enhance communication and to ensure success when communicating the required Edge Server configuration elements to the people who will do the actual configuration work. We recommend that you use the diagrams and associated reference architectures to plan your deployment.

1.3.9.10.1 Single Consolidated Edge with Private IP Addresses and NAT

Single Consolidated Edge with Private IP Addresses and NAT

Planning > Planning for External User Access > Scenarios for External User Access >

Topic Last Modified: *2012-09-08*

If your organization requires support for fewer than 15,000 Access Edge service client connections, 1,000 active Lync Server Web Conferencing service client connections, and 500 concurrent A/V Edge sessions, and high availability of the Edge Server is not important, this topology offers the advantages of lower hardware cost and simpler deployment. If you need greater capacity or you require high availability, you need to deploy a scaled consolidated Edge Server topology. For details, see one of the following:

- Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses

Using NAT
- Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses
- Scaled Consolidated Edge with Hardware Load Balancers

The figure does not show Directors, an optional server role deployed in the internal network between the Edge Servers and your Front End pools or server. For details about the topology for Directors, see Components Required for the Director. The figure represents a single reverse proxy.

Note:

The figure shown is for orientation and example IP addressing, but does not intend to represent actual communication flows with the correct incoming and outgoing traffic. The figure represents a high level view of possible traffic. Details for traffic flow as they pertain to incoming (to listening ports) and outgoing (to destination servers or clients) is represented in the Port Summary diagram in each scenario. For example, TCP 443 is actually inbound (to the Edge or reverse proxy) only, and is only a two-way flow from a protocol (TCP) perspective. Additionally, the figure shows the nature of traffic as it changes when NAT (network address translation) occurs (destination address is changed on inbound, source address is changed on outbound). Example external and internal firewall, and server interfaces are shown for reference purposes only. Finally, example default gateway and route relationships are shown, where applicable. Note also that the diagram uses the *.com* DNS zone to represent the external DNS zone for both reverse proxy and Edge Servers, and the *.net* DNS zone refers to the internal DNS zone.

New to Microsoft Lync Server 2013 is support for IPv6 addressing. Much like IPv4 addressing, IPv6 addresses must be assigned in such a way that the addresses are part of your assigned IPv6 address space. The addresses in this topic are for example only. You must acquire IPv6 addresses that will function in your deployment, provide the correct scope and will interoperate with internal and external addressing. Windows Server provides a feature that is important to transitional IPv6 operation and IPv4 to IPv6 communication called the *dual stack*. The dual stack is a separate and distinct network stack for IPv4 and for IPv6. The dual stack is what allows you to assign addressing for IPv4 and IPv6 concurrently, and allows the server to communicate with other hosts and clients based on what their requirements are.

Typical address types that you will use for IPv6 addressing will be the IPv6 global addresses (similar to public IPv4 addresses), IPv6 unique local addresses (similar to the private IPv4 address ranges) and IPv6 link-local addresses (similar to automatic private IP addresses in Windows Server for IPv4)

Network address translation technologies (NAT) for IPv6 exist that will allow for NAT IPv6 to IPv4 (commonly referred to as NAT64) and for NAT IPv6 to IPv6 (commonly referred to as NAT66). The existence of NAT technologies means that the five scenarios presented for Lync Server Edge Servers are still valid.

Warning:

IPv6 is a complex topic and requires careful planning with your networking team and your Internet provider to ensure that the addresses you assign at the Windows server level and at the Lync Server 2013 level will work as expected. See the links at the end of this topic for additional resources on IPv6 addressing and planning.

Planning for External User Access > Scenarios for External User Access > Single Consolidated Edge with Private IP Addresses and NAT >

Topic Last Modified: *2012-10-22*

Microsoft Lync Server 2013 uses certificates to mutually authenticate other servers and to encrypt data from server to server and server to client. Certificates require name matching of the domain name system (DNS) records associated with the servers and the subject name (SN) and subject alternative name (SAN) on the certificate. To successfully map servers, DNS records and certificate entries, you must carefully plan your intended server fully qualified domain names as registered in DNS and the SN and SAN entries on the certificate.

The certificate assigned to the external interfaces of the Edge Server is requested from a public certification authority (CA). Public CAs that have demonstrated success in supplying certificates for the purposes of Unified Communications are listed in the following article: http://go.microsoft.com/fwlink/p/?linkid=3052&kbid=929395. When requesting the certificate, you can use the certificate request generated by the Lync Server Deployment Wizard or create the request manually using Lync Server Management Shell cmdlets or by a process provided by a public CA. For details on Lync Server Management Shell cmdlets for certificate management, see Certificate and Authentication Cmdlets When assigning the certificate, the certificate is assigned to the Access Edge service interface, the Web Conferencing Edge service interface, and the Audio/Video Authentication service. The Audio/Video Authentication service should not be confused with the A/V Edge service which does not use a certificate to encrypt the audio and video streams. The internal Edge Server interface can use a certificate from an internal (to your organization) CA or a certificate from a public CA. The internal interface certificate uses only the SN and does not need or use SAN entries.

Note:

The following table shows a second SIP entry (sip.fabrikam.com) in the subject alternative name list for reference. For each SIP domain in your organization, you need to add a corresponding FQDN listed in the certificate subject alternative name list.

Certificates Required for Single Consolidated Edge with Private IP Addresses using NAT

Component	Subject name (SN)	Subject alternative names (SAN)/Order	Comments
Single consolidated Edge (External Edge)	sip.contoso.com	webcon.contoso.com sip.contoso.com sip.fabrikam.com	Certificate must be from a Public CA, and must have the server EKU and client EKU if public IM connectivity with AOL is to be deployed. The certificate is assigned to the external Edge interfaces for: • Access Edge • Conferencing Edge

			- A/V Edge Note that SANs are automatically added to the certificate based on your definitions in Topology Builder. You add SAN entries as needed for additional SIP domains and other entries that you need to support. The subject name is replicated in the SAN and must be present for correct operation.
Single consolidated Edge (Internal Edge)	lsedge.contoso.net	No SAN required	Certificate can be issued by a public or private CA, and must contain the server EKU. The certificate is assigned to the internal Edge interface.

Certificate Summary – Public Instant Messaging Connectivity

Component	**Subject name**	**Subject alternative names (SAN)/Order**	**Comments**
External/Access Edge	sip.contoso.com	sip.contoso.com webcon.contoso.com sip.fabrikam.com	Certificate must be from a Public CA, and must have the server EKU and client EKU if public IM connectivity with AOL is to be deployed. The certificate is assigned to the external Edge interfaces for: - Access Edge - Conferencing Edge - A/V Edge Note that SANs are automatically added to the certificate based on your definitions in Topology Builder. You add SAN entries as needed for additional SIP domains and other entries that you need to support. The subject name is replicated in the SAN and must be present for correct operation.

Certificate Summary for Extensible Messaging and Presence Protocol

Component	**Subject name**	**Subject alternative**	**Comments**

		names (SAN)/Order	
Assign to Access Edge service of Edge Server or Edge pool	sip.contoso.com	webcon.contoso.com sip.contoso.com sip.fabrikam.com xmpp.contoso.com ***.contoso.com**	The first three SAN entries are the normal SAN entries for a full Edge Server. The contoso.com is the entry required for federation with the XMPP partner at the root domain level. This entry will allow XMPP for all domains with the suffix *.contoso.com.

1.3.9.10.1.2 Port Summary - Single Consolidated Edge with Private IP Addresses Using NAT

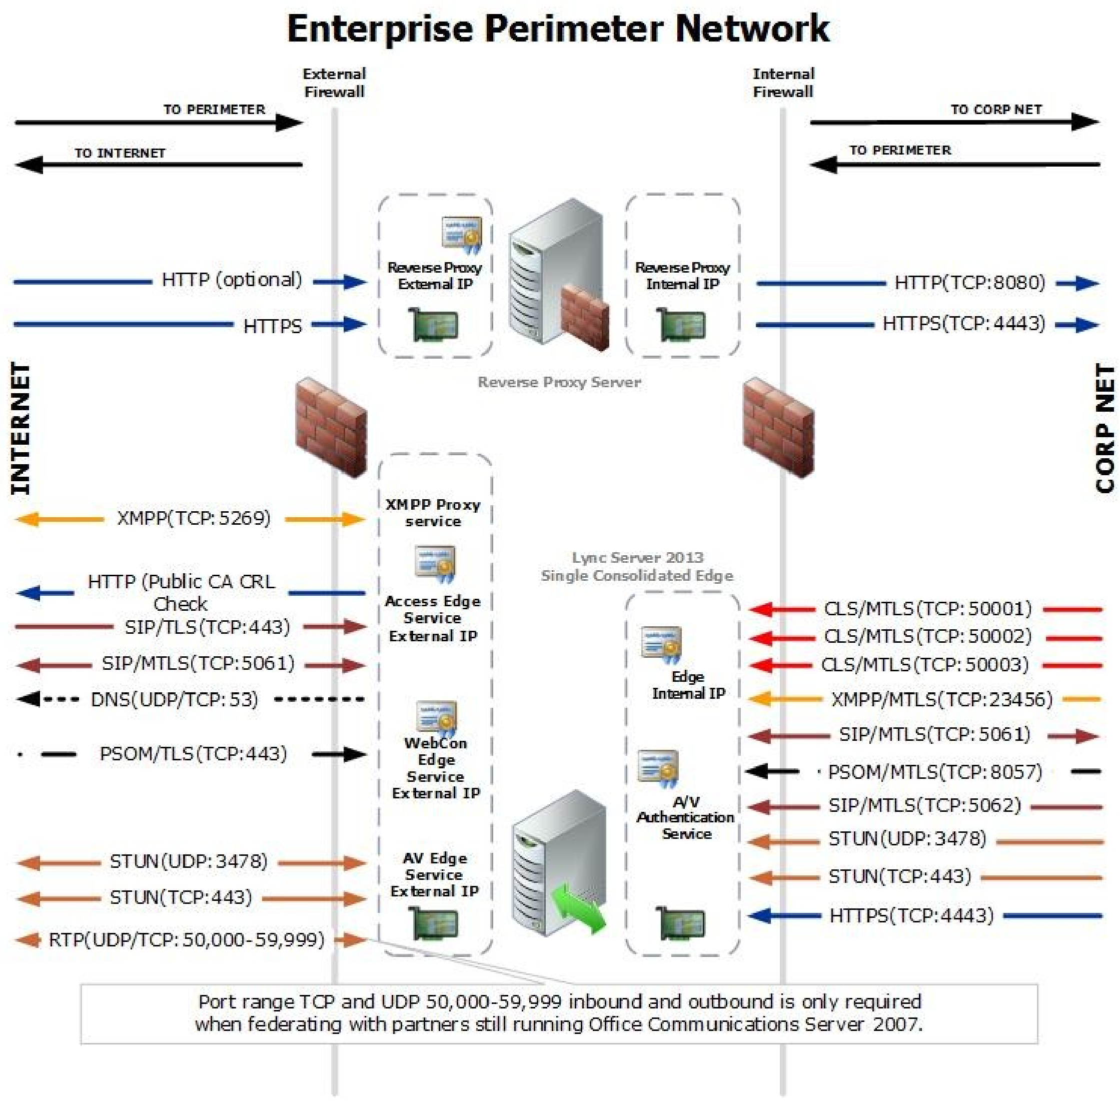
Port Summary - Single Consolidated Edge with Private IP Addresses Using NAT

Planning > Network Planning for Lync Server > Port Requirements >

Topic Last Modified: *2013-02-22*

The Lync Server 2013, Edge Server functionality described in this scenario architecture is very similar to what was implemented in Lync Server 2010. The most noticeable addition is the port **5269 over TCP** entry for the extensible messaging and presence protocol (XMPP). Lync Server 2013 optionally deploys an XMPP proxy on the Edge Server or Edge pool and the XMPP gateway server on the Front End Server or Front End pool.

In addition to IPv4, the Edge Server now supports IPv6. For clarity, only IPv4 is used in the scenarios.



Port and Protocol Details

We recommend that you open only the ports required to support the functionality for which you are providing external access.

For remote access to work for any edge service, it is mandatory that SIP traffic is allowed to flow bi-directionally as shown in the Inbound/Outbound edge traffic figure. Stated another way, the SIP messaging to and from the Access Edge service is involved in instant messaging (IM), presence, web conferencing, audio/video (A/V), and federation.

Firewall Summary for Single Consolidated Edge with Private IP Addresses using NAT: External Interface

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
XMPP/TCP/5269	Any	XMPP Proxy service (shares IP address with Access Edge service)	XMPP Proxy service accepts traffic from XMPP contacts in defined XMPP

			federations
Access/HTTP/TCP/80	Edge Server Access Edge service	Any	Certificate revocation/ CRL check and retrieval
Access/DNS/TCP/53	Edge Server Access Edge service	Any	DNS query over TCP
Access/DNS/UDP/53	Edge Server Access Edge service	Any	DNS query over UDP
Access/SIP(TLS)/ TCP/443	Any	Edge Server Access Edge service	Client-to-server SIP traffic for external user access
Access/SIP(MTLS)/ TCP/5061	Any	Edge Server Access Edge service	For federated and public IM connectivity using SIP
Access/SIP(MTLS)/ TCP/5061	Edge Server Access Edge service	Any	For federated and public IM connectivity using SIP
Web Conferencing/ PSOM(TLS)/TCP/443	Any	Edge Server Web Conferencing Edge service	Web Conferencing media
A/V/RTP/TCP/50,000-59,999	Edge Server A/V Edge service	Any	Required for federating with partners running Office Communications Server 2007, Office Communications Server 2007 R2, Lync Server 2010 and Lync Server 2013.
A/V/RTP/UDP/50,000-59,999	Edge Server A/V Edge service	Any	Required only for federation with partners running Office Communications Server 2007.
A/V/RTP/TCP/50,000-59,999	Any	Edge Server A/V Edge service	Required only for federation with partners running Office Communications Server 2007
A/V/RTP/UDP/50,000-59,999	Any	Edge Server A/V Edge service	Required only for federation with partners running Office Communications Server 2007
A/V/STUN,MSTURN/ UDP/3478	Edge Server A/V Edge service	Any	3478 outbound is used to determine

			the version of Edge Server that Lync Server is communicating with and also for media traffic from Edge Server-to-Edge Server. Required for federation with Lync Server 2010, Windows Live Messenger, and Office Communications Server 2007 R2, and also if multiple Edge pools are deployed within a company.
A/V/STUN,MSTURN/ UDP/3478	Any	Edge Server A/V Edge service	STUN/TURN negotiation of candidates over UDP/3478
A/V/STUN,MSTURN/ TCP/443	Any	Edge Server A/V Edge service	STUN/TURN negotiation of candidates over TCP/443
A/V/STUN,MSTURN/ TCP/443	Edge Server A/V Edge service	Any	STUN/TURN negotiation of candidates over TCP/443

Firewall Summary for Single Consolidated Edge with Private IP Addresses Using NAT: Internal Interface

Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Comments
XMPP/MTLS/ TCP/23456	Any (can be defined as Standard Edition server IP, Standard Edition server IP address, or pool IP address running the XMPP Gateway service)	Edge Server internal interface	Outbound XMPP traffic from XMPP Gateway service running on Front End Server or Front End pool
SIP/MTLS/TCP/5061	Any (can be defined as Director, Director pool IP address, Front End Server or Front End pool IP address)	Edge Server internal interface	Outbound SIP traffic (from Director, Director pool IP address, Front End Server or Front End pool IP address) to Edge Server internal interface
SIP/MTLS/TCP/5061	Edge Server internal interface	Any (can be defined as Director, Director pool IP address, Front End Server or Front	Inbound SIP traffic (to Director, Director pool IP address, Front End Server or Front End

		End pool IP address)	pool IP address) from Edge Server internal interface
PSOM/MTLS/TCP/8057	Any (can be defined as Front End Server IP address, or each Front End Server IP address in a Front End pool)	Edge Server internal interface	Web conferencing traffic from Front End Server or each Front End Server if in a pool, to Edge Server internal interface
SIP/MTLS/TCP/5062	Any (can be defined as Front End Server IP address, or Front End pool IP address or any Survivable Branch Appliance or Survivable Branch Server using this Edge Server)	Edge Server internal interface	Authentication of A/V users (A/V authentication service) from Front End Server or Front End pool IP address or any Survivable Branch Appliance or Survivable Branch Server using this Edge Server
STUN/MSTURN/UDP/3478	Any	Edge Server internal interface	Preferred path for A/V media transfer between internal and external users, Survivable Branch Appliance or Survivable Branch Server
STUN/MSTURN/TCP/443	Any	Edge Server internal interface	Fallback path for A/V media transfer between internal and external users, Survivable Branch Appliance or Survivable Branch Server if UDP communication cannot be established, TCP is used for file transfer and desktop sharing
HTTPS/TCP/4443	Any (can be defined as the Front End Server IP address, or pool that holds the Central Management store)	Edge Server internal interface	Replication of changes from the Central Management store to the Edge Server
MTLS/TCP/50001	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line

			(ClsController.exe) or agent (ClsAgent.exe) commands and log collection
MTLS/TCP/50002	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection
MTLS/TCP/50003	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection

Firewall Summary for Federation

Role/Protocol/TCP or UDP/Port	**Source IP address**	**Destination IP address**	**Notes**
Access/SIP(MTLS)/ TCP/5061	Access Edge service public IP address	Any	For federated and public IM connectivity using SIP

Firewall Summary – Public Instant Messaging Connectivity

Role/Protocol/TCP or UDP/Port	**Source IP address**	**Destination IP address**	**Notes**
Access/SIP(MTLS)/ TCP/5061	Public IM connectivity partners	Edge Server Access Edge service	For federated and public IM connectivity using SIP
Access/SIP(MTLS)/ TCP/5061	Edge Server Access Edge service	Public IM connectivity partners	For federated and public IM connectivity using SIP
Access/SIP(TLS)/ TCP/443	Clients	Edge Server Access Edge service	Client-to-server SIP traffic for external

			user access
A/V/RTP/TCP/50,000-59,999	Edge Server A/V Edge service	Live Messenger clients	Used for A/V sessions with Windows Live Messenger if public IM connectivity is configured.
A/V/STUN,MSTURN/UDP/3478	Edge Server A/V Edge service	Live Messenger clients	Required for public IM connectivity with Windows Live Messenger
A/V/STUN,MSTURN/UDP/3478	Live Messenger clients	Edge Server A/V Edge service	Required for public IM connectivity with Windows Live Messenger

Firewall Summary for Extensible Messaging and Presence Protocol

Protocol/TCP or UDP/Port	Source (IP address)	Destination (IP address)	Comments
XMPP/TCP/5269	Any	Edge Server Access Edge serviceinterface IP address	Standard server-to-server communication port for XMPP. Allows communication to the Edge Server XMPP proxy from federated XMPP partners
XMPP/TCP/5269	Edge Server Access Edge service interface IP address	Any	Standard server-to-server communication port for XMPP. Allows communication from the Edge Server XMPP proxy to federated XMPP partners
XMPP/MTLS/TCP/23456	Any	Each internal Edge Server Interface IP	Internal XMPP traffic from the XMPP Gateway on the Front End Server or Front End pool to the Edge Server internal IP address or each Edge pool member's internal IP address

1.3.9.10.1.3 DNS Summary - Single Consolidated Edge with Private IP Addresses Using NAT

DNS Summary - Single Consolidated Edge with Private IP Addresses Using NAT

Network Planning for Lync Server > Domain Name System (DNS) Requirements > DNS

Requirements for Edge Servers and Features >

Topic Last Modified: *2012-09-08*

DNS record requirements for remote access to Lync Server 2013 are fairly straightforward compared to those for certificates and ports. Also, many records are optional, depending on how you configure clients running Lync 2013 and whether you enable federation.

For details about Lync 2013 DNS requirements, see Determine DNS Requirements.

For details about automatic configuration of clients running Lync 2013 if split-brain DNS is not configured, see "Automatic Configuration without Split-Brain DNS" in Determine DNS Requirements.

The following table contains a summary of the DNS records that are required to support the single consolidated edge topology shown in the Single Consolidated Edge Topology figure. Note that certain DNS records are required only for automatic configuration of Lync 2013 and Lync 2010 clients. If you plan to use group policy objects (GPOs) to configure Lync clients, the associated automatic configuration records are not necessary.

IMPORTANT: Edge Server Network Adapter Requirements

To avoid routing issues, verify that there are at least two network adapters in your Edge Servers and that the default gateway is set only on the network adapter associated with the external interface. For example, as shown in the Single Consolidated Edge Topology figure in Single Consolidated Edge with Private IP Addresses and NAT, the default gateway would point to the external firewall (10.45.16.1).

You can configure two network adapters in your Edge Server as follows:

- **Network adapter 1 (Internal Interface)**
  Internal interface with 172.25.33.10 assigned.
  No default gateway is defined.
  Ensure that there is a route from the network containing the Edge internal interface to any networks that contain servers running Lync Server 2013 or Lync Server 2013 clients (for example, from 172.25.33.0 to 192.168.10.0).
- **Network adapter 2 (External Interface)**
  Three private IP addresses are assigned to this network adapter, for example 10.45.16.10 for Access Edge, 10.45.16.20 for Web Conferencing Edge, 10.45.16.30 for AV Edge

  Note:

  It is possible, though not recommended, to use a single IP address for all three Edge service interfaces. Though this does save IP addresses, it requires different port numbers for each service. The default port number is 443/TCP, which ensures that most remote firewalls will allow the traffic. Changing the port values to (for example) 5061/TCP for the Access Edge, 444/TCP for the Web Conferencing Edge and 443/TCP for the AV Edge might cause problems for remote users where a firewall that they are behind does not allow the traffic over 5061/TCP and 444/TCP. Additionally, three distinct IP addresses makes troubleshooting easier due to being able to filter on IP address.

  Access Edge IP address is primary with default gateway set to integrated router (10.45.16.1).
  Web conferencing and A/V Edge IP addresses secondary.

Tip:

Configuring the Edge Server with two network adapters is one of two options. The other option is to use one network adapter for the internal side and three network adapters for the external side of the Edge Server. The main benefit of this option is a distinct network adapter per Edge Server service, and potentially more concise data collection when troubleshooting is necessary

DNS Records Required for Single Consolidated Edge with Private IP Addresses Using NAT (Example)

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
External DNS/A	sip.contoso.com	131.107.155.10	Access Edge external interface (Contoso) Repeat as necessary for all SIP domains with Lync enabled users
External DNS/A	webcon.contoso.com	131.107.155.20	Web Conferencing Edge external interface
External DNS/A	av.contoso.com	131.107.155.30	A/V Edge external interface
External DNS/ SRV/443	_sip._tls.contoso.com	sip.contoso.com	Access Edge external interface. Required for automatic configuration of Lync 2013 and Lync 2010 clients to work externally. Repeat as necessary for all SIP domains with Lync enabled users.
External DNS/ SRV/5061	_sipfederationtls._tcp .contoso.com	sip.contoso.com	SIP Access Edge external interface Required for automatic DNS discovery of federated partners known as "Allowed SIP Domain" (called enhanced federation in previous releases).Repeat as necessary for all SIP domains with Lync enabled users
Internal DNS/A	lsedge.contoso.net	172.25.33.10	Consolidated Edge internal interface

◆Important:

The records listed in the previous table are shown with either a *.net* extension or a *.com* extension to highlight which zone they need to reside in if you are not using split-brain DNS. If you are using split-brain DNS, all records would be in the same *.com* zone, with the only distinction being whether they are in the internal or external DNS zone version. For details, see "Split-Brain DNS" in Determine DNS Requirements.

Records Required for Federation

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5061	_sipfederationtls._tcp.contoso.com	sip.contoso.com	SIP Access Edge external interface Required for automatic DNS discovery of your federation to other potential federation partners, and is known as "Allowed SIP Domains" (called enhanced federation in previous releases).Repeat as necessary for all SIP domains with Lync enabled users **Important:** This SRV record is required for mobility and the push notification clearing house

DNS Summary – Public Instant Messaging Connectivity

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
External DNS/A	sip.contoso.com	Access Edge service interface	Access Edge external interface (Contoso) Repeat as necessary for all SIP domains with Lync enabled users

DNS Summary for Extensible Messaging and Presence Protocol

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5269	_xmpp-server._tcp.contoso.com	xmpp.contoso.com	XMPP proxy external interface on the Access Edge service or Edge pool.Repeat as necessary for all internal SIP domains with Lync enabled users where contact with XMPP contacts is allowed through the configuration of the External Access Policy

			through a global policy, site policy where the user is located, or user policy applied to the Lync-enabled user. An allowed XMPP domain must also be configured in the XMPP Federated Partners policy. See topics in **See Also** for additional details
External DNS/A	xmpp.contoso.com (for example)	IP address of Access Edge service on your Edge Server or Edge pool hosting XMPP proxy	Points to the Access Edge service or Edge pool that hosts the XMPP proxy service. Typically, the SRV record that you create will point to this host (A or AAAA) record

Planning > Planning for External User Access > Scenarios for External User Access >

Topic Last Modified: *2012-09-08*

If your organization needs support for fewer than 15,000 Access Edge service client connections, 1,000 active Lync Server Web Conferencing service client connections, and 500 concurrent A/V Edge sessions, and high availability of the Edge Server is not important, this topology offers the advantages of lower hardware cost and simpler deployment. If you need greater capacity or you require high availability, you should deploy a scaled consolidated Edge Server topology.

- Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT
- Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses
- Scaled Consolidated Edge with Hardware Load Balancers

◆**Important:**
When using public IP address on the Edge Server, the default gateway on the Edge Server is no longer your firewall or router, but the router or firewall at your public perimeter edge – which will be a public address. The reverse proxy continues to use the router or firewall associated with the outermost perimeter network. The difference between the reverse proxy and the Edge Server with public IP addresses is that the reverse proxy is still using NAT and the Edge Server is using a route relationship.

The figure does not show Directors, an optional server role deployed in the internal network between the Edge Servers and your Front End pools or server. For details about the topology for Directors, see Components Required for the Director. The figure represents a single reverse proxy.

Note:

The figure shown is for orientation and example IP addressing, but does not intend to represent actual communication flows with the correct incoming and outgoing traffic. The figure represents a high level view of possible traffic. Details for traffic flow as they pertain to incoming (to listening ports) and outgoing (to destination servers or clients) is represented in the Port Summary diagram in each scenario. For example, TCP 443 is actually inbound (to the Edge or reverse proxy) only, and is only a two-way flow from a protocol (TCP) perspective. Additionally, the figure shows the nature of traffic as it changes when NAT (network address translation) occurs (destination address is changed on inbound, source address is changed on outbound). Example external and internal firewall, and server interfaces are shown for reference purposes only. Finally, example default gateway and route relationships are shown, where applicable. Note also that the diagram uses the *.com* DNS zone to represent the external DNS zone for both reverse proxy and Edge Servers, and the *.net* DNS zone refers to the internal DNS zone.

New to Microsoft Lync Server 2013 is support for IPv6 addressing. Much like IPv4 addressing, IPv6 addresses must be assigned in such a way that the addresses are part of your assigned IPv6 address space. The addresses in this topic are for example only. You must acquire IPv6 addresses that will function in your deployment, provide the correct scope and will interoperate with internal and external addressing. Windows Server provides a feature that is important to transitional IPv6 operation and IPv4 to IPv6 communication called the *dual stack*. The dual stack is a separate and distinct network stack for IPv4 and for IPv6. The dual stack is what allows you to assign addressing for IPv4 and IPv6 concurrently, and allows the server to communicate with other hosts and clients based on what their requirements are.

Typical address types that you will use for IPv6 addressing will be the IPv6 global addresses (similar to public IPv4 addresses), IPv6 unique local addresses (similar to the private IPv4 address ranges) and IPv6 link-local addresses (similar to automatic private IP addresses in Windows Server for IPv4)

Network address translation technologies (NAT) for IPv6 exist that will allow for NAT IPv6 to IPv4 (commonly referred to as NAT64) and for NAT IPv6 to IPv6 (commonly referred to as NAT66). The existence of NAT technologies means that the five scenarios presented for Lync Server Edge Servers are still valid.

Warning:

IPv6 is a complex topic and requires careful planning with your networking team and your Internet provider to ensure that the addresses you assign at the Windows server level and at the Lync Server 2013 level will work as expected. See the links at the end of this topic for additional resources on IPv6 addressing and planning.

Planning for External User Access > Scenarios for External User Access > Single Consolidated Edge with Public IP Addresses >

Topic Last Modified: *2012-09-08*

Microsoft Lync Server 2013 uses certificates to mutually authenticate other servers and to encrypt data from server to server and server to client. Certificates require name matching of the domain name system (DNS) records associated with the servers and the subject name (SN) and subject alternative name (SAN) on the certificate. To successfully map servers, DNS records and certificate entries, you must carefully plan your intended server fully qualified domain names as registered in DNS and the SN and SAN entries on the certificate.

The certificate assigned to the external interfaces of the Edge Server is requested from a public certification authority (CA). Public CAs that have demonstrated success in supplying certificates for the purposes of Unified Communications are listed in the following article: http://go.microsoft.com/fwlink/p/?linkid=3052&kbid=929395 When requesting the certificate, you can use the certificate request generated by the Lync Server Deployment Wizard or create the request manually or by a process provided by the public CA. When assigning the certificate, the certificate is assigned to the Access Edge service interface, the Web Conferencing Edge service interface, and the Audio/Video Authentication service. The Audio/Video Authentication service should not be confused with the A/V Edge service which does not use a certificate to encrypt the audio and video streams. The internal Edge Server interface can use a certificate from an internal (to your organization) CA or a certificate from a public CA. The internal interface certificate uses only the SN and does not need or use SAN entries.

Note:

The following table shows a second SIP entry (sip.fabrikam.com) in the subject alternative name list for reference. For each SIP domain in your organization, you need to add a corresponding FQDN listed in the certificate subject alternative name list.

Certificates Required for Single Consolidated Edge with Public IP Addresses

Component	Subject name (SN)	Subject alternative names (SAN)/Order	Comments
Single consolidated Edge (External Edge)	sip.contoso.com	webcon.contoso.com sip.contoso.com sip.fabrikam.com	Certificate must be from a Public CA, and must have the server EKU and client EKU if public IM connectivity with AOL is to be deployed. The certificate is assigned to the external Edge interfaces for: • Access Edge • Conferencing Edge • A/V Edge

			Note that SANs are automatically added to the certificate based on your definitions in Topology Builder. You add SAN entries as needed for additional SIP domains and other entries that you need to support. The subject name is replicated in the SAN and must be present for correct operation.
Single consolidated Edge (Internal Edge)	lsedge.contoso.net	No SAN required	Certificate can be issued by a public or private CA, and must contain the server EKU. The certificate is assigned to the internal Edge interface.

Certificate Summary – Public Instant Messaging Connectivity

Component	**Subject name**	**Subject alternative names (SAN)/Order**	**Comments**
External/Access Edge	sip.contoso.com	sip.contoso.com webcon.contoso.com sip.fabrikam.com	Certificate must be from a Public CA, and must have the server EKU and client EKU if public IM connectivity with AOL is to be deployed. The certificate is assigned to the external Edge interfaces for: • Access Edge • Conferencing Edge • A/V Edge Note that SANs are automatically added to the certificate based on your definitions in Topology Builder. You add SAN entries as needed for additional SIP domains and other entries that you need to support. The subject name is replicated in the SAN and must be present for correct operation.

Certificate Summary for Extensible Messaging and Presence Protocol

Component	**Subject name**	**Subject alternative names (SAN)/Order**	**Comments**

Assign to Access Edge service of Edge Server or Edge pool	sip.contoso.com	webcon.contoso.com sip.contoso.com sip.fabrikam.com xmpp.contoso.com ***.contoso.com**	The first three SAN entries are the normal SAN entries for a full Edge Server. The contoso.com is the entry required for federation with the XMPP partner at the root domain level. This entry will allow XMPP for all domains with the suffix *.contoso.com.

1.3.9.10.2.2 Port Summary - Single Consolidated Edge with Public IP Addresses

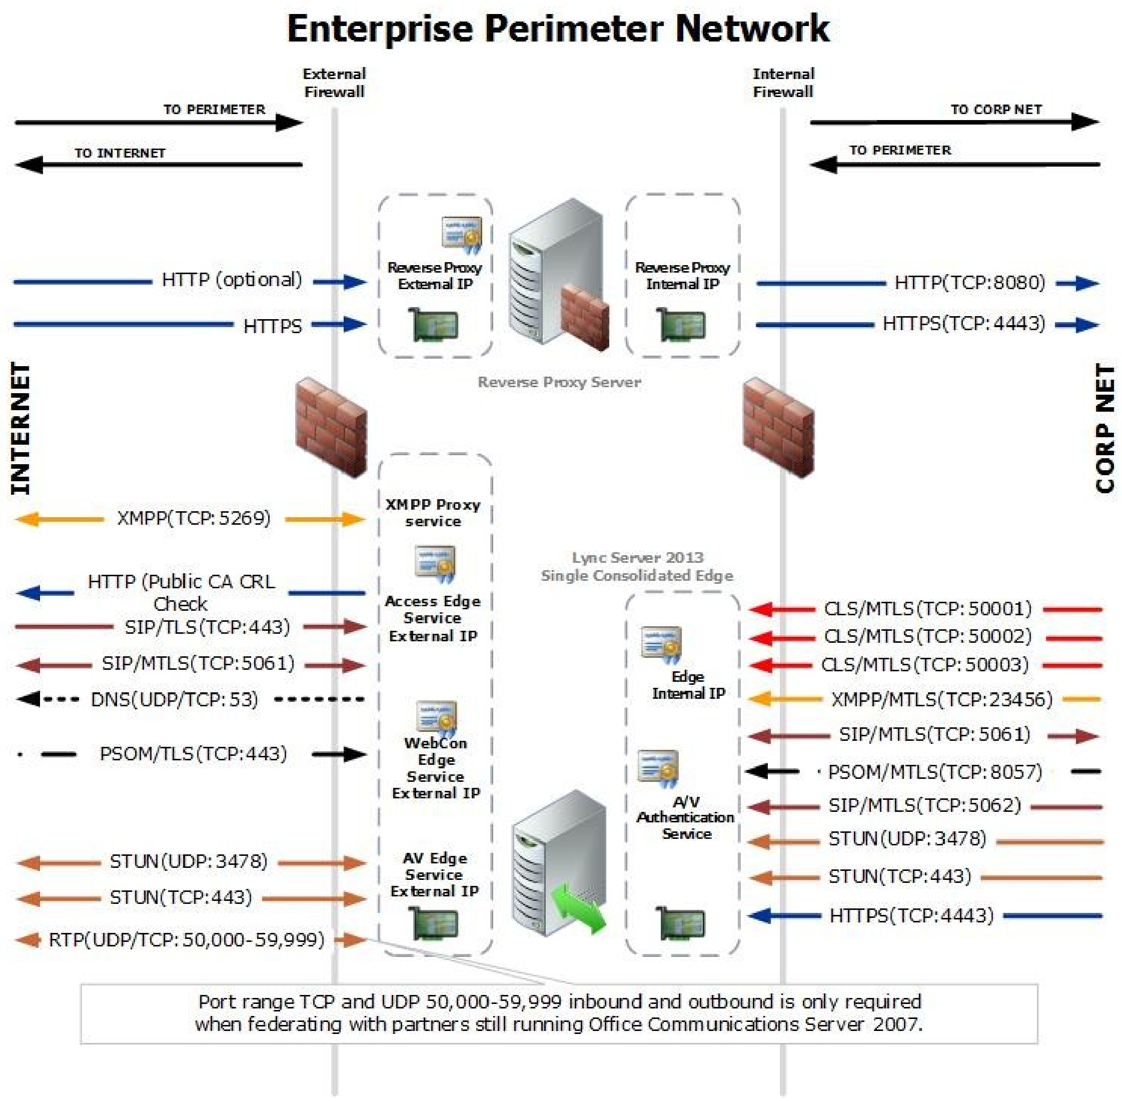
Port Summary - Single Consolidated Edge with Public IP Addresses

Planning > Network Planning for Lync Server > Port Requirements >

Topic Last Modified: *2013-02-21*

The Lync Server 2013, Edge Server functionality described in this scenario architecture is very similar to what was implemented in Lync Server 2010. The most noticeable addition is the port **5269 over TCP** entry for the extensible messaging and presence protocol (XMPP). Lync Server 2013 optionally deploys an XMPP proxy on the Edge Server or Edge pool and the XMPP gateway server on the Front End Server or Front End pool. Planning information for the reverse proxy and federation are found in Scenarios for Reverse Proxy and Scenarios for Federation, Public Instant Messaging Connectivity, and XMPP Federation sections, respectively.

In addition to IPv4, the Edge Server now supports IPv6. For clarity, only IPv4 is used in the scenarios.



Port and Protocol Details

We recommend that you open only the ports required to support the functionality for which you are providing external access.

For remote access to work for any edge service, it is mandatory that SIP traffic is allowed to flow bidirectionally as shown in the Inbound/Outbound edge traffic figure. Stated another way, the SIP messaging to and from the Access Edge service is involved in instant messaging (IM), presence, web conferencing, audio/video (A/V) and federation.

Firewall Summary for Single Consolidated Edge with Public IP Addresses: External Interface

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
XMPP/TCP/5269	Any	XMPP Proxy service (shares IP address with Access Edge service)	XMPP Proxy service accepts traffic from XMPP contacts in defined XMPP

			federations
Access/HTTP/TCP/80	Edge Server Access Edge service public IP address	Any	Certificate revocation/ CRL check and retrieval
Access/DNS/TCP/53	Edge Server Access Edge service public IP address	Any	DNS query over TCP
Access/DNS/UDP/53	Edge Server Access Edge service public IP address	Any	DNS query over UDP
Access/SIP(TLS)/ TCP/443	Any	Edge Server Access Edge service public IP address	Client-to-server SIP traffic for external user access
Access/SIP(MTLS)/ TCP/5061	Any	Edge Server Access Edge service public IP address	For federated and public IM connectivity using SIP
Access/SIP(MTLS)/ TCP/5061	Edge Server Access Edge service public IP address	Any	For federated and public IM connectivity using SIP
Web Conferencing/ PSOM(TLS)/TCP/443	Any	Edge Server Web Conferencing Edge service public IP address	Web Conferencing media
A/V/RTP/TCP/50,000-59,999	Edge Server Access Edge service public IP address	Any	Required for federating with partners running Office Communications Server 2007, Office Communications Server 2007 R2, Lync Server 2010 and Lync Server 2013.
A/V/RTP/UDP/50,000-59,999	Edge Server A/V Edge service public IP address	Any	Required only for federation with partners running Office Communications Server 2007
A/V/RTP/TCP/50,000-59,999	Any	Edge Server A/V Edge service public IP address	Required only for federation with partners running Office Communications Server 2007.
A/V/RTP/UDP/50,000-59,999	Any	Edge Server A/V Edge service public IP address	Required only for federation with partners running Office Communications

			Server 2007.
A/V/STUN,MSTURN/ UDP/3478	Edge Server A/V Edge service public IP address	Any	3478 outbound is used to determine the version of Edge Server that Lync Server is communicating with and also for media traffic from Edge Server-to-Edge Server. Required for federation with Lync Server 2010, Windows Live Messenger, and Office Communications Server 2007 R2, and also if multiple Edge pools are deployed within a company.
A/V/STUN,MSTURN/ UDP/3478	Any	Edge Server A/V Edge service public IP address	STUN/TURN negotiation of candidates over UDP/3478
A/V/STUN,MSTURN/ TCP/443	Any	Edge Server A/V Edge service public IP address	STUN/TURN negotiation of candidates over TCP/443
A/V/STUN,MSTURN/ TCP/443	Edge Server A/V Edge service public IP address	Any	STUN/TURN negotiation of candidates over TCP/443

Firewall Summary for Single Consolidated Edge with Public IP Addresses: Internal Interface

Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Comments
XMPP/MTLS/ TCP/23456	Any (can be defined as Standard Edition server IP, Standard Edition server IP address, or pool IP address running the XMPP Gateway service)	Edge Server internal interface	Outbound XMPP traffic from XMPP Gateway service running on Front End Server or Front End pool
SIP/MTLS/TCP/5061	Any (can be defined as Director, Director pool IP address, Front End Server or Front End pool IP address)	Edge Server IP, or pool that holds the internal interface	Outbound SIP traffic (from Director, Director pool IP address, Front End Server or Front End pool IP address) to Edge Server internal interface

SIP/MTLS/TCP/5061	Edge Server internal interface	Any (can be defined as Director, Director pool IP address, Front End Server or Front End pool address)	Inbound SIP traffic (to Director, Director pool IP address, Front End Server or Front End pool IP address) from Edge Server internal interface
PSOM/MTLS/TCP/8057	Any (can be defined as Front End Server IP address, or each Front End Server IP address in a Front End pool)	Edge Server internal interface	Web conferencing traffic from Front End Server or each Front End Server if in a pool, to Edge Server internal interface
SIP/MTLS/TCP/5062	Any (can be defined as Front End Server IP address, or Front End pool IP address or any Survivable Branch Appliance or Survivable Branch Server using this Edge Server)	Edge Server internal interface	Authentication of A/V users (A/V authentication service) from Front End Server or Front End pool IP address or any Survivable Branch Appliance or Survivable Branch Server using this Edge Server
STUN/MSTURN/UDP/3478	Any	Edge Server internal interface	Preferred path for A/V media transfer between internal and external users, Survivable Branch Appliance or Survivable Branch Server
STUN/MSTURN/TCP/443	Any	Edge Server internal interface	Fallback path for A/V media transfer between internal and external users, Survivable Branch Appliance or Survivable Branch Server if UDP communication cannot be established, TCP is used for file transfer and desktop sharing
HTTPS/TCP/4443	Any (can be defined as the Front End Server IP address, or pool that holds the Central Management store)	Edge Server internal interface	Replication of changes from the Central Management store to the Edge Server
MTLS/TCP/50001	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized

			Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection
MTLS/TCP/50002	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection
MTLS/TCP/50003	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection

Firewall Summary for Federation

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
Access/SIP(MTLS)/ TCP/5061	Access Edge service public IP address	Any	For federated and public IM connectivity using SIP

Firewall Summary – Public Instant Messaging Connectivity

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
Access/SIP(MTLS)/ TCP/5061	Public IM connectivity partners	Edge Server Access Edge service	For federated and public IM connectivity using SIP
Access/SIP(MTLS)/ TCP/5061	Edge Server Access Edge service	Public IM connectivity partners	For federated and public IM connectivity using SIP

Access/SIP(TLS)/ TCP/443	Clients	Edge Server Access Edge service	Client-to-server SIP traffic for external user access
A/V/RTP/TCP/50,000-59,999	Edge Server A/V Edge service	Live Messenger clients	Used for A/V sessions with Windows Live Messenger if public IM connectivity is configured.
A/V/STUN,MSTURN/ UDP/3478	Edge Server A/V Edge service	Live Messenger clients	Required for public IM connectivity with Windows Live Messenger
A/V/STUN,MSTURN/ UDP/3478	Live Messenger clients	Edge Server A/V Edge service	Required for public IM connectivity with Windows Live Messenger

Firewall Summary for Extensible Messaging and Presence Protocol

Protocol/TCP or UDP/Port	Source (IP address)	Destination (IP address)	Comments
XMPP/TCP/5269	Any	Edge Server Access Edge service interface IP address	Standard server-to-server communication port for XMPP. Allows communication to the Edge Server XMPP proxy from federated XMPP partners
XMPP/TCP/5269	Edge Server Access Edge service interface IP address	Any	Standard server-to-server communication port for XMPP. Allows communication from the Edge Server XMPP proxy to federated XMPP partners
XMPP/MTLS/ TCP/23456	Any	Each internal Edge Server Interface IP	Internal XMPP traffic from the XMPP Gateway on the Front End Server or Front End pool to the Edge Server internal IP address or each Edge pool member's internal IP address

1.3.9.10.2.3 DNS Summary - Single Consolidated Edge w ith Public IP Addresses

DNS Summary - Single Consolidated Edge with Public

IP Addresses

Network Planning for Lync Server > Domain Name System (DNS) Requirements > DNS Requirements for Edge Servers and Features >

Topic Last Modified: *2012-09-08*

DNS record requirements for remote access to Lync Server 2013 are fairly straightforward compared to those for certificates and ports. Also, many records are optional, depending on how you configure clients running Lync 2013 and whether you enable federation.

For details about Lync 2013 DNS requirements, see Determine DNS Requirements.

For details about automatic configuration of clients running Lync 2013 if split-brain DNS is not configured, see "Automatic Configuration without Split-Brain DNS" in Determine DNS Requirements.

The following table contains a summary of the DNS records that are required to support the single consolidated edge topology shown in the Single Consolidated Edge Topology figure. Note that certain DNS records are required only for automatic configuration of Lync 2013 and Lync 2010 clients. If you plan to use group policy objects (GPOs) to configure Lync clients, the associated automatic configuration records are not necessary.

IMPORTANT: Edge Server Network Adapter Requirements

To avoid routing issues, verify that there are at least two network adapters in your Edge Servers and that the default gateway is set only on the network adapter associated with the external interface. For example, as shown in the Single Consolidated Edge Topology with Public IP Addresses figure in Single Consolidated Edge with Public IP Addresses, the default gateway would point to the external router at your Internet perimeter or firewall that can provide a public IP addresses. The network relationship for Edge Server interfaces is a route relationship instead of a NAT relationship.

You can configure two network adapters in your Edge Server as follows:

- **Network adapter 1 (Internal Interface)**
  Internal interface with 172.25.33.10 assigned.
  No default gateway is defined.
  Ensure that there is a route from the network containing the Edge internal interface to any networks that contain servers running Lync Server 2013 or Lync Server 2013 clients (for example, from 172.25.33.0 to 192.168.10.0).
- **Network adapter 2 (External Interface)**
  Three public IP addresses are assigned to this network adapter, for example 131.107.155.10 for Access Edge, 131.107.155.20 for Web Conferencing Edge, 131.107.155.30 for AV Edge.

  > **Note:**
  > It is possible, though not recommended, to use a single IP address for all three Edge service interfaces. Though this does save IP addresses, it requires different port numbers for each service. The default port number is 443/TCP, which ensures that most remote firewalls will allow the traffic. Changing the port values to (for example) 5061/TCP for the Access Edge, 444/TCP for the Web Conferencing Edge and 443/TCP for the AV Edge might cause problems for remote users where a firewall that they are behind does not allow the traffic over 5061/TCP and 444/TCP. Additionally, three distinct IP addresses makes troubleshooting easier due to being able to filter on IP address.

  The Access Edge public IP address is primary with default gateway set to the public router (131.107.155.1).
  Web conferencing and A/V Edge public IP addresses are additional IP

addresses in the **Advanced** section of the properties of **Internet Protocol Version 4 (TCP/IPv4)** and **Internet Protocol Version 6 (TCP/IPv6)** of the **Local Area Connection Properties** in Windows Server.

Tip:

Configuring the Edge Server with two network adapters is one of two options. The other option is to use one network adapter for the internal side and three network adapters for the external side of the Edge Server. The main benefit of this option is a distinct network adapter per Edge Server service, and potentially more concise data collection when troubleshooting is necessary

DNS Records Required for Single Consolidated Edge with Public IP Addresses (Example)

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
External DNS/A	sip.contoso.com	131.107.155.10	Access Edge external interface (Contoso) Repeat as necessary for all SIP domains with Lync enabled users
External DNS/A	webcon.contoso.com	131.107.155.20	Web Conferencing Edge external interface
External DNS/A	av.contoso.com	131.107.155.30	A/V Edge external interface
External DNS/ SRV/443	_sip._tls.contoso.com	sip.contoso.com	Access Edge external interface. Required for automatic configuration of Lync 2013 and Lync 2010 clients to work externally. Repeat as necessary for all SIP domains with Lync enabled users.
External DNS/ SRV/5061	_sipfederationtls._tcp .contoso.com	sip.contoso.com	SIP Access Edge external interface Required for automatic DNS discovery of federated partners known as "Allowed SIP Domain" (called enhanced federation in previous releases).Repeat as necessary for all SIP domains with Lync enabled users
Internal DNS/A	lsedge.contoso.net	172.25.33.10	Consolidated Edge internal interface

Important:

The records listed in the previous table are shown with either a *.net* extension or a *.com* extension to highlight which zone they need to reside in if you are not using split-brain

DNS. If you are using split-brain DNS, all records would be in the same zone, with the only distinction being whether they are in the internal or external version. For details, see “Split-Brain DNS” in Determine DNS Requirements.

Records Required for Federation

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5061	_sipfederationtls._tcp.contoso.com	sip.contoso.com	SIP Access Edge external interface Required for automatic DNS discovery of your federation to other potential federation partners, and is known as “Allowed SIP Domains” (called enhanced federation in previous releases).Repeat as necessary for all SIP domains with Lync enabled users ◆**Important:** This SRV record is required for mobility and the push notification clearing house

DNS Summary – Public Instant Messaging Connectivity

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
External DNS/A	sip.contoso.com	Access Edge service interface	Access Edge external interface (Contoso) Repeat as necessary for all SIP domains with Lync enabled users

DNS Summary for Extensible Messaging and Presence Protocol

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5269	_xmpp-server._tcp.contoso.com	xmpp.contoso.com	XMPP proxy external interface on the Access Edge service or Edge pool.Repeat

			as necessary for all internal SIP domains with Lync enabled users where contact with XMPP contacts is allowed through the configuration of the External Access Policy through a global policy, site policy where the user is located, or user policy applied to the Lync-enabled user. An allowed XMPP domain must also be configured in the XMPP Federated Partners policy. See topics in **See Also** for additional details
External DNS/A	xmpp.contoso.com (for example)	IP address of Access Edge service on your Edge Server or Edge pool hosting XMPP proxy	Points to the Access Edge service or Edge pool that hosts the XMPP proxy service. Typically, the SRV record that you create will point to this host (A or AAAA) record

Topic Last Modified: *2012-09-08*

In the Edge Server pool topology, two or more Edge Servers are deployed as a load-balanced pool in the perimeter network of the data center. Domain Name System (DNS) load balancing is used for traffic to both the external and internal Edge interfaces.

If your organization requires support for more than 15,000 Access Edge service client connections, 1,000 active Lync Server Web Conferencing service client connections, or 500 concurrent A/V Edge sessions, and/or high availability of the Edge Server is important, this topology offers the advantages of scalability and failover support.

The figure does not show Directors, an optional server role deployed in the internal network between the Edge Servers and your Front End pools or server. For details about the topology for Directors, see Components Required for the Director. The figure represents a single reverse proxy.

Note:

The figure shown is for orientation and example IP addressing, but does not intend to represent actual communication flows with the correct incoming and outgoing traffic. The figure represents a high level view of possible traffic. Details for traffic flow as they pertain to incoming (to listening ports) and outgoing (to destination servers or clients) is represented in the Port Summary diagram in each scenario. For example, TCP 443 is actually inbound (to the Edge or reverse proxy) only, and is only a two-way flow from a protocol (TCP) perspective. Additionally, the figure shows the nature of traffic as it changes when NAT (network address translation) occurs (destination address is changed on inbound, source address is changed on outbound). Example external and internal firewall, and server interfaces are shown for reference purposes only. Finally, example default gateway and route relationships are shown, where applicable. Note also that the diagram uses the *.com* DNS zone to represent the external DNS zone for both reverse proxy and Edge Servers, and the *.net* DNS zone refers to the internal DNS zone.

New to Microsoft Lync Server 2013 is support for IPv6 addressing. Much like IPv4 addressing, IPv6 addresses must be assigned in such a way that the addresses are part of your assigned IPv6 address space. The addresses in this topic are for example only. You must acquire IPv6 addresses that will function in your deployment, provide the correct scope and will interoperate with internal and external addressing. Windows Server provides a feature that is important to transitional IPv6 operation and IPv4 to IPv6 communication called the *dual stack*. The dual stack is a separate and distinct network stack for IPv4 and for IPv6. The dual stack is what allows you to assign addressing for IPv4 and IPv6 concurrently, and allows the server to communicate with other hosts and clients based on what their requirements are.

Typical address types that you will use for IPv6 addressing will be the IPv6 global addresses (similar to public IPv4 addresses), IPv6 unique local addresses (similar to the private IPv4 address ranges) and IPv6 link-local addresses (similar to automatic private IP addresses in Windows Server for IPv4)

Network address translation technologies (NAT) for IPv6 exist that will allow for NAT IPv6 to IPv4 (commonly referred to as NAT64) and for NAT IPv6 to IPv6 (commonly referred to as NAT66). The existence of NAT technologies means that the five scenarios presented for Lync Server Edge Servers are still valid.

⚠**Warning:**

IPv6 is a complex topic and requires careful planning with your networking team and your Internet provider to ensure that the addresses you assign at the Windows server level and at the Lync Server 2013 level will work as expected. See the links at the end of this topic for additional resources on IPv6 addressing and planning.

Protocols, example IP addressing details, and server addressing are the intent of this diagram. No protocol direction is intended to be part of this diagram. Refer to the scenario Port Summary topic for detailed port and protocols.

Important:

If you are using Call Admission Control (CAC), you still must assign IPv4 addresses to the Edge Server internal interface. CAC uses IPv4 addresses and must have them available to operate.

Planning for External User Access > Scenarios for External User Access > Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT >

Topic Last Modified: *2012-09-08*

Microsoft Lync Server 2013 uses certificates to mutually authenticate other servers and to encrypt data from server to server and server to client. Certificates require name matching of the domain name system (DNS) records associated with the servers and the subject name (SN) and subject alternative name (SAN) on the certificate. To successfully map servers, DNS records and certificate entries, you must carefully plan your intended server fully qualified domain names as registered in DNS and the SN and SAN entries on the certificate.

The certificate assigned to the external interfaces of the Edge Server is requested from a public certification authority (CA). Public CAs that have demonstrated success in supplying certificates for the purposes of Unified Communications are listed in the following article: http://go.microsoft.com/fwlink/p/?linkid=3052&kbid=929395 When requesting the certificate, you can use the certificate request generated by the Lync Server Deployment Wizard or create the request manually or by a process provided by the public CA. When assigning the certificate, the certificate is assigned to the Access Edge service interface, the Web Conferencing Edge service interface, and the Audio/Video Authentication service. The Audio/Video Authentication service should not be confused with the A/V Edge service which does not use a certificate to encrypt the audio and video streams. The internal Edge Server interface can use a certificate from an internal (to your organization) CA or a certificate from a public CA. The internal interface certificate uses only the SN and does not need or use SAN entries.

Note:

The following table shows a second SIP entry (sip.fabrikam.com) in the subject alternative name list for reference. For each SIP domain in your organization, you need to add a corresponding FQDN listed in the certificate subject alternative name list.

Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT

Component	Subject name (SN)	Subject alternative names (SAN)/Order	Comments
Scaled consolidated Edge (External Edge)	sip.contoso.com	webcon.contoso.com sip.contoso.com sip.fabrikam.com	Certificate must be from a Public CA, and must have the server EKU and client EKU if public IM connectivity with AOL is to be deployed. Additionally, for scaled Edge Servers, the certificate private key must be exportable and the certificate and private key copied to each Edge Server. The certificate is assigned to the external Edge interfaces for: • Access Edge • Conferencing Edge • A/V Edge Note that SANs are automatically added to the certificate based on your definitions in Topology Builder. You add SAN entries as needed for additional SIP domains and other entries that you need to support. The subject name is replicated in the SAN and must be present for correct operation.
Scaled consolidated Edge (Internal Edge)	lsedge.contoso.net	No SAN required	Certificate can be issued by a public or private CA, and must contain the server EKU. The certificate is assigned to the internal Edge interface.

Certificate Summary – Public Instant Messaging Connectivity

Component	Subject name	Subject alternative names (SAN)/Order	Comments
External/Access Edge	sip.contoso.com	sip.contoso.com webcon.contoso.com sip.fabrikam.com	Certificate must be from a Public CA, and must have the server EKU and client EKU if public IM connectivity with AOL is to be deployed. The certificate is assigned to the external Edge interfaces for: • Access Edge • Conferencing Edge • A/V Edge Note that SANs are

			automatically added to the certificate based on your definitions in Topology Builder. You add SAN entries as needed for additional SIP domains and other entries that you need to support. The subject name is replicated in the SAN and must be present for correct operation.

Certificate Summary for Extensible Messaging and Presence Protocol

Component	**Subject name**	**Subject alternative names (SAN)/Order**	**Comments**
Assign to Access Edge service of Edge Server or Edge pool	sip.contoso.com	webcon.contoso.com sip.contoso.com sip.fabrikam.com xmpp.contoso.com ***.contoso.com**	The first three SAN entries are the normal SAN entries for a full Edge Server. The contoso.com is the entry required for federation with the XMPP partner at the root domain level. This entry will allow XMPP for all domains with the suffix *.contoso.com.

1.3.9.10.3.2 Port Summary - Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT

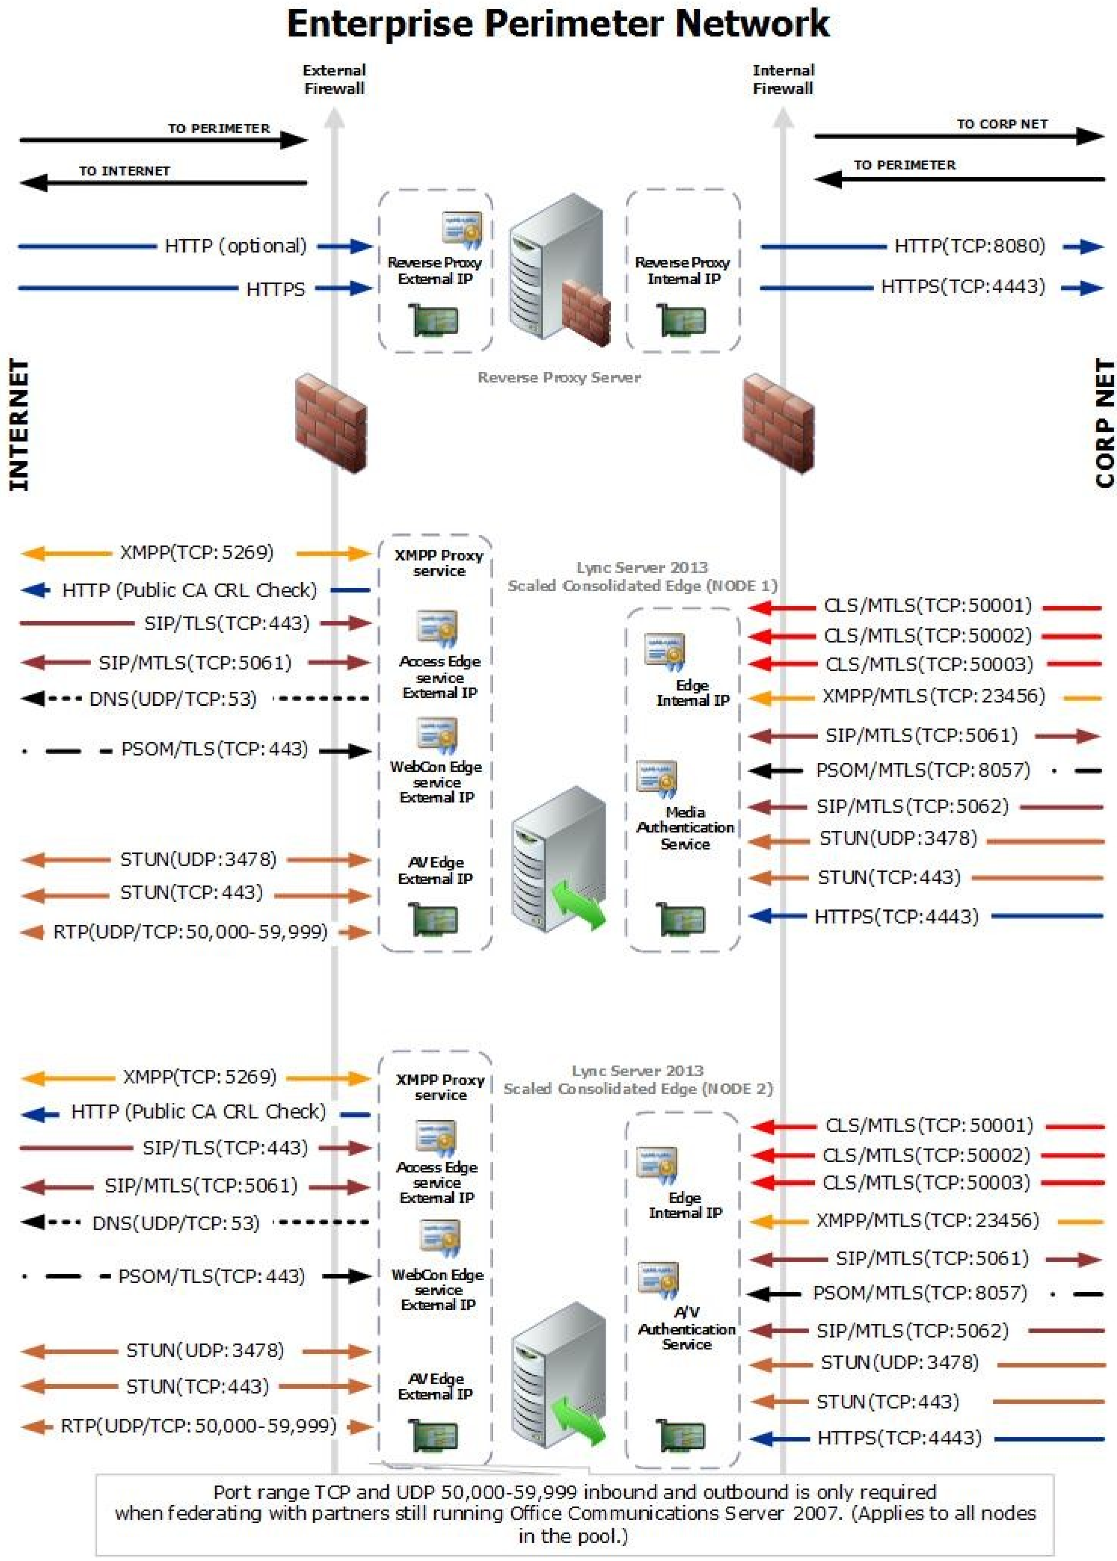
Port Summary - Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT

Planning > Network Planning for Lync Server > Port Requirements >

Topic Last Modified: *2012-12-04*

The Lync Server 2013, Edge Server functionality described in this scenario architecture is very similar to what was implemented in Lync Server 2010. The most noticeable addition is the port **5269 over TCP** entry for the extensible messaging and presence protocol (XMPP). Lync Server 2013 optionally deploys an XMPP proxy on the Edge Server or Edge pool and the XMPP gateway server on the Front End Server or Front End pool.

In addition to IPv4, the Edge Server now supports IPv6. For clarity, only IPv4 is used in the scenarios.



Port range TCP and UDP 50,000-59,999 inbound and outbound is only required when federating with partners still running Office Communications Server 2007. (Applies to all nodes in the pool.)

Port and Protocol Details

It is recommended that you open only the ports required to support the functionality for

which you are providing external access.

For remote access to work for any edge service, it is mandatory that SIP traffic is allowed to flow bi-directionally as shown in the Inbound/Outbound edge traffic figure. Stated another way, the SIP messaging to and from the Access Edge service is involved in instant messaging (IM), presence, web conferencing, audio/video (A/V) and federation.

Firewall Summary for Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT: External Interface – Node 1 and Node 2 (Example)

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
XMPP/TCP/5269	Any	XMPP Proxy service (shares IP address with Access Edge service)	XMPP Proxy service accepts traffic from XMPP contacts in defined XMPP federations
XMPP/TCP/5269	XMPP Proxy service (shares IP address with Access Edge service)	Any	XMPP Proxy service sends traffic to XMPP contacts in defined XMPP federations
Access/HTTP/TCP/80	Edge Server Access Edge service	Any	Certificate revocation/ CRL check and retrieval
Access/DNS/TCP/53	Edge Server Access Edge service	Any	DNS query over TCP
Access/DNS/UDP/53	Edge Server Access Edge service	Any	DNS query over UDP
Access/SIP(TLS)/ TCP/443	Any	Edge Server Access Edge service	Client-to-server SIP traffic for external user access
Access/SIP(MTLS)/ TCP/5061	Any	Edge Server Access Edge service	For federated and public IM connectivity using SIP
Access/SIP(MTLS)/ TCP/5061	Edge Server Access Edge service	Any	For federated and public IM connectivity using SIP
Web Conferencing/ PSOM(TLS)/TCP/443	Any	Edge Server Web Conferencing Edge service	Web Conferencing media
A/V/RTP/TCP/50,000-59,999	Edge Server A/V Edge service	Any	Required for federating with partners running Office Communications Server 2007, Office Communications Server 2007 R2, Lync Server 2010 and Lync Server 2013.
A/V/RTP/UDP/50,000-	Edge Server A/V Edge	Any	Required only for

59,999	service		federation with partners running Office Communications Server 2007.
A/V/RTP/TCP/50,000-59,999	Any	Edge Server A/V Edge service	Required only for federation with partners running Office Communications Server 2007
A/V/RTP/UDP/50,000-59,999	Any	Edge Server A/V Edge service	Required only for federation with partners running Office Communications Server 2007
A/V/STUN,MSTURN/UDP/3478	Edge Server A/V Edge service	Any	3478 outbound is used to determine the version of Edge Server that Lync Server is communicating with and also for media traffic from Edge Server-to-Edge Server. Required for federation with Lync Server 2010, Windows Live Messenger, and Office Communications Server 2007 R2, and also if multiple Edge pools are deployed within a company.
A/V/STUN,MSTURN/UDP/3478	Any	Edge Server A/V Edge service	STUN/TURN negotiation of candidates over UDP/3478
A/V/STUN,MSTURN/TCP/443	Any	Edge Server A/V Edge service	STUN/TURN negotiation of candidates over TCP/443
A/V/STUN,MSTURN/TCP/443	Edge Server A/V Edge service	Any	STUN/TURN negotiation of candidates over TCP/443

Firewall Summary for Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT: Internal Interface – Node 1 and Node 2 (Example)

Protocol/TCP or	Source IP address	Destination IP	Comments

UDP/Port		address	
XMPP/MTLS/TCP/23456	Any (can be defined as Front End Server address, or Front End pool IP address running the XMPP Gateway service)	Edge Server internal interface IP address	Outbound XMPP traffic from XMPP Gateway service running on Front End Server or Front End pool
SIP/MTLS/TCP/5061	Any (can be defined as Director, Director pool IP address, Front End Server or Front End pool IP address)	Edge Server internal interface	Outbound SIP traffic (from Director, Director pool IP address, Front End Server or Front End pool IP address) to Edge Server internal interface
SIP/MTLS/TCP/5061	Edge Server internal interface	Any (can be defined as Director, Director pool IP address, Front End Server or Front End pool IP address)	Inbound SIP traffic (to Director, Director pool IP address, Front End Server or Front End pool IP address) from Edge Server internal interface
PSOM/MTLS/TCP/8057	Any (can be defined as Front End Server IP address, or each Front End Server IP address in a Front End pool)	Edge Server internal interface	Web conferencing traffic from Front End Server or each Front End Server if in a pool, to Edge Server internal interface
SIP/MTLS/TCP/5062	Any (can be defined as Front End Server IP address, or Front End pool IP address or any Survivable Branch Appliance or Survivable Branch Server using this Edge Server)	Edge Server internal interface	Authentication of A/V users (A/V authentication service) from Front End Server or Front End pool IP address or any Survivable Branch Appliance or Survivable Branch Server using this Edge Server
STUN/MSTURN/UDP/3478	Any	Edge Server internal interface	Preferred path for A/V media transfer between internal and external users, Survivable Branch Appliance or Survivable Branch Server
STUN/MSTURN/TCP/443	Any	Edge Server internal interface	Fallback path for A/V media transfer between internal and external users, Survivable Branch Appliance or Survivable Branch

			Server if UDP communication cannot be established, TCP is used for file transfer and desktop sharing
HTTPS/TCP/4443	Any (can be defined as the Front End Server IP address, or pool that holds the Central Management store)	Edge Server internal interface	Replication of changes from the Central Management store to the Edge Server
MTLS/TCP/50001	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection
MTLS/TCP/50002	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection
MTLS/TCP/50003	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection

Firewall Summary for Federation

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
Access/SIP(MTLS)/	Access Edge service	Any	For federated and

TCP/5061	public IP address		public IM connectivity using SIP

Firewall Summary – Public Instant Messaging Connectivity

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
Access/SIP(MTLS)/ TCP/5061	Public IM connectivity partners	Edge Server Access Edge service	For federated and public IM connectivity using SIP
Access/SIP(MTLS)/ TCP/5061	Edge Server Access Edge service	Public IM connectivity partners	For federated and public IM connectivity using SIP
Access/SIP(TLS)/ TCP/443	Clients	Edge Server Access Edge service	Client-to-server SIP traffic for external user access
A/V/RTP/TCP/50,000-59,999	Edge Server A/V Edge service	Live Messenger clients	Used for A/V sessions with Windows Live Messenger if public IM connectivity is configured.
A/V/STUN,MSTURN/ UDP/3478	Edge Server A/V Edge service	Live Messenger clients	Required for public IM connectivity with Windows Live Messenger
A/V/STUN,MSTURN/ UDP/3478	Live Messenger clients	Edge Server A/V Edge service	Required for public IM connectivity with Windows Live Messenger

Firewall Summary for Extensible Messaging and Presence Protocol

Protocol/TCP or UDP/Port	Source (IP address)	Destination (IP address)	Comments
XMPP/TCP/5269	Any	Edge Server Access Edge service interface IP address	Standard server-to-server communication port for XMPP. Allows communication to the Edge Server XMPP proxy from federated XMPP partners
XMPP/TCP/5269	Edge Server Access Edge service interface IP address	Any	Standard server-to-server communication port for XMPP. Allows communication from

			the Edge Server XMPP proxy to federated XMPP partners
XMPP/MTLS/ TCP/23456	Any	Each internal Edge Server interface IP	Internal XMPP traffic from the XMPP Gateway on the Front End Server or Front End pool to the Edge Server internal IP address or each Edge pool member's internal IP address

1.3.9.10.3.3 DNS Summary - Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT

DNS Summary - Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT

Network Planning for Lync Server > Domain Name System (DNS) Requirements > DNS Requirements for Edge Servers and Features >

Topic Last Modified: *2012-09-08*

DNS record requirements for remote access to Lync Server 2013 are fairly straightforward compared to those for certificates and ports. Also, many records are optional, depending on how you configure clients running Lync 2013 and whether you enable federation.

For details about Lync 2013 DNS requirements, see Determine DNS Requirements.

For details about configuring automatic configuration of Lync 2013 clients if split-brain DNS is not configured, see the "Automatic Configuration without Split Brain DNS" section in Determine DNS Requirements.

The following table contains a summary of the DNS records that are required to support the single consolidated edge topology shown in the Single Consolidated Edge Topology figure. Note that certain DNS records are required only for automatic configuration of Lync 2013 clients. If you plan to use group policy objects (GPOs) to configure Lync clients, the associated records are not necessary.

IMPORTANT: Edge Server Network Adapter Requirements

To avoid routing issues, verify that there are at least two network adapters in your Edge Servers and that the default gateway is set only on the network adapter associated with the external interface. For example, as shown in the Scaled Consolidated Edge Scenario figure in Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT, the default gateway would point to the external firewall.

You can configure two network adapters in each of your Edge Server as follows:

- **Network adapter 1 - Node 1 (Internal Interface)**
  Internal interface with 172.25.33.10 assigned.
  No default gateway is defined.
  Ensure that there is a route from the network containing the Edge internal

interface to any networks that contain servers running Lync Server 2013 or Lync Server 2013 clients (for example, from 172.25.33.0 to 192.168.10.0).

- **Network adapter 1 - Node 2 (Internal Interface)**
  Internal interface with 172.25.33.11 assigned.
  No default gateway is defined.
  Ensure that there is a route from the network containing the Edge internal interface to any networks that contain servers running Lync Server 2013 or Lync Server 2013 clients (for example, from 172.25.33.0 to 192.168.10.0).
- **Network adapter 2 Node 1 (External Interface)**
  Three private IP addresses are assigned to this network adapter, for example 10.45.16.10 for Access Edge, 10.45.16.20 for Web Conferencing Edge, 10.45.16.30 for AV Edge.

  Note:

  It is possible, though not recommended, to use a single IP address for all three Edge service interfaces. Though this does save IP addresses, it requires different port numbers for each service. The default port number is 443/TCP, which ensures that most remote firewalls will allow the traffic. Changing the port values to (for example) 5061/TCP for the Access Edge, 444/TCP for the Web Conferencing Edge and 443/TCP for the AV Edge might cause problems for remote users where a firewall that they are behind does not allow the traffic over 5061/TCP and 444/TCP. Additionally, three distinct IP addresses makes troubleshooting easier due to being able to filter on IP address.

  The Access Edge public IP address is primary with default gateway set to the integrated router (10.45.16.1).
  Web conferencing and A/V Edge private IP addresses are additional IP addresses in the **Advanced** section of the properties of **Internet Protocol Version 4 (TCP/IPv4)** and **Internet Protocol Version 6 (TCP/IPv6)** of the **Local Area Connection Properties** in Windows Server.
- **Network adapter 2 Node 2 (External Interface)**
  Three private IP addresses are assigned to this network adapter, for example 10.45.16.11 for Access Edge, 10.45.16.21 for Web Conferencing Edge, 10.45.16.31 for AV Edge.
  The Access Edge public IP address is primary with default gateway set to the integrated router (10.45.16.1).
  Web conferencing and A/V Edge private IP addresses are additional IP addresses in the **Advanced** section of the properties of **Internet Protocol Version 4 (TCP/IPv4)** and **Internet Protocol Version 6 (TCP/IPv6)** of the **Local Area Connection Properties** in Windows Server.

Tip:

Configuring the Edge Server with two network adapters is one of two options. The other option is to use one network adapter for the internal side and three network adapters for the external side of the Edge Server. The main benefit of this option is a distinct network adapter per Edge Server service, and potentially more concise data collection when troubleshooting is necessary

DNS Records Required for Scaled Consolidated Edge, DNS Load Balancing with Private IP Addresses Using NAT (Example)

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
External DNS/A	sip.contoso.com	131.107.155.10 and 131.107.155.11	Access Edge external interface (Contoso) Repeat as necessary for all SIP domains with Lync enabled users
External DNS/A	webcon.contoso.com	131.107.155.20 and 131.107.155.21	Web Conferencing Edge external

			interface
External DNS/A	av.contoso.com	131.107.155.30 and 131.107.155.31	A/V Edge external interface
External DNS/ SRV/443	_sip._tls.contoso.com	sip.contoso.com	Access Edge external interface. Required for automatic configuration of Lync 2013 and Lync 2010 clients to work externally. Repeat as necessary for all SIP domains with Lync enabled users.
External DNS/ SRV/5061	_sipfederationtls._tcp .contoso.com	sip.contoso.com	SIP Access Edge external interface. Required for automatic DNS discovery of federated partners known as “Allowed SIP Domain” (called enhanced federation in previous releases). Repeat as necessary for all SIP domains with Lync enabled users
Internal DNS/A	lsedge.contoso.net	172.25.33.10 and 172.25.33.11	Consolidated Edge internal interface

Records Required for Federation

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5061	_sipfederationtls._tcp .contoso.com	sip.contoso.com	SIP Access Edge external interface Required for automatic DNS discovery of your federation to other potential federation partners, and is known as “Allowed SIP Domains” (called enhanced federation in previous releases).Repeat as necessary for all SIP domains with Lync enabled users ◆**Important:** This SRV record is required for mobility and the push

			notification clearing house

DNS Summary – Public Instant Messaging Connectivity

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
External DNS/A	sip.contoso.com	Access Edge service interface	Access Edge external interface (Contoso) Repeat as necessary for all SIP domains with Lync enabled users

DNS Summary for Extensible Messaging and Presence Protocol

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5269	_xmpp-server._tcp.contoso.com	xmpp.contoso.com	XMPP proxy external interface on the Access Edge service or Edge pool.Repeat as necessary for all internal SIP domains with Lync enabled users where contact with XMPP contacts is allowed through the configuration of the External Access Policy through a global policy, site policy where the user is located, or user policy applied to the Lync-enabled user. An allowed XMPP domain must also be configured in the XMPP Federated Partners policy. See topics in **See Also** for additional details
External DNS/A	xmpp.contoso.com (for example)	IP address of Access Edge service on your Edge Server or Edge pool hosting XMPP proxy	Points to the Access Edge service or Edge pool that hosts the XMPP proxy service. Typically, the SRV record that you create will point to

			this host (A or AAAA) record

1.3.9.10.4 Scaled Consolidated Edge, DNS Load Balancing w ith Public IP Addresses

Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses

Planning > Planning for External User Access > Scenarios for External User Access >

Topic Last Modified: *2012-09-08*

In the Edge Server pool topology, two or more Edge Servers are deployed as a load-balanced pool in the perimeter network of the data center. Domain Name System (DNS) load balancing is used for traffic to both the external and internal Edge interfaces.

If your organization requires support for more than 15,000 Access Edge service client connections, 1,000 active Lync Server Web Conferencing service client connections, or 500 concurrent A/V Edge sessions, and/or high availability of the Edge Server is important, this topology offers the advantages of scalability and failover support.

The figure does not show Directors, an optional server role deployed in the internal network between the Edge Servers and your Front End pools or server. For details about the topology for Directors, see Components Required for the Director. The figure represents a single reverse proxy.

Note:

The figure shown is for orientation and example IP addressing, but does not intend to represent actual communication flows with the correct incoming and outgoing traffic. The figure represents a high level view of possible traffic. Details for traffic flow as they pertain to incoming (to listening ports) and outgoing (to destination servers or clients) is represented in the Port Summary diagram in each scenario. For example, TCP 443 is actually inbound (to the Edge or reverse proxy) only, and is only a two-way flow from a protocol (TCP) perspective. Additionally, the figure shows the nature of traffic as it changes when NAT (network address translation) occurs (destination address is changed on inbound, source address is changed on outbound). Example external and internal firewall, and server interfaces are shown for reference purposes only. Finally, example default gateway and route relationships are shown, where applicable. Note also that the diagram uses the *.com* DNS zone to represent the external DNS zone for both reverse proxy and Edge Servers, and the *.net* DNS zone refers to the internal DNS zone.

New to Microsoft Lync Server 2013 is support for IPv6 addressing. Much like IPv4 addressing, IPv6 addresses must be assigned in such a way that the addresses are part of your assigned IPv6 address space. The addresses in this topic are for example only. You must acquire IPv6 addresses that will function in your deployment, provide the correct scope and will interoperate with internal and external addressing. Windows Server provides a feature that is important to transitional IPv6 operation and IPv4 to IPv6 communication called the *dual stack*. The dual stack is a separate and distinct network stack for IPv4 and for IPv6. The dual stack is what allows you to assign addressing for IPv4 and IPv6 concurrently, and allows the server to communicate with other hosts and clients based on what their requirements are.

Typical address types that you will use for IPv6 addressing will be the IPv6 global addresses (similar to public IPv4 addresses), IPv6 unique local addresses (similar to the private IPv4 address ranges) and IPv6 link-local addresses (similar to automatic private IP addresses in Windows Server for IPv4)

Network address translation technologies (NAT) for IPv6 exist that will allow for NAT IPv6 to IPv4 (commonly referred to as NAT64) and for NAT IPv6 to IPv6 (commonly referred to as NAT66). The existence of NAT technologies means that the five scenarios presented for Lync Server Edge Servers are still valid.

⚠ **Warning:**

IPv6 is a complex topic and requires careful planning with your networking team and your Internet provider to ensure that the addresses you assign at the Windows server level and at the Lync Server 2013 level will work as expected. See the links at the end of this topic for additional resources on IPv6 addressing and planning.

Protocols, example IP addressing details, and server addressing are the intent of this diagram. No protocol direction is intended to be part of this diagram. Refer to the scenario Port Summary topic for detailed port and protocols.

Important:

If you are using Call Admission Control (CAC), you still must assign IPv4 addresses to the Edge Server internal interface. CAC uses IPv4 addresses and must have them available to operate.

Planning for External User Access > Scenarios for External User Access > Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses >

Topic Last Modified: *2012-09-08*

Microsoft Lync Server 2013 uses certificates to mutually authenticate other servers and to encrypt data from server to server and server to client. Certificates require name matching of the domain name system (DNS) records associated with the servers and the subject name (SN) and subject alternative name (SAN) on the certificate. To successfully map servers, DNS records and certificate entries, you must carefully plan your intended server fully qualified domain names as registered in DNS and the SN and SAN entries on the certificate.

The certificate assigned to the external interfaces of the Edge Server is requested from a public certification authority (CA). Public CAs that have demonstrated success in supplying certificates for the purposes of Unified Communications are listed in the following article: http://go.microsoft.com/fwlink/p/?linkid=3052&kbid=929395 When requesting the certificate, you can use the certificate request generated by the Lync Server Deployment Wizard or create the request manually or by a process provided by the public CA. When assigning the certificate, the certificate is assigned to the Access Edge service interface, the Web Conferencing Edge service interface, and the Audio/Video Authentication service. The Audio/Video Authentication service should not be confused with the A/V Edge service which does not use a certificate to encrypt the audio and video streams. The internal Edge Server interface can use a certificate from an internal (to your organization) CA or a certificate from a public CA. The internal interface certificate uses only the SN and does not need or use SAN entries.

Note:

The following table shows a second SIP entry (sip.fabrikam.com) in the subject alternative name list for reference. For each SIP domain in your organization, you need to add a corresponding FQDN listed in the certificate subject alternative name list.

Scaled Consolidated Edge using DNS Load Balancing with Public IP Addresses

Component	Subject name	Subject	Comments

		alternative names (SAN)/Order	
Scaled consolidated Edge (External Edge)	sip.contoso.com	webcon.contoso.com sip.contoso.com sip.fabrikam.com	Certificate must be from a Public CA, and must have the server EKU and client EKU if public IM connectivity with AOL is to be deployed. Additionally, for scaled Edge Servers, the certificate private key must be exportable and the certificate and private key copied to each Edge Server. The certificate is assigned to the external Edge interfaces for: • Access Edge • Conferencing Edge • A/V Edge Note that SANs are automatically added to the certificate based on your definitions in Topology Builder. You add SAN entries as needed for additional SIP domains and other entries that you need to support. The subject name is replicated in the SAN and must be present for correct operation.
Scaled consolidated Edge (Internal Edge)	lsedge.contoso.net	No SAN required	Certificate can be issued by a public or private CA, and must contain the server EKU. The certificate is assigned to the internal Edge interface.

Certificate Summary – Public Instant Messaging Connectivity

Component	Subject name	Subject alternative names (SAN)/Order	Comments
External/Access Edge	sip.contoso.com	sip.contoso.com webcon.contoso.com sip.fabrikam.com	Certificate must be from a Public CA, and must have the server EKU and client EKU if public IM connectivity with AOL is to be deployed. The certificate is assigned to the external Edge interfaces for: • Access Edge • Conferencing Edge • A/V Edge Note that SANs are automatically added to the

			certificate based on your definitions in Topology Builder. You add SAN entries as needed for additional SIP domains and other entries that you need to support. The subject name is replicated in the SAN and must be present for correct operation.

Certificate Summary for Extensible Messaging and Presence Protocol

Component	**Subject name**	**Subject alternative names (SAN)/Order**	**Comments**
Assign to Access Edge service of Edge Server or Edge pool	sip.contoso.com	webcon.contoso.com sip.contoso.com sip.fabrikam.com xmpp.contoso.com ***.contoso.com**	The first three SAN entries are the normal SAN entries for a full Edge Server. The contoso.com is the entry required for federation with the XMPP partner at the root domain level. This entry will allow XMPP for all domains with the suffix *.contoso.com.

1.3.9.10.4.2 Port Summary - Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses

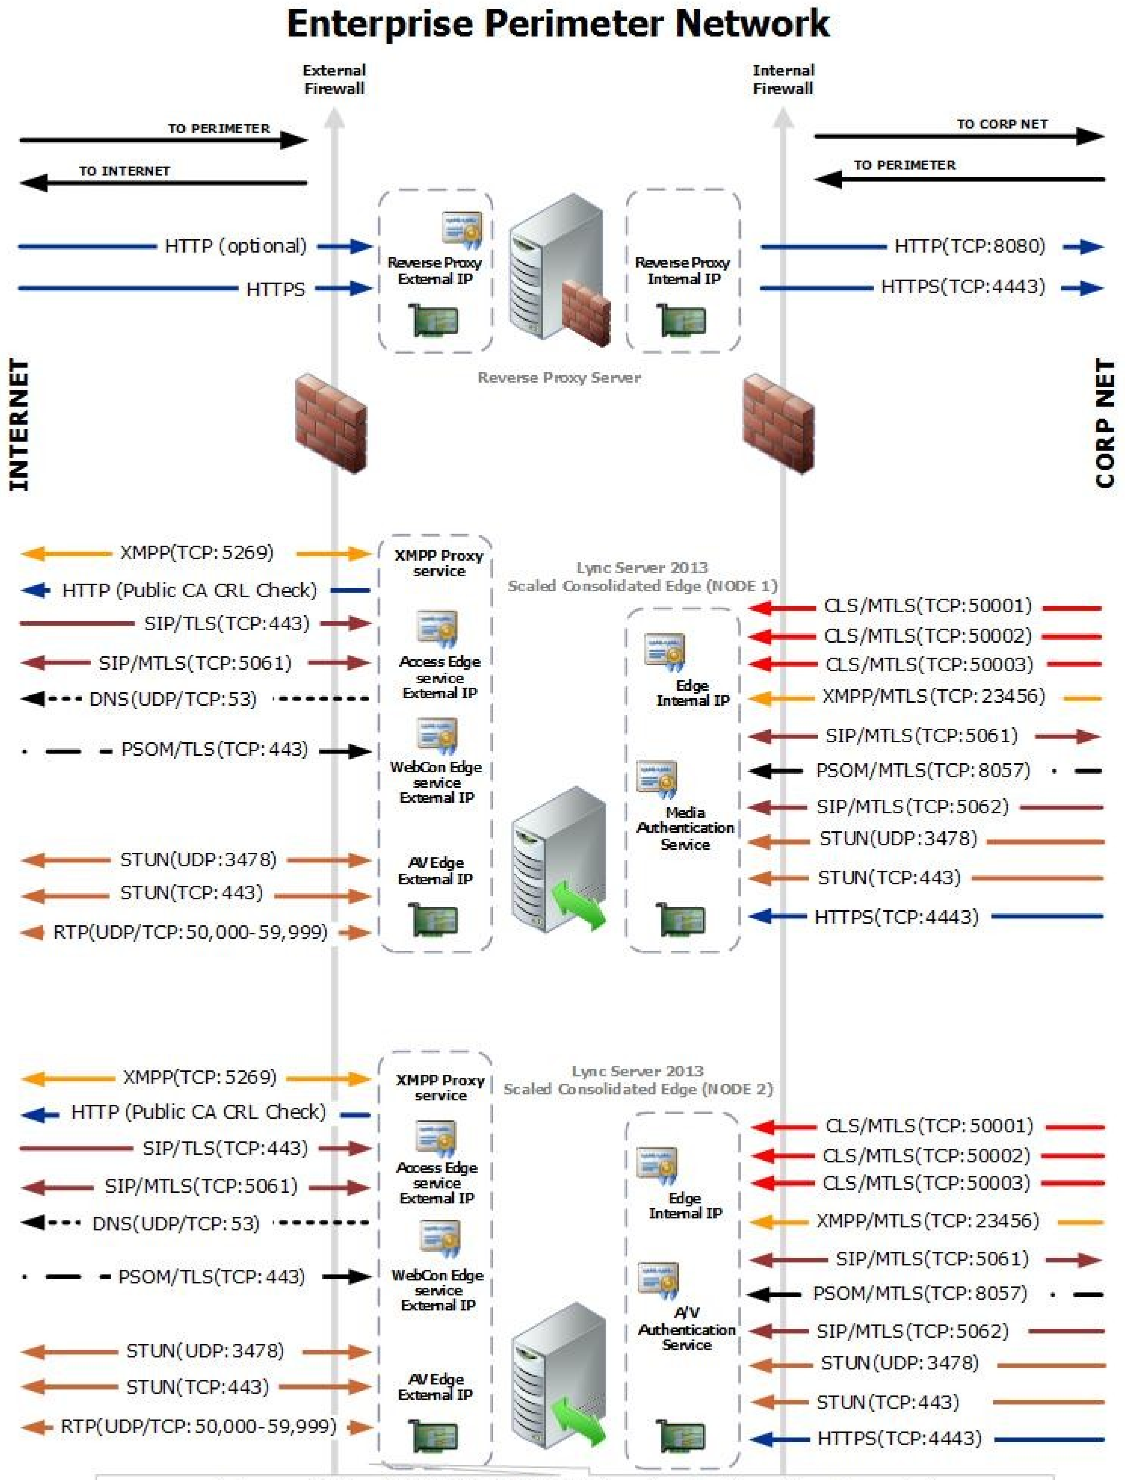
Port Summary - Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses

Planning > Network Planning for Lync Server > Port Requirements >

Topic Last Modified: *2012-12-04*

The Lync Server 2013, Edge Server functionality described in this scenario architecture is very similar to what was implemented in Lync Server 2010. The most noticeable addition is the port **5269 over TCP** entry for the extensible messaging and presence protocol (XMPP). Lync Server 2013 optionally deploys an XMPP proxy on the Edge Server or Edge pool and the XMPP gateway server on the Front End Server or Front End pool.

In addition to IPv4, the Edge Server now supports IPv6. For clarity, only IPv4 is used in the scenarios.



Port range TCP and UDP 50,000-59,999 inbound and outbound is only required when federating with partners still running Office Communications Server 2007. (Applies to all nodes in the pool.)

Port and Protocol Details

It is recommended that you open only the ports required to support the functionality for

which you are providing external access.

For remote access to work for any edge service, it is mandatory that SIP traffic is allowed to flow bi-directionally as shown in the Inbound/Outbound edge traffic figure. Stated another way, the SIP messaging to and from the Access Edge service is involved in instant messaging (IM), presence, web conferencing, audio/video (A/V) and federation.

Firewall Summary for Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses: External Interface – Node 1 and Node 2 (Example)

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
XMPP/TCP/5269	Any	XMPP Proxy service (shares IP address with Access Edge service)	XMPP Proxy service accepts traffic from XMPP contacts in defined XMPP federations
Access/HTTP/TCP/80	Edge Server Access Edge service public IP address	Any	Certificate revocation/ CRL check and retrieval
Access/DNS/TCP/53	Edge Server Access Edge service public IP address	Any	DNS query over TCP
Access/DNS/UDP/53	Edge Server Access Edge service public IP address	Any	DNS query over UDP
Access/SIP(TLS)/ TCP/443	Any	Edge Server Access Edge service public IP address	Client-to-server SIP traffic for external user access
Access/SIP(MTLS)/ TCP/5061	Any	Edge Server Access Edge service public IP address	For federated and public IM connectivity using SIP
Access/SIP(MTLS)/ TCP/5061	Edge Server Access Edge service public IP address	Any	For federated and public IM connectivity using SIP
Web Conferencing/ PSOM(TLS)TCP/443	Any	Edge Server Web Conferencing Edge service public IP address	Web Conferencing media
A/V/RTP/TCP/50,000-59,999	Edge Server A/V Edge service public IP address	Any	Required for federating with partners running Office Communications Server 2007, Office Communications Server 2007 R2, Lync Server 2010 and Lync Server 2013.
A/V/RTP/UDP/50,000-59,999	Edge Server A/V Edge service public IP	Any	Required only for federation with

	address		partners running Office Communications Server 2007.
A/V/RTP/TCP/50,000-59,999	Any	Edge Server A/V Edge service public IP address	Required only for federation with partners running Office Communications Server 2007
A/V/RTP/UDP/50,000-59,999	Any	Edge Server A/V Edge service public IP address	Required only for federation with partners running Office Communications Server 2007
A/V/STUN,MSTURN/ UDP/3478	Edge Server A/V Edge service public IP address	Any	3478 outbound is used to determine the version of Edge Server that Lync Server is communicating with and also for media traffic from Edge Server-to-Edge Server. Required for federation with Lync Server 2010, Windows Live Messenger, and Office Communications Server 2007 R2, and also if multiple Edge pools are deployed within a company.
A/V/STUN,MSTURN/ UDP/3478	Any	Edge Server A/V Edge service public IP address	STUN/TURN negotiation of candidates over UDP/3478
A/V/STUN,MSTURN/ TCP/443	Any	Edge Server A/V Edge service public IP address	STUN/TURN negotiation of candidates over TCP/443
A/V/STUN,MSTURN/ TCP/443	Edge Server A/V Edge service	Any	STUN/TURN negotiation of candidates over TCP/443

Firewall Summary for Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses: Internal Interface – Node 1 and Node 2 (Example)

Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Comments

XMPP/MTLS/TCP/23456	Any (can be defined as Front End Server address, or Front End pool IP address running the XMPP Gateway service)	Edge Server internal interface	Outbound XMPP traffic from XMPP Gateway service running on Front End Server or Front End pool
SIP/MTLS/TCP/5061	Any (can be defined as Director, Director pool IP address, Front End Server or Front End pool IP address)	Edge Server internal interface	Outbound SIP traffic (from Director, Director pool IP address, Front End Server or Front End pool IP address) to Edge Server internal interface
SIP/MTLS/TCP/5061	Edge Server internal interface	Any (can be defined as Director, Director pool IP address, Front End Server or Front End pool IP address)	Inbound SIP traffic (to Director, Director pool IP address, Front End Server or Front End pool IP address) from Edge Server internal interface
PSOM/MTLS/TCP/8057	Any (can be defined as Front End Server IP address, or each Front End Server IP address in a Front End pool)	Edge Server internal interface	Web conferencing traffic from Front End Server or each Front End Server if in a pool, to Edge Server internal interface
SIP/MTLS/TCP/5062	Any (can be defined as Front End Server IP address, or Front End pool IP address or any Survivable Branch Appliance or Survivable Branch Server using this Edge Server)	Edge Server internal interface	Authentication of A/V users (A/V authentication service) from Front End Server or Front End pool IP address or any Survivable Branch Appliance or Survivable Branch Server using this Edge Server
STUN/MSTURN/UDP/3478	Any	Edge Server internal interface	Preferred path for A/V media transfer between internal and external users, Survivable Branch Appliance or Survivable Branch Server
STUN/MSTURN/TCP/443	Any	Edge Server internal interface	Fallback path for A/V media transfer between internal and external users, Survivable Branch Appliance or Survivable Branch Server if UDP

			communication cannot be established, TCP is used for file transfer and desktop sharing
HTTPS/TCP/4443	Any (can be defined as the Front End Server IP address, or pool that holds the Central Management store)	Edge Server internal interface	Replication of changes from the Central Management store to the Edge Server
MTLS/TCP/50001	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection
MTLS/TCP/50002	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection
MTLS/TCP/50003	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection

Firewall Summary for Federation

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
Access/SIP(MTLS)/ TCP/5061	Access Edge service public IP address	Any	For federated and public IM connectivity

			using SIP

Firewall Summary – Public Instant Messaging Connectivity

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
Access/SIP(MTLS)/ TCP/5061	Public IM connectivity partners	Edge Server Access Edge service	For federated and public IM connectivity using SIP
Access/SIP(MTLS)/ TCP/5061	Edge Server Access Edge service	Public IM connectivity partners	For federated and public IM connectivity using SIP
Access/SIP(TLS)/ TCP/443	Clients	Edge Server Access Edge service	Client-to-server SIP traffic for external user access
A/V/RTP/TCP/50,000-59,999	Edge Server A/V Edge service	Live Messenger clients	Used for A/V sessions with Windows Live Messenger if public IM connectivity is configured.
A/V/STUN,MSTURN/ UDP/3478	Edge Server A/V Edge service	Live Messenger clients	Required for public IM connectivity with Windows Live Messenger
A/V/STUN,MSTURN/ UDP/3478	Live Messenger clients	Edge Server A/V Edge service	Required for public IM connectivity with Windows Live Messenger

Firewall Summary for Extensible Messaging and Presence Protocol

Protocol/TCP or UDP/Port	Source (IP address)	Destination (IP address)	Comments
XMPP/TCP/5269	Any	Edge Server Access Edge serviceinterface IP address	Standard server-to-server communication port for XMPP. Allows communication to the Edge Server XMPP proxy from federated XMPP partners
XMPP/TCP/5269	Edge Server Access Edge serviceinterface IP address	Any	Standard server-to-server communication port for XMPP. Allows communication from the Edge Server XMPP

			proxy to federated XMPP partners
XMPP/MTLS/ TCP/23456	Any	Each internal Edge Server Interface IP	Internal XMPP traffic from the XMPP Gateway on the Front End Server or Front End pool to the Edge Server internal IP address or each Edge pool member's internal IP address

1.3.9.10.4.3 DNS Summary - Scaled Consolidated Edge, DNS Load Balancing w ith Public IP Addresses

DNS Summary - Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses

Network Planning for Lync Server > Domain Name System (DNS) Requirements > DNS Requirements for Edge Servers and Features >

Topic Last Modified: *2012-10-20*

DNS record requirements for remote access to Lync Server 2013 are fairly straightforward compared to those for certificates and ports. Also, many records are optional, depending on how you configure clients running Lync 2013 and whether you enable federation.

For details about Lync 2013 DNS requirements, see Determine DNS Requirements.

For details about configuring automatic configuration of Lync 2013 clients if split-brain DNS is not configured, see the "Automatic Configuration without Split Brain DNS" section in Determine DNS Requirements.

The following table contains a summary of the DNS records that are required to support the single consolidated edge topology shown in the Single Consolidated Edge Topology figure. Note that certain DNS records are required only for automatic configuration of Lync 2013 clients. If you plan to use group policy objects (GPOs) to configure Lync clients, the associated records are not necessary.

IMPORTANT: Edge Server Network Adapter Requirements

To avoid routing issues, verify that there are at least two network adapters in your Edge Servers and that the default gateway is set only on the network adapter associated with the external interface. For example, as shown in the Scaled Consolidated Edge Scenario figure in Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses , the default gateway would point to the external firewall.

You can configure two network adapters in each of your Edge Server as follows:

- **Network adapter 1 - Node 1 (Internal Interface)**
  Internal interface with 172.25.33.10 assigned.
  No default gateway is defined.
  Ensure that there is a route from the network containing the Edge internal interface to any networks that contain servers running Lync Server 2013 or

Lync Server 2013 clients (for example, from 172.25.33.0 to 192.168.10.0).

- **Network adapter 1 - Node 2 (Internal Interface)**
  Internal interface with 172.25.33.11 assigned.
  No default gateway is defined.
  Ensure that there is a route from the network containing the Edge internal interface to any networks that contain servers running Lync Server 2013 or Lync Server 2013 clients (for example, from 172.25.33.0 to 192.168.10.0).
- **Network adapter 2 Node 1 (External Interface)**
  Three private IP addresses are assigned to this network adapter, for example 131.107.155.10 for Access Edge service, 131.107.155.20 for Web Conferencing Edge service, 131.107.155.30 for A/V Edge service.
  The Access Edge service public IP address is primary with default gateway set to the public router (131.107.155.1).
  Web Conferencing Edge service and A/V Edge service private IP addresses are additional IP addresses in the **Advanced** section of the properties of **Internet Protocol Version 4 (TCP/IPv4)** and **Internet Protocol Version 6 (TCP/IPv6)** of the **Local Area Connection Properties** in Windows Server.

  Note:
  It is possible, though not recommended, to use a single IP address for all three Edge service interfaces. Though this does save IP addresses, it requires different port numbers for each service. The default port number is 443/TCP, which ensures that most remote firewalls will allow the traffic. Changing the port values to (for example) 5061/TCP for the Access Edge service, 444/TCP for the Web Conferencing Edge service and 443/TCP for the A/V Edge service might cause problems for remote users where a firewall that they are behind does not allow the traffic over 5061/TCP and 444/TCP. Additionally, three distinct IP addresses makes troubleshooting easier due to being able to filter on IP address.

- **Network adapter 2 Node 2 (External Interface)**
  Three private IP addresses are assigned to this network adapter, for example 131.107.155.11 for Access Edge service, 131.107.155.21 for Web Conferencing Edge service, 131.107.155.31 for A/V Edge service.
  The Access Edge service public IP address is primary with default gateway set to the public router (131.107.155.1).
  Web Conferencing Edge service and A/V Edge service private IP addresses are additional IP addresses in the **Advanced** section of the properties of **Internet Protocol Version 4 (TCP/IPv4)** and **Internet Protocol Version 6 (TCP/IPv6)** of the **Local Area Connection Properties** in Windows Server.

Tip:
Configuring the Edge Server with two network adapters is one of two options. The other option is to use one network adapter for the internal side and three network adapters for the external side of the Edge Server. The main benefit of this option is a distinct network adapter per Edge Server service, and potentially more concise data collection when troubleshooting is necessary

DNS Records Required for Scaled Consolidated Edge, DNS Load Balancing with Public IP Addresses (Example)

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
External DNS/A	sip.contoso.com	131.107.155.10 and 131.107.155.11	Access Edge service external interface (Contoso) Repeat as necessary for all SIP domains with Lync enabled users
External DNS/A	webcon.contoso.com	131.107.155.20 and 131.107.155.21	Web Conferencing Edge service external

			interface
External DNS/A	av.contoso.com	131.107.155.30 and 131.107.155.31	A/V Edge service external interface
External DNS/ SRV/443	_sip._tls.contoso.com	sip.contoso.com	Access Edge service external interface. Required for automatic configuration of Lync 2013 and Lync 2010 clients to work externally. Repeat as necessary for all SIP domains with Lync enabled users.
External DNS/ SRV/5061	_sipfederationtls._tcp .contoso.com	sip.contoso.com	Access Edge service external interface Required for automatic DNS discovery of federated partners known as “Allowed SIP Domain” (called enhanced federation in previous releases). Repeat as necessary for all SIP domains with Lync enabled users
Internal DNS/A	lsedge.contoso.net	172.25.33.10 and 172.25.33.11	Consolidated Edge internal interface

Records Required for Federation

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5061	_sipfederationtls._tcp .contoso.com	sip.contoso.com	SIP Access Edge service external interface Required for automatic DNS discovery of your federation to other potential federation partners, and is known as “Allowed SIP Domains” (called enhanced federation in previous releases). **◆Important:** Repeat as necessary for all SIP domains with Lync enabled users and Microsoft Lync Mobile clients

			that use either the Push Notification Service or the Apple Push Notification service

DNS Summary – Public Instant Messaging Connectivity

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
External DNS/A	sip.contoso.com	Access Edge service interface	Access Edge service external interface (Contoso)Repeat as necessary for all SIP domains with Lync enabled users

DNS Summary for Extensible Messaging and Presence Protocol

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5269	_xmpp-server._tcp.contoso.com	xmpp.contoso.com	XMPP proxy external interface on the Access Edge service or Edge pool.Repeat as necessary for all internal SIP domains with Lync enabled users where contact with XMPP contacts is allowed through the configuration of the External Access Policy through a global policy, site policy where the user is located, or user policy applied to the Lync-enabled user. An allowed XMPP domain must also be configured in the XMPP Federated Partners policy. See topics in **See Also** for additional details
External DNS/A	xmpp.contoso.com (for example)	IP address of Access Edge service on your Edge Server or Edge pool hosting XMPP	Points to the Access Edge service or Edge pool that hosts the XMPP proxy service.

		proxy	Typically, the SRV record that you create will point to this host (A or AAAA) record

Topic Last Modified: *2012-10-21*

In the Edge pool topology, two or more Edge Servers are deployed as a load-balanced pool in the perimeter network of the data center. Hardware load balancing is used for traffic to both the external and internal Edge Server interfaces.

If your organization requires support for more than 15,000 Access Edge service client connections, 1,000 active Web Conferencing Edge service client connections, or 500 concurrent A/V Edge service sessions, and high availability of the Edge Server is important, this topology offers the advantages of scalability and failover support.

The figure does not show Directors, an optional server role deployed in the internal network between the Edge Servers and your Front End pools or server. . For details about the topology for Directors, see Components Required for the Director.

Note:

The figure shown is for orientation and example IP addressing, but does not intend to represent actual communication flows with the correct incoming and outgoing traffic. The figure represents a high level view of possible traffic. Details for traffic flow as they pertain to incoming (to listening ports) and outgoing (to destination servers or clients) is represented in the Port Summary diagram in each scenario. For example, TCP 443 is actually inbound (to the Edge Server or reverse proxy) only, and is only a two-way flow from a protocol (TCP) perspective. Additionally, the figure shows the nature of traffic as it changes when NAT (network address translation) occurs (destination address is changed on inbound, source address is changed on outbound). Example external and internal firewall, and server interfaces are shown for reference purposes only. Finally, example default gateway and route relationships are shown, where applicable. Note also that the diagram uses the *.com* DNS zone to represent the external DNS zone for both reverse proxy and Edge Servers, and the *.net* DNS zone refers to the internal DNS zone.

New to Microsoft Lync Server 2013 is support for IPv6 addressing. Much like IPv4 addressing, IPv6 addresses must be assigned in such a way that the addresses are part of your assigned IPv6 address space. The addresses in this topic are for example only. You must acquire IPv6 addresses that will function in your deployment, provide the correct scope and will interoperate with internal and external addressing. Windows Server provides a feature that is important to transitional IPv6 operation and IPv4 to IPv6 communication called the *dual stack*. The dual stack is a separate and distinct network stack for IPv4 and for IPv6. The dual stack is what allows you to assign addressing for IPv4 and IPv6 concurrently, and allows the server to communicate with other hosts and clients based on what their requirements are.

Typical address types that you will use for IPv6 addressing will be the IPv6 global addresses (similar to public IPv4 addresses), IPv6 unique local addresses (similar to the private IPv4 address ranges) and IPv6 link-local addresses (similar to automatic private IP addresses in Windows Server for IPv4)

Network address translation technologies (NAT) for IPv6 exist that will allow for NAT IPv6 to IPv4 (commonly referred to as NAT64) and for NAT IPv6 to IPv6 (commonly referred to as NAT66). The existence of NAT technologies means that the five scenarios presented for Lync Server Edge Servers are still valid.

⚠**Warning:**

IPv6 is a complex topic and requires careful planning with your networking team and your Internet provider to ensure that the addresses you assign at the Windows server level and at the Lync Server 2013 level will work as expected. See the links at the end of this topic for additional resources on IPv6 addressing and planning.

Hardware Load Balancer Configuration

For details, see the “Hardware Load Balancer Requirements for A/V Edge” section in Components Required for External User Access.

Protocols, example IP addressing details, and server addressing are the intent of this diagram. No protocol direction is intended to be part of this diagram. Refer to the scenario Port Summary topic for detailed port and protocols.

◆Important:

If you are using Call Admission Control (CAC), you still must assign IPv4 addresses to the Edge Server internal interface. CAC uses IPv4 addresses and must have them available to operate.

Planning for External User Access > Scenarios for External User Access > Scaled Consolidated Edge with Hardware Load Balancers >

Topic Last Modified: *2012-10-22*

Microsoft Lync Server 2013 uses certificates to mutually authenticate other servers and to encrypt data from server to server and server to client. Certificates require name matching of the domain name system (DNS) records associated with the servers and the subject name (SN) and subject alternative name (SAN) on the certificate. To successfully map servers, DNS records and certificate entries, you must carefully plan your intended server fully qualified domain names as registered in DNS and the SN and SAN entries on the certificate.

The certificate assigned to the external interfaces of the Edge Server is requested from a public certification authority (CA). Public CAs that have demonstrated success in supplying certificates for the purposes of Unified Communications are listed in the following article: http://go.microsoft.com/fwlink/p/?linkid=3052&kbid=929395. When requesting the certificate, you can use the certificate request generated by the Lync Server Deployment Wizard or create the request manually or by a process provided by the public CA. When assigning the certificate, the certificate is assigned to the Access Edge service interface, the Web Conferencing Edge service interface, and the Audio/Video Authentication service. The Audio/Video Authentication service should not be confused with the A/V Edge service, which does not use a certificate to encrypt the audio and video streams. The internal Edge Server interface can use a certificate from an internal (to your organization) CA or a certificate from a public CA. The internal interface certificate uses only the SN and does not need or use SAN entries.

Note:
The following table shows a second SIP entry (sip.fabrikam.com) in the subject alternative name list for reference. For each SIP domain in your organization, you need to add a corresponding FQDN listed in the certificate subject alternative name list.

Certificates Required for Scaled Consolidated Edge with Hardware Load Balancers

Component	Subject name	Subject alternative names (SAN)/Order	Comments
Single	sip.contoso.com	webcon.contoso.com	Certificate must be from a Public CA, and must have the server

consolidated Edge Server (External Edge)		sip.contoso.com sip.fabrikam.com	EKU and client EKU if public IM connectivity with AOL is to be deployed. Additionally, for scaled Edge Servers, the certificate private key must be exportable and the certificate and private key copied to each Edge Server.The certificate is assigned to the external Edge interfaces for: • Access Edge service • Web Conferencing Edge service • A/V Edge service Note that SANs are automatically added to the certificate based on your definitions in Topology Builder. You add SAN entries as needed for additional SIP domains and other entries that you need to support. The subject name is replicated in the SAN and must be present for correct operation.
Single consolidated Edge Server (Internal Edge)	lsedge.contoso.net	No SAN required	Certificate can be issued by a public or private CA, and must contain the server EKU. The certificate is assigned to the internal Edge Server interface.

Certificate Summary – Public Instant Messaging Connectivity

Component	Subject name	Subject alternative names (SAN)/Order	Comments
External/Access Edge service	sip.contoso.com	sip.contoso.com webcon.contoso.com sip.fabrikam.com	Certificate must be from a Public CA, and must have the server EKU and client EKU if public IM connectivity with AOL is to be deployed. The certificate is assigned to the external Edge interfaces for: • Access Edge service • Web Conferencing Edge service • A/V Edge service Note that SANs are automatically added to the certificate based on your definitions in Topology Builder.

			You add SAN entries as needed for additional SIP domains and other entries that you need to support. The subject name is replicated in the SAN and must be present for correct operation.

Certificate Summary for Extensible Messaging and Presence Protocol

Component	Subject name	Subject alternative names (SAN)/Order	Comments
Assign to Access Edge service of Edge Server or Edge pool	sip.contoso.com	webcon.contoso.com sip.contoso.com sip.fabrikam.com xmpp.contoso.com ***.contoso.com**	The first three SAN entries are the normal SAN entries for a full Edge Server. The contoso.com is the entry required for federation with the XMPP partner at the root domain level. This entry will allow XMPP for all domains with the suffix *.contoso.com.

1.3.9.10.5.2 Port Summary - Scaled Consolidated Edge w ith Hardw are Load Balancers

Port Summary - Scaled Consolidated Edge with Hardware Load Balancers

Planning > Network Planning for Lync Server > Port Requirements >

Topic Last Modified: *2012-12-04*

The Lync Server 2013, Edge Server functionality described in this scenario architecture is very similar to what was implemented in Lync Server 2010. The most noticeable addition is the port **5269 over TCP** entry for the extensible messaging and presence protocol (XMPP). Lync Server 2013 optionally deploys an XMPP proxy on the Edge Server or Edge pool and the XMPP gateway server on the Front End Server or Front End pool.

In addition to IPv4, the Edge Server now supports IPv6. For clarity, only IPv4 is used in the scenarios.

Port range TCP and UDP 50,000-59,999 inbound and outbound is only required when federating with partners still running Office Communications Server 2007. (Applies to all nodes in a pool)

Port and Protocol Details

It is recommended that you open only the ports required to support the functionality for which you are providing external access.

For remote access to work for any edge service, it is mandatory that SIP traffic is allowed to flow bi-directionally as shown in the Inbound/Outbound edge traffic figure. Stated another way, the SIP messaging to and from the Access Edge service is involved in instant messaging (IM), presence, web conferencing, audio/video (A/V) and federation.

Firewall Summary for Scaled Consolidated Edge, Hardware Load Balanced: External Interface – Node 1 and Node 2 (Example)

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
Access/HTTP/TCP/80	Edge Server Access Edge service public IP address	Any	Certificate revocation/ CRL check and retrieval
Access/DNS/TCP/53	Edge Server Access Edge service public IP address	Any	DNS query over TCP
Access/DNS/UDP/53	Edge Server Access Edge service public IP address	Any	DNS query over UDP
A/V/RTP/TCP/50,000-59,999	Edge Server A/V Edge service IP address	Any	Required for federating with partners running Office Communications Server 2007, Office Communications Server 2007 R2, Lync Server 2010 and Lync Server 2013.
A/V/RTP/UDP/50,000-59,999	Edge Server A/V Edge service public IP address	Any	Required only for federation with partners running Office Communications Server 2007.
A/V/RTP/TCP/50,000-59,999	Any	Edge Server A/V Edge service public IP address	Required only for federation with partners running Office Communications Server 2007
A/V/RTP/UDP/50,000-59,999	Any	Edge Server A/V Edge service public IP address	Required only for federation with partners running Office Communications Server 2007
A/V/STUN,MSTURN/ UDP/3478	Edge Server A/V Edge service public IP address	Any	3478 outbound is used to determine the version of Edge Server that Lync Server is communicating with and also for media

			traffic from Edge Server-to-Edge Server. Required for federation with Lync Server 2010, Windows Live Messenger, and Office Communications Server 2007 R2, and also if multiple Edge pools are deployed within a company.
A/V/STUN,MSTURN/ UDP/3478	Any	Edge Server A/V Edge service public IP address	STUN/TURN negotiation of candidates over UDP/3478
A/V/STUN,MSTURN/ TCP/443	Any	Edge Server A/V Edge service public IP address	STUN/TURN negotiation of candidates over TCP/443
A/V/STUN,MSTURN/ TCP/443	Edge Server A/V Edge service public IP address	Any	STUN/TURN negotiation of candidates over TCP/443

Firewall Summary for Scaled Consolidated Edge, Hardware Load Balanced: Internal Interface Node 1 and Node 2

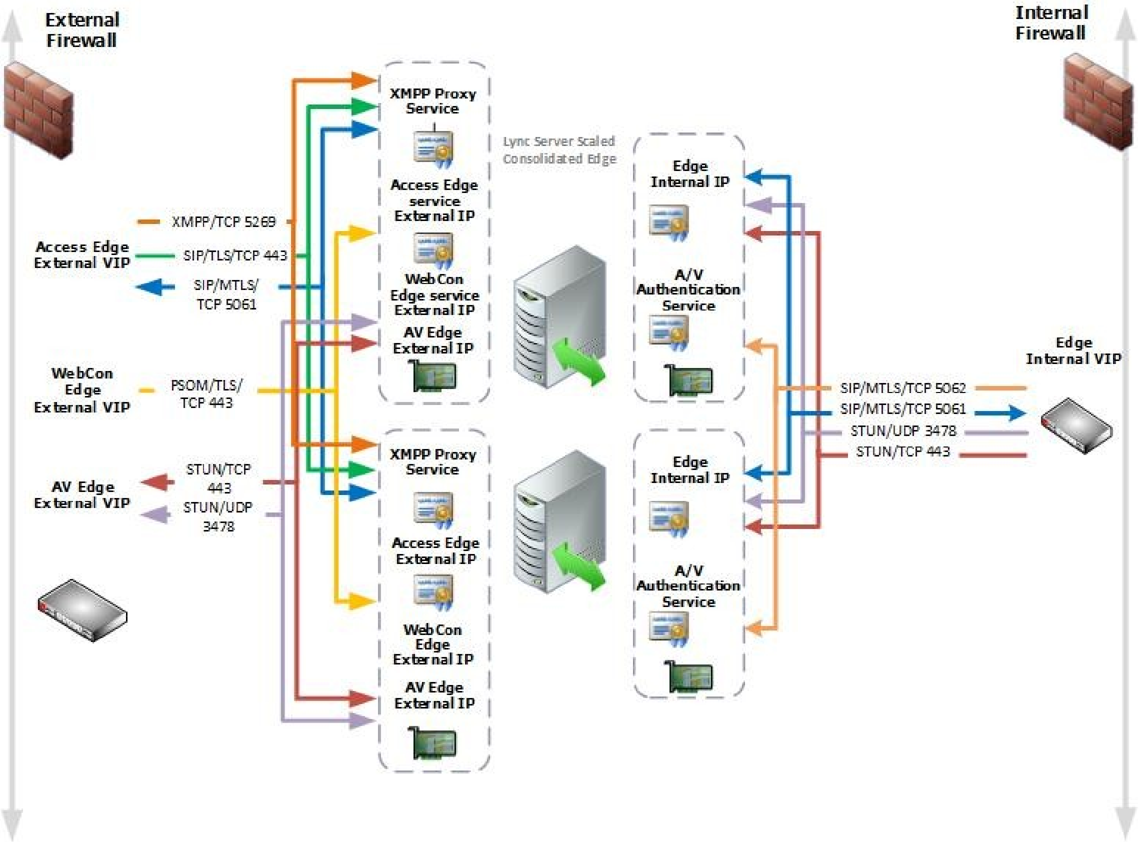
Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
XMPP/MTLS/ TCP/23456	Any (can be defined as Front End Server address, or Front End pool virtual IP address running the XMPP Gateway service)	Edge Server internal interface	Outbound XMPP traffic from XMPP Gateway service running on Front End Server or Front End pool
HTTPS/TCP/4443	Any (can be defined as the Front End Server server IP or pool that holds the Central Management store)	Edge Server Internal interface	Replication of changes from the Central Management store to the Edge Server
PSOM/MTLS/TCP/8057	Any (can be defined as Director IP, Front End Server IP or Pool virtual IP)	Edge Server Internal interface	Web conferencing traffic from Internal deployment to Internal Edge Server interface
STUN/MSTURN/ UDP/3478	Any (can be defined as Director IP, Front End Server IP or Pool virtual IP)	Edge Server Internal interface	Preferred path for A/V media transfer between internal and external users, Survivable Branch Appliance or

			Survivable Branch Server
STUN/MSTURN/ TCP/443	Any (can be defined as Director IP, Front End Server IP or Pool virtual IP)	Edge Server Internal interface	Fallback path for A/V media transfer between internal and external users, Survivable Branch Appliance or Survivable Branch Server if UDP communication cannot be established, TCP is used for file transfer and desktop sharing
MTLS/TCP/50001	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection
MTLS/TCP/50002	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection
MTLS/TCP/50003	Any	Edge Server internal interface	Centralized Logging Service controller using Lync Server Management Shell and Centralized Logging Service cmdlets, ClsController command line (ClsController.exe) or agent (ClsAgent.exe) commands and log collection

Hardware load balancers have specific requirements when deployed to provide availability and load balancing for Lync Server. The requirements are defined in the following figure and tables. Third party vendors may use different terminology for the requirements defined here. It will be necessary to map the requirements of Lync Server to the features and configuration options provided by your hardware load balancer vendor.

When configuring hardware load balancers, consider the following requirements:

- Source Network Address Translation (SNAT) can be configured on the hardware load balancer (HLB) for Access Edge service and Web Conferencing Edge service
- SNAT cannot be configured on the A/V Edge service– the A/V Edge service must respond with the real server address, not the HLB virtual IP (VIP), for simple traversal of UDP over NAT (STUN)/traversal using relay NAT (TURN)/ federation TURN (FTURN) to work properly
- Public IP addresses are used on each server interface and on the VIPs of the HLB, and your public IP address requirements are N+1, where there is a public IP address for each real server interface and one for each HLB VIP. Where you have 2 Edge servers in the pool, this results in 6 public IP addresses, where 3 are used for the HLB VIPs, and one for each Edge server interface (a total of six for the servers)
- For the Access Edge service and Web Conferencing Edge service, (and using NAT on the HLB) the client contacts the VIP, the VIP changes the source IP address from the client to its own IP address. The server interface addresses the return address to the VIP, the VIP changes the source address from the server interface IP address and sends the packet to the client
- For the A/V Edge service, the VIP must NOT change the source IP address, and the real server address is returned to the client directly – you cannot configure NAT on the HLB for AV traffic
- For AV, the external firewall will retain the real server public IP address for all packets
- Once established, client to A/V Edge service communication is to the real server, not the HLB
- Internal edge to internal servers and clients must be routed, and persistent routes are set for all internal networks that host servers or clients
- The HLB Access Edge service VIP will act as the default gateway for each Edge server interface



External Port Settings Required for Scaled Consolidated Edge, Hardware Load Balanced: External Interface Virtual IPs

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
XMPP/TCP/5269	Any	XMPP Proxy service (shares IP address with Access Edge service)	XMPP Proxy service accepts traffic from XMPP contacts in defined XMPP federations
XMPP/TCP/5269	XMPP Proxy service (shares IP address with Access Edge service)	Any	XMPP Proxy service sends traffic to XMPP contacts in defined XMPP federations
Access/SIP(TLS)/ TCP/443	Any	Access Edge service public VIP address	Client-to-server SIP traffic for external user access
Access/SIP(MTLS)/ TCP/5061	Any	Access Edge service public VIP address	SIP signaling, federated and public IM connectivity using SIP
Access/SIP(MTLS)/ TCP/5061	Access Edge service public VIP address	Federated partner	SIP signaling, federated and public IM connectivity using SIP

Web Conferencing/ PSOM(TLS)/TCP/443	Any	Edge Server Web Conferencing Edge service public VIP address	Web Conferencing media
A/V/STUN,MSTURN/ UDP/3478	Any	Edge Server A/V Edge service public VIP address	STUN/TURN negotiation of candidates over UDP/3478
A/V/STUN,MSTURN/ TCP/443	Any	Edge Server A/V Edge service public VIP address	STUN/TURN negotiation of candidates over TCP/443

Firewall Summary for Scaled Consolidated Edge, Hardware Load Balanced: Internal Interface Virtual IPs

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
Access/SIP(MTLS)/ TCP/5061	Any (can be defined as Director, Director pool virtual IP address, Front End Server or Front End pool virtual IP address)	Edge Server Internal VIP interface	Outbound SIP traffic (from Director, Director pool virtual IP address, Front End Server or Front End pool virtual IP address)to Internal Edge VIP
Access/SIP(MTLS)/ TCP/5061	Edge Server Internal VIP interface	Any (can be defined as Director, Director pool virtual IP address, Front End Server or Front End pool virtual IP address)	Inbound SIP traffic (to Director, Director pool virtual IP address, Front End Server or Front End pool virtual IP address) from Edge Server internal interface
SIP/MTLS/TCP/5062	Any (can be defined as Front End Server IP address, or Front End pool IP address or any Survivable Branch Appliance or Survivable Branch Server using this Edge Server)	Edge Server Internal VIP interface	Authentication of A/V users (A/V authentication service) from Front End Server or Front End pool IP address or any Survivable Branch Appliance or Survivable Branch Server using this Edge Server
STUN/MSTURN/ UDP/3478	Any	Edge Server Internal VIP interface	Preferred path for A/V media transfer between internal and external users
STUN/MSTURN/ TCP/443	Any	Edge Server Internal VIP interface	Fallback path for A/V media transfer between internal and external users if UDP communication cannot

			be established, TCP is used for file transfer and desktop sharing
STUN/MSTURN/ TCP/443	Edge Server Internal VIP interface	Any	Fallback path for A/V media transfer between internal and external users if UDP communication cannot be established, TCP is used for file transfer and desktop sharing

1.3.9.10.5.3 DNS Summary - Scaled Consolidated Edge w ith Hardw are Load Balancers

DNS Summary - Scaled Consolidated Edge with Hardware Load Balancers

Network Planning for Lync Server > Domain Name System (DNS) Requirements > DNS Requirements for Edge Servers and Features >

Topic Last Modified: *2013-01-27*

DNS record requirements for remote access to Lync Server 2013 are fairly straightforward compared to those for certificates and ports. Also, many records are optional, depending on how you configure clients running Lync 2013 and whether you enable federation.

For details about Lync 2013 DNS requirements, see Determine DNS Requirements.

For details about configuring automatic configuration of Lync 2013 clients if split-brain DNS is not configured, see the "Automatic Configuration without Split Brain DNS" section in Determine DNS Requirements.

The following table contains a summary of the DNS records that are required to support the Scaled Consolidated Edge Topology (Hardware Load Balanced) figure. Note that certain DNS records are required only for automatic configuration for Lync clients. If you plan to use group policy objects (GPOs) to configure Lync clients, the associated records are not necessary.

IMPORTANT: Edge Server Network Adapter Requirements

To avoid routing issues, verify that there are at least two network adapters in your Edge Servers and that the default gateway is set only on the network adapter associated with the external interface. For example, as shown in the Scaled Consolidated Edge Scenario figure in Scaled Consolidated Edge with Hardware Load Balancers, the default gateway would point to the external firewall.

You can configure two network adapters in each of your Edge Servers as follows:

- **Network adapter 1 (Internal Interface)**
  Internal interface with 172.25.33.10 assigned.
  No default gateway.
  Ensure there is a route from the network containing the Edge Server internal interface to any networks that contain Lync Server clients or servers running Lync Server (for example, from 172.25.33.0 to 192.168.10.0).
- **Network adapter 2 (External Interface)**

Three public IP addresses are assigned to this network adapter, for example 131.107.155.10 for Access Edge service, 131.107.155.20 for Web Conferencing Edge service, 131.107.155.30 for A/V Edge service.

Note:

The IP addresses that are assigned to the actual external network interfaces of the Edge Server may depend on which hardware load balancer you choose. Refer to the documentation for your hardware load balancer to understand the actual IP address requirements.
It is possible, though not recommended, to use a single IP address for all three Edge service interfaces. Though this does save IP addresses, it requires different port numbers for each service. The default port number is 443/TCP, which ensures that most remote firewalls will allow the traffic. Changing the port values to (for example) 5061/TCP for the Access Edge service, 444/TCP for the Web Conferencing Edge service and 443/TCP for the A/V Edge service might cause problems for remote users where a firewall that they are behind does not allow the traffic over 5061/TCP and 444/TCP. Additionally, three distinct IP addresses makes troubleshooting easier due to being able to filter on IP address.

Access Edge service IP address is primary with default gateway set to Internet-facing router (131.107.155.1).
Web Conferencing Edge service and A/V Edge service IP addresses secondary.

Tip:

Configuring the Edge Server with two network adapters is one of two options. The other option is to use one network adapter for the internal side and three network adapters for the external side of the Edge Server. The main benefit of this option is a distinct network adapter per Edge Server service, and potentially more concise data collection when troubleshooting is necessary

DNS Records Required for Scaled Consolidated Edge, Hardware Load Balanced (Example)

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
External DNS/A	sip.contoso.com	131.107.155.10	Access Edge service external interface (Contoso). Repeat as necessary for all SIP domains with Lync enabled users
External DNS/A	webcon.contoso.com	131.107.155.20	Web Conferencing Edge service external interface
External DNS/A	av.contoso.com	131.107.155.30	A/V Edge service external interface
External DNS/ SRV/443	_sip._tls.contoso.com	sip.contoso.com	Access Edge service external interface. Required for automatic configuration of Lync 2013 and Lync 2010 clients to work externally. Repeat as necessary for all SIP domains with Lync enabled users.
External DNS/	_sipfederationtls._tcp	sip.contoso.com	SIP Access Edge

SRV/5061	.contoso.com		service external interface Required for automatic DNS discovery of federated partners known as "Allowed SIP Domain" (called enhanced federation in previous releases). Repeat as necessary for all SIP domains with Lync enabled users and Microsoft Lync Mobile clients that use either the Push Notification Service or the Apple Push Notification service
Internal DNS/A	lsedge.contoso.net	172.25.33.10	Consolidated Edge internal interface

1.3.9.10.6 Planning for Autodiscover

Planning for Autodiscover

Planning > Planning for External User Access > Scenarios for External User Access >

Topic Last Modified: *2013-02-16*

Autodiscover was introduced for Lync Server in the Cumulative Update for Lync Server 2010: November 2011. The primary purpose for this initial implementation of Autodiscover was to provide a means for Lync Mobile to locate the Mobility service (Mcx). The Autodiscover service in Lync Server 2013 is now a service used by all clients to locate server and user services. The Microsoft Lync Server 2013 Autodiscover service runs on Directors and Front End Servers.

💡**Tip:**
For a more technical understanding of Autodiscover and what is communicated to clients, see Understanding Autodiscover. Mobility is still a distinct scenario and the Mobility services still require some special planning. For additional details, see Planning for Mobility.

When Autodiscover was introduced in Lync Server 2010, there were compromises that needed to be made in order to implement a service that required potential certificate changes to existing server deployments. Autodiscover could be used over port TCP 443 for HTTPS or over port TCP 80 for HTTP. If the decision was made to use HTTPS, certificates on reverse proxies, Directors, and Front End Servers needed to be reissued in order to accommodate the required `lyncdiscover.<domain>` and `lyncdiscoverinternal.<domain>` DNS records. If the decision was to use HTTP, the reissue of certificates could be avoided by using DNS CNAME (or alias) records to use existing names on the certificates. Using HTTP did mean that the initial communications were unencrypted.

Because Lync Server 2013 uses Autodiscover for all clients, the main scenario is to use HTTPS exclusively and to create certificates with lyncdiscover.<domain> as part of the configuration of reverse proxies, Directors and Front End Servers. If you are implementing Autodiscover into an upgraded deployment from Lync Server 2010, you may want to use

HTTP to avoid reissuing certificates. Guidance for both scenarios is provided in the following sections.

Important:

The subject alternative name list on certificates used by the external web services publishing rule must contain a *lyncdiscover.<sipdomain>* entry for each SIP domain within your organization. For details about the subject alternative name entries that are required for Directors, Front End Servers, and reverse proxies, see Certificate Summary - Autodiscover.

- Certificate Summary - Autodiscover
- Port Summary - Autodiscover
- DNS Summary - Autodiscover
- Hybrid and Split-Domain - Autodiscover

1.3.9.10.6.1 Certificate Summary - Autodiscover

Certificate Summary - Autodiscover

Planning for External User Access > Scenarios for External User Access > Planning for Autodiscover >

Topic Last Modified: *2013-02-14*

The Lync Server 2013 Autodiscover Service runs on the Director and Front End pool servers, and when published in DNS, can be used by Lync clients to locate server and user services. If you are upgrading from Lync Server 2010 and did not deploy Mobility, before clients can use automatic discovery, you must modify certificate subject alternative name lists on any Director and Front End Server running the Autodiscover Service. In addition, it may be necessary to modify the subject alternative name lists on certificates used for external web service publishing rules on reverse proxies.

The decision about whether to use subject alternative name lists on reverse proxies is based on whether you publish the Autodiscover Service on port 80 or on port 443:

- **Published on port 80** No certificate changes are required if the initial query to the Autodiscover Service occurs over port 80. This is because mobile devices running Lync will access the reverse proxy on port 80 externally and then be bridged to a Director or Front End Server on port 8080 internally. For details, see the "Initial Autodiscover Process Using Port 80" section Technical Requirements for Mobility.
- **Published on port 443** The subject alternative name list on certificates used by the external web services publishing rule must contain a *lyncdiscover.<sipdomain>* entry for each SIP domain within your organization.

  Important:

  We highly recommend using HTTPS over HTTP. HTTPS uses certificates to encrypt traffic. HTTP does not provide for encryption, and any data sent will be plain text.

Reissuing certificates by using an internal certificate authority is typically a simple process. But for public certificates used on the web service publishing rule, adding multiple subject alternative name entries can become expensive. To work around this issue, we support the initial automatic discovery connection over port 80, which is then redirected to port 8080 on the Director or Front End Server.

Note:

If your Lync Server 2013 infrastructure uses internal certificates that are issued from an internal certification authority (CA) and you plan to support mobile devices connecting wirelessly, either the root certificate chain from the internal CA must be installed on the mobile devices or you must change to a public certificate on your Lync Server 2013 infrastructure.

This topic describes the added subject alternative names required for the Director, Front End Server and reverse proxy. Only the added subject alternative names (SAN) are referenced. Refer to the planning sections for guidance on the other entries on certificates. For details, see Scenarios for the Director, Scenarios for External User Access, and Scenarios for Reverse Proxy.

The following tables define the Autodiscover SAN entries for the Director pool, the Front End pool, and the reverse proxy:

Director Pool Certificate Requirements

Description	Subject alternative name entry
Internal Autodiscover Service URL	SAN=lyncdiscoverinternal.<*internal domain name*>
External Autodiscover Service URL	SAN=lyncdiscover.<*sipdomain*>

Note:
You assign the newly updated certificate with the new SAN entry to the Default certificate. Alternatively, you can use SAN=*.<*sipdomain*>.

Front End Pool Certificate Requirements

Description	Subject alternative name entry
Internal Autodiscover Service URL	SAN=lyncdiscoverinternal.<*internal domain name*>
External Autodiscover Service URL	SAN=lyncdiscover.<*sipdomain*>

Note:
You assign the newly updated certificate with the new SAN entry to the Default certificate. Alternatively, you can use SAN=*.<*sipdomain*>

Reverse Proxy (Public CA) Certificate Requirements

Description	Subject alternative name entry
External Autodiscover Service URL	SAN=lyncdiscover.<*sipdomain*>

Note:
You assign the newly updated certificate with the new SAN entry to the SSL Listener on the reverse proxy.

1.3.9.10.6.2 Port Summary - Autodiscover

Port Summary - Autodiscover

Planning for External User Access > Scenarios for External User Access > Planning for Autodiscover >

Topic Last Modified: *2013-03-05*

The Lync Server 2013 Autodiscover Service runs on the Director and Front End pool servers, and when published in DNS using the `lyncdiscover.<domain>` and `lyncdiscoverinternal.<domain>` host records, can be used by clients to locate Lync Server features. In order for mobile devices running Lync Mobile to use Autodiscover, you may first need to modify certificate subject alternative name lists on any Director and

Front End Server running the Autodiscover Service. In addition, it may be necessary to modify the subject alternative name lists on certificates used for external web service publishing rules on reverse proxies.

The decision about whether to use subject alternative name lists on reverse proxies is based on whether you publish the Autodiscover Service on port 80 or on port 443:

- **Published on port 80** For Mobile devices, no certificate changes are required if the initial query to the Autodiscover Service occurs over port 80. This is because mobile devices running Lync will access the reverse proxy on port 80 externally and then be redirected to a Director or Front End Server on port 8080 internally.
- **Published on port 443** The subject alternative name list on certificates used by the external web services publishing rule must contain a `lyncdiscover.<sipdomain>` entry for each SIP domain within your organization.

◆**Important:**
For new installations or upgrades from Lync Server 2010 where you deployed Mobility, you either used Port 80 for Autodiscover of the Mobility service, or reissued certificates with the proper subject name and subject alternative names in place. Review the certificates on your Director and Front End Server to confirm which path you chose.

Firewall Details for Reverse Proxy Server: External Interface

Protocol/TCP or UDP/Port	**Source IP Address**	**Destination IP Address**	**Notes**
HTTP/TCP/80	Any	Reverse proxy listener	(Optional) Redirection to HTTPS if user enters http://*<publishedSiteFQDN>*. Also required if using Office Web Apps for conferencing and the Autodiscover Service for mobile devices running Lync in situations where the organization does not want to modify the external web service publishing rule certificate.
HTTPS/TCP/443	Any	Reverse proxy listener	Address book downloads, Address Book Web Query service, Autodiscover, client updates, meeting content, device updates, group expansion, Office Web Apps for conferencing, dial-in conferencing, and meetings.

Firewall Details for Reverse Proxy Server: Internal Interface

Protocol/TCP or UDP/Port	Source IP Address	Destination IP Address	Notes
HTTP/TCP/8080	Internal reverse proxy interface	Front End Server, Front End pool, Director, Director pool, Office Web Apps for conferencing	Required if using the Autodiscover Service for mobile devices running Lync in situations where the organization does not want to modify the external web service publishing rule certificate. Traffic sent to port 80 on the reverse proxy external interface is redirected to a pool on port 8080 from the reverse proxy internal interface so that the pool Web Services can distinguish it from internal web traffic.
HTTPS/TCP/4443	Internal reverse proxy interface	Front End Server, Front End pool, Director, Director pool, Office Web Apps for conferencing	Traffic sent to port 443 on the reverse proxy external interface is redirected to a pool on port 4443 from the reverse proxy internal interface so that the pool web services can distinguish it from internal web traffic.

1.3.9.10.6.3 DNS Summary - Autodiscover

DNS Summary - Autodiscover

See Also

Planning for External User Access > Scenarios for External User Access > Planning for Autodiscover >

Topic Last Modified: *2013-02-13*

Autodiscover is a flexible service in that it will accept communication over HTTP or HTTPS. To accomplish this, the domain name system (DNS) and the certificates used by servers that host the Autodiscover service must be configured correctly. Certificate requirements are covered in Certificate Summary - Autodiscover.

Important:

DNS lookup logic for the Lync Server clients uses a specific order of resolution. You should always include both the lyncdiscoverinternal.<domain> and the lyncdiscover.<domain> in your DNS. Excluding the lyncdiscoverinternal.<domain> record will cause internal clients to fail to connect to the intended services or receive the incorrect Autodiscover response.

Internal DNS Records

Record type	Host name	Resolves to

CNAME	Lyncdiscoverinternal.*<internal domain name>*	Internal Web Services FQDN for your Director pool, if you have one, or for your Front End pool if you do not have a Director.
A (host, if IPv6, AAAA)	lyncdiscoverinternal.*<internal domain name>*	Internal Web Services IP address (virtual IP (VIP) address if you use a load balancer) of your Director pool, if you have one, or of your Front End pool if you do not have a Director.

You need to create one of the following external DNS records:

External DNS Records

Record type	Host name	Resolves to
CNAME	lyncdiscover.*<sipdomain>*	External Web Services FQDN for your Director pool, if you have one, or for your Front End pool if you do not have a Director.
A (host, if IPv6, AAAA)	lyncdiscover.*<sipdomain>*	External or public IP address of the reverse proxy.

Note:

External traffic goes through the reverse proxy.

Note:

Mobile device clients do not support multiple Secure Sockets Layer (SSL) certificates from different domains. Therefore, CNAME redirection to different domains is not supported over HTTPS. For example, a DNS CNAME record for lyncdiscover.contoso.com that redirects to an address of director.contoso.net is not supported over HTTPS. In such a topology, a mobile device client needs to use HTTP for the first request, so that the CNAME redirection is resolved over HTTP. Subsequent requests then use HTTPS. To support this scenario, you need to configure your reverse proxy with a web publishing rule for port 80 (HTTP). For details, see "To create a web publishing rule for port 80" in Configuring the Reverse Proxy for Mobility. CNAME redirection to the same domain is supported over HTTPS. In this case, the destination domain's certificate covers the originating domain.

Configuring the Reverse Proxy for Mobility

Concepts

Certificate Summary - Autodiscover

1.3.9.10.6.4 Hybrid and Split-Domain - Autodiscover

Hybrid and Split-Domain - Autodiscover

Planning for External User Access > Scenarios for External User Access > Planning for Autodiscover >

Topic Last Modified: *2013-02-14*

A shared SIP address space, also known as a *split-domain* deployment, or a *hybrid* deployment, is a configuration where users are deployed across an on-premise deployment and an online environment. The desired outcome is to have a user, regardless of where their home server is located (on-premise or online), log into the deployment and be redirected to their home server location. To accomplish this, the Autodiscover feature of Lync Server 2013 is used to redirect the online user to the online topology. You can do this by configuring the Autodiscover uniform resource locator (URL) by using the Lync Server Management Shell, the **Get-CsHostingProvider** cmdlet, and the **Set-CsHostingProvider** cmdlet.

Mobility for the Split Domain Deployment

You will need to collect and record the following deployed attributes:

- From the Lync Server Management Shell, type

```
Get-CsHostingProvider
```

- In the results, find the online provider with the attribute **ProxyFQDN**. For example, sipfed.online.lync.com.
- Record the value of the ProxyFQDN.
- Enable federation in the on-premise Lync Server Control Panel, allowing federation with the online provider.
- Enable federation for the online provider. By default, all online users are enabled for domain federation and can communicate with all domains.
- If you will define blocked and allowed domains, determine the domains that you will explicitly allow or explicitly block.
- For online federation, you must plan for firewall exceptions, certificates, and DNS host (A or AAAA, if using IPv6) records. Additionally, you must configure federation policies. For details, see Planning for Lync Server and Office Communications Server Federation.

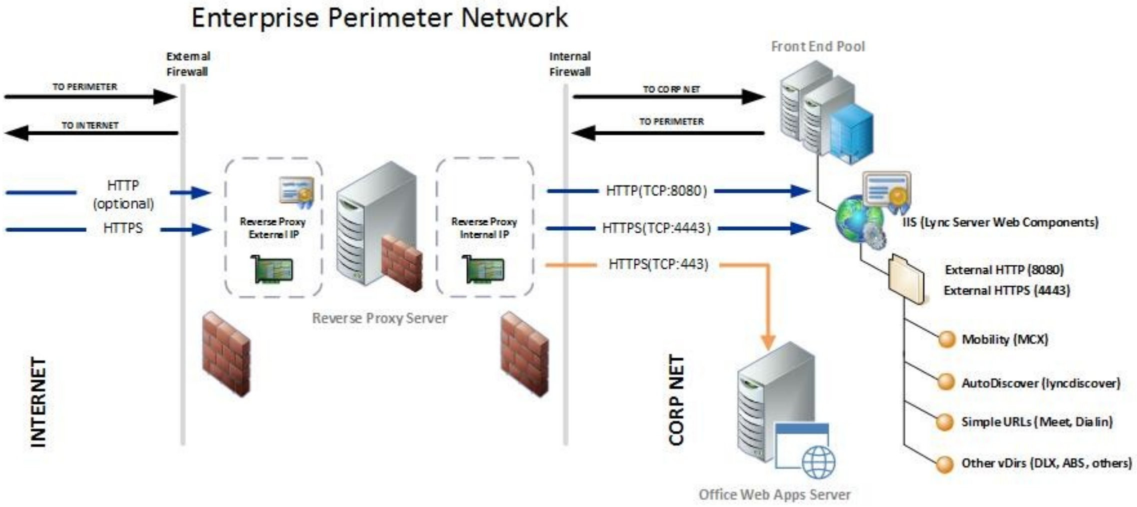
1.3.9.10.7 Scenarios for Reverse Proxy

Scenarios for Reverse Proxy

Planning > Planning for External User Access > Scenarios for External User Access >

Topic Last Modified: *2013-01-21*

Reverse proxies are required in Lync Server 2013 for providing access to services and resources such as the meeting and dial-in Simple URLs, address book, meeting content, distribution list expansion, mobility services, and others. The typical reverse proxy scenario in Lync Server 2013 is to allow external clients (for example, the desktop client or Lync Web App client) access to the Director or Front End Server external Web Services.



During the planning phase, you define the requirements for the reverse proxy in a Lync Server 2013 deployment. The reverse proxy enables access to features for the following external clients:

- Microsoft Lync 2013 desktop client
- Microsoft Lync Web App
- Microsoft Lync Mobile
- Lync Windows Store app

When planning your Lync Server 2013 deployment, you map the actual requirements for Lync Server 2013 to the reverse proxy features.

1. External clients will connect to the reverse proxy on port TCP 443 and will use secure socket layer (SSL) or transport layer security (TLS). Microsoft Lync Mobile clients can connect on port TCP 80, but only when performing the initial connection to the Lync discover services and the administrator has configured the proper domain name system (DNS) CNAME (or alias) records, and accepts that this communication will not be encrypted.
2. Lync Server 2013 external web services (deployed on the Front End Server and/or the Director) expect a connection from a reverse proxy on port TCP 4443, and it expects that the connection will be SSL/TLS.

> **Important:**
>
> The suggested default listening ports for the external web services are TCP 8080 for HTTP traffic, and TCP 4443 for HTTPS traffic. Topology Builder provides an opportunity to override the defaults and define your own listening ports for the external web services. It's important to note that the reverse proxy communicates with the external web services, and the external clients communicate with the reverse proxy. The external client communicates with the reverse proxy on port TCP 443, but you can redefine what port the reverse proxy communicates with the external web services on. The options in Topology Builder to override the default listening ports for the web services allows you to resolve listening port conflicts that may arise in your infrastructure.

3. Lync Server 2013 external web services expect an unmodified Host Header from the client to identify what service and web server directory the client is attempting to use. Requests should appear as if they came from the reverse proxy
4. The external web services use defined web server virtual directories (vDir) that provide the services offered to clients. Specific externally identifiable web services are:
   - The "Meet" vDir for web conference meetings

- The “Dialin” vDir for phone access and phone conferencing
- The “Autodiscover” vDir for Lync Windows Store app, Lync Mobile, and the desktop client Lync 2013. Autodiscover in Lync Server 2013 is known by the DNS name “lyncdiscover”
- Services not defined are accessed by the external client by direct calls to the external web services. For example, distribution group expansion (DLX) and the address book service (ABS) are accessed by direct calls to the external web services and associated vDirs. The client knows the actual path to the vDir and constructs a uniform record locator (URL) based on this information. The client would access the address book service using a URL similar to `https://externalweb.contoso.com/abs/handler`
- The Office Web Apps Server when conferencing is defined and configured as part of the Lync Server topology

> **Note:**
> The Office Web Apps Server is a separate role server and is not configured as part of the external web services. This server is separately published for client access.

5. Define SSL bridging for each service. The external port TCP 443 is mapped to the external web services port of TCP 4443. For unencrypted HTTP, port TCP 80 is mapped to the external web services port TCP 8080
6. Plan for reverse proxy listeners to publish web server resources
7. Request and configure the certificate for the reverse proxy based on the services that will be offered. If configured with the correct subject alternative names, this certificate can be shared by all configured listeners on the reverse proxy server

Resources available for planning your reverse proxy deployment:

- Data Collection
- Certificate Summary - Reverse Proxy
- Port Summary - Reverse Proxy
- DNS Summary - Reverse Proxy

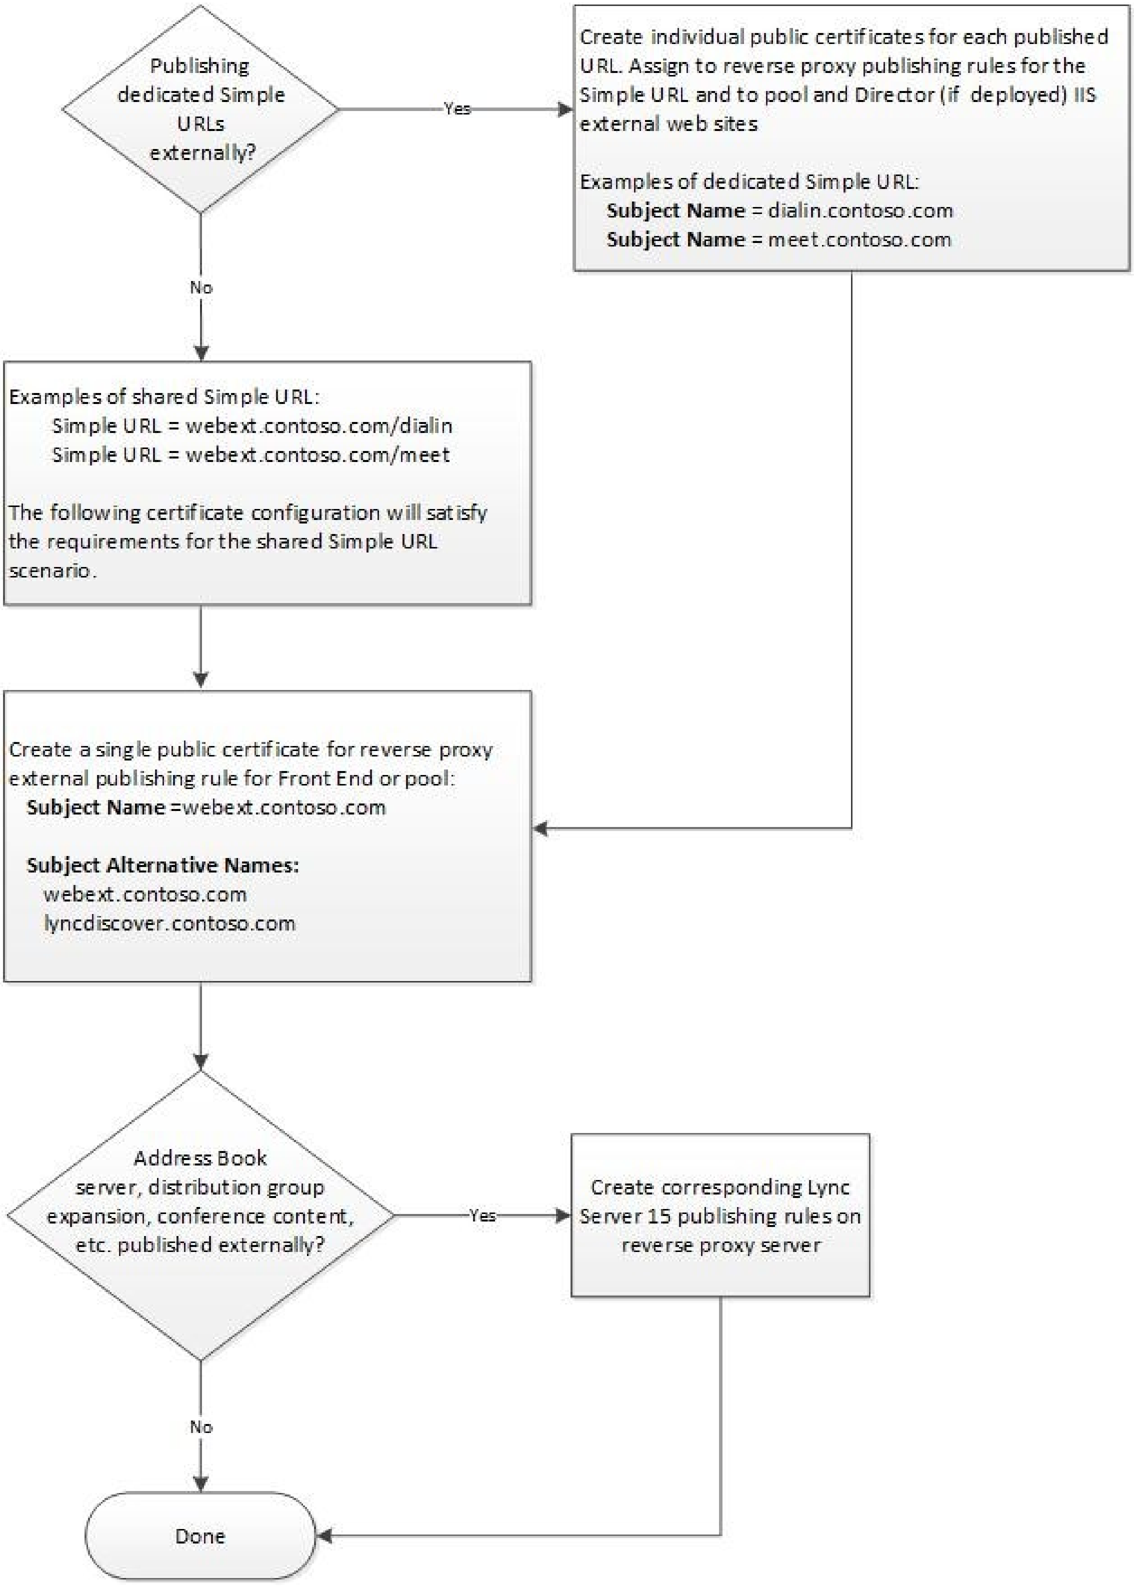
1.3.9.10.7.1 Certificate Summary - Reverse Proxy

Certificate Summary - Reverse Proxy

Planning for External User Access > Scenarios for External User Access > Scenarios for Reverse Proxy >

Topic Last Modified: *2012-11-14*

Certificate requirements for the reverse proxy are much simpler than that for the Edge Servers. The provided flowchart presents the requirements necessary. The accompanying table presents typical certificate subject name and subject alternative names in relation to the scenarios that we have been reviewed in the Edge Server discussions. For more details on the Edge Server scenarios, see Scenarios for External User Access.



Publishing dedicated Simple URLs externally?

Create individual public certificates for each published URL. Assign to reverse proxy publishing rules for the Simple URL and to pool and Director (if deployed) IIS external web sites

Examples of dedicated Simple URL:
Subject Name = dialin.contoso.com
Subject Name = meet.contoso.com

Examples of shared Simple URL:
Simple URL = webext.contoso.com/dialin
Simple URL = webext.contoso.com/meet

The following certificate configuration will satisfy the requirements for the shared Simple URL scenario.

Create a single public certificate for reverse proxy external publishing rule for Front End or pool:
Subject Name =webext.contoso.com

Subject Alternative Names:
webext.contoso.com
lyncdiscover.contoso.com

Address Book server, distribution group expansion, conference content, etc. published externally?

Create corresponding Lync Server 15 publishing rules on reverse proxy server

Reverse Proxy: External Interface

Component	Subject name	Subject alternative name (SAN)/Order	Comments
Reverse Proxy	webext.contoso.com	webext.contoso.com webdirext.contoso.com dialin.contoso.com meet.contoso.com officewebapps01.contoso.com lyncdiscover.contoso.com (Optional):*.contoso.com	Certificate must be issued by a public CA and with the server EKU. Services include Address Book Service, distribution group expansion Office Web Apps for conferencing, and Lync IP Device publishing rules. Subject alternative name includes: • External Web Services FQDN for Front End Server or Front End pool • External Web Services FQDN for Director or Director pool • Dial-in conferencing • Online meeting publishing rule • Office Web Apps for conferencing • Lyncdiscover (Autodiscover) The optional wildcard replaces both meet and dialin SAN

1.3.9.10.7.2 Port Summary - Reverse Proxy

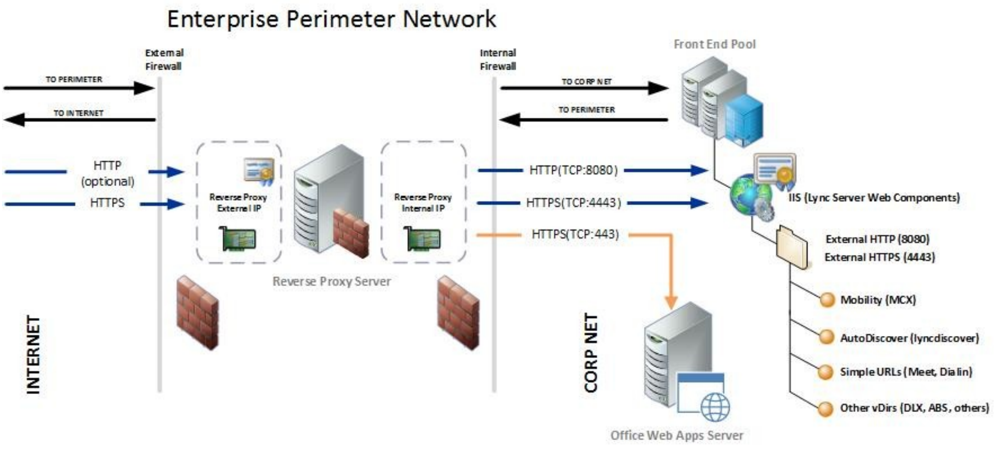
Port Summary - Reverse Proxy

Planning > Network Planning for Lync Server > Port Requirements >

Topic Last Modified: *2013-02-15*

The reverse proxy has minimal requirements for firewall and port/protocol.

- External firewall requirements are the HTTPS/TCP/443 and the optional HTTP/TCP/80. HTTPS is used for SSL and TLS secure communications through the reverse proxy. HTTP is used if you choose to allow access to the Autodiscover Service when modifying certificates might prove difficult or not cost justified.
- Clients expect to contact the Office Web Apps Server on HTTPS. The Office Web Apps Server expects communication from internal clients on HTTPS/TCP/443. The recommended configuration is to allow HTTPS/TCP/443 from the reverse proxy to the Office Web Apps Server.
- Port 8080 is used to route traffic from the reverse proxy internal interface to the Front End Server, Front End pool virtual IP (VIP) or the optional Director or Director pool VIP. Port TCP 8080 is required for mobile devices running Lync to locate the Autodiscover Service in situations where modifying the external web service publishing rule certificate is undesirable (for example, if you have a large number of SIP domains). If you choose to acquire new certificates with the necessary SAN entries, the port TCP 8080 is not needed and is optional.
- Port 4443 is used for traffic from the reverse proxy internal interface to the Front End Server, Front End pool virtual IP (VIP) or the optional Director or Director pool VIP



Caution:

Do not confuse the 4443 over TCP from the reverse proxy to the internal deployment for the port 4443 over TCP traffic from the Standard Edition server or the Front End pool that manages the Central Management store role.

Port and Protocol Details

Firewall Details for Reverse Proxy Server: External Interface

Protocol/TCP or UDP/Port	Source IP Address	Destination IP Address	Notes
HTTP/TCP/80	Any	Reverse proxy listener	(Optional) Redirection to HTTPS if user enters http://*<publishedSiteFQDN>*. Also required if using Office Web Apps for conferencing and the Autodiscover Service for mobile devices running Lync in situations where the organization does not want to modify the external web service publishing rule certificate.
HTTPS/TCP/443	Any	Reverse proxy listener	Address book downloads, Address Book Web Query service, Autodiscover, client updates, meeting content, device updates, group expansion, Office Web Apps for conferencing, dial-in

			conferencing, and meetings.

Firewall Details for Reverse Proxy Server: Internal Interface

Protocol/TCP or UDP/Port	Source IP Address	Destination IP Address	Notes
HTTP/TCP/8080	Internal reverse proxy interface	Front End Server, Front End pool, Director, Director pool	Required if using the Autodiscover Service for mobile devices running Lync in situations where the organization does not want to modify the external web service publishing rule certificate. Traffic sent to port 80 on the reverse proxy external interface is redirected to a pool on port 8080 from the reverse proxy internal interface so that the pool Web Services can distinguish it from internal web traffic.
HTTPS/TCP/4443	Internal reverse proxy interface	Front End Server, Front End pool, Director, Director pool	Traffic sent to port 443 on the reverse proxy external interface is redirected to a pool on port 4443 from the reverse proxy internal interface so that the pool web services can distinguish it from internal web traffic.
HTTPS/TCP/443	Internal reverse proxy interface	Office Web Apps for conferencing	

1.3.9.10.7.3 DNS Summary - Reverse Proxy

DNS Summary - Reverse Proxy

Network Planning for Lync Server > Domain Name System (DNS) Requirements > DNS Requirements for Edge Servers and Features >

Topic Last Modified: *2012-10-31*

You configure two network adapters in your reverse proxy as follows:

Reverse Proxy Network Adapter

Requirements

- **Network adapter 1 (Internal Interface)** example
  Internal interface with 172.25.33.40 assigned.
  No default gateway is defined.
  Ensure there is a route from the network containing the reverse proxy internal interface to any networks that contain Lync Server Front End pool servers (for example, from 172.25.33.0 to 192.168.10.0).
- **Network adapter 2 (External Interface)** example
  A minimum of one public IP address is assigned to this network adapter.
  Gateway is defined to point to the router or integrated firewall in your outer perimeter. (10.45.16.1 in the scenario examples)

DNS Records Required for Reverse Proxy

Location/TYPE/Port	FQDN	IP address	Maps to/comments
External DNS/A	webext.contoso.com	Assigned listener for externally published resources	External web services from the internal deployment. Additional records can be defined and created for all pools and single servers for any SIP domain that will use this reverse proxy, and has defined external web services.
External DNS/A	webdirext.contoso.com	Assigned listener for externally published resources	External web services for the Directors or Director pools in your deployment. You can define as many Directors as there are distinct Directors, of which may be associated with other SIP domains. **Important:** Defining the DNS records for and publishing the Directors is not an either the Front End pool or the Director decision. You must define and publish both the Director and the Front End pool external web services if you are using Directors. Specific traffic types (for authentication and other uses) will be sent to the Director first, if it is defined in the topology.

External DNS/A	dialin.contoso.com	Assigned listener for externally published resources	Dial-in conferencing published externally
External DNS/A	meet.contoso.com	Assigned listener for externally published resources	Conferences published externally
External DNS/A	officewebapps01.contoso.com	Assigned listener for Office Web Apps Server	Office Web Apps Server deployed internally or in the perimeter, and published for external client access
External DNS/A	lyncdiscover.contoso.com	Assigned listener for externally published resources	Lync Discover External record for externally published AutoDiscover, and includes Mobility, Microsoft Lync Web App, and scheduler Web app
External DNS/A	lsrp.contoso.com	Assigned listener for externally published resources	Reference record for the reverse proxy external name

1.3.9.10.8 Scenarios for Federation, Public Instant Messaging Connectivity, and XMPP Federation

Scenarios for Federation, Public Instant Messaging Connectivity, and XMPP Federation

Planning > Planning for External User Access > Scenarios for External User Access >

Topic Last Modified: *2012-10-20*

Edge Servers can be configured to allow your internal and external users access to contacts at partner organizations or services. Federations, as these partner agreements are known, can provide any or all of the following to the contacts in your organization on the partner federation or contacts in the partner federation to yours:

- Instant messaging and presence
- Collaboration and conferencing, for example – Web conferencing
- Audio conferencing, video conferencing, or both

In some cases the communication, for example instant messaging (IM) and presence between a Microsoft Lync Server 2013 and an extensible messaging and presence protocol (XMPP) contact, is peer-to-peer only - supporting only you and the contact at the federated partner. In other cases, such as a Lync Server, Lync Server 2010 to Lync Server 2013 federation, multiple participants can be invited to join into the conversation.

In this section are resources to assist you in planning for federation:

- Planning for Lync Server and Office Communications Server Federation
- Planning for Public Instant Messaging Connectivity
- Planning for Extensible Messaging and Presence Protocol (XMPP) Federation

1.3.9.10.8.1 Planning for Lync Server and Office Communications Server Federation

Planning for Lync Server and Office Communications Server Federation

See Also

Planning for External User Access > Scenarios for External User Access > Scenarios for Federation, Public Instant Messaging Connectivity, and XMPP Federation >

Topic Last Modified: *2013-02-13*

Federation between Microsoft Lync Server 2013, Lync Server 2010 and Office Communications Server supports peer-to-peer and multi-party communications. Peer-to-peer conversations can be escalated to multi-party conversations, allowing for ad hoc meetings. Meetings – Web conferencing or audio/visual conferences – can be scheduled to include contacts inside your organization as well as contacts in partners that you federate with.

Federation first appeared in Microsoft Office Live Communications Server 2005 and supported one kind of federation, Direct Federation. Direct Federation required you to know the federation partner's session initiation protocol (SIP) domain and the fully qualified domain name (FQDN) of the partner's Edge Server. Live Communications Server 2005 with SP1 introduced additional federation types, all of which required domain name system (DNS) SRV records to be published by the federated partner to locate their Edge Server. The terminology for that release was:

- *Open Enhanced Federation*: Accept any SIP domain name and use DNS SRV to locate the partner Edge Server
- *Enhanced Federation*: Configure the partner's SIP domain name as a federation partner for your organization and use DNS SRV to find the partner Edge Server
- *Direct Federation*: Configure the partner's SIP domain name and the FQDN to the partner's Edge Server
- *Server Allow List*: Accept any domain, use DNS SRV to find the Edge Server of a hosting provider or a public instant messaging (IM) connectivity provider

Microsoft Office Communications Server 2007 introduced updated naming for federation types to better define what each federation type actually accomplished:

- Open Enhanced Federation became known as *Discovered Partner Domain*
- Enhanced Federation became known as *Allowed Partner Domain*
- Direct Federation became known as *Allowed Partner Server*
- Server Allow List became known as *Hosting Provider* and *Public IM Provider*

Microsoft Lync Server 2010 introduced a narrower definition of Hosting Provider in accordance with Microsoft Lync Online 2010 and Microsoft Office 365 and also made it subject to the same allowed list defined by the Allowed Partner Domain federation type.

Enabling federation between Microsoft Lync Server 2013, Lync Server 2010 and Office Communications Server uses the Edge Servers and reverse proxies to enforce the rules and allowed partner domains that you define. From a planning perspective, federating with other Lync Server, Office Communications Server requires the following:

- Enable federation in Topology Builder. For details, see the Deployment topic Configuring SIP Federation, XMPP Federation and Public Instant Messaging.
- Determine your requirements for federated domain discovery:
  - For manual configuration of federation, you must have the fully qualified domain name (FQDN) of the partner's Edge Server and domain name, or online domain name, which is entered in the Lync Server Control Panel, **Federation and External Access**, **SIP Federated Domains**. Create a **New** policy or **Edit** an existing policy to either allow or block domains by FQDN.

> **⚠Warning:**
>
> Manual configuration of a federation partner's Edge Server is prone to failure in the event that the partner changes the IP address of their Edge Server.

> **Note:**
>
> For **New SIP Federated Domains**, you must provide the **Domain name (or FQDN)** for Microsoft Lync Online, Microsoft Office 365. For Microsoft Lync Server 2013, Lync Server 2010 and Office Communications Server you must also provide an **Access Edge service (FQDN)**

- For discovered partner federation, where partners can discover your Edge Server, you create an SRV record in your external DNS - _sipfederationtls._tcp.contoso.com – which points to the port 5061 and the host (A) record of your Edge Server

> **Important:**
>
> If you are supporting Microsoft Lync Mobile clients on either Windows Phone or Apple iPhone, iPad, or other Apple devices and are using the Push Notification Service or Push Notification Service, you must plan for _sipfederationtls._tcp. <*SIP domain*> SRV records for each SIP domain that you have Lync Mobile clients. Android and Nokia Symbian Lync Mobile do not use push notification and are not subject to this requirement.

- Configure external user access policies to support federated domains
- Open firewall ports for session initiation protocol (SIP), web conferencing and audio/visual to accommodate the federation or contacts that you are enabling. For details, see: Determine External A/V Firewall and Port Requirements

The following information will aid you in defining the certificate, port/protocol and DNS requirements for federation with Microsoft Lync Server 2013 and Lync Server 2010.

Planning for certificates, firewall and port/protocol requirements and DNS requirements is generally a straight forward process if you have planned or deployed your Microsoft Lync Server 2013 Edge Servers. Because federation is an additional feature that uses the existing Edge Server, the planning requirements are generally met by the Edge Server planning and deployment. You should use the following tables to determine that your requirements are met and make changes in port/protocol and DNS accordingly.

> **Important:**
>
> If you have a pool of Edge Servers and are federating with Lync Server 2013 or Lync Server 2010 partners, then you can use either DNS load balancing or hardware load balancers on the internal and external facing sides of the Edge Servers. If you are federating with Office Communications Server 2007 or Office Communications Server 2007 R2, hardware load balancing will provide failover support in the event of an Edge Server. Office Communications Server 2007 and Office Communications Server 2007 R2 are not DNS load balancing aware. The partner Edge Servers will establish communication with the first Edge Server in your pool that responds. If that Edge Server fails, communication does not automatically failover.

Certificate requirements are typically met through the planning of certificates for your chosen Edge Server or pooled Edge Server plan.

Topic Last Modified: *2012-10-20*

Port, protocol and firewall requirements for federation with Microsoft Lync Server 2013, Lync Server 2010 and Office Communications Server are similar to those for the deployed Edge Server. Clients initiate communication with the Access Edge service over TLS/SIP/TCP 443. Federated partners however, will initiate communications to the Access Edge service over MTLS/SIP/TCP 5061.

Firewall Summary for Federation

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
Access/SIP(MTLS)/ TCP/5061	Access Edge service public IP address	Any	For federated and public IM connectivity using SIP

Network Planning for Lync Server > Domain Name System (DNS) Requirements > DNS Requirements for Edge Servers and Features >

Topic Last Modified: *2012-10-20*

The domain name system (DNS) records that will be required for defining a federation with Office Communications Server or Lync Server partners is determined by your decision to either allow automatic DNS discovery of your domain by other perspective partners. If you publish the _sipfederationtls._tcp. <*SIP domain name*> SRV record, any other SIP federated domain will be able to "discover" your federation. You can control which federated domains can communicate with you by using the Allows domains and Blocked Domains settings in the Lync Server Control Panel, or by setting the allowed or blocked domains configuration using the Lync Server Management Shell and the **Get**, **Set**, **New**, **Remove-CsAllowedDomain** and **-CsBlockedDomain** PowerShell cmdlets. For additional information on how to configure theses settings and the use of the PowerShell cmdlets, see **Related Topics** at the end of this topic.

The DNS records summary table depicts the required entries for an open, or discoverable, federation. If you do not want to implement Federation Discovery, You can decide to not configure the _sipfederationtls._tcp. <*SIP domain name*> record.

◆**Important:**
There are specific scenarios in which you must have the _sipfederationtls._tcp. <*SIP domain name*> SRV record, but you do not want to have a discoverable federation. One such instance is where you have deployed mobility for your users. The mobility push notification clearinghouse (PNCH) is a special type of federation that is used for Microsoft Lync Mobile clients on Apple iPhone or Windows Phone. The _sipfederationtls._tcp. <*SIP domain name*> SRV record is used in the case of mobility and PNCH. To mitigate this issue and control your discoverability, clear the setting **Enable partner domain discovery** to turn off discovery.

Records Required for Federation

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5061	_sipfederationtls._tcp .contoso.com	sip.contoso.com	Access Edge service external interface Required for automatic DNS discovery of your federation to other potential federation

			partners, and is known as “Allowed SIP Domains” (called enhanced federation in previous releases).Repeat as necessary for all SIP domains with Lync enabled users ◆**Important:** This SRV record is required for mobility and the push notification clearing house. In cases where there is more than one SIP domain, create and publish an SRV record for each domain that will have Lync Mobile clients. The Push Notification Service and Apple Push Notification service may not operate as expected if there is not an explicit SRV record for each SIP domain that the deployment supports.

1.3.9.10.8.2 Planning for Public Instant Messaging Connectivity

Planning for Public Instant Messaging Connectivity

Planning for External User Access > Scenarios for External User Access > Scenarios for Federation, Public Instant Messaging Connectivity, and XMPP Federation >

Topic Last Modified: *2013-02-17*

Public Instant Messaging Connectivity is a class of federation, and is configured to allow your internal and external Lync Server 2013 users to add contacts from any of the following:

- Messenger contacts
- Yahoo! contacts
- America Online (AOL) contacts

◆**Important:**

- As of September 1st, 2012, the Microsoft Lync Public IM Connectivity User

Subscription License (PIC USL) is no longer available for the purchase for new or renewing agreements. Customers with active licenses will be able to continue to federate with Yahoo! Messenger until the service shutdown date (exact date is still to be decided, but no sooner than June 2013).
- The PIC USL is a per-user, per-month subscription license that is required for Lync Server or Office Communications Server to federate with Yahoo! Messenger. Microsoft's ability to provide this service has been contingent upon support from Yahoo!, the underlying agreement for which will not be renewed.
- More than ever, Lync is a powerful tool for connecting across organizations and with individuals around the world. Federation with Windows Live Messenger requires no additional user/device licenses beyond the Lync Standard CAL. Skype federation will be added to this list, enabling Lync users to reach hundreds of millions of people through IM and voice.

This class of federation requires the following planning considerations:

- Windows Live Messenger users can have peer-to-peer audio/visual communication with Lync Server 2013 users, in addition to instant messaging. Your Edge Servers must meet specific port and protocol requirements. For details, see Determine External A/V Firewall and Port Requirements.
- Yahoo instant messaging has no unique requirements, other than those typically used in the planning and deployment of the typical Edge Server that is providing federation.
- America Online requires that your Edge Server certificate assigned to the Access Edge service has a client enhanced key usage (EKU).
- Certificate Summary - Public Instant Messaging Connectivity
- Port Summary - Public Instant Messaging Connectivity

Topic Last Modified: *2013-02-19*

To configure certificates for public Instant Messaging connectivity, you should first notice that there is nothing different from other SIP federation types or even standard Edge Server certificates, except that America Online (AOL) requires a unique certificate configuration. In addition to the usual server enhanced key usage (EKU), America Online requires the certificate or certificates (in the case of an Edge pool) to also contain the client EKU. The client EKU is an addition to the certificate, and is part of the external public certificate that is assigned to your Edge Server.

Certificate Summary – Public Instant Messaging Connectivity

Component	**Subject name**	**Subject alternative names (SAN)/Order**	**Comments**
External/Access Edge	sip.contoso.com	sip.contoso.com webcon.contoso.c	The certificate must be from a Public CA, and must have the server EKU and client EKU if

		om sip.fabrikam.com	public IM connectivity with AOL is to be deployed. The certificate is assigned to the external Edge Server interfaces for: • Access Edge service • Web Conferencing Edge service • A/V Edge service Note that SANs are automatically added to the certificate based on your definitions in Topology Builder. You add SAN entries as needed for additional SIP domains and other entries that you need to support. The subject name is replicated in the SAN and must be present for correct operation.

Planning > Network Planning for Lync Server > Port Requirements >

Topic Last Modified: *2013-02-16*

To configure your firewall for ports and protocols necessary to support public instant messaging connectivity, first note that SIP/MTLS/TCP 5061 is bidirectional to account for the ability of contacts in the public IM provider to contact Lync clients, or for Lync to contact public IM contacts.

Windows Live Messenger can participate in audio/video communications with Lync clients. This accounts for the very similar firewall port and protocol configuration that you would typically have on the firewall to support Lync clients as external users.

◆**Important:**
More than ever, Lync is a powerful tool for connecting across organizations and with individuals around the world. Federation with Windows Live Messenger requires no additional user/device licenses beyond the Lync Standard Client Access License (CAL). Skype federation will be added to this list, enabling Lync users to reach hundreds of millions of people with IM and voice. Federation with Messenger client contacts will officially end on March 15, 2013, except for mainland China. Skype will become the federation client for federated users who previously used Messenger.

Firewall Summary – Public Instant Messaging Connectivity

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
Access/SIP(MTLS)/TCP/5061	Public IM connectivity partners	Edge Server Access interface	For federated and public IM connectivity that use SIP.
Access/SIP(MTLS)/TCP/5061	Edge Server Access interface	Public IM connectivity partners	For federated and public IM connectivity that use SIP.
Access/SIP(TLS)/TCP/443	Clients	Edge Server Access interface	Client-to-server SIP traffic for external user access.
A/V/RTP/TCP/50,000-59,999	Edge Server Access interface	Live Messenger clients	Used for A/V sessions with Windows Live Messenger if public IM connectivity is configured.
A/V/STUN,MSTURN/UDP/3478	Edge Server Access interface	Live Messenger clients	Required for public IM connectivity with Windows Live Messenger.
A/V/STUN,MSTURN/UDP/3478	Live Messenger clients	Edge Server Access interface	Required for public IM connectivity with Windows Live Messenger.

Topic Last Modified: *2012-10-22*

Previous versions of Lync Server and Office Communications Server provided an extensible messaging and presence protocol (XMPP) gateway that could be deployed as a separate server role to allow federating with XMPP deployments. In Microsoft Lync Server 2013, the XMPP functionality can be deployed as a feature. XMPP functionality is installed in two parts: an XMPP proxy that runs on the Edge Server and the XMPP gateway that runs on the Front End Servers.

Deployment and configuration of XMPP is covered in Deploying External User Access You plan for supporting XMPP in your organization by defining port and protocol rules on your firewall, configuration of certificates, and adding DNS records. The following topics in this section summarize the information that you will need to successfully plan XMPP federation for your deployment.

Important:

The XMPP capability of Lync Server 2013 is tested and supported by Microsoft for instant messaging federation with Google Talk. For any other XMPP systems contact the third-party vendor to verify that they support federation with Lync Server 2013, and for any deployment or troubleshooting recommendations.

Certificate requirements for enabling and establishing communications with extensible messaging and presence protocol (XMPP) partners require the additional record of your XMPP domains. The record that is included on the certificate as a subject alternative name (SAN) will be the domain that can participate in XMPP communications. The domain can be the root-level domain (for example, contoso.com) if you want to enable XMPP for your entire domain, or can be selected child domains (for example, corp.contoso.com, finance.contoso.com) if you are enabling XMPP for a subset of users.

Certificate Summary for Extensible Messaging and Presence Protocol

Component	Subject name	Subject alternative names (SAN)/Order	Comments
Assign to Access Edge service of Edge Server or Edge pool	sip.contoso.com	webcon.contoso.com sip.contoso.com sip.fabrikam.com contoso.com	The first three SAN entries are the normal SAN entries for a full Edge Server. The contoso.com is the entry required for federation with the XMPP partner at the root domain level. This entry will allow XMPP for all domains with the suffix contoso.com.

Topic Last Modified: *2012-10-20*

To configure extensible messaging and presence protocol (XMPP) for your deployment, you create two domain name system (DNS) records in an external DNS server that will resolve the records to the Access Edge service of your Edge Server or Edge pool.

DNS Summary for Extensible Messaging and Presence Protocol

Location/TYPE/Port	FQDN	IP address/FQDN host record	Maps to/Comments
External DNS/ SRV/5269	_xmpp-server._tcp.contoso.com	xmpp.contoso.com	XMPP proxy external interface on the Access Edge service or Edge pool.Repeat as necessary for all internal SIP domains with Lync enabled users where contact with XMPP contacts is allowed through the configuration of the External Access Policy through a global policy, site policy where the user is located, or user policy applied to the Lync-enabled user. An allowed XMPP domain must also be configured in the XMPP Federated Partners policy. See topics in **See Also** for additional details
External DNS/A	xmpp.contoso.com (for example)	IP address of Access Edge service on your Edge Server or Edge pool hosting XMPP proxy	Points to the Access Edge service or Edge pool that hosts the XMPP proxy service. Typically, the SRV record that you create will point to this host (A or AAAA) record

With Lync Server 2013, you can deploy the mobility feature to provide Lync 2013 functionality on mobile devices. This section provides details about the mobility feature and how to plan for your deployment.

- Mobility Features and Capabilities
- Topologies and Components for Mobility
- Technical Requirements for Mobility
- Defining Your Mobility Requirements
- Deployment Process for Mobility

1.3.9.10.9.1 Mobility Features and Capabilities

Mobility Features and Capabilities

Planning for External User Access > Scenarios for External User Access > Planning for Mobility >

***Topic Last Modified:** 2013-02-19*

`The information in this topic pertains to Cumulative Updates for Lync Server 2013`

The mobility feature introduced in the Cumulative Updates for Lync Server 2013: February 2013 supports Lync 2010 Mobile and Lync 2013 Mobile clients functionality. When you deploy the Lync Server 2013 Mobility Service, users can use supported Apple iOS, Android, and Windows Phone, or Nokia Symbian mobile devices to perform activities such as sending and receiving instant messages, viewing contacts, and viewing presence. In addition, mobile devices support some Enterprise Voice features, such as click to join a conference, Call via Work, single number reach, voice mail, and missed calls. New features introduced in the Cumulative Updates for Lync Server 2013: February 2013 include Voice over IP (VoIP) capability and video (H.264) for meeting attendee.

The mobility feature introduced in the Cumulative Updates for Lync Server 2013: February 2013 supports Lync 2013 Mobile client functionality. The Cumulative Updates for Lync Server 2013: February 2013 install Unified Communications Web API, or UCWA. UCWA is the component used for Lync 2013 Mobile clients. In Lync Server 2013, Mcx is used for Lync 2010 Mobile clients. Cumulative Updates for Lync Server 2013: February 2013 introduce UCWA as the new entry point for mobility services. Lync Server 2013 concurrently implements the Mobility Service (Mcx), introduced in the Cumulative Updates for Lync Server 2010: November 2011, and provides support for Lync 2010 Mobile. When you deploy the Cumulative Updates for Lync Server 2013: February 2013, users can use supported Apple iOS, Android, and Windows Phone mobile devices to perform such activities as:

> **Important:**
>
> Features supported by the Mobility Service from the Cumulative Updates for Lync Server 2010: November 2011 are noted with (Mcx). All listed features are supported by the UCWA, introduced in the Cumulative Updates for Lync Server 2013: February 2013.

- Send and receive instant messages (Mcx)
- View presence (Mcx)
- View contacts (Mcx)
- Click to join a conference (Mcx)
- Call via work (Mcx)
- Single number reach (Mcx)

- Voice mail (Mcx)
- Missed call notification (Mcx)
- Voice over IP (VoIP)
- Attendee video (H.264)

Note:
Lync 2010 Mobile provided a client for Nokia Symbian devices. Lync 2013 Mobile will not have a client for Nokia Symbian-based devices.

Apple iPad users will have access to enhanced capabilities. After joining a meeting by using audio call back, an iPad user will be able to view uploaded Microsoft PowerPoint presentations within a meeting, share applications and desktops, view the meeting participant list, and receive notifications of other content types that are being shared within the meeting.

Tip:
With single number reach, a user receives calls on a mobile phone that were dialed to the work number. With Call via Work, the user places an outbound call from the Lync Mobile client by using a work phone number instead of the mobile phone number. With dial-out, the client sends a request to Mcx or UCWA (based on the Lync Mobile version) to make the call for them. The server initiates the call and then calls the user back on the mobile phone. When the user answers, the server completes the call by dialing the other party. By using Call via Work, users can maintain their work identity during a call, which means that the call recipient does not see the caller's mobile number, and the caller avoids incurring outbound calling charges.

Note:
Not all features work exactly the same on all mobile devices. For details about features supported on mobile devices, see the Mobile Client Comparison Tables at http://go.microsoft.com/fwlink/p/?LinkId=234777. For details about supported devices and operating systems, see the requirements topics under Planning for Mobile Clients.

When you use the Lync Server 2013 Autodiscover feature, mobile applications can automatically locate Lync Server 2013 Web Services without requiring users to manually enter the URLs in their device settings. Manually entering URLs in mobile device settings is also supported, primarily for troubleshooting purposes.

Important:
The Mcx and UCWA are complimentary services and both are deployed to support Lync 2010 Mobile and Lync 2013 Mobile clients. Lync 2013 Mobile will not be able to sign in to Lync Server 2010 deployments. Lync 2010 Mobile and Lync 2013 Mobile will be able to use a Lync Server 2013 deployment with the Cumulative Updates for Lync Server 2013: February 2013 applied.

The mobility feature also supports *push notifications* for mobile devices that do not support applications running in the background. A push notification is a notification that is sent to a mobile device about an event that occurs while a mobile application is inactive. For example, a missed instant messaging (IM) invitation can result in a push notification.

Mcx, UCWA, Autodiscover Service, and support for push notifications are provided in Lync Server 2013. Updated client features, capabilities, and the use of UCWA as the mobility entry point are introduced in the Cumulative Updates for Lync Server 2013: February 2013.

Topic Last Modified: *2013-02-17*

`The information in this topic pertains to Cumulative Updates for Lync Server 2013`

To support Lync mobile applications on mobile devices, Lync Server 2013 provides three services: Lync Server 2013 Mcx Mobility Service, Lync Server 2013 Autodiscover Service, and Lync Server 2013 Push Notification Service. The Cumulative Updates for Lync Server 2013: February 2013 adds a complimentary, but advanced, service for Lync 2013 Mobile clients—mobility support through the use of the Unified Communications Web API, or UCWA. This section briefly describes these components and identifies the Lync Server 2013 topologies that support mobility.

Note:

Mobility services are also available in hybrid deployments. You are not required to deploy services for supporting mobility if your users are homed online. You do need to define a setting for the Autodiscover Service to enable mobile users to find their online identity.

Important:

If you are planning any external user connectivity (for example, federation, external user access, or mobility features), you must use Edge Servers with Standard Edition server and the Front End Server or Front End pool. The Standard Edition server and the Front End Server or Front End pool do not have the necessary components to enable external users to access your internal deployment, or for the internal deployment to communicate with your external users. For all scenarios that include external users collaborating or communicating with internal users, including mobility, you must deploy at least one Edge Server and one reverse proxy.

Push notification uses a type of federation to the Lync Online services, which hosts the Push Notification Clearing House (PNCH). Push notification refers to the sound alerts, on-screen alerts (text), and badges that are pushed by applications to the Apple iPhone, iPad, and Windows Phone, when the mobile device is inactive. PNCH receives push notifications from Lync Server. When PNCH receives a notification of a message, PNCH forwards a notification to mobile clients through either the Apple Push Notification Services or Lync Server 2013 Push Notification Service, based on the mobile client that the message is intended for. PNCH is a required service for these mobile clients. To federate to Lync Online, PNCH uses Edge Servers and certificates to ensure confidentiality and authentication, policies, and correctly configured domain name system (DNS) records. Nokia Symbian and Android-based Lync Mobile clients do not use PNCH.

For details about planning and deploying Edge Servers, see Planning for External User Access and Deploying External User Access.

The Lync 2013 Mobile clients for Apple devices introduced with the Cumulative Updates for Lync Server 2013: February 2013 no longer use push notification or the push notification clearing house (PNCH). Lync 2013 Mobile clients on Windows Phone still use push notification and the (PNCH).

Mobility Components

The services that support mobility are as follows:

- **Lync Server 2013 Unified Communications Web API (UCWA)** Provides services for real-time communications with mobile and web clients in Lync Server 2013. When you deploy the Cumulative Updates for Lync Server 2013: February 2013 to the Front End Server and Director, the installation creates a virtual directory in the internal and external web services (Ucwa). A web component that is part of the Ucwa virtual directory accepts calls from UCWA-enabled clients. The client apps communicate over a REST interface for presence, contacts, instant messaging, VoIP, video conferencing, and collaboration. UCWA uses a P-GET based channel to send events, such as an incoming call, incoming instant message, or a message to the client app.

> **Note:**
> *REST* or representational state transfer, is a software architectural style for distributed systems that has been widely adopted in many forms and is well suited to the requirements of Web services in general.

- **Lync Server 2013 Mobility Service (Mcx)** This service supports Lync functionality, such as instant messaging (IM), presence, and contacts, on mobile devices. The Mobility Service is installed on every Front End Server in each pool that is to support Lync functionality on mobile devices. When you install Lync Server 2013, a new virtual directory (Mcx) is created under both the internal website and the external website on your Front End Servers.

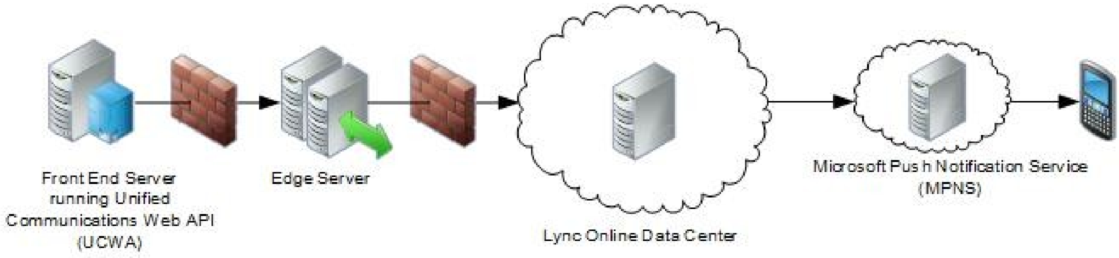
> **Important:**
> Lync Server 2013 with the Cumulative Updates for Lync Server 2013: February 2013 supports both the Mobility service introduced in the Cumulative Update for Lync Server 2010: November 2011, commonly known as Mcx, and the UCWA web component. The combination of these two mobility services provides interoperability and use by users with Lync 2010 Mobile and Lync 2013 Mobile clients on Lync Server 2013.

- **Lync Server 2013 Autodiscover Service** This service identifies the location of the user and enables mobile devices and other Lync clients to locate resources—such as the internal and external URLs for Lync Server 2013 Web Services, and the URL for the Mcx or UCWA—regardless of network location. Automatic discovery uses hardcoded host names (lyncdiscoverinternal for users inside the network; lyncdiscover for users outside the network) and the SIP domain of the user. It supports client connections that use either HTTP or HTTPS.
  The Autodiscover Service is installed on every Front End Server and on every Director in each pool that is to support Lync functionality on mobile devices. When you install the Autodiscover Service, a new virtual directory (Autodiscover) is created under both the internal website and the external website, on both Front End Servers and Directors.

> **Note:**
> The Autodiscover Service is listed here because it remains a critical component when providing mobile client services. The role of Autodiscover in Lync Server 2013 has been expanded to provide services for all clients. For details about planning for the Autodiscover Service, see Planning for Autodiscover.

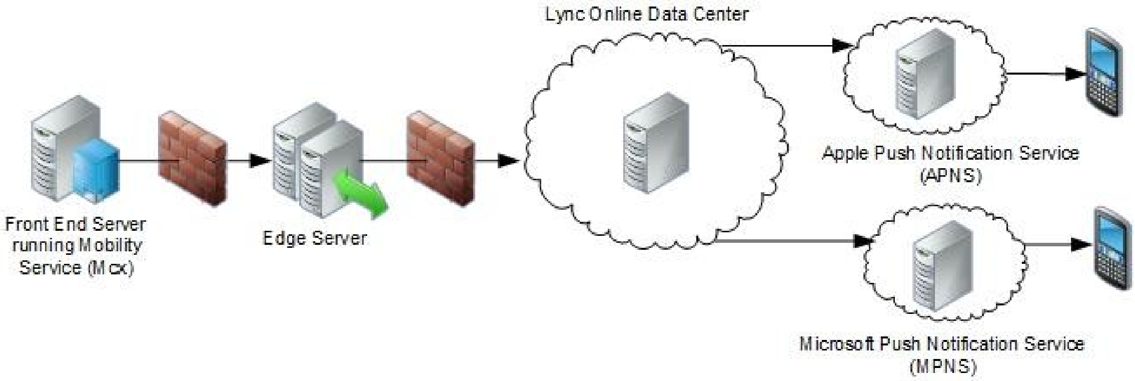
- **Push Notification Service** This service is a cloud-based service that is located in the Lync Online data center. When the Lync mobile application on a supported Apple iOS device or Windows Phone is inactive, it cannot respond to new events, such as a new instant messaging (IM) invitation, a missed instant message, a missed call, or voice mail, because these devices do not support mobile applications running in the background. In these cases, a notification of the new event—called a *push notification*—is sent to the mobile device. The Mobility Service sends the notification to the cloud-based Push Notification Service, which then sends the notification either to the Apple Push Notification Service (APNS) (for supported Apple iOS devices) or to the Microsoft Push Notification Service (MPNS) (for Windows Phone), which then sends it on to the mobile device. The user can then respond to the notification on the mobile device to activate the application.
  The Lync 2010 Mobile on Apple and Windows Phone devices use push notifications. The Lync 2013 Mobile client for Apple devices introduced with the Cumulative Updates for Lync Server 2013: February 2013 no longer uses push notification or the push notification clearing house (PNCH).

The following diagram illustrates how the Push Notification Service fits within a Lync Server 2013 topology that uses UCWA and Lync 2013 Mobile clients.



Front End Server running Unified Communications Web API (UCWA)
Edge Server
Lync Online Data Center
Microsoft Push Notification Service (MPNS)

Introduced in Cumulative Update for Lync Server 2010: November 2011, the Mcx service provides services to Lync 2010 Mobile clients. The following diagram illustrates the Push Notification Service as it applies to a topology using Mcx and Lync 2010 Mobile clients.



Lync Online Data Center
Apple Push Notification Service (APNS)
Front End Server running Mobility Service (Mcx)
Edge Server
Microsoft Push Notification Service (MPNS)

Supported Topologies

Applying the Cumulative Updates for Lync Server 2013: February 2013 adds the UCWA web components to support mobility for Lync 2013 Mobile client features in the following topologies:

- Lync Server 2013 Standard Edition
- Lync Server 2013 Enterprise Edition

The Edge Server can be a Lync Server 2010 Edge Server.

A Lync Server 2013 deployment without the Cumulative Updates for Lync Server 2013: February 2013 will use the Mcx Mobility Service and can provide services only for Lync 2010 Mobile.

Important:
The Mobility Service is supported on Front End Servers that is collocated with the Mediation Server role with two network interfaces, but you must take appropriate steps to configure the interfaces. You must assign the IP addresses to the specific interface that will communicate as the Mediation Server, and the network interface IP that will communicate as the Front End Server. You can do this in Topology Builder by selecting the correct IP address for each service, instead of using the default **Use all configured IP addresses**.

1.3.9.10.9.3 Technical Requirements for Mobility

Technical Requirements for Mobility

Planning for External User Access > Scenarios for External User Access > Planning for Mobility >

Topic Last Modified: *2013-02-19*

Some information in this topic pertains to Cumulative Updates for Lync Server 201

Mobile users encounter various mobile application scenarios that require special planning. For example, someone might start using a mobile application while away from work by connecting through the 3G network, then switch to the corporate Wi-Fi network when arriving at work, and then switch back to 3G when leaving the building. You need to plan your environment to support such network transitions and guarantee a consistent user experience. This section describes the infrastructure requirements that you must have in order to support mobile applications and automatic discovery of mobility resources.

Note:

Although mobile applications can also connect to other Lync Server 2013 services, the requirement to send all mobile application web requests to the same external web fully qualified domain name (FQDN) applies only to the Lync Server 2013 Mobility Service. Other mobility services do not require this configuration.

The requirement for cookie affinity in hardware load balancers is dramatically reduced, and you substitute Transmission Control Protocol (TCP) affinity if you are using the Lync Mobile delivered with Lync Server 2013. Cookie affinity can still be used, but the web services no longer require it.

Important:

All Mobility Service traffic goes through the reverse proxy, regardless of where the origination point is—internal or external. In the case of a single reverse proxy or a farm of reverse proxies, or a device that is providing the reverse proxy function, an issue can arise when the internal traffic is egressing through an interface and attempting to immediately ingress on the same interface. This often leads to a Security rule violation known as TCP packet spoofing or just spoofing. *Hair pinning* (the egress and immediate ingress of a packet or series of packets) must be allowed in order for mobility to function. One way to resolve this issue is to use a reverse proxy that is separate from the firewall (the spoofing prevention rule should always be enforced at the firewall, for security purposes). The hairpin can occur at the external interface of the reverse proxy instead of the firewall external interface. You detect the spoofing at the firewall, and relax the rule at the reverse proxy, thereby allowing the hairpin that mobility requires.
Use the Domain Name System (DNS) host or CNAME records to define the reverse proxy for the hairpin behavior (not the firewall), if at all possible.

Lync Server 2013 supports mobility services for Lync 2010 Mobile and Lync 2013 mobile clients. Both clients use the Lync Server 2013 Autodiscover Service to find its mobility entry point, but differ on which mobility service they use. Lync 2010 Mobile uses the Mobility Service known as *Mcx*, introduced with the Cumulative Update for Lync Server 2010: November 2011. Lync 2013 mobile clients use the Unified Communications Web API, or *UCWA*, as their mobility service provider.

Internal and External DNS Configuration

The Mobility Services Mcx (introduced with the Cumulative Update for Lync Server 2010: November 2011) and UCWA (introduced in the Cumulative Updates for Lync Server 2013: February 2013) use DNS in the same way.

When you use Automatic Discovery, mobile devices use DNS to locate resources. During the DNS lookup, a connection is first attempted to the FQDN that is associated with the internal DNS record (lyncdiscoverinternal.<*internal domain name*>). If a connection cannot be made by using the internal DNS record, a connection is attempted by using the external DNS record (lyncdiscover.<*sipdomain*>). A mobile device that is internal to the network connects to the internal Autodiscover Service URL, and a mobile device that is external to the network connects to the external Autodiscover Service URL. External Autodiscover requests go through the reverse proxy. The Lync Server 2013 Autodiscover Service returns all Web Services URLs for the user's home pool, including the Mobility Service (Mcx and UCWA) URLs. However, both the internal Mobility Service URL and the external Mobility Service URL are associated with the external Web Services FQDN. Therefore, regardless of whether a mobile device is internal or external to the network, the device always connects to the Lync Server 2013 Mobility Service externally through the reverse proxy.

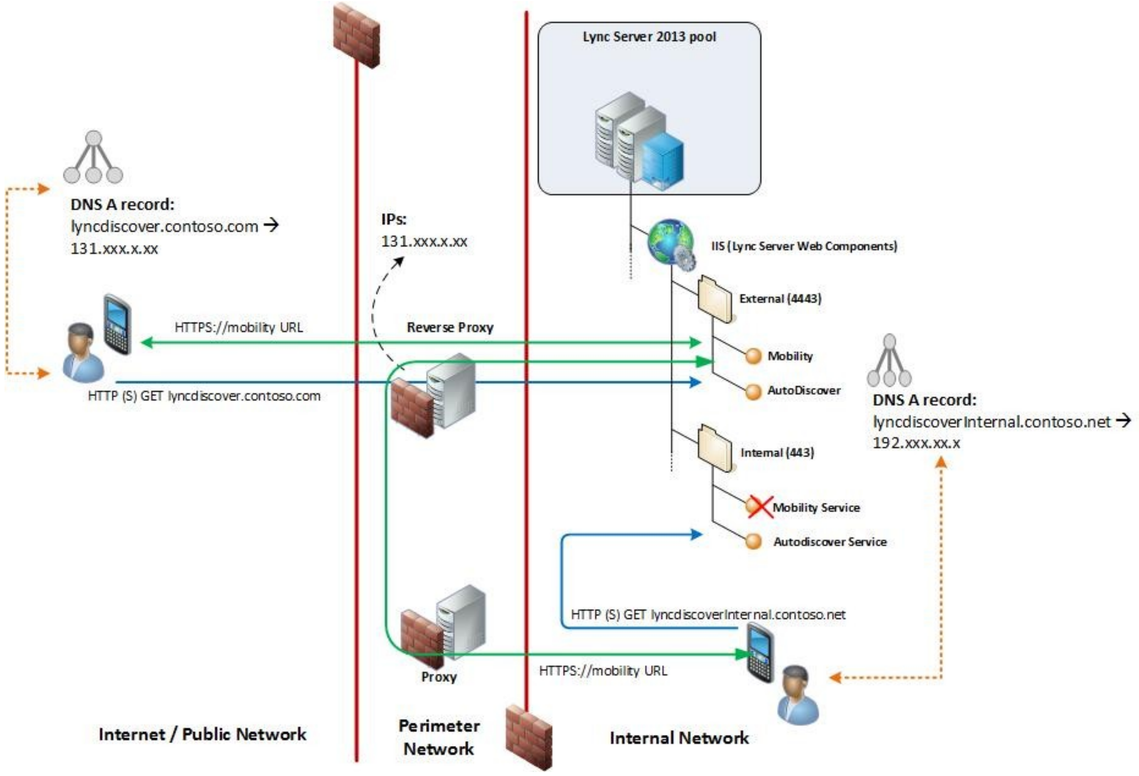
Note:

It is important to understand that your deployment can consist of multiple distinct namespaces for internal and external use. Your SIP domain name may be different than the internal deployment domain name. For example, your SIP domain may be **contoso.com**, while your internal deployment may be **contoso.net**. Users who log in to Lync Server will use the SIP domain name, such as **john@contoso.com**. When addressing the external web services (defined in Topology Builder as **External web services**), the domain name and the SIP domain name will be consistent, as defined in DNS. When addressing the internal Web services (defined in Topology Builder as **Internal web services**), the default name of the internal web services will be the FQDN of the Front End Server, Front End pool, Director, or Director pool. You have the option to override the internal web services name. You should use the internal domain name (and not the SIP domain name) for internal web services and define the DNS host A (or, for IPv6, AAAA) record to reflect the overridden name. For example, the default internal web services FQDN may be **pool01.contoso.net**. An overridden internal web services FQDN may be **webpool.contoso.net**. Defining the web services in this way helps to ensure that the internal and external locality of the services—and not the locality of the user who is using them—is observed.

However, because the web services are defined in Topology Builder and the internal web services name can be overridden, as long as the resulting web services name, the certificate that validates it, and the DNS records that define it, are consistent, you can define the internal web services with any domain name—including the SIP domain name—that you want. Ultimately, the resolution for the name to the IP address is determined by DNS host records and a consistent namespace.

For the purposes of this topic and the examples, the internal domain name is used to illustrate the topology and the DNS definitions.

The following diagram illustrates the flow of mobile application web requests for the Mobility Service and for the Autodiscover Service when using an internal and external DNS configuration.



Note:

The diagram illustrates generic web services. A virtual directory named Mobility depicts the Mobility services Mcx and/or UCWA. If you have not applied the Cumulative Updates for Lync Server 2013: February 2013, you may or may not have the virtual directory Ucwa defined on your internal and external Web services. You will have a virtual directory Autodiscover, and you may have a virtual directory Mcx.
Autodiscover and the discovery of services work the same way, regardless of the mobility services technology that you have deployed.

To support mobile users from both inside and outside the corporate network, your internal and external web FQDNs must meet some prerequisites. In addition, you may need to meet other requirements, depending on the features you choose to implement:

- New DNS, CNAME or A (host, if IPv6, AAAA) records, for automatic discovery.
- New firewall rule, if you want to support push notifications through your Wi-Fi network.
- Subject alternative names on internal server certificates and reverse proxy certificates, for automatic discovery.
- Front End Server hardware load balancer configuration changes source affinity.
- .

Your topology must meet the following requirements to support the Mobility Service and the Autodiscover Service:

- The Front End pool internal web FQDN must be distinct from the Front End pool external web FQDN.
- The internal web FQDN must only resolve to and be accessible from inside the corporate network.
- The external web FQDN must only resolve to and be accessible from the Internet.
- For a user who is inside the corporate network, the Mobility Service URL must be addressed to the external web FQDN. This requirement is for the Mobility

Service and applies only to this URL.
- For a user who is outside the corporate network, the request must go to the external web FQDN of the Front End pool or Director.

If you support automatic discovery, you need to create the following DNS records for each SIP domain:

- An internal DNS record to support mobile users who connect from within your organization's network.
- An external, or public, DNS record to support mobile users who connect from the Internet.

The internal automatic discovery URL should not be addressable from outside your network. The external automatic discovery URL should not be addressable from within your network. However, if you cannot meet this requirement for the external URL, mobile client functionally will probably not be affected, because the internal URL is always tried first.

The DNS records can be either CNAME records or A (host, if IPv6, AAAA) records.

Note:
Mobile device clients do not support multiple Secure Sockets Layer (SSL) certificates from different domains. Therefore, CNAME redirection to different domains is not supported over HTTPS. For example, a DNS CNAME record for lyncdiscover.contoso.com that redirects to an address of director.contoso.net is not supported over HTTPS. In such a topology, a mobile device client needs to use HTTP for the first request, so that the CNAME redirection is resolved over HTTP. Subsequent requests then use HTTPS. To support this scenario, you need to configure your reverse proxy with a web publishing rule for port 80 (HTTP). For details, see "To create a web publishing rule for port 80" in Configuring the Reverse Proxy for Mobility. CNAME redirection to the same domain is supported over HTTPS. In this case, the destination domain's certificate covers the originating domain.

For details about the DNS records required for your scenario, see DNS Summary - Autodiscover.

Port and Firewall Requirements

If you support push notifications and want Apple mobile devices to receive push notifications over your Wi-Fi network, you also need to open port 5223 on your enterprise Wi-Fi network. Port 5223 is an outbound TCP port used by the Apple Push Notification Service (APNS). The mobile device initiates the connection. For details, see http://support.apple.com/kb/TS1629 .

⚠**Warning:**
An Apple device using the Lync 2013 Mobile client does not require push notifications.

For additional details and guidance on port and protocol requirements for Autodiscover, see Port Summary - Autodiscover.

Certificate Requirements

If you support automatic discovery for Lync mobile clients, you need to modify the subject alternative name lists on certificates to support secure connections from the mobile clients. You need to request and assign new certificates, adding the subject alternative name entries described in this section, for each Front End Server and Director that runs the Autodiscover Service. The recommended approach is to also modify the subject alternative names lists on certificates for your reverse proxies. You need to add subject alternative name entries for every SIP domain in your organization.

Reissuing certificates by using an internal certificate authority is typically a simple process, but adding multiple subject alternative name entries to public certificates used by the reverse proxy can be expensive. If you have many SIP domains, making the addition of subject alternative names very expensive, you can configure the reverse proxy to make the initial Autodiscover Service request over port 80 using HTTP, instead of port 443 using HTTPS (the default configuration). The request is then redirected to port 8080 on the Director or Front End pool. When you publish the initial Autodiscover Service request on port 80, you do not need to change certificates for the reverse proxy, because the request uses HTTP rather than HTTPS. This approach is supported, but we do not recommend it.

Internet Information Services (IIS) Requirements

We recommend that you use IIS 7.5 or IIS 8.0 for mobility. The Mobility Service installer sets flags in ASP.NET to improve performance. IIS 7.5 is installed by default on Windows Server 2008 R2 and IIS 8.0 is installed on Windows Server 2012. The Mobility Service installer automatically changes the ASP.NET settings.

Hardware Load Balancer Requirements

On the hardware load balancer that is supporting the Front End pool, the external Web Services virtual IPs (VIPs) for Web Services traffic must be configured for source. Source affinity helps to ensure that multiple connections from a single client are sent to one server to maintain session state. For details about affinity requirements, see Load Balancing Requirements.

If you plan to support Lync mobile clients only over your internal Wi-Fi network, you should configure the internal Web Services VIPS for source as described for external Web Services VIPs. In this situation, you should use source_addr (or TCP) affinity for the internal Web Services VIPs on the hardware load balancer. For details, see Load Balancing Requirements.

Reverse Proxy Requirements

If you support automatic discovery for Lync mobile clients, you need to update the current publishing rule as follows:

- If you decide to update the subject alternative names lists on the reverse proxy certificates and use HTTPS for the initial Autodiscover Service request, you must update the web publishing rule for lyncdiscover.<*sipdomain*>. Typically, this is combined with the publishing rule for the external Web Services URL on the Front End pool.
- If you decide to use HTTP for the initial Autodiscover Service request so that you do not need to update the subject alternative names list on the reverse proxy certificates, you must create a new web publishing rule for port HTTP/ TCP 80, if one does not already exist. If a rule for HTTP/TCP 80 does already exist, you can update that rule to include the lyncdiscover.<*sipdomain*> entry.

1.3.9.10.9.4 Autodiscover Service Requirements

Autodiscover Service Requirements

Planning for External User Access > Scenarios for External User Access > Planning for Mobility >

Topic Last Modified: *2013-02-25*

The Microsoft Lync Server 2013 Autodiscover Service runs on the Director and Front End pool servers, and when published in DNS, can be used by mobile devices running Lync Mobile to locate mobility services. Before mobile devices running Lync Mobile can take advantage of automatic discovery, you need to modify certificate subject alternative name lists on any Director and Front End Server running the Autodiscover Service. In addition, it may be necessary to modify the subject alternative name lists on certificates used for external web service publishing rules on reverse proxies.

For details about the subject alternative name entries that are required for Directors, Front End Servers, and reverse proxies, see Technical Requirements for Mobility in Planning for Mobility.

The decision about using subject alternative name lists on reverse proxies is based on whether you publish the Autodiscover Service on port 80 or on port 443:

- **Published on port 80** No certificate changes are required if the initial query to the Autodiscover Service occurs over port 80. This is because mobile devices running Lync will access the reverse proxy on port 80 externally and then be redirected to a Director or Front End Server on port 8080 internally. For details, see the "Initial Autodiscover Process Using Port 80" section later in this topic.
- **Published on port 443** The subject alternative name list on certificates used by the external web services publishing rule must contain a *lyncdiscover.<sipdomain>* entry for each SIP domain within your organization.

Reissuing certificates using an internal certificate authority is typically a simple process but for public certificates used on the web service publishing rule, adding multiple subject alternative name entries can become expensive. To work around this issue, we support the initial automatic discovery connection over port 80, which is then redirected to port 8080 on the Director or Front End Server.

For example, assume that a mobile client running Lync Mobile is configured to sign in to Lync Server 2013 using the automatic discovery feature using HTTP for the initial request.

Initial Autodiscover Process for Mobile Devices Using Port 80

1. Mobile device running Lync Mobile looks up lyncdiscover.contoso.com using DNS, where an A record exists.
2. External DNS returns the IP address for the external web services to the client.
3. Mobile device running Lync Mobile sends request http:// lyncdiscover.contoso.com?sipuri=lyncUser1@contoso.com to the reverse proxy
4. The web publishing rule will bridge the request from port 80 externally to port 8080 internally, which will then route it to either a Director or Front End Server.
   Since the request is HTTP and not HTTPS, no modifications are needed to the certificate on the external web service publishing rule to support the Autodiscover Service.
5. The Autodiscover Service returns the external web service URLs (in HTTPS format).
6. The mobile device running Lync Mobile can then reconnect to the reverse proxy on port 443 and is redirected over 4443 to the mobility service running on the user's home pool.
   Since the HTTPS query is to the external web services URL vs. the Autodiscover Service URL, it succeeds because the certificate will already

contain subject alternative name entries for the external web services fully qualified domain names (FQDNs).
In this scenario, there are no certificate changes required to support mobility.

> **Note:**
> If the target web server has a certificate that does not have a matching value for lyncdiscover.contoso.com as a subject alternative name list value:
> a. Web server responds with a "Server Hello" and no certificate.
> b. Mobile device running Lync Mobile immediately terminates the session.
> If the target web server has a certificate that includes lyncdiscover.contoso.com as a subject alternative name list value:
> a. Web server responds with a "Server hello" and a certificate.
> b. Mobile device running Lync Mobile validates the certificate and completes the handshake.

To support an initial connection to the Autodiscover Service using port 80 on your reverse proxy server, you can create an http publishing rule similar to this example for a Forefront Threat Management Gateway 2010 reverse proxy web publishing rule:

1. Create a new web publishing rule (for example, **Lync Server Autodiscover (HTTP)**).
2. In **Public Name**, enter lyncdiscover.contoso.com.
3. On the **Bridging** tab, select only the option to bridge requests from Port 80 to Port 8080.
4. On the **Authentication** tab, select **No authentication**, and **Client cannot authenticate directly**.
5. Commit changes, and move the rule to the top of the list of Lync rules (first in processing order).

Mobility for the Split Domain Deployment

A shared SIP address space, also known as a *split-domain*, or a *hybrid deployment* is a configuration where users are deployed across an on-premise deployment and an online environment. The desired outcome is to have a user, regardless of where their home server is located (on-premise or online), to log into the deployment and be redirected to their home server location. To accomplish this, the Autodiscover feature of Microsoft Lync Server 2013 is used to redirect the online user to the online topology. This is done by configuring the Autodiscover uniform resource locator (URL) by using the Lync Server Management Shell and the cmdlets **Get-CsHostingProvider** and **Set-CsHostingProvider**.

You will need to collect and record the following deployed attributes:

- From the Lync Server Management Shell, type

```
Get-CsHostingProvider
```

- In the results, find the online provider with the attribute **ProxyFQDN**. For example, sipfed.online.lync.com
- Record the value of the ProxyFQDN
- Enable federation in the on-premise Lync Server Control Panel, allowing federation with the online provider
- Enable federation for the online provider. By default, all online users are enabled for domain federation and can communicate with all domains
- If you will define blocked and allowed domains, determine the domains that you will explicitly allow or explicitly block
- For online federation, you must plan for firewall exceptions, certificates and DNS host (A or AAAA, if using IPv6) records. Additionally, you must configure federation policies. For details, see Planning for Lync Server and Office Communications Server Federation

1.3.9.10.9.5 Defining Your Mobility Requirements

Defining Your Mobility Requirements

See Also

Planning for External User Access > Scenarios for External User Access > Planning for Mobility >

Topic Last Modified: *2013-02-14*

Some information in this topic pertains to Cumulative Updates for Lync Server 201

During the planning phase for the Lync Server 2013 mobility feature, when you are using Lync 2010 Mobile and Lync 2013 Mobile clients, you make decisions that determine your deployment steps.

Here are the decisions that you must consider:

- **Do you want to use automatic discovery for Lync mobile clients?**
  If you want to support automatic discovery, you need to create new internal and external Domain Name System (DNS) records, add subject alternative names to certificates on the Front End Servers, Directors, and reverse proxy, and modify the existing publishing rules on the reverse proxy. For details, see Technical Requirements for Mobility. With automatic discovery, users can automatically locate Lync Server 2013 Web Services from anywhere inside or outside the corporate network, without entering URLs in their mobile device settings.
  If you use manual settings instead of automatic discovery, mobile users need to manually enter the following URLs in their mobile devices:
    - https://<ExtPoolFQDN>/Autodiscover/autodiscoverservice.svc/Root for external access
    - https://<IntPoolFQDN>/AutoDiscover/ autodiscoverservice.svc/Root for internal access

  We strongly recommend using automatic discovery. The primary use of manual settings is for troubleshooting.
- **If you decide to support automatic discovery, are you willing to update certificates on the reverse proxy with subject alternative names for each SIP domain?**
  If you have many SIP domains, updating public certificates on the reverse proxy can become very expensive. If this is the case, you can choose to implement automatic discovery so that the initial Autodiscover Service request uses HTTP on port 80, instead of using HTTPS on port 443. However, this is not the recommended approach. If you decide to choose this alternative, you do not need to update the certificates on the reverse proxy, but you need to create a web publishing rule for HTTP on port 80. For more details, see Technical Requirements for Mobility.
- **Do you want to support Lync mobile clients both internal and external to the corporate network, or support clients only inside the corporate network?**
  If you want to support mobile clients internal and external to your network, mobile devices can access mobility features from any location. The default configuration is to support clients both internal and external to the corporate network.
  Although the default configuration enables mobile client traffic to go through the external site, you can restrict mobile client traffic to the internal corporate network. When you restrict the traffic to the internal network, users can use Lync mobile applications on their mobile devices only when they are inside the network.
  For deployments that support mobility using the Mcx mobility service and Lync 2010 Mobile, you run the **Set-CsMcxConfiguration** cmdlet. To set mobility for internal use only, you would use a command similar to the following:

```
Set-CsMcxConfiguration -Identity site:Redmond -ExposedWebURL Internal
```

Note:

There are no additional configurations required for UCWA. UCWA does not have an equivalent internal-only configuration.

Important:

If you are using a Lync Server 2013 Front End Server or Front End pools and **you do not have** any Lync Server 2010 Front End Servers or Front End pools, **there is no requirement for cookie-based persistence**. If you need to retain any Lync Server 2010 Front End Servers or Front End pools, the same rules still apply as in Lync Server 2010 for cookie-based persistence.

- **Do you want to support push notifications for Apple iOS devices and Windows Phones?**
  If you support push notifications, supported Apple iOS devices and Windows Phones receive a notification of events that occur when the mobile application is inactive. You must configure your Edge Server to have a federation relationship with the cloud-based Lync Server Push Notification Service, which is located in the Lync Online datacenter, and run a cmdlet to enable push notifications.
  If you want to support push notifications over your Wi-Fi network, in addition to supporting push notifications over the mobile device providers' 3G or data networks, you must open port 5223 outbound on your enterprise Wi-Fi network. Supporting push notifications over the Wi-Fi network supports mobile devices that use only Wi-Fi and mobile devices that have poor indoor reception.

  Important:

  Opening port TCP 5223 is required only when supporting Apple devices running the Lync 2010 Mobile client.

  If you do not support push notifications, users of Apple mobile devices and Windows Phones will not find out about events—such as instant message invitations or missed messages—that occur when the mobile application is inactive.

  Note:

  Lync 2013 Mobile clients on Apple devices do not require push notification. The Lync 2013 Mobile clients on Windows Phone use push notification. Planning for push notification and the push notification clearinghouse remain the same for Lync Mobile on Windows Phone and Apple devices that are not able to run the Lync 2013 Mobile client.

- **Do you want all users to have access to mobility features, or do you want to be able to specify which users have access to these features?**
  The table describes features available to users in Lync Server 2013. The defaults allow Call via Work, allow Voice over IP (VoIP), and enable Mobility. Here is the full set of available options:

Feature/Paramater Name/Scope (Policy parameter names may not be the same)	Description	Introduced
Enable Mobility Parameter Name : `EnableMobility` Scope: Global/Site/User	Administrative setting to control users in a given scope that have the Lync Mobile installed, If the policy is set to False, the user would not be able to sign into the client. The default setting is	Cumulative Update for Lync Server 2010: November 2011

	True.	
Enable Outside Voice Parameter Name : `EnableOutsideVoice` Scope: Global/Site/User	Controls a user's ability to use Call Via Work, a feature that enables users to make and receive calls by using their work number instead of their mobile number. If set to False, the user will not be able to make or receive calls by using their work number from their mobile device. The default setting is True	Cumulative Update for Lync Server 2010: November 2011
Enable IP Audio and Video Parameter Name : `EnableIPAudioVideo` Scope: Global/Site/User	Controls whether a user can use VoIP to make or receive voice or video calls on their mobile device. If set to False, the user will not be able to make or receive VoIP or video calls on their device. The default setting is True.	Microsoft Lync Server 2013
Require WiFi for IP Audio Parameter Name : `RequireWiFiForIPAudio` Scope: Global/Site/User	This setting defines whether the client will be required to make and receive calls over VoIP on WiFi instead of the cellular data network. If set to True, the user can make and receive VoIP calls only when connected to a WiFi network. The default setting is False.	Microsoft Lync Server 2013
Require WiFi for IP Video Parameter Name : `RequireWiFiForIPVideo` Scope: Global/Site/User	This setting defines whether the client will be required to make and receive video calls on Wi-Fi instead of on the cellular data network. If set to True, the user can make and receive video calls only when connected to a Wi-Fi network. The default setting is False.	Microsoft Lync Server 2013

For a description of the policy settings that you can configure, and how to manage the policies, see New-CsMobilityPolicy, Set-CsMobilityPolicy, Get-CsMobilityPolicy, Grant-CsMobilityPolicy and Remove-CsMobilityPolicy.

- **Do you want users who are not enabled for Enterprise Voice to be able to**

use Click to Join to join conferences?
For users to have access to mobility features and Call via Work, they must be enabled for Enterprise Voice. However, users who are not enabled for Enterprise Voice can join conferences by clicking the link on their mobile device, if they have an appropriate voice policy assigned to them. You can either assign a specific voice policy to these users or make sure that a global policy or site-level policy exists that applies to them. The voice policy that you assign must have public switched telephone network (PSTN) usage records and routes that define the areas to which users can dial out to join a conference. For details about setting voice policy, PSTN usage records, and routes, see Configuring Voice Policies, PSTN Usage Records, and Voice Routes.

> **Note:**
> Mobile users who want to use Click to Join require a voice policy, along with the related PSTN usage records and voice routes, because clicking the link on the mobile device results in an outbound call from Lync Server 2013.

1.3.9.10.9.6 Deployment Process for Mobility

Deployment Process for Mobility

Planning for External User Access > Scenarios for External User Access > Planning for Mobility >

Topic Last Modified: *2013-02-19*

```
Some information in this topic pertains to Cumulative Updates for Lync Server 201
```

This section describes the sequence of steps required to deploy the Lync Server 2013 mobility feature.

Mobility Deployment Process

Phase	Steps	Permissions	Deployment documentation
Create Domain Name System (DNS) records	• Create an internal DNS CNAME or A (host, if IPv6, AAAA) record to resolve the internal Autodiscover Service URL. • Create an external DNS CNAME or A (host, if IPv6, AAAA) record to resolve the external Autodiscover Service URL.	Domain Admins DnsAdmins	Creating DNS Records for the Autodiscover Service
Modify certificates	Add subject alternative name entries to the following certificates to support secure connections for mobile users: • Director certificate • Front End pool certificate	Local administrator	Modifying Certificates for Mobility

	• Reverse proxy certificate		
Configure the reverse proxy	• Assign certificates updated with subject alternative names to the Secure Sockets Layer (SSL) Listener. • Reconfigure the web publishing rule for the external Autodiscover Service URL. • Be sure that a web publishing rule exists for the external Lync Server 2013 Web Services URL on your Front End pool. Or • If you choose to use HTTP for the initial Autodiscover request and do not update subject alternative name lists on the certificates, configure a new web publishing rule or reconfigure an existing publishing rule for port 80 HTTP.	Local administrator	Configuring the Reverse Proxy for Mobility
Test your mobility deployment for Lync 2010 Mobile using the Mcx Mobility Service	Run **Test-CsMcxP2PIM** to test sending an instant message from one person to another. See the Lync Server Management Shell cmdlet documentation for Test-CsMcxP2PIM for a complete list of options.	CsAdministrator	Verifying Your Mobility Deployment
Test your mobility deployment for Lync 2013 Mobile clients using the UCWA Web components	Use the **Test-CsUcwaConference** cmdlet to test and verify that pre-defined test users or a pair of actual users can use UCWA to create and participate in a conference. See the Lync Server Management Shell cmdlet documentation for Test-CsUcwaConference for a complete list of options.	CsAdministrator	Verifying Your Mobility Deployment

Configure for push notifications	- For Lync Server 2013 Edge Servers, add a Lync Server online hosting provider and configure hosting provider federation. - For Lync Server 2010 Edge Servers, add a Lync Server online hosting provider and configure hosting provider federation. - For Office Communications Server 2007 R2 Edge Servers, add a federated partner. - If you want to support push notifications over a Wi-Fi network, configure a firewall rule outbound for TCP port 5223. - Use the **Set-CsPushNotificationConfiguration** cmdlet to enable push notifications to the Apple Push Notification Service (APNS) and Microsoft Push Notification Service (MPNS). This feature is disabled by default. - Use the **Test-CsFederatedPartner** cmdlet to test the federation configuration and the **Test-CsMCXPushNotification** cmdlet to test push notifications. **Note:** Push notifications are used for Lync 2010 Mobile clients on Apple devices and Windows Phone Push notification is required for Lync 2013 Mobile clients on Windows Phone	RtcUniversalServerAdmins	Configuring for Push Notifications

	only		
Configure mobility policy	Use the **Set-CsMobilityPolicy** cmdlet to allow or disallow: • Call via Work • Enable IP Audio and IP Video • Require WiFi for IP Audio and/or IP Video	CsAdministrator	Configuring Mobility Policy

1.3.9.10.10 Scenarios for the Director

Scenarios for the Director

See Also

Planning > Planning for External User Access > Scenarios for External User Access >

Topic Last Modified: *2012-10-22*

A Director is a server running Microsoft Lync Server 2013 communications software that can authenticate user requests, but does not home any user accounts. The Director also hosts web services similar to the Front End Server and will authenticate web ticket requests and provide other services.

Important:

If you deploy Directors, you must publish the Director web services externally through the reverse proxy as well as the web services of the Front End Server. The topics following describe the planning process for the possible Director topologies.

- Overview of the Director
- Components Required for the Director
- Hardware and Software Requirements for the Director
- Single Director
- Scaled Director Pool

1.3.9.10.10.1 Overview of the Director

Overview of the Director

Planning for External User Access > Scenarios for External User Access > Scenarios for the Director >

Topic Last Modified: *2012-09-08*

A Director is a server running Lync Server 2013 that authenticates user requests, but does not home any user accounts. You optionally can deploy a Director in the following two scenarios:

- If you enable access by external users by deploying Edge Servers, you should also deploy a Director. In this scenario, the Director authenticates the external users, and then passes their traffic on to internal servers. When a Director is used to authenticate external users, it relieves Front End pool servers from

the overhead of performing authentication of these users. It also helps insulate internal Front End pools from malicious traffic such as denial-of-service attacks. If the network is flooded with invalid external traffic in such an attack, this traffic ends at the Director.
- If you deploy multiple Front End pools at a central site, by adding a Director to that site you can streamline authentication requests and improve performance. In this scenario, all requests go first to the Director, which then routes them to the correct Front End pool.

1.3.9.10.10.2 Components Required for the Director

Components Required for the Director

Planning for External User Access > Scenarios for External User Access > Scenarios for the Director >

Topic Last Modified: *2012-09-08*

The only component required to create and configure a Director is to deploy the Director server role. You do this by using Topology Builder and define either a single computer pool or a multiple computer pool in the Director pool node. After you have defined the Director or Director pool, run the Lync Server Deployment Wizard on the computer that will be a Director. In the case of a Director pool, you run the Lync Server Deployment Wizard on each server that will be a member of the pool.

Topologies

You can implement a single Director server or a Director pool. The Director is always a separate server or pool, not collocated with any other server role in Lync Server 2013.

Note:

If you do not deploy Directors, the Front End Server or Front End pool will assume the Director role.

A pool of Directors must be load balanced. You can do one of the following:

- Create a topology that uses a hardware load balancer for web services and Domain Name System (DNS) load balancing for the other traffic types.
  Scaled Director Pool - DNS Load Balancing and Hardware Load Balancer
- Create a topology that uses a hardware load balancer for load balancing needed for the Director pool.
  Scaled Director Pool - Hardware Load Balancer

1.3.9.10.10.3 Hardw are and Softw are Requirements for the Director

Hardware and Software Requirements for the Director

Planning for External User Access > Scenarios for External User Access > Scenarios for the Director >

Topic Last Modified: *2012-10-20*

This section details the hardware and software requirements for the Director, and the supported collocation scenarios for the Director.

Hardware Requirements for the Director

The following table lists the hardware requirements for the Director:

Hardware Requirements for the Director

Hardware component	Minimum requirement
CPU	• 64-bit processor, quad-core, 2.0 GHz or higher • 64-bit dual processor, dual-core, 2.0 GHz or higher
Memory	4 gigabytes (GB)
Disk	• 10K RPM hard disk drive (HDD) • High-performance solid state drive (SSD) with performance equal to or better than 10K RPM HDD • 2x RAID 10 (striped and mirrored) 15K RPM disks for database data files
Network	• Dual 1 gigabit per second (Gbps) network adapters (recommended) • Single 1 Gbps network adapter (supported)

Software Requirements for the Director

The Director role can be deployed only on servers running Lync Server 2013 Enterprise Edition.

One of the following 64-bit operating systems is required for the Directors:

- The Windows Server 2008 R2 Standard operating system with Service Pack 1
- The Windows Server 2008 R2 Enterprise operating system with Service Pack 1
- The Windows Server 2008 R2 Datacenter operating system with Service Pack 1
- The Windows Server 2012 Standard operating system
- The Windows Server 2012 Datacenter operating system

Lync Server 2013 also requires installation of the following programs and updates detailed in the topic Additional Server Support and Requirements.

Supported Collocation

The Director server role cannot be collocated with any other server role in Lync Server 2013. However, if you do not deploy a Director, the Front End Servers will assume the role.

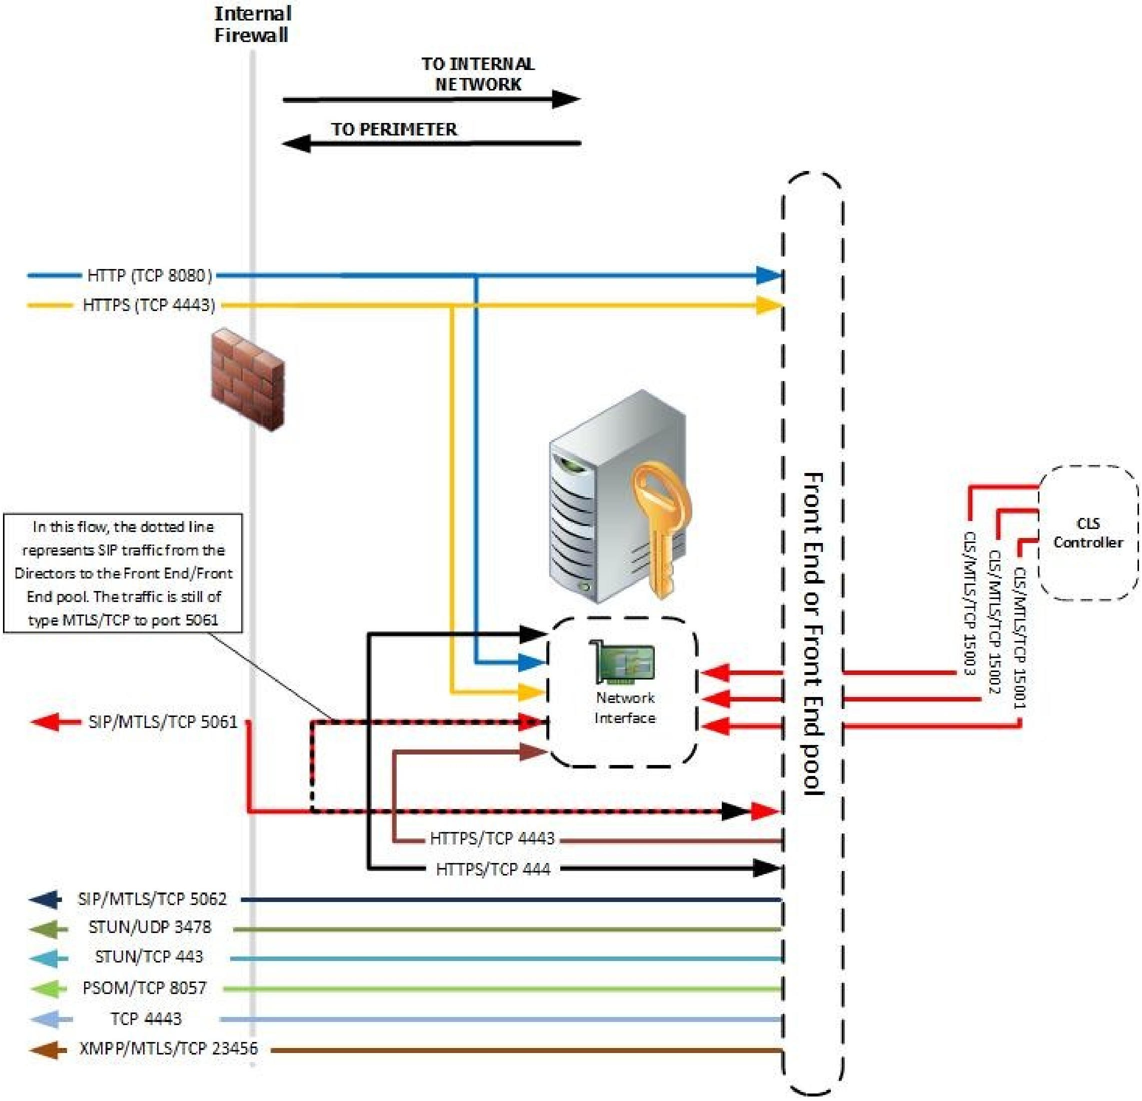
1.3.9.10.10.4 Single Director

Single Director

Planning for External User Access > Scenarios for External User Access > Scenarios for the Director >

Topic Last Modified: *2012-10-22*

The Director can be deployed in either a single Director configuration or as a Director pool. This section defines a topology and configuration for a single Director. If you are planning on deploying a pool of Directors for the purposes of handling higher capacity and for high availability, see the topic Scaled Director Pool for planning considerations for that topology.



In this flow, the dotted line represents SIP traffic from the Directors to the Front End/Front End pool. The traffic is still of type MTLS/TCP to port 5061

- Certificate Summary - Single Director
- Port Summary - Single Director
- DNS Summary - Single Director

Certificate Summary - Single Director

Scenarios for External User Access > Scenarios for the Director > Single Director >

Topic Last Modified: *2012-09-08*

Certificate requirements for a single Director consist of a default certificate that has a subject name and subject alternative names for services that the Director can receive. Additionally, there is an OAuth Token certificate for server to server authentication purposes.

Certificates for Director

Component	Subject name (SN)	Subject alternative names (SAN)	Comments
Default	dir01.contoso.net	dir01.contoso.net dialin.contoso.com meet.contoso.com lyncdiscoverinternal.contoso.com lyncdiscover.contoso.com (Optionally) *.contoso.com	Director certificates can be requested from either an internally managed certification authority (CA) or from a public CA. The Director responds to requests from the reverse proxy in the perimeter or from the Edge Server. Internal clients will not use the Director. Or, a wildcard entry for the simple URLs
OAuthTokenIssuer	dir01.contoso.net	No Entry	**Important:** Note that the minimum key length is 1024, but you may receive a warning that the minimum recommended key length is 2048 bits. The OAuthTokenIssuer certificate is a single-purpose certificate for the purpose of authenticating servers in a large-scale environment, and can be requested from an internal CA or from a public CA. The certificate is required.

Port Summary - Single Director

Scenarios for External User Access > Scenarios for the Director > Single Director >

Topic Last Modified: *2012-10-20*

Firewall port requirements for a single Director consist of the ports that are used to establish communication with the Director from the internal interface or internal-facing network of the reverse proxy. Microsoft Lync Server 2013 by default expects ports HTTP/ TCP 8080 and HTTPS/TCP 4443 to be open from the reverse proxy to the Director, as well as the Front End pool and Front End Server. Additionally, there must be session initiation protocol (SIP) communication from the Edge Server internal interface to the Director and to the Front End pool and Front End Server. The SIP protocol uses SIP/MTLS/TCP 5061 from the Edge Server to the Front End pool and Front End Server. A rule that allows SIP/ MTLS/TCP 5061 communication from the Director, Front End pool and Front End Server to the Edge Server internal interface must be created as well.

Single Director Ports and Protocols for Firewall Definitions

Role/Protocol/TCP or UDP/Port	Source IP address	Destination IP address	Notes
HTTP/TCP 8080	Reverse proxy internal interface	Director	Initially received by the external side of the reverse proxy, the communication is sent on to the Director and Front End Server web services
HTTPS/TCP 4443	Reverse proxy internal interface	Director	Initially received by the external side of the reverse proxy, the communication is sent on to the Director and Front End Server web services
HTTPS/TCP 444	Director	Front End server or Front End pool	Inter-server communication between the Director and the Front End Server
HTTP/TCP 80	Internal Clients	Director web services	The Director provides web services to internal and external clients.
HTTPS/TCP 443	Internal Clients	Director web services	The Director provides web services to internal and external clients.
SIP/MTLS/TCP 5061	Edge Server internal interface	Director	SIP communication from the Edge Server to the Director, and the Front End Server.
MTLS/TCP/50001	Any	Edge Server internal interface	Centralized Logging Service controller (ClsController.exe) or agent (ClasAgent.exe) commands and log collection
MTLS/TCP/50002	Any	Edge Server internal interface	Centralized Logging Service controller (ClsController.exe) or agent (ClasAgent.exe) commands and log collection

MTLS/TCP/50003	Any	Edge Server internal interface	Centralized Logging Service controller (ClsController.exe) or agent (ClasAgent.exe) commands and log collection

DNS Summary - Single Director

Scenarios for External User Access > Scenarios for the Director > Single Director >

Topic Last Modified: *2012-10-20*

The following table contains a summary of the DNS records that are required to support the single Director. The role of the Director requires similar DNS records as the Front End Server. The number of records needed is reflected in the subject alternative names required on the Director certificate. Different from the Front End Server, the Director does not host user accounts or host the Mobility Services.

DNS Records Required for the Director

Location/TYPE/Port	FQDN/DNS Record	IP Address/FQDN	Maps to/Comments
Internal DNS/A	dir01.contoso.net	Director	Director host record used for replication and server to server
Internal DNS/A	sip.contoso.com	Director	Inbound session initiation protocol (SIP) from the internal Edge interface of the Edge Server
Internal DNS/A	dialin.contoso.com	Director	Published dialin web services from reverse proxy
Internal DNS/A	meet.contoso.com	Director	Published meet web services from reverse proxy
Internal DNS/A	webdirexternal.contoso.com	Director	Published and defined by the reverse proxy Web Ticket external web services for the Director

1.3.9.10.10.5 Scaled Director Pool

Scaled Director Pool

Planning for External User Access > Scenarios for External User Access > Scenarios for the Director >

Topic Last Modified: *2012-09-08*

The Director can be deployed in either a single Director configuration, or as a Director pool. This section defines a topology and configuration for two pooled Director topologies.

If you are planning on deploying a single Director, see the topic Single Director for planning considerations for that topology.

- Scaled Director Pool - DNS Load Balancing and Hardware Load Balancer
- Scaled Director Pool - Hardware Load Balancer

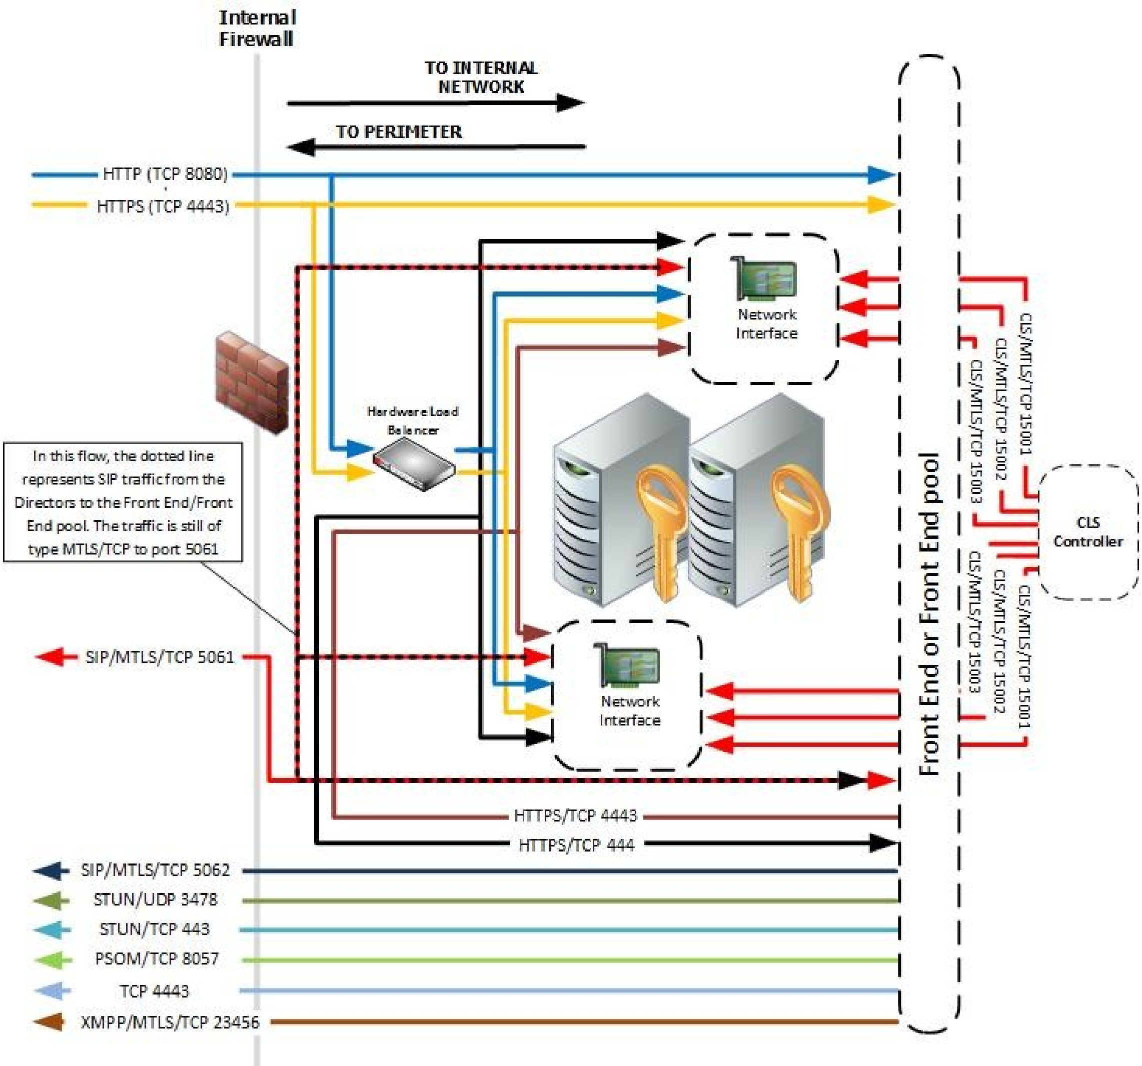
Scaled Director Pool - DNS Load Balancing and Hardware Load Balancer

Scenarios for External User Access > Scenarios for the Director > Scaled Director Pool >

Topic Last Modified: *2012-10-22*

A scaled Director pool, where there are more than one Director deployed to handle additional capacity and to provide high availability, requires load balancing to distribute client and server communication to all members of the pool. A Director hosts web services much like a Front End pool. To provide the load balancing, you can use either hardware load balancing or domain name system (DNS) load balancing and hardware load balancing. Hardware load balancing is required for the web services, and DNS load balancing alone does not provide the capabilities required for the web services.

The following topics describe the planning considerations for deploying a Director pool using DNS load balancing in conjunction with hardware load balancing. If you intend to use hardware load balancing, but not DNS load balancing for the Director pool, see the topic Scaled Director Pool - Hardware Load Balancer that describes the planning requirements for that topology.



In this flow, the dotted line represents SIP traffic from the Directors to the Front End/Front End pool. The traffic is still of type MTLS/TCP to port 5061

1.3.10 Planning for Enterprise Voice

Planning for Enterprise Voice

Microsoft Lync Server 2013 > Planning >

Topic Last Modified: *2012-09-21*

The deployment process for Enterprise Voice depends on your existing topology, infrastructure, and the Enterprise Voice functionality that you want to support. The required procedures will depend on what features you choose, but there are other planning considerations that you must make at a high level.

In general, consider the type and number of sites that you want to deploy and their geographical locations, the call volume at each site, the types of network links that connect sites, whether you want to provide redundancy and failover for voice functionality for each site, and whether you want to use existing PBX equipment. There are certain considerations, such as high availability, that you should consider when you plan for Lync Server communications software as a whole. These considerations are discussed in topics throughout this section, as needed.

Planning Considerations

For planning decisions that pertain to the deployment of a particular Enterprise Voice capability or deployment scenario or component, consult the topics in this section.

- Defining Your Organization's Requirements for Enterprise Voice
- Estimating Voice Usage and Traffic
- Network Settings for the Advanced Enterprise Voice Features
- Planning for Enterprise Voice Resiliency
- Components Required for Enterprise Voice
- Deployment Guidelines for Enterprise Voice
- Deployment Process Overview for Enterprise Voice
- Moving Users to Enterprise Voice

1.3.10.1 Defining Your Organization's Requirements for Enterprise Voice

Defining Your Organization's Requirements for Enterprise Voice

See Also

Microsoft Lync Server 2013 > Planning > Planning for Enterprise Voice >

Topic Last Modified: *2012-08-07*

This topic provides an overview of the considerations you need to make about the regions, sites, and the links between sites in your topology and how those are important when you deploy Enterprise Voice. For details to help you make these decisions, see Network Settings for the Advanced Enterprise Voice Features in the Planning documentation.

Sites and Regions

First, identify the sites in your topology where you will deploy Enterprise Voice and the network regions to which those sites belong. In particular, consider how you will provide public switched telephone network (PSTN) connectivity to each site. For manageability and logistical reasons, the regions to which these sites belong can be a deciding factor. Decide where gateways will be deployed locally, where Survivable Branch Appliances (SBAs) will be deployed, and where you can configure SIP trunks (either locally or at the central site) to an Internet telephony service provider (ITSP).

Network Links Between Sites

You also need to consider the bandwidth usage that you expect on the network links between your central site and its branch sites. If you have, or plan to deploy, resilient WAN links between sites, we recommend that you deploy a gateway at each branch site to provide local direct inward dial (DID) termination for users at those sites. If you have resilient WAN links, but the bandwidth on a WAN link is likely to be constrained, configure call admission control for that link. If you do not have resilient WAN links, host fewer than 1000 users at your branch site, and do not have local trained Lync Server administrators available, we recommend that you deploy a Survivable Branch Appliance at the branch site. If you host between 1000 and 5000 users at your branch site, lack a resilient WAN connection, and have trained Lync Server administrators available, we recommend that you deploy a Survivable Branch Server with a small gateway at the branch site. Consider also enabling media bypass on constrained links if you have a gateway peer that supports media bypass.

1.3.10.2 Estimating Voice Usage and Traffic

Estimating Voice Usage and Traffic

Planning > Capacity Planning > Capacity Planning Using the User Models >

Topic Last Modified: *2012-08-07*

The Microsoft Lync Server 2013, Planning Tool uses the following metric to estimate user traffic at each site and the number of ports that are required to support that traffic.

- For **Light traffic** (one PSTN call per user per hour), figure 15 users per port.
- For **Medium traffic** (2 PSTN calls per user per hour), figure 10 users per port.
- For **Heavy traffic** (3 or more PSTN per user calls per hour), figure 5 users per port.

The number of ports in turn determines the number of Mediation Servers and gateways that will be required. The public switched telephone network (PSTN) gateways that most organizations consider deploying range in size from 2 ports to as many as 960 ports. (There are even larger gateways, but these are used mainly by telephony service providers.)

For example, an organization with 10,000 users and medium traffic would require 1000 ports. The number of gateways required would equal the total number of ports required as determined by the total capacity of the gateways.

Microsoft Lync Server 2013 > Planning > Planning for Enterprise Voice >

Topic Last Modified: *2012-10-10*

Lync Server has three advanced Enterprise Voice features: call admission control (CAC), emergency services (E9-1-1), and media bypass. These features share certain configuration requirements for network regions, network sites, and association of each subnet in the Lync Server topology with a network site. For details about planning for deployment of these features, see:

- Planning for Call Admission Control
- Planning for Emergency Services (E9-1-1)
- Planning for Media Bypass

For details about deploying each of these features, see Deploying Advanced Enterprise Voice Features in the Deployment documentation.

This topic provides an overview of the configuration requirements that are common to all three advanced Enterprise Voice features.

Network Regions

A network region is a network hub or network backbone used only in the configuration of call admission control (CAC), E9-1-1, and media bypass.

> **Note:**
> Network regions are not the same as Lync Server dial-in conferencing regions, which are required to associate dial-in conferencing access numbers with one or more Lync Server dial plans. For details about dial-in conferencing regions, see Dial-In Conferencing Requirements in the Planning documentation.

CAC requires that every network region have an associated Lync Server central site, which manages media traffic within the region (that is, it makes decisions based on policies that you have configured, regarding whether or not a real-time audio or video session can be established). Lync Server central sites do not represent geographical locations, but rather logical groups of servers that are configured as a pool or a set of pools. For details about central sites, see Reference Topologies in the Planning documentation. Also see Supported Lync Server 2013 Topologies in the Supportability documentation.

To configure a network region, you can either use the **Regions** tab on the **Network Configuration** section of Lync Server Control Panel, or run the **New-CsNetworkRegion** or **Set-CsNetworkRegion** Lync Server Management Shell cmdlets. For instructions, see Create or Modify a Network Region in the Deployment documentation, or refer to the Lync Server Management Shell documentation.

The same network region definitions are shared by all three advanced Enterprise Voice features. If you have already created network regions for one feature, you do not need to create new network regions for the other features. You may, however, need to modify an existing network region definition to apply feature-specific settings. For example, if you have created network regions for E9-1-1 (which do not require an associated central site) and, later, you deploy call admission control, you must modify each of the network region definitions to specify a central site.

To associate a Lync Server central site with a network region, you specify the central site name, either by using the **Network Configuration** section of Lync Server Control Panel, or by running the **New-CsNetworkRegion** or **Set-CsNetworkRegion** Lync Server Management Shell cmdlets. For instructions, see Create or Modify a Network Region in the Deployment documentation, or refer to the Lync Server Management Shell documentation.

Network Sites

A network site represents a geographical location, such as a branch office, a regional office, or a main office. Each network site must be associated with a specific network region.

Note:

Network sites are used only by the advanced Enterprise Voice features. They are not the same as the branch sites that you configure in your Lync Server topology. For details about branch sites, see Reference Topologies in the Planning documentation. Also see Supported Lync Server 2013 Topologies in the Supportability documentation.

To configure a network site and associate it with a network region, you can either use the **Network Configuration** section of Lync Server Control Panel, or run the Lync Server Management Shell **New-CsNetworkSite** or **Set-CsNetworkSite** cmdlets. For details, see Create or Modify a Network Site in the Deployment documentation, or refer to the Lync Server Management Shell documentation.

Identify IP Subnets

For each network site, you will need to work with your network administrator to determine which IP subnets are assigned to each network site. If your network administrator has already organized the IP subnets into network regions and network sites, then your work is significantly simplified.

For example, the New York site in the North America region can be assigned the following IP subnets: 172.29.80.0/23, 157.57.216.0/25, 172.29.91.0/23, 172.29.81.0/24. If Bob, who usually works in Detroit, travels to the New York office for training, turns on his computer and connects to the network, his computer will get an IP address in one of the four ranges that are allocated for New York—for example, 172.29.80.103.

Warning:

The IP subnets specified during network configuration on the server must match the format that is provided by client computers in order to be properly used for media bypass. A Lync client takes its local IP address and masks the IP address with the associated subnet mask. When determining the bypass ID associated with each client, the Registrar will compare the list of IP subnets associated with each network site against the subnet that is provided by the client for an exact match. For this reason, it is important that subnets entered during network configuration on the server are actual subnets instead of virtual subnets. (If you deploy call admission control, but not media bypass, call admission control will function properly even if you configure virtual subnets.)
For example, if a Lync client signs in on a computer with an IP address of 172.29.81.57 with an IP subnet mask of 255.255.255.0, it will request the bypass ID that is associated with subnet 172.29.81.0. If the subnet is defined as 172.29.0.0/16, although the client belongs to the virtual subnet, the Registrar will not consider this a match because the Registrar is specifically looking for subnet 172.29.81.0. Therefore, it is important that the administrator enters subnets exactly as provided by Lync clients (which are provisioned with subnets during network configuration, either statically or by Dynamic Host Configuration Protocol (DHCP).)

Associating Subnets with Network Sites

Every subnet in the enterprise network must be associated with a network site (that is, every subnet needs to be associated with a geographic location). This association of subnets enables the advanced Enterprise Voice features to locate the endpoints geographically. For example, locating the endpoints enables CAC to regulate the flow of real-time audio and video data going to and from the network site.

To associate subnets with network sites, you can either use the **Network Configuration** section of Lync Server Control Panel, or you can use the Lync Server Management Shell. For instructions, see Associate a Subnet with a Network Site in the Deployment documentation, or refer to the Lync Server Management Shell documentation.

1.3.10.4 Components Required for Enterprise Voice

Components Required for Enterprise Voice

Microsoft Lync Server 2013 > Planning > Planning for Enterprise Voice >

Topic Last Modified: *2012-10-20*

This section describes all components that are used by one or more Enterprise Voice features. They include the following:

- Front End Server VoIP Components
- Mediation Server Component
- PSTN Connectivity Components
- Perimeter Network VoIP Components

Front End Server VoIP Components

Planning > Planning for Enterprise Voice > Components Required for Enterprise Voice >

Topic Last Modified: *2012-10-01*

The VoIP components located on Front End Servers are as follows:

- Translation Service
- Inbound Routing component
- Outbound Routing component
- Exchange UM Routing component
- Intercluster Routing component
- Mediation Server Component

Translation Service

The Translation Service is the server component that is responsible for translating a dialed number into the E.164 format or another format, according to the normalization rules that are defined by the administrator. The Translation Service can translate to formats other than E.164 if your organization uses a private numbering system or uses a gateway or PBX that does not support E.164.

Inbound Routing Component

The Inbound Routing component handles incoming calls largely according to preferences that are specified by users on their Enterprise Voice clients. It also facilitates delegate ringing and simultaneous ringing, if configured by the user. For example, users specify whether unanswered calls are forwarded or simply logged for notification. If call forwarding is enabled, users can specify whether unanswered calls should be forwarded to another number or to a Exchange UM server that has been configured to provide call answering. The Inbound Routing component is installed by default on all Standard Edition server and Front End Servers.

Outbound Routing Component

The Outbound Routing component routes calls to PBX or PSTN destinations. It applies call authorization rules, as defined by the user’s voice policy, to callers and determines the optimal PSTN gateway for routing each call. The Outbound Routing component is installed by default on all Standard Edition server and Front End Servers.

The routing logic that is used by the Outbound Routing component is in large measure configured by network or telephony administrators according to the requirements of their organizations.

Exchange UM Routing Component

The Exchange UM routing component handles routing between Lync Server and servers running Exchange Unified Messaging (UM), to integrate Lync Server with Unified Messaging features.

The Exchange UM routing component also handles rerouting of voice mail over the PSTN if Exchange UM servers are unavailable. If you have Enterprise Voice users at branch sites that do not have a resilient WAN link to a central site, the Survivable Branch Appliance that you deploy at the branch site provides voice mail survivability for branch users during a WAN outage. When the WAN link is unavailable, the Survivable Branch Appliance does the following:

- reroutes unanswered calls over the PSTN to the Exchange Unified Messaging server in the central site
- provides the ability for a user to retrieve voice mail messages over the PSTN
- queues missed call notifications, and then uploads them to the Exchange UM server when the WAN link is restored.

To enable voice mail rerouting, we recommend that your Exchange administrator configure Exchange UM Auto Attendant (AA) to accept messages only.

For details about these features, see Planning for Exchange Unified Messaging Integration and Planning for Enterprise Voice Resiliency, respectively.

Intercluster Routing Component

The Intercluster routing component is responsible for routing calls to the callee's primary Registrar pool. If that is unavailable, the component routes the call to the callee's backup Registrar pool. If the callee's primary and backup Registrar pools are unreachable over the IP network, the Intercluster routing component reroutes the call over the PSTN to the user's telephone number.

Other Front End Server Components Required for VoIP

Other components residing on the Front End Server or Director that provide essential support for VoIP, but are not themselves VoIP components, include the following:

- **User Services.** Perform reverse number lookup on the destination phone number of each incoming call and match that number to the SIP URI of the destination user. Using this information, the Inbound Routing component distributes the call to that user's registered SIP endpoints. User Services is a core component on all Front End Servers and Directors.
- **User Replicator.** Extracts user phone numbers from Active Directory Domain Services (AD DS) and writes them to tables in the RTC database, where they are available to User Services and Address Book Server. User Replicator is a core component on all Front End Servers.
- **Address Book Server.** Provides global address list information from Active Directory Domain Services (AD DS) to Lync Server clients. It also retrieves user and contact information from the RTC database, writes the information to the Address Book files, and then stores the files on a shared folder where they are downloaded by Lync clients. The Address Book Server writes the information to the RTCAb database, which is used by the Address Book Web Query service to respond to user search queries from Microsoft Lync 2010 Mobile. It optionally normalizes enterprise user phone numbers that are written to the RTC database for the purpose of provisioning user contacts in Lync. The Address Book service is installed by default on all Front End Servers. The Address Book Web Query service is installed by default with the Web services on each Front End Servers.

1.3.10.4.2 Mediation Server Component

Mediation Server Component

Planning > Planning for Enterprise Voice > Components Required for Enterprise Voice >

Topic Last Modified: *2012-09-21*

You must deploy Lync Server 2013, Mediation Server if you deploy the Enterprise Voice workload. This section describes basic functionality, dependencies, basic topologies, and planning guidelines.

The Mediation Server translates signaling and, in some configurations, media between your internal Lync Server 2013, Enterprise Voice infrastructure and a public switched telephone network (PSTN) gateway or a Session Initiation Protocol (SIP) trunk. On the Lync Server 2013 side, Mediation Server listens on a single mutual TLS (MTLS) transport address. On the gateway side, Mediation Server listens on all associated listening ports associated with trunks defined in the Topology document. All qualified gateways must support TLS, but can enable TCP as well. TCP is supported for gateways that do not support TLS.

If you also have an existing Public Branch Exchange (PBX) in your environment, Mediation Server handles calls between Enterprise Voice users and the PBX. If your PBX is an IP-PBX, you can create a direct SIP connection between the PBX and Mediation Server. If your PBX is a Time Division Multiplex (TDM) PBX, you must also deploy a PSTN gateway between Mediation Server and the PBX.

The Mediation Server is collocated with the Front End Server by default. The Mediation Server can also be deployed in a stand-alone pool for performance reasons, or if you deploy SIP trunking, in which case the stand-alone pool is strongly recommended.

If you deploy Direct SIP connections to a qualified PSTN gateway that supports media bypass and DNS load balancing, a stand-alone Mediation Server pool is not necessary. A stand-alone Mediation Server pool is not necessary because qualified gateways are capable of DNS load balancing to a pool of Mediation Servers and they can receive traffic from any Mediation Server in a pool.

We also recommend that you collocate the Mediation Server on a Front End pool when you have deployed IP-PBXs or connect to an Internet Telephony Server Provider’s Session Border Controller (SBC), as long as any of the following conditions are met:

- The IP-PBX or SBC is configured to receive traffic from any Mediation Server in the pool and can route traffic uniformly to all Mediation Servers in the pool.
- The IP-PBX does not support media bypass, but the Front End pool that is hosting the Mediation Server can handle voice transcoding for calls to which media bypass does not apply.

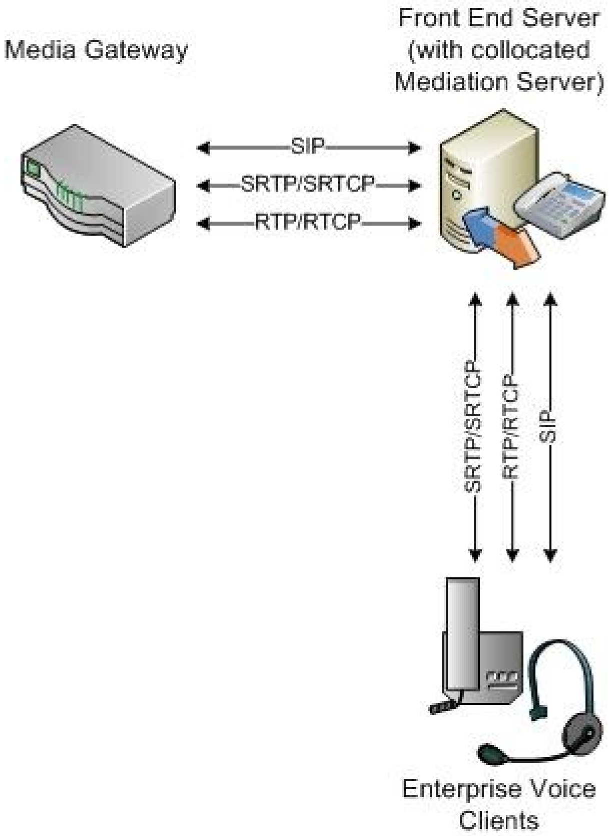
You can use the Microsoft Lync Server 2013, Planning Tool to evaluate whether the Front End pool where you want to collocate the Mediation Server can handle the load. If your environment cannot meet these requirements, then you must deploy a stand-alone Mediation Server pool.

The main functions of the Mediation Server are as follows:

- Encrypting and decrypting SRTP on the Lync Server side
- Translating SIP over TCP (for gateways that do not support TLS) to SIP over mutual TLS
- Translating media streams between Lync Server and the gateway peer of the Mediation Server
- Connecting clients that are outside the network to internal ICE components, which enable media traversal of NAT and firewalls
- Acting as an intermediary for call flows that a gateway does not support, such

as calls from remote workers on an Enterprise Voice client
- In deployments that include SIP trunking, working with the SIP trunking service provider to provide PSTN support, which eliminates the need for a PSTN gateway

The following figure shows the signaling and media protocols that are used by the Mediation Server when communicating with a basic PSTN gateway and the Enterprise Voice infrastructure.



Note:
If you are using TCP or RTP/RTCP (instead of SRTP or SRTCP) on the network between the PSTN gateway and the Mediation Server, we recommend that you take measures to help ensure the security and privacy of the network.

1.3.10.4.2.1 M:N Trunk

M:N Trunk

Planning for Enterprise Voice > Components Required for Enterprise Voice > Mediation Server Component >

Topic Last Modified: *2012-10-01*

Lync Server 2013 supports greater flexibility in the definition of a trunk for call routing purposes from previous releases. A trunk is a logical association between a Mediation Server and listening port number with a gateway and a listening port number. This implies several things: A Mediation Server can have multiple trunks to the same gateway; a Mediation Server can have multiple trunks to different gateways; conversely a gateway can have multiple trunks to different Mediation Servers.

A root trunk is still required to be created when a gateway is added to the Lync topology using Topology Builder. The number of gateways that a given Mediation Server can handle depends on the processing capacity of the server during peak busy hours. If you deploy a Mediation Server on hardware that exceeds the minimum hardware requirements for Lync Server 2013, as described in Supported Hardware in the Supportability documentation, then the estimate of how many active non-bypass calls a stand-alone Mediation Server can handle is approximately 1000 calls. When deployed on hardware meeting these specifications, the Mediation Server is expected to perform transcoding, but still route calls for multiple gateways even if the gateways do not support media bypass.

When defining a call route, you specify the trunks associated with that route, but you do not specify which Mediation Servers are associated with that route. Instead, you use Topology Builder to associate trunks with Mediation Servers. In other words, routing determines which trunk to use for a call, and, subsequently, the Mediation Server associated with that trunk is sent the signaling for that call.

The Mediation Server can be deployed as a pool; this pool can be collocated with a Front End pool, or it can be deployed as a stand-alone pool. When a Mediation Server is collocated with a Front End pool, the pool size can be at most 12 (the limit of the Registrar pool size). Taken together, these new capabilities increase the reliability and deployment flexibility for Mediation Servers, but they require associated capabilities in the following peer entities:

- **PSTN gateway.** A Lync Server 2013 qualified gateway must implement DNS load balancing, which enables a qualified public switched telephone network (PSTN) gateway to act as a load balancer for one pool of Mediation Servers, and thereby to load-balance calls across the pool.
- **Session Border Controller.** For a SIP trunk, the peer entity is a Session Border Controller (SBC) at an Internet telephony service provider. In the direction from the Mediation Server pool to the SBC, the SBC can receive connections from any Mediation Server in the pool. In the direction from the SBC to the pool, traffic can be sent to any Mediation Server in the pool. One method of achieving this is through DNS load balancing, if supported by the service provider and SBC. An alternative is to give the service provider the IP addresses of all Mediation Servers in the pool, and the service provider will provision these in their SBC as a separate SIP trunk for each Mediation Server. The service provider will then handle the load balancing for its own servers. Not all service providers or SBCs may support these capabilities. Furthermore, the service provider may charge extra for this capability. Typically, each SIP trunk to the SBC incurs a monthly fee.
- **IP-PBX.** In the direction from the Mediation Server pool to the IP-PBX SIP termination, the IP-PBX can receive connections from any Mediation Server in the pool. In the direction from the IP-PBX to the pool, traffic can be sent to any Mediation Server in the pool. Because most IP-PBXs do not support DNS load balancing, we recommend that individual direct SIP connections be defined from the IP-PBX to each Mediation Server in the pool. The IP-PBX will then handle its own load balancing by distributing traffic over the trunk group. The assumption is that the trunk group has a consistent set of routing rules at the IP-PBX. Whether a particular IP-PBX supports this trunk group concept and how it intersects with the IP-PBX's own redundancy and clustering architecture needs to be determined before you can decide whether a Mediation Server

cluster can interact correctly with an IP-PBX.

A Mediation Server pool must have a uniform view of the peer gateway with which it interacts. This means that all members of the pool access the same definition of the peer gateway from the configuration store and are equally likely to interact with it for outgoing calls. Therefore, there is no way to segment the pool so that some Mediation Servers communicate with only certain gateway peers for outgoing calls. If such segmentation is necessary, a separate pool of Mediation Servers must be used. This would be the case, for example, if the associated capabilities in PSTN gateways, SIP trunks, or IP-PBXs to interact with a pool as detailed earlier in this topic are not present.

A particular PSTN gateway, IP-PBX, or SIP trunk peer can route to multiple Mediation Servers or trunks. The number of gateways that a particular pool of Mediation Servers can control depends on the number of calls that use media bypass. If a large number of calls use media bypass, a Mediation Server in the pool can handle many more calls, because only signaling layer processing is necessary.

1.3.10.4.2.2 Call Admission Control and Mediation Server

Call Admission Control and Mediation Server

Planning for Enterprise Voice > Components Required for Enterprise Voice > Mediation Server Component >

Topic Last Modified: *2012-09-21*

Call admission control (CAC), first introduced in Lync Server 2010, manages real-time session establishment, based on available bandwidth, to help prevent poor Quality of Experience (QoE) for users on congested networks. To support this capability, the Mediation Server, which provides signaling and media translation between the Enterprise Voice infrastructure and a gateway or SIP trunking provider, is responsible for bandwidth management for its two interactions on the Lync Server side and on the gateway side. In call admission control, the terminating entity for a call handles the bandwidth reservation. The gateway peers (PSTN gateway, IP-PBX, SBC) that the Mediation Server interacts with on the gateway side do not support Lync Server 2013 call admission control. Thus, the Mediation Server has to handle bandwidth interactions on behalf of its gateway peer. Whenever possible, the Mediation Server will reserve bandwidth in advance. If that is not possible (for example, if the locality of the ultimate media endpoint on the gateway side is unknown for an outgoing call to the gateway peer), bandwidth is reserved when the call is placed. This behavior can result in oversubscription of bandwidth, but it is the only way to prevent false rings.

Media bypass and bandwidth reservation are mutually exclusive. If a media bypass is employed for a call, call admission control is not performed for that call. The assumption here is that there are no links with constrained bandwidth involved in the call. If call admission control is used for a particular call that involves the Mediation Server, that call cannot employ media bypass.

For details about media bypass or call admission control, see Planning for Media Bypass or Planning for Call Admission Control in the Planning documentation.

1.3.10.4.2.3 Enhanced 9-1-1 (E9-1-1) and Mediation Server

Enhanced 9-1-1 (E9-1-1) and Mediation Server

Planning for Enterprise Voice > Components Required for Enterprise Voice > Mediation Server

Component >

Topic Last Modified: *2012-09-29*

The Mediation Server has extended capabilities so that it can correctly interact with Enhanced 9-1-1 (E9-1-1) service providers. No special configuration is needed on the Mediation Server; the SIP extensions required for E9-1-1 interaction are, by default, included in the Mediation Server's SIP protocol for its interactions with a gateway peer (PSTN gateway, IP-PBX, or the SBC of an Internet Telephony Service Provider, including E9-1-1 Service Providers)

Whether the SIP trunk to an E9-1-1 Service Provider can be terminated on an existing Mediation Server pool or will require stand-alone Mediation Servers will depend on whether the E9-1-1 SBC can interact with a pool of Mediation Servers. For details, see M:N Trunk.

1.3.10.4.2.4 Media Bypass and Mediation Server

Media Bypass and Mediation Server

See Also

Planning for Enterprise Voice > Components Required for Enterprise Voice > Mediation Server Component >

Topic Last Modified: *2012-09-21*

Media bypass is a Lync Server capability that enables an administrator to configure call routing to flow directly between the user endpoint and the public switched telephone network (PSTN) gateway without traversing the Mediation Server. Media bypass improves call quality by reducing latency, unnecessary translation, possibility of packet loss, and the number of potential points of failure. Where a remote site without a Mediation Server is connected to a central site by one or more WAN links with constrained bandwidth, media bypass lowers the bandwidth requirement by enabling media from a client at a remote site to flow directly to its local gateway without first having to flow across the WAN link to a Mediation Server at the central site and back.This reduction in media processing also complements the Mediation Server's ability to control multiple gateways.

Media bypass and call admission control (CAC) are mutually exclusive. If media bypass is employed for a call, CAC is not performed for that call. The assumption is that there are no links with constrained bandwidth involved in the call.

Planning for Media Bypass

1.3.10.4.2.5 Components and Topologies for Mediation Server

Components and Topologies for Mediation Server

Planning for Enterprise Voice > Components Required for Enterprise Voice > Mediation Server Component >

Topic Last Modified: *2012-09-21*

This topic describes the components on which the Mediation Server is dependent and the topologies in which the Mediation Server can be deployed

Dependencies

The Mediation Server has the following dependencies:

- **Registrar.** Required. The Registrar is the next hop for signaling in the Mediation Server interactions with the Lync Server 2013 network. Note that Mediation Server can be collocated on a Front End Server along with the Registrar, in addition to being installed in a stand-alone pool consisting only of Mediation Servers. The Registrar is collocated with a Mediation Server and PSTN gateway on a Survivable Branch Appliance.
- **Monitoring Server.** Optional but highly recommended. The Monitoring Server allows the Mediation Server to record quality metrics associated with its media sessions.
- **Edge Server.** Required for external user support. The Edge Server allows the Mediation Server to interact with users who are located behind a NAT or firewall.

Topologies

The Lync Server 2013, Mediation Server is by default collocated with an instance of the Registrar on a Standard Edition server, a Front End pool, or Survivable Branch Appliance. All Mediation Servers in a Front End pool must be configured identically.

Where performance is an issue, it may be preferable to deploy one or more Mediation Servers in a dedicated stand-alone pool. Or, if you are deploying SIP trunking, we recommend that you deploy a stand-alone Mediation Server pool.

If you deploy Direct SIP connections to a qualified PSTN gateway that supports media bypass and DNS load balancing, a stand-alone Mediation Server pool is not necessary. A stand-alone Mediation Server pool is not necessary because qualified gateways are capable of DNS load balancing to a pool of Mediation Servers and they can receive traffic from any Mediation Server in a pool.

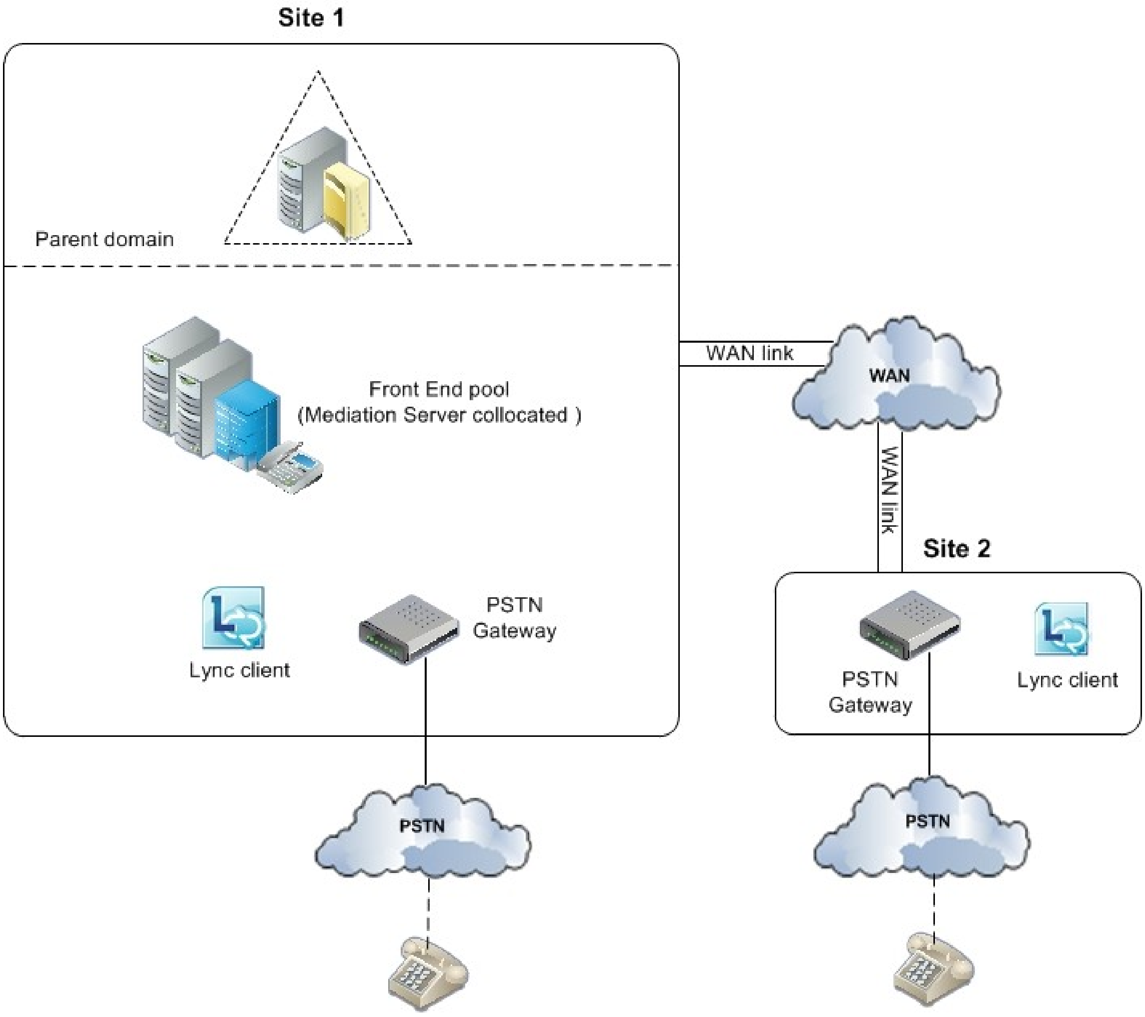
We also recommend that you collocate the Mediation Server on a Front End pool when you have deployed IP-PBXs or connect to an Internet Telephony Server Provider’s Session Border Controller (SBC), as long as any of the following conditions are met:

- The IP-PBX or SBC is configured to receive traffic from any Mediation Server in the pool and can route traffic uniformly to all Mediation Servers in the pool.
- The IP-PBX does not support media bypass, but the Front End pool that is hosting the Mediation Server can handle voice transcoding for calls to which media bypass does not apply.

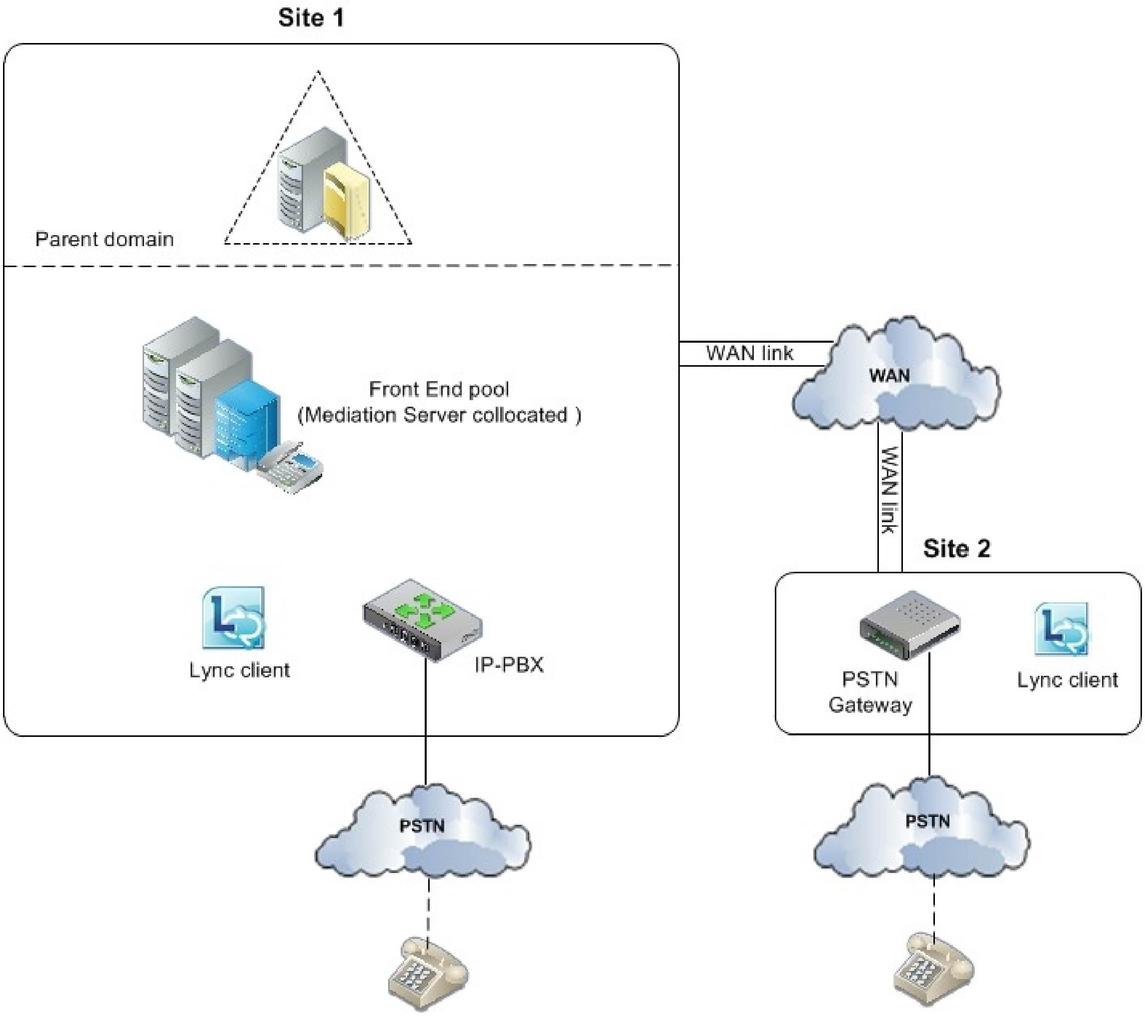
You can use the Microsoft Lync Server 2013, Planning Tool to evaluate whether the Front End pool where you want to collocate the Mediation Server can handle the load. If your environment cannot meet these requirements, then you must deploy a stand-alone Mediation Server pool.

For details about which topology to deploy, see Deployment Guidelines for Mediation Server.

The following figure shows a simple topology consisting of two sites connected by a WAN link. Mediation Server is collocated with the Registrar on a Front End pool at Site 1. The Mediation Servers at Site 1 controls both the PSTN gateway at Site 1 and the gateway at Site 2. In this topology, media bypass is enabled globally to use site and region information, and the trunks to each PSTN gateway (GW1 and GW2) have bypass enabled.



The next figure shows a simple topology where the Mediation Server is collocated with the Registrar on Front End pool at Site 1 and has a Direct SIP connection to the IP-PBX at Site 1. In this figure, the Mediation Server also controls a PSTN gateway at Site 2. Assume that Lync users exist at both Sites 1 and 2. Also assume that the IP-PBX has an associated media processor that must be traversed by all media originating from Lync endpoints before being sent to media endpoints controlled by the IP-PBX. In this topology, media bypass is enabled globally to use site and region information, and the trunks to the PBX and PSTN gateway have media bypass enabled.



For details about planning for PBX topologies, see Deployment Guidelines for Mediation Server and Direct SIP Deployment Options.

The last figure in this topic shows a topology where the Mediation Server is connected to the SBC of an Internet Telephony Service Provider. For details about SIP trunk topologies, see SIP Trunking.

1.3.10.4.2.6 Deployment Guidelines for Mediation Server

Deployment Guidelines for Mediation Server

Planning > Capacity Planning > Capacity Planning Using the User Models >

Topic Last Modified: *2012-10-12*

This topic describes planning guidelines for Mediation Server deployment. After reviewing these guidelines, we recommend that you use the Planning Tool to create and view possible alternative topologies, which can serve as models for what the final tailored topology that you decide to deploy would look like.

Collocated or Stand-alone Mediation Server?

Mediation Server is by default collocated on the Standard Edition server or Front End Server in a Front End pool at central sites. The number of public switched telephone network (PSTN) calls that can be handled and the number of machines required in the pool will depend on the following:

- The number of gateway peers that the Mediation Server pool controls
- The high-volume traffic periods through those gateways
- The percentage of calls that are calls whose media bypass the Mediation Server

When planning, be sure to take into account the media processing requirements for PSTN calls and A/V conferences that are not configured for media bypass, as well as the processing needed to handle signaling interactions for the number of busy-hour calls that need to be supported. If there is not enough CPU, then you must deploy a stand-alone pool of Mediation Servers; and PSTN gateways, IP-PBXs, and SBCs will need to be split into subsets that are controlled by the collocated Mediation Servers in one pool and the stand-alone Mediation Servers in one or more stand-alone pools.

If you deployed PSTN gateways, IP-PBXs, or Session Border Controllers (SBCs) that do not support the correct capabilities to interact with a pool of Mediation Servers, including the following, then they will need to be associated with a stand-alone pool consisting of a single Mediation Server:

- Perform network layer Domain Name System (DNS) load balancing across Mediation Servers in a pool (or otherwise route traffic uniformly to all Mediation Servers in a pool)
- Accept traffic from any Mediation Server in a pool

You can use the Microsoft Lync Server 2013, Planning Tool to evaluate whether collocating the Mediation Server with your Front End pool can handle the load. If your environment cannot meet these requirements, then you must deploy a stand-alone Mediation Server pool.

Central Site and Branch Site Considerations

Mediation Servers at the central site can be used to route calls for IP-PBXs or PSTN gateways at branch sites. If you deploy SIP trunks, however, you must deploy a Mediation Server at the site where each trunk terminates. Having a Mediation Server at the central site route calls for an IP-PBX or PSTN gateway at a branch site does not require the use of media bypass. However, if you can enable media bypass, doing so will reduce media path latency and, consequently, result in improved media quality because the media path is no longer required to follow the signaling path. Media bypass will also decrease the processing load on the pool.

Note:

Media bypass will not interoperate with every PSTN gateway, IP-PBX, and SBC. Microsoft has tested a set of PSTN gateways and SBCs with certified partners and has done some testing with Cisco IP-PBXs. Media bypass is supported only with products and versions listed on Unified Communications Open Interoperability Program – Lync Server at http://go.microsoft.com/fwlink/p/?LinkId=268730.

If branch site resiliency is required, a Survivable Branch Appliance or combination of a Front End Server, a Mediation Server, and a gateway must be deployed at the branch site. (The assumption with branch site resiliency is that presence and conferencing are not resilient at the site.) For guidance on branch site planning for voice, see Planning for Branch-Site Voice Resiliency.

For interactions with an IP-PBX, if the IP-PBX does not correctly support early media interactions with multiple early dialogs and RFC 3960 interactions, there can be clipping of the first few words of the greeting for incoming calls from the IP-PBX to Lync endpoints. This behavior can be more severe if a Mediation Server at a central site is routing calls for an IP-PBX where the route terminates at a branch site, because more time is needed for signaling to complete. If you experience this behavior, deploying a Mediation Server at the branch site is the only way to reduce clipping of the first few words.

Finally, if your central site has a TDM PBX, or if your IP-PBX does not eliminate the need for a PSTN gateway, then you must deploy a gateway on the call route connecting Mediation Server and the PBX.

Note:

To improve the media performance of standalone Mediation Server, you should enable receive-side scaling (RSS) on the network adapters on these servers. RSS enables incoming packets to be handled in parallel by multiple processors on the server. For details, see "Receive-Side Scaling Enhancements in Windows Server" at http://go.microsoft.com/fwlink/p/?LinkId=268731. For details about how to enable RSS, see your network adapter documentation.

1.3.10.4.3 PSTN Connectivity Components

PSTN Connectivity Components

Planning > Planning for Enterprise Voice > Components Required for Enterprise Voice >

Topic Last Modified: *2012-10-04*

An enterprise-grade VoIP solution must provide for calls to and from the public switched telephone network (PSTN) without any decline in Quality of Service (QoS). In addition, users should not be aware of the underlying technology when they place and receive calls. From the user's perspective, a call between the Enterprise Voice infrastructure and the PSTN should seem like just another SIP session.

For PSTN connections, you can either deploy a SIP trunk or a PSTN gateway (with a PBX, also known as a Direct SIP link, or without a PBX).

SIP Trunking

As an alternative to using PSTN gateways, you can connect your Enterprise Voice solution to the PSTN by using SIP trunking. SIP trunking enables the following scenarios:

- An enterprise user inside or outside the corporate firewall can make a local or long-distance call specified by an E.164-compliant number that is terminated on the PSTN as a service of the corresponding service provider.
- Any PSTN subscriber can contact an enterprise user inside or outside the corporate firewall by dialing a Direct Inward Dialing (DID) number associated with that enterprise user.

The use of this deployment solution requires a SIP trunking service provider.

PSTN gateways

PSTN gateways are third-party devices that translate signaling and media between the

Enterprise Voice infrastructure and a PSTN or a PBX. PSTN gateways work with the Mediation Server to present a PSTN or PBX call to an Enterprise Voice client. The Mediation Server also presents calls from Enterprise Voice clients to the PSTN gateway for routing to the PSTN or PBX. For a list of partners who work with Microsoft to provide devices that work with Lync Server, see the Microsoft Unified Communications Partners website at http://go.microsoft.com/fwlink/p/?linkId=202836.

Private Branch Exchanges

If you have an existing voice infrastructure that uses a private branch exchange (PBX), you can use your PBX with Lync Server Enterprise Voice.

The supported Enterprise Voice-PBX integration scenarios are as follows:

- IP-PBX that supports media bypass, with a Mediation Server.
- IP-PBX that requires a stand-alone PSTN gateway.
- Time division multiplexing (TDM) PBX, with a stand-alone PSTN gateway.

Note:

Media bypass will not interoperate with every PSTN gateway, IP-PBX, and SBC. Microsoft has tested a set of PSTN gateways and SBCs with certified partners and has done some testing with Cisco IP-PBXs. Media bypass is supported only with products and versions listed on Unified Communications Open Interoperability Program – Lync Server at http://go.microsoft.com/fwlink/p/?linkId=214406.

For details about partners who offer Enterprise Voice solutions, see the Microsoft Unified Communications Partners website at http://go.microsoft.com/fwlink/p/?linkId=202836.

For details about partners who offer Enterprise Voice hardware solutions, including PSTN gateways, see the Microsoft Unified Communications Partners website http://go.microsoft.com/fwlink/p/?linkId=202836.

1.3.10.4.4 Perimeter Network VoIP Components

Perimeter Network VoIP Components

Planning > Planning for Enterprise Voice > Components Required for Enterprise Voice >

Topic Last Modified: *2012-09-21*

Outside callers who use unified communications clients for individual or conference calls rely on Edge Server for voice communication with coworkers.

On an Edge Server, the Access Edge service provides SIP signaling for calls from Lync users who are outside your organization’s firewall. The A/V Edge service enables media traversal of NAT and firewalls. A caller who uses a unified communications (UC) client from outside the corporate firewall relies on the A/V Edge service for both individual and conference calls.

The A/V Authentication service is collocated with, and provides authentication services for, the A/V Edge service. Outside users who attempt to connect to the A/V Edge service require an authentication token that is provided by the A/V Authentication Service before their calls can go through.

1.3.10.5 Planning for PSTN Connectivity

Planning for PSTN Connectivity

Microsoft Lync Server 2013 > Planning > Planning for Enterprise Voice >

Topic Last Modified: *2012-09-21*

An enterprise-grade VoIP solution must provide for calls to and from the public switched telephone network (PSTN) without any decline in Quality of Service (QoS). Users who place and receive calls should not be aware of the underlying technology: from the user's perspective, a call between the Enterprise Voice infrastructure and the PSTN should seem like just another phone call.

Lync Server 2013 provides reliable, scalable PSTN connectivity by using the following options:

- **SIP trunks** to an Internet telephony service provider (ITSP)
- **Direct SIP connections** to a PSTN gateway
- **Direct SIP connections** to a PBX

Depending on its size, geographic coverage, and existing voice infrastructure, an enterprise may use one, two, or even all three of these options at various locations.

- SIP Trunking
- Direct SIP Connections
- M:N Trunk

1.3.10.5.1 SIP Trunking

SIP Trunking

Planning > Planning for Enterprise Voice > Planning for PSTN Connectivity >

Topic Last Modified: *2012-08-13*

Session Initiation Protocol (SIP) is used to initiate and manage Voice over IP (VoIP) communications sessions for basic telephone service and for additional real-time communication services, such as instant messaging, conferencing, presence detection, and multimedia. This section provides planning information for implementing *SIP trunks*, a type of SIP connection that extends beyond the boundary of your local network.

What is SIP Trunking?

A SIP trunk is an IP connection that establishes a SIP communications link between your organization and an Internet telephony service provider (ITSP) beyond your firewall. Typically, a SIP trunk is used to connect your organization’s central site to an ITSP. In some cases, you may also opt to use SIP trunking to connect your branch site to an ITSP.

SIP Trunks vs. Direct SIP Connections

The term *trunk* is derived from circuit-switched technology. It refers to a dedicated physical line that connects telephone switching equipment. Like their predecessor, time division multiplexing (TDM) trunks, SIP trunks are connections between two separate SIP networks—the Lync Server 2013 enterprise and the ITSP. Unlike circuit-switched trunks, SIP trunks are virtual connections that can be established over any of the supported SIP trunking connection types. For details about the supported connection types, see How Do I Implement SIP Trunking?.

Direct SIP connections, on the other hand, are SIP connections that do not cross the local network boundary (that is, they connect to a public switched telephone network (PSTN) gateway or private branch exchange (PBX) within your internal network). For details about how you can use direct SIP connections with Lync Server 2013, see Direct SIP Connections.

In This Section

- Overview of SIP Trunking
- How Do I Implement SIP Trunking?
- Components and Topologies for SIP Trunking
- Branch Site SIP Trunking
- SIP Trunk Deployment Checklist

1.3.10.5.1.1 Overview of SIP Trunking

Overview of SIP Trunking

Planning for Enterprise Voice > Planning for PSTN Connectivity > SIP Trunking >

Topic Last Modified: *2012-10-05*

Deploying SIP trunking can be a big step toward simplifying your organization’s telecommunications and preparing for up-to-date enhancements to real-time communications. One of the primary advantages of SIP trunking is that you can consolidate your organization’s connections to the public switched telephone network (PSTN) at a central site, as opposed to its predecessor, time division multiplexing (TDM) trunking, which typically requires a separate trunk from each branch site.

SIP Trunking in Lync Server

The Lync Server 2013 SIP trunking capabilities enable the following:

- An enterprise user, whether inside or outside the corporate firewall, can make a local call or a long-distance call that is specified by an E.164-compliant number that is terminated on the PSTN as a service of the corresponding service provider.
- Any PSTN subscriber can contact an enterprise user inside or outside the corporate firewall by dialing a Direct Inward Dialing (DID) number that is associated with that enterprise user.

Cost Savings

The cost savings associated with SIP trunking can be substantial:

- Long distance calls typically cost much less through a SIP trunk.
- You can cut manageability costs and reduce the complexity of deployment.
- Basic rate interface (BRI) and primary rate interface (PRI) fees can be eliminated if you connect a SIP trunk directly to your ITSP at significantly lower cost. In TDM trunking, service providers charge for calls by the minute. The cost of SIP trunking may be based on bandwidth usage, which you can buy in smaller, more economical increments. (The actual cost depends on the service model of the ITSP you choose.)

SIP Trunking vs. Hosting a PSTN Gateway or IP-PBX

Because SIP trunks connect directly to your service provider, you can eliminate your PSTN gateways and their management cost and complexity. Using a SIP trunk can lead to substantial cost savings through reduced maintenance and administration.

Expanded VoIP Services

Voice features are often the primary motivation for deploying SIP trunking, but voice support is just the first step. With SIP trunking, you can extend VoIP capabilities and enable Lync Server 2013 to deliver a richer set of services. For example:

- Enhanced presence detection for devices that are not running Lync Server 2013 can provide better integration with mobile phones, enabling you to see when a user is on a mobile phone call.
- E9-1-1 emergency calling enables the authorities who answer 911 calls to determine the caller's location from his or her telephone number.

Note:
Contact your ITSP for a list of services that they support and can enable for your organization.

1.3.10.5.1.2 How Do I Implement SIP Trunking?

How Do I Implement SIP Trunking?

Planning for Enterprise Voice > Planning for PSTN Connectivity > SIP Trunking >

Topic Last Modified: *2013-03-09*

To implement SIP trunking, you must route the connection through a Mediation Server, which acts as a proxy for communications sessions between Lync Server 2013 clients and the service provider and transcodes media, when necessary.

Each Mediation Server has an internal network interface and an external network interface. The internal interface connects to the Front End Servers. The external interface is commonly called the gateway interface because it has traditionally been used to connect the Mediation Server to a public switched telephone network (PSTN) gateway or an IP-PBX. To implement a SIP trunk, you connect the external interface of the Mediation Server to the external edge component of the ITSP.

Note:
The external edge component of the ITSP could be a Session Border Controller (SBC), a router, or a gateway.

For details about Mediation Servers, see Mediation Server Component.

Centralized vs. Distributed SIP Trunking

Centralized SIP trunking routes all Voice over Internet Protocol (VoIP) traffic, including branch site traffic, through your central site. The centralized deployment model is simple, cost-effective, and is generally the recommended approach for implementing SIP trunks with Lync Server 2013.

Distributed SIP trunking is a deployment model in which you implement a local SIP trunk at one or more branch sites. VoIP traffic is then routed from the branch site directly to a service provider without going through the central site.

Distributed SIP trunking is required only in the following cases:

- The branch site requires survivable phone connectivity (for example, if the WAN goes down). This requirement should be analyzed for each branch site; some of your branches may require redundancy and failover, whereas others may not.
- Resiliency is required between two central sites. You need to make sure that a

SIP trunk terminates at each central site. For example, if you have Dublin and Tukwila central sites and both use only one site's SIP trunk, if the trunk goes down, the other site's users cannot make PSTN calls.
- The branch site and central site are in different countries/regions. For compatibility and legal reasons, you need at least one SIP trunk per country/ region. For example, in the European Union, communications cannot leave a country/region without terminating locally at a centralized point.

Depending on the geographical location of sites and how much traffic you anticipate within your enterprise, you may not want to route all users through the central SIP trunk, or you may opt to route some users through a SIP trunk at their branch site. To analyze your needs, answer the following questions:
- How big is each site (that is, how many users are enabled for Enterprise Voice)?
- Which direct inward dialing (DID) numbers at each site get the most phone calls?

The decision whether to deploy centralized or distributed SIP trunking requires a cost-benefit analysis. In some cases, it may be advantageous to opt for the distributed deployment model even if it is not required. In a completely centralized deployment, all branch site traffic is routed over WAN links. Instead of paying for the bandwidth required for WAN linking, you may want to use distributed SIP trunking. For example, you may want to deploy a Standard Edition server at a branch site with federation to the central site, or you may want to deploy a Survivable Branch Appliance or a Survivable Branch Server with a small gateway.

Note:

For details about distributed SIP trunking, see Branch Site SIP Trunking.

Supported SIP Trunking Connection Types

Lync Server supports the following connection types for SIP trunking:
- Multiprotocol Label Switching (MPLS) is a private network that directs and carries data from one network node to the next. The bandwidth in an MPLS network is shared with other subscribers, and each data packet is assigned a label to distinguish one subscriber's data from another's. This connection type does not require a virtual private network (VPN). A potential drawback is that excessive IP traffic can interfere with VoIP operation unless VoIP traffic is given priority.
- A private connection with no other traffic—for example, a leased fiber-optic connection or T1 line—is typically the most reliable and secure connection type. This connection type provides the highest call-carrying capacity, but it is typically the most expensive. VPN is not required. Private connections are appropriate for organizations with high call volumes or stringent security and availability requirements.
- The Internet is the least expensive connection type, but it is also the least reliable. Internet connection is the only Lync Server SIP trunking connection type that requires VPN.

Selecting a Connection Type

The most appropriate SIP trunking connection type for your enterprise depends on your needs and your budget.
- For a mid-size or larger enterprise, an MPLS network usually provides the greatest value. It can provide the necessary bandwidth at a cheaper rate than a specialized private network.
- Large enterprises may require a private fiber-optic, T1, T3 or higher connection (E1, E3 or higher in the European Union).
- For a small enterprise or branch site with low call volume, SIP trunking through the Internet may be the best choice. This connection type is not recommended

for mid-size or larger sites.

Bandwidth Requirements

The amount of bandwidth your implementation requires depends on call capacity (the number of concurrent calls you must be able to support). You need to consider bandwidth availability, so that you can take full advantage of the peak capacity that you have paid for. Use the following formula to calculate SIP trunk peak bandwidth requirement:

SIP Trunk Peak Bandwidth = Max Simultaneous Calls x (64 kbps + header size)

Note:
Header size is 20 bytes maximum.

Codec Support

Lync Server 2013 supports only the following codecs:

- G.711 a-law (used primarily outside North America)
- G.711 µ-law (used in North America)

Internet Telephony Service Provider

How you implement the service provider side of a SIP trunk connection varies from one ITSP to another. For deployment information, contact your service provider. For a list of certified SIP trunking service providers, see Microsoft Unified Communications Open Interoperability Program website.

For details about Microsoft certified SIP trunking providers, contact your Microsoft representative.

Important:
You must use a Microsoft certified service provider to ensure that your ITSP supports all of the functionality that traverses the SIP trunk (for example, setting up and managing sessions and supporting all of the extended VoIP services). Microsoft technical support does not extend to configurations that use noncertified providers. If you currently use an Internet service provider that is not certified for SIP trunking, you can opt to continue using that provider as your ISP and use a provider certified by Microsoft for SIP trunking.

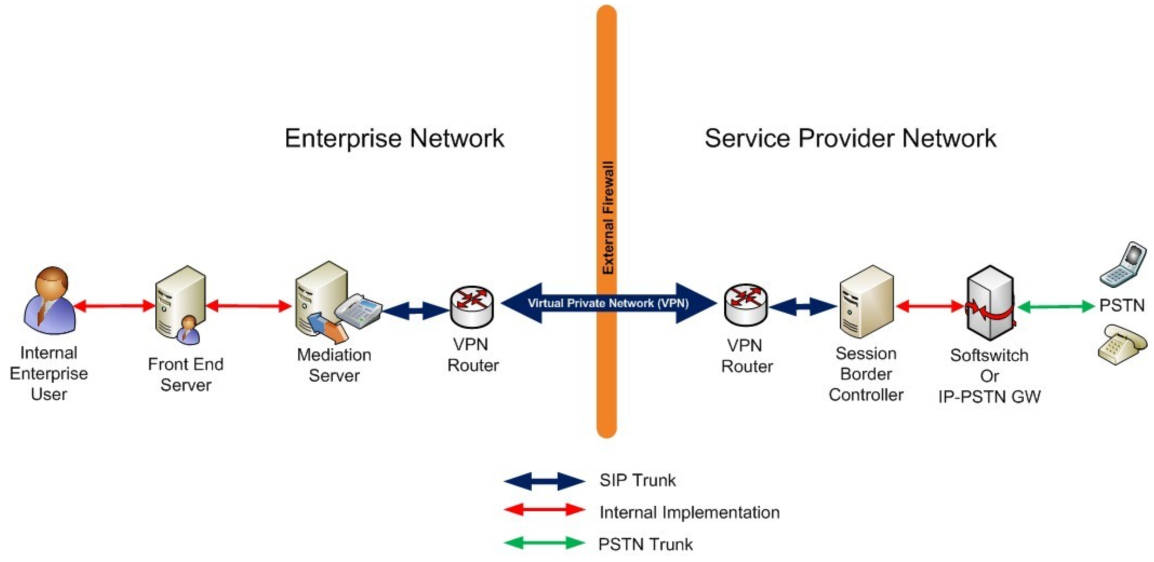
1.3.10.5.1.3 Components and Topologies for SIP Trunking

Components and Topologies for SIP Trunking

Planning for Enterprise Voice > Planning for PSTN Connectivity > SIP Trunking >

Topic Last Modified: *2012-09-21*

The following figure depicts the SIP trunking topology in Lync Server.



As shown in the diagram, an IP virtual private network (VPN) is used for connectivity between the enterprise network and the public switched telephone network (PSTN) service provider. The purpose of this private network is to provide IP connectivity, enhance security, and (optionally) obtain Quality of Service (QoS) guarantees. Because of the nature of a VPN, you do not need to use Transport Layer Security (TLS) for SIP signaling traffic or secure real-time transport protocol (SRTP) for the media traffic. Connections between the enterprise and the service provider therefore consist of plain TCP connections for SIP and plain real-time transport protocol (RTP) (over UDP) for media tunneled through an IP VPN. Ensure that all firewalls between the VPN routers have ports open to allow the VPN routers to communicate, and that the IP addresses on the external edges of the VPN routers are publicly routable.

Important:

Contact your service provider to determine whether it provides support for high availability, including failover. If so, you will need to determine the procedures for setting it up. For example, do you need to configure only one IP address and one SIP trunk on each Mediation Server, or do you need to configure multiple SIP trunks on each Mediation Server?
If you have multiple central sites, also ask whether the service provider has the ability to enable connections to and from another central site.

Note:

For SIP trunking, we strongly recommend that you deploy stand-alone Mediation Servers. For details, see Deploying Mediation Servers and Defining Peers in the Deployment documentation.

Securing the Mediation Server for SIP Trunking

For security purposes, you should set up a virtual LAN (VLAN) for each connection between the two VPN routers. The actual process for setting up a VLAN varies from one router manufacturer to another. For details, contact your router vendor.

We recommend that you follow these guidelines:

- Set up a virtual LAN (VLAN) between the Mediation Server and the VPN router in the perimeter network (also known as DMZ, demilitarized zone, and screened subnet).
- Do not allow broadcast or multicast packets to be transferred from the router

to the VLAN.
- Block any routing rules that route traffic from the router to anywhere but the Mediation Server.

If you use a VPN server, we recommend that you follow these guidelines:

- Set up a VLAN between the VPN server and the Mediation Server.
- Do not allow broadcast or multicast packets to be transmitted from the VPN server to the VLAN.
- Block any routing rule that routes VPN server traffic to anywhere but the Mediation Server.
- Encrypt data on the VPN by using generic routing encapsulation (GRE).

1.3.10.5.1.4 Branch Site SIP Trunking

Branch Site SIP Trunking

Planning for Enterprise Voice > Planning for PSTN Connectivity > SIP Trunking >

Topic Last Modified: *2012-09-21*

In some cases, you may need to implement distributed SIP trunking at selected branch sites. To determine whether a SIP trunk is needed for a branch site, review the information in How Do I Implement SIP Trunking?.

For details about the supported topology options for deploying SIP trunks in branch sites, see Branch-Site Resiliency Solutions.

Example Branch Site SIP Trunk Requirements Analysis

When you decide to deploy a branch site SIP trunk, you need to perform a site-specific cost analysis. For example, an enterprise that has a central site in Redmond, Washington, and a branch site in New York, should do an analysis to determine whether to implement a SIP trunk from the New York site to a local service provider.

To determine whether a distributed SIP trunk in New York is cost-effective, identify which Direct Inward Dialing (DID) numbers will use the SIP trunk, and analyze the number of calls New York makes to areas other than Redmond (425). You can have DID termination for the branch site at the central site. For example, the Redmond central site can host DID numbers for the New York branch site. If the cost of implementing a distributed SIP trunk is less than the cost of those calls, consider implementing a SIP trunk at the New York branch site.

Other Branch Site SIP Trunk Requirements

The choice between a deploying a SIP trunk instead of a gateway is based on the difference between the public switched telephone network (PSTN) long distance toll charges of each option. If you deploy a branch site SIP trunk, you also need to determine your resiliency and bandwidth requirements. If the link between your branch site and central site is resilient and has sufficient bandwidth, you can deploy a SIP trunk or a gateway. You do not need to deploy a Survivable Branch Appliance at the branch site. If the link between your branch site and central site is not resilient, deploy a Survivable Branch Appliance, or deploy a Survivable Branch Server with either a gateway or SIP trunk at the branch site.

1.3.10.5.1.5 SIP Trunk Deployment Checklist

SIP Trunk Deployment Checklist

Planning for Enterprise Voice > Planning for PSTN Connectivity > SIP Trunking >

Topic Last Modified: *2012-09-21*

Before you can deploy a SIP trunk, you and your service provider must exchange some basic connection information about your respective SIP trunk endpoints.

Get the following information for each ITSP gateway that you will connect to:

- IP address
- Fully qualified domain name (FQDN)

Note:

The service provider may ask you to connect to more than one ITSP gateway. In that case, you must configure a connection between each ITSP gateway and each Mediation Server in your pool.

The information you give to your service provider depends on your SIP trunk connection type:

- For Multiprotocol Label Switching (MPLS) or private network connections, give the ITSP the publicly routable IP Address of the router in your perimeter network (also known as DMZ, demilitarized zone, and screened subnet). Verify that the gateway or Session Border Controller (SBC) at the ITSP can reach this address. Also give the ITSP the FQDN of your Mediation Server.
- For virtual private network (VPN) connections, give the ITSP the IP address of your VPN server.

Certificate Considerations

To determine whether you need a certificate for SIP trunking, check with your ITSP about protocol support:

1. If your ITSP supports Transmission Control Protocol (TCP) only, you do not need a certificate.
2. If your ITSP supports Transport Layer Security (TLS), the ITSP must provide you with a certificate.

Note:

SIP works in conjunction with real-time transport protocol (RTP) or secure real-time transport protocol (SRTP), the protocols that manage the actual voice data in Voice over Internet Protocol (VoIP) calls.

Deployment Process

To implement the Lync Server side of the SIP trunk connection, follow these steps:

1. Using the Lync Server Topology Builder, create and configure the SIP domain topology. For details, see Define and Configure a Topology in Topology Builder in the Deployment documentation.
2. Using the Lync Server Control Panel, configure voice routing for the new SIP domain. For details, see Configuring Trunks in the Deployment documentation.
3. Test connectivity by using the **Test-CsPstnOutboundCall** cmdlet. For details, see the Lync Server Management Shell documentation or Help for Lync Server Management Shell.

1.3.10.5.2 Direct SIP Connections

Direct SIP Connections

Planning > Planning for Enterprise Voice > Planning for PSTN Connectivity >

Topic Last Modified: *2012-08-13*

You can use *direct SIP connections* to connect Lync Server to either of the following:

- An IP-PBX (for details, see Direct SIP Deployment Options).
- A PSTN gateway (for details, see PSTN Gateway Deployment Options).

To implement a direct SIP connection, you follow essentially the same deployment steps as you would to implement a SIP trunk. In both cases, you implement the connection by using the external interface of a Mediation Server. The only difference is that you connect SIP trunks to an external entity, such as an ITSP gateway, and you connect direct SIP connections to an internal entity within your local network, such as an IP-PBX or a public switched telephone network (PSTN) gateway.

In This Section

- Direct SIP Deployment Options
- PSTN Gateway Deployment Options

1.3.10.5.2.1 Direct SIP Deployment Options

Direct SIP Deployment Options

Planning for Enterprise Voice > Planning for PSTN Connectivity > Direct SIP Connections >

Topic Last Modified: *2012-09-21*

This topic provides example topologies for deploying direct SIP connections.

Lync Server Stand-Alone

If your organization uses one of the deployments described in this section, you can use Lync Server 2013 as the sole telephony solution for part or all of an organization. This section describes the following deployments in detail:

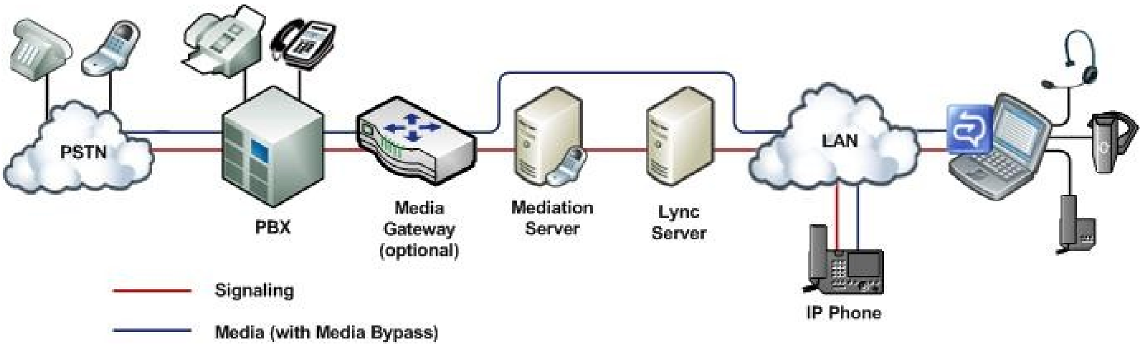
- **Incremental deployment:** This option assumes that you have an existing private branch exchange (PBX) infrastructure and you intend to introduce Enterprise Voice incrementally to smaller groups or teams within your organization.
- **Lync Server VoIP-only deployment:** this option assumes that you are considering deploying Enterprise Voice at a site that does not have a traditional telephony infrastructure.

Incremental Deployment

In incremental deployment, Lync Server 2013 is the sole telephony solution for individual teams or departments, while the rest of the users in an organization continue to use a PBX. This incremental deployment strategy provides one way to introduce IP telephony into your enterprise through controlled pilot programs. Workgroups whose communication needs are best served by Microsoft Unified Communications are moved to Enterprise Voice, while other users remain on the existing PBX. Additional workgroups can be migrated to Enterprise Voice, as needed.

The incremental option is recommended if you have clearly defined user groups that have communication requirements in common and that lend themselves to centralized management. This option is also effective if you have teams or departments that are spread over wide geographic areas, where the savings in long-distance charges can be significant. In fact, this option is useful for creating virtual teams whose members may be scattered across the globe. You can create, modify, or disband such teams in rapid response to shifting business requirements.

The following figure shows the generic topology for deployment of Enterprise Voice behind a PBX. This is the recommended topology for incremental deployment.



Note:
If you are connecting your Lync Server deployment to a certified Direct SIP partner, a public switched telephone network (PSTN) gateway between the Mediation Server and the PBX is not required. For a list of certified Direct SIP partners, see the Microsoft Unified Communications Open Interoperability Program website at http://go.microsoft.com/fwlink/p/?linkId=203309.

Note:
The media path shown in this figure has media bypass enabled (the recommended configuration). If you opt to disable media bypass, the media path is routed through the Mediation Server.

In this topology, selected departments or workgroups are enabled for Enterprise Voice. A PSTN gateway links the Voice over Internet Protocol (VoIP)-enabled workgroup to the PBX. Users who are enabled for Enterprise Voice, including remote workers, communicate across the IP network. Calls by Enterprise Voice users to the PSTN and to coworkers who are not enabled for Enterprise Voice are routed to the appropriate PSTN gateway. Calls from colleagues who are still on the PBX system, or from callers on the PSTN, are routed to the PSTN gateway, which forwards the calls to Lync Server for routing.

There are two recommended configurations for connecting Enterprise Voice to an existing PBX infrastructure for interoperability: Enterprise Voice behind the PBX and Enterprise Voice in front of the PBX.

Enterprise Voice Behind the PBX
When Enterprise Voice is deployed behind the PBX, all calls from the PSTN arrive at the PBX, which routes calls to Enterprise Voice users to a PSTN gateway, and calls to PBX users to the PBX.

Enterprise Voice in Front of the PBX
When Enterprise Voice is deployed in front of the PBX, all calls arrive at the PSTN gateway, which routes calls for Enterprise Voice users to Lync Server and calls for PBX users to the PBX. Calls to the PSTN from both Enterprise Voice and PBX users are routed over the IP network to the most cost-efficient PSTN gateway. The following table shows the advantages and disadvantages of this configuration.

Advantages and Disadvantages of Deploying Enterprise Voice in Front of PBX

Advantages	Disadvantages

PBX still serves users not enabled for Enterprise Voice.	Existing gateways may not support the features or capacity that you want.
PBX handles all earlier devices.	Requires a trunk from gateway to the PBX and from the gateway to the Mediation Server. You may need more trunks from the service provider.
Enterprise Voice users keep the same phone numbers.	

Lync Server VoIP-Only Deployment

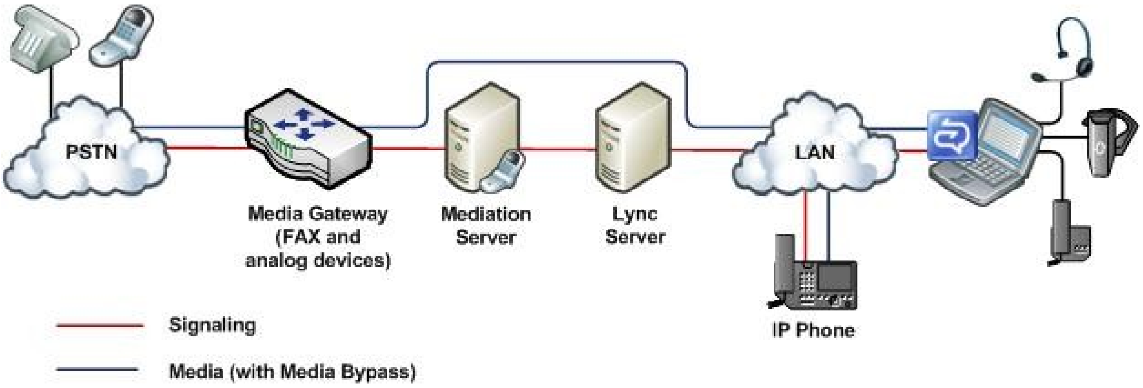
Enterprise Voice provides new businesses, and also new office sites for existing businesses, with the opportunity to implement a full-featured VoIP solution without having to worry about PBX integration or incurring the substantial deployment and maintenance costs of an IP-PBX infrastructure. This solution supports both on-site and remote workers.

In this deployment, all calls are routed over the IP network. Calls to the PSTN are routed to the appropriate PSTN gateway. Lync 2013 or Lync Phone Edition serves as a softphone. Remote call control is unavailable and unnecessary because there are no PBX phones for users to control. Voice mail and auto-attendant services are available through the optional deployment of Exchange Unified Messaging (UM).

Note:

In addition to the network infrastructure that is required to support Lync Server 2013, a VoIP-only deployment can use a small, qualified gateway to support fax machines and analog devices.

The following figure shows a typical topology for a VoIP-only deployment.



PSTN
Media Gateway (FAX and analog devices)
Mediation Server
Lync Server
LAN
IP Phone
Signaling
Media (with Media Bypass)

Note:

The media path shown in this figure has media bypass enabled (the recommended configuration). If you opt to disable media bypass, the media path is routed through the Mediation Server.

1.3.10.5.2.2 PSTN Gateway Deployment Options

PSTN Gateway Deployment Options

Planning for Enterprise Voice > Planning for PSTN Connectivity > Direct SIP Connections >

Topic Last Modified: *2012-09-21*

PSTN Gateways

Public switched telephone network (PSTN) gateways are third-party hardware components that translate signaling and media between the Enterprise Voice infrastructure and the PSTN, either directly or through connection to SIP trunks. In either topology, the gateway terminates the PSTN. The gateway is isolated in its own subnet and is connected to the enterprise network through the Mediation Server.

An enterprise with multiple sites would typically deploy one or more gateways at each site. Branch sites can connect to the PSTN either through a gateway, or through a Survivable Branch Appliance, which combines gateway and servers in a single box. If branch sites use a gateway, both a Registrar and Mediation Server are required on site, unless the WAN link is resilient. One or more Mediation Servers, which are collocated on Front End Servers, can route calls for the one or more gateways at each site. We recommend that the Registrar, Mediation Server, and gateway required on site are deployed as a Survivable Branch Appliance.

Determining the number, size, and location of PSTN gateways is perhaps the most important and expensive decision you must make when planning your Enterprise Voice infrastructure.

Here are the main questions to consider. Keep in mind that the answers to these questions are all interdependent

- How many PSTN gateways are needed? The answer depends on the number of users, the anticipated number of simultaneous calls (traffic load), and the number of sites (each site needs one).
- What size should the gateways be? The answer depends on the number of users at the site and on the traffic load.
- Where should the gateways be located? The answer depends in part on the topology and in part on the geographic distribution of your organization.

You should also consider your gateway topology options (for details, see Gateway Topologies later in this topic).

M:N Trunk Support

The Mediation Servers can route calls through multiple gateways, Session Border Controllers (SBCs) provided by Internet telephony service providers, or a combination of the two. Additionally, multiple Mediation Servers in the pool can interact with multiple gateways. The logical route defined between a Mediation Server and gateway is called a *trunk*. When an internal user places a PSTN call, outbound routing logic on the Front End pool chooses which trunk to route over out of all possible combinations that may be available for routing that particular call. With DNS load balancing, if a call fails to reach a gateway due to an issue with a particular Mediation Server in the pool, the call will be retried to an alternate Mediation Server in the pool.

For details about planning for multiple gateways, see M:N Trunk.

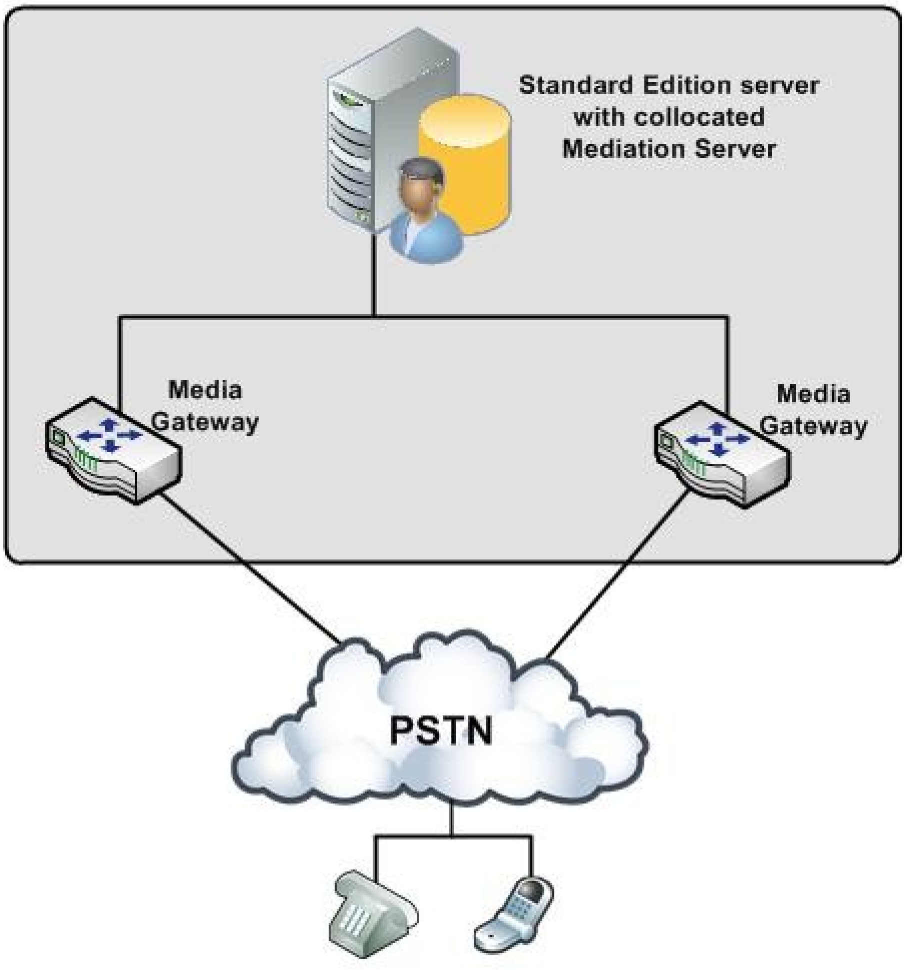
For details about other outbound routing enhancements, see Voice Routes.

Gateway Topologies

When you consider the fundamental questions of gateway deployment, follow these steps:

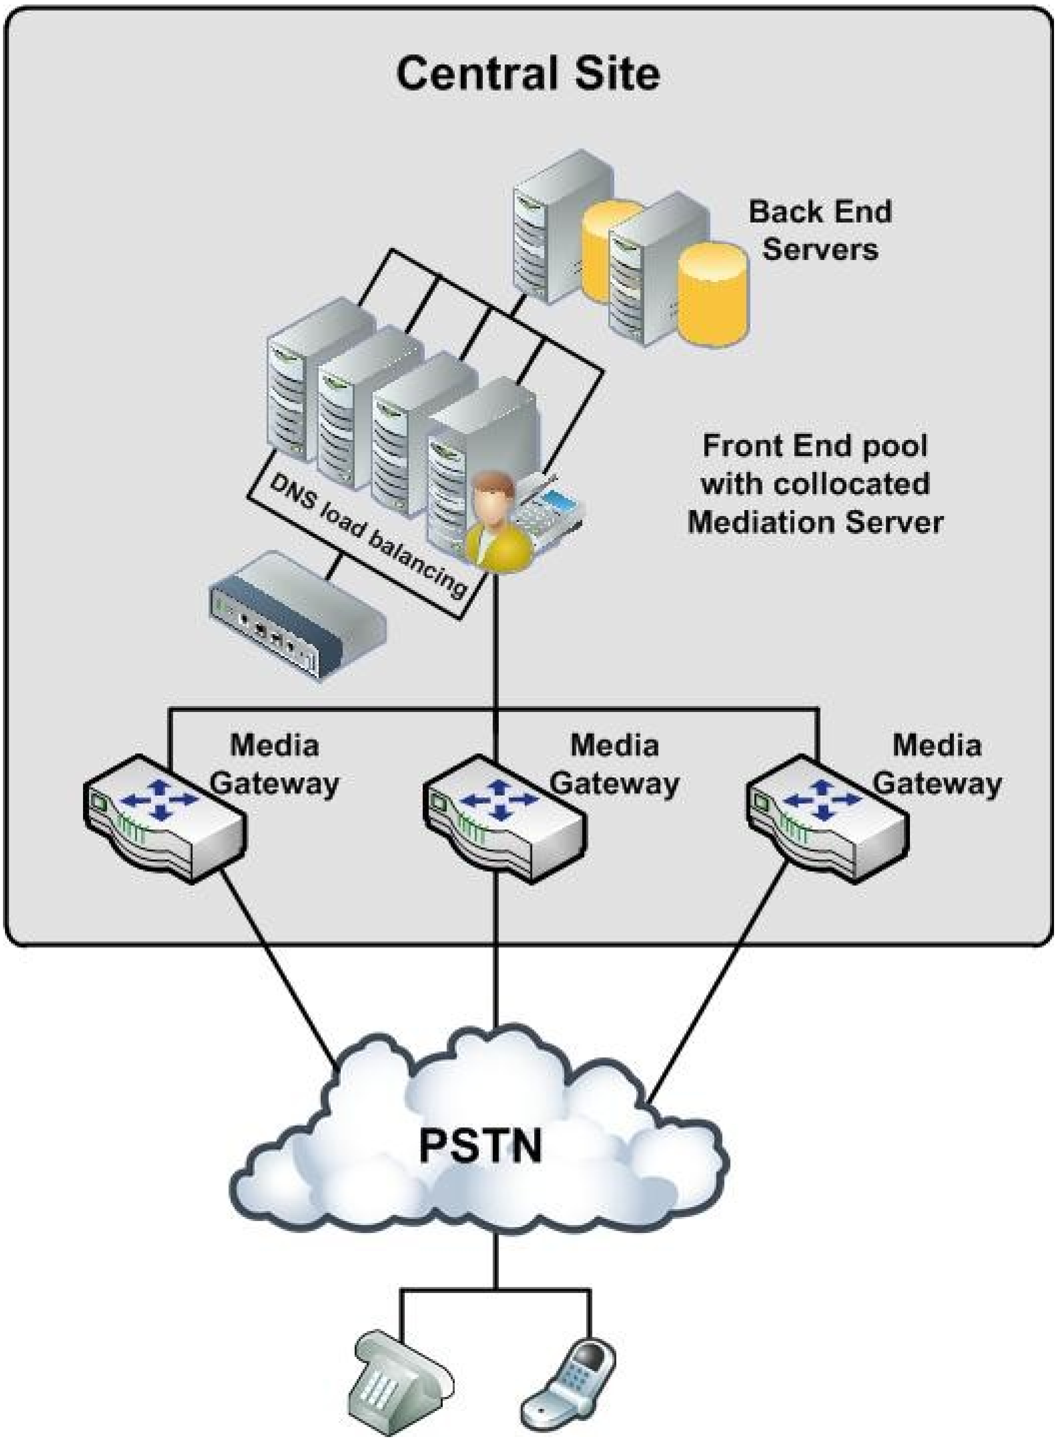
1. Count the sites at which you want to provide PSTN connectivity by using Enterprise Voice.
2. Estimate the traffic at each site (number of users and average number of calls per hour per user).
3. Deploy one or more gateways at each site to handle the anticipated traffic.

The resulting distributed gateway topology is shown in the following figure.



With this topology, calls among workers at each site and between sites are all routed over your intranet. Calls to the PSTN are routed over the enterprise IP network to the gateways that are closest to the location of the destination numbers.But what if your organization supports dozens or hundreds or even thousands of sites spread across one or more continents, as many financial institutions and other large enterprises do? In such cases, deploying a separate gateway at each site is not practical.

To address this issue, many large companies prefer to deploy one or a few large telephony central sites, as shown in the following figure.



In this topology, several large gateways sufficient to accommodate the anticipated user load are deployed at each central site. All calls to users in the enterprise are forwarded by the company's telephone service provider to a central site. Routing logic at the central site determines whether the call should be routed over the intranet or to the PSTN.

Gateway Location

Gateway location may also determine the types of gateways that you choose and how they are configured. There are dozens of PSTN protocols, none of which is a worldwide standard. If all your gateways are located in a single country/region, this is not an issue, but if you locate gateways in several countries/regions, each must be configured according to the PSTN standards of that country/region. Moreover, gateways that are certified for operation in, for example, Canada, may not be certified in India, Brazil, or the European Union.

Gateway Size and Number

The PSTN gateways that most organizations will consider deploying range in size from 2 to as many as 960 ports. (There are even larger gateways, but these are used mainly by telephone service providers.) When estimating the number of ports your organization requires, use the following guidelines:

- Organizations with light telephony usage (one PSTN call per user per hour) should allocate one port for every 15 users. For example, if you have 20 users, you will require a gateway with two ports.
- Organizations with moderate telephony usage (two PSTN calls per user per hour) should allocate one port for every 10 users. For example, if you have 100 users, you will require a total of 10 ports allocated among one or more gateways.
- Organizations with heavy telephony usage (three or more PSTN calls per user per hour) should allocate one port for every five users. For example, if you have 47,000 users, you will require a total of 9,400 ports allocated among at least 10 large gateways.
- Additional ports can be acquired as the number of users or amount of traffic in your organization increases.

For any given number of users you must support, you have the choice of deploying fewer, larger gateways, or smaller ones. As a rule, a minimum of two gateways for an organization is recommended to maintain availability if one gateway fails.

Each PSTN gateway that you deploy must have at least one corresponding Mediation Server.

1.3.10.5.3 M:N Trunk

M:N Trunk

Planning for Enterprise Voice > Components Required for Enterprise Voice > Mediation Server Component >

Topic Last Modified: *2012-10-01*

Lync Server 2013 supports greater flexibility in the definition of a trunk for call routing purposes from previous releases. A trunk is a logical association between a Mediation Server and listening port number with a gateway and a listening port number. This implies several things: A Mediation Server can have multiple trunks to the same gateway; a Mediation Server can have multiple trunks to different gateways; conversely a gateway can have multiple trunks to different Mediation Servers.

A root trunk is still required to be created when a gateway is added to the Lync topology using Topology Builder. The number of gateways that a given Mediation Server can handle depends on the processing capacity of the server during peak busy hours. If you deploy a Mediation Server on hardware that exceeds the minimum hardware requirements for Lync Server 2013, as described in Supported Hardware in the Supportability documentation, then the estimate of how many active non-bypass calls a stand-alone Mediation Server can handle is approximately 1000 calls. When deployed on hardware meeting these specifications, the Mediation Server is expected to perform transcoding, but still route calls for multiple gateways even if the gateways do not support media bypass.

When defining a call route, you specify the trunks associated with that route, but you do not specify which Mediation Servers are associated with that route. Instead, you use Topology Builder to associate trunks with Mediation Servers. In other words, routing determines which trunk to use for a call, and, subsequently, the Mediation Server associated with that trunk is sent the signaling for that call.

The Mediation Server can be deployed as a pool; this pool can be collocated with a Front End pool, or it can be deployed as a stand-alone pool. When a Mediation Server is collocated with a Front End pool, the pool size can be at most 12 (the limit of the Registrar pool size). Taken together, these new capabilities increase the reliability and deployment flexibility for Mediation Servers, but they require associated capabilities in the following peer entities:

- **PSTN gateway.** A Lync Server 2013 qualified gateway must implement DNS load balancing, which enables a qualified public switched telephone network (PSTN) gateway to act as a load balancer for one pool of Mediation Servers, and thereby to load-balance calls across the pool.
- **Session Border Controller.** For a SIP trunk, the peer entity is a Session Border Controller (SBC) at an Internet telephony service provider. In the direction from the Mediation Server pool to the SBC, the SBC can receive connections from any Mediation Server in the pool. In the direction from the SBC to the pool, traffic can be sent to any Mediation Server in the pool. One method of achieving this is through DNS load balancing, if supported by the service provider and SBC. An alternative is to give the service provider the IP addresses of all Mediation Servers in the pool, and the service provider will provision these in their SBC as a separate SIP trunk for each Mediation Server. The service provider will then handle the load balancing for its own servers. Not all service providers or SBCs may support these capabilities. Furthermore, the service provider may charge extra for this capability. Typically, each SIP trunk to the SBC incurs a monthly fee.
- **IP-PBX.** In the direction from the Mediation Server pool to the IP-PBX SIP termination, the IP-PBX can receive connections from any Mediation Server in the pool. In the direction from the IP-PBX to the pool, traffic can be sent to any Mediation Server in the pool. Because most IP-PBXs do not support DNS load balancing, we recommend that individual direct SIP connections be defined from the IP-PBX to each Mediation Server in the pool. The IP-PBX will then handle its own load balancing by distributing traffic over the trunk group. The assumption is that the trunk group has a consistent set of routing rules at the IP-PBX. Whether a particular IP-PBX supports this trunk group concept and how it intersects with the IP-PBX's own redundancy and clustering architecture needs to be determined before you can decide whether a Mediation Server cluster can interact correctly with an IP-PBX.

A Mediation Server pool must have a uniform view of the peer gateway with which it interacts. This means that all members of the pool access the same definition of the peer gateway from the configuration store and are equally likely to interact with it for outgoing calls. Therefore, there is no way to segment the pool so that some Mediation Servers communicate with only certain gateway peers for outgoing calls. If such segmentation is necessary, a separate pool of Mediation Servers must be used. This would be the case, for example, if the associated capabilities in PSTN gateways, SIP trunks, or IP-PBXs to interact with a pool as detailed earlier in this topic are not present.

A particular PSTN gateway, IP-PBX, or SIP trunk peer can route to multiple Mediation Servers or trunks. The number of gateways that a particular pool of Mediation Servers can control depends on the number of calls that use media bypass. If a large number of calls use media bypass, a Mediation Server in the pool can handle many more calls, because only signaling layer processing is necessary.

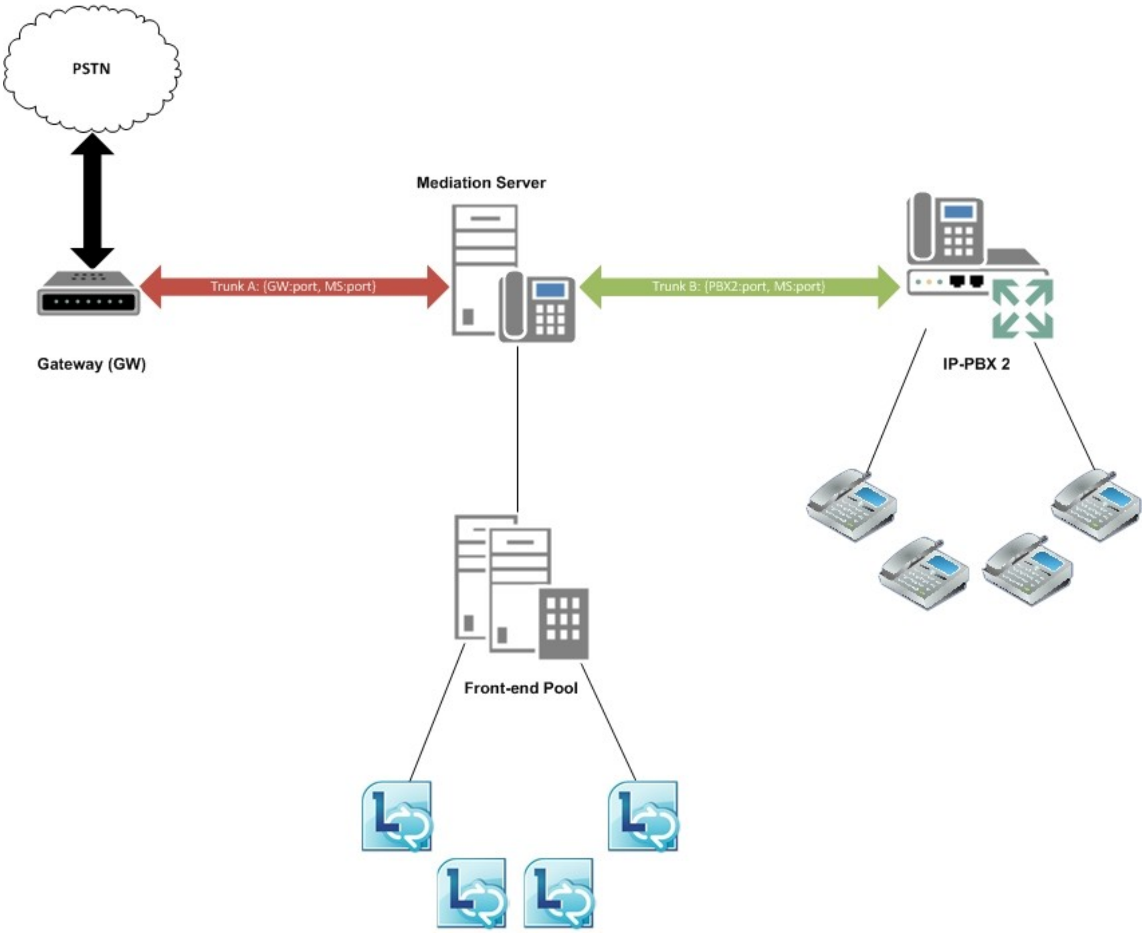
Inter-Trunk Routing

Planning > Planning for Enterprise Voice > Planning for PSTN Connectivity >

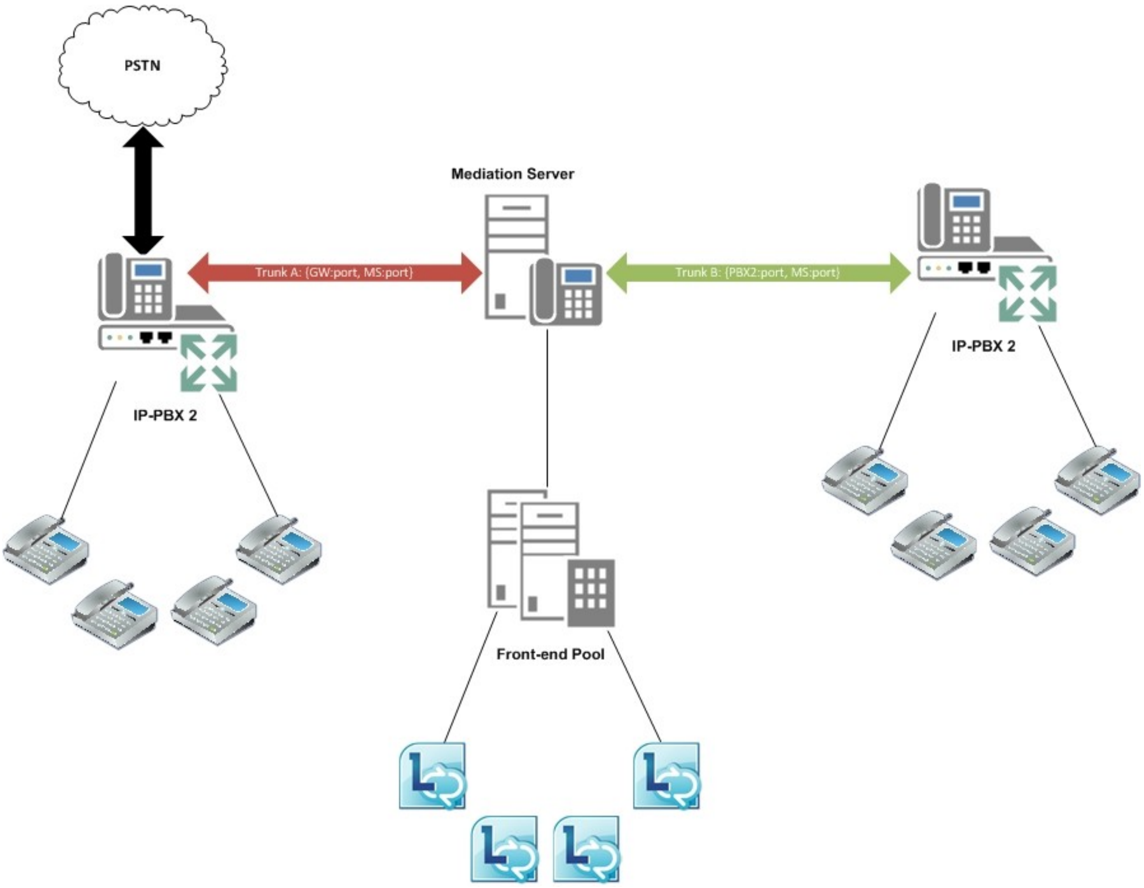
Topic Last Modified: *2012-10-08*

Lync Server 2013 provides basic session management through the support of intertrunk routing. This new capability enables Lync Server to provide call control functionalities to downstream telephony systems. Intertrunk routing can interconnect an IP-PBX to a public switched telephone network (PSTN) gateway so that calls from a private branch exchange (PBX) phone can be routed to the PSTN, and incoming PSTN calls can be routed to a PBX phone. Similarly, Lync Server can interconnect two or more IP-PBX systems so that calls can be placed and received between PBX phones from the different IP-PBX systems.

The following figure illustrates Lync Server 2013 providing interconnectivity between a PSTN gateway and an IP-PBX.



The next figure illustrates Lync Server 2013 connecting two IP-PBX systems.



1.3.10.5.5 Translation Rules

Translation Rules

[Planning](#) > [Planning for Enterprise Voice](#) > [Planning for PSTN Connectivity](#) >

Topic Last Modified: *2012-10-05*

Lync Server 2013 Enterprise Voice requires that all dial strings be normalized to E.164 format for the purpose of performing reverse number lookup (RNL). In Microsoft Lync Server 2010, translation rules are supported only for called numbers. New in Microsoft Lync Server 2013, translation rules are also supported for calling numbers. The *trunk peer* (that is, the associated gateway, private branch exchange (PBX), or SIP trunk) may require that numbers be in a local dialing format. To translate numbers from E.164 format to a local dialing format, you can define one or more translation rules to manipulate the request URI before you route it to the trunk peer. For example, you could write a translation rule to remove +44 from the beginning of a dial string and replace it with 0144.

By performing outbound route translation on the server, you can reduce the configuration requirements on each individual trunk peer in order to translate phone numbers into a local dialing format. When you plan which gateways, and how many gateways, to associate with a specific Mediation Server cluster, it may be useful to group trunk peers with similar local dialing requirements. This can reduce the number of required translation rules and the time it takes to write them.

Important:

Associating one or more translation rules with an Enterprise Voice trunk configuration should be used as an alternative to configuring translation rules on the trunk peer. Do not associate translation rules with an Enterprise Voice trunk configuration if you have configured translation rules on the trunk peer, because the two rules might conflict.

Example Translation Rules

The following examples of translation rules show how you can develop rules on the server to translate numbers from E.164 format to a local format for the trunk peer.

For details about how to implement translation rules, see Defining Translation Rules in the Deployment documentation.

Description	Starting Digits	Length	Digits to Remove	Digits to Add	Matching Pattern	Translation	Example
Conventional long-distance dialing in U.S. (strip out the '+')	+1	Exactly 12	1	0	^\+(1\d{10})$	$1	+14255551010 becomes 14255551010
U.S. international long-distance dialing (strip out '+' and add 011)	+	At least 11	1	011	^\+(\d{9}\d+)$	011$1	+441235551010 becomes 011441235551010

1.3.10.5.6 Planning Outbound Voice Routing

Planning Outbound Voice Routing

See Also

Planning > Planning for Enterprise Voice > Planning for PSTN Connectivity >

Topic Last Modified: *2012-09-21*

Outbound call routing applies to calls that are destined for a public switched telephone network (PSTN) gateway, trunk, or private branch exchange (PBX). When a user places a call, the server normalizes the phone number to E.164 format, if necessary, and attempts to match it to a SIP URI. If the server cannot make the match, it applies outbound call routing logic based on the supplied dial string. You define that logic by configuring the server settings that are described in the following table.

Lync Server Outbound Call Routing Settings

Object	Description
Dial Plan	A dial plan is a named set of normalization rules that translates phone numbers for a

	named location, individual user, or contact object into a single standard (E.164) format for purposes of phone authorization and call routing.
Normalization rule	Normalization rules define how phone numbers expressed in various formats are to be routed for each specified location, user, or contact object. The same dial string may be interpreted and translated differently, depending on the location from which it is dialed and the person or contact object that makes the call. A set of normalization rules associated with a particular location constitutes a dial plan.
Voice policy	A voice policy associates one or more PSTN usage records with one user or a group of users. A voice policy also provides a list of calling features that you can enable or disable.
PSTN usage record	A PSTN usage record specifies a class of call (such as internal, local, or long distance) that can be made by various users, or groups of users, in an organization.
Call Route	A call route associates destination phone numbers with particular trunks and PSTN usage records. A PSTN gateway is considered a trunk.

This section provides guidelines for configuring the following outbound call routing server settings:

- Dial Plans and Normalization Rules
- Voice Policies
- PSTN Usage Records
- Voice Routes

1.3.10.5.6.1 Dial Plans and Normalization Rules

Dial Plans and Normalization Rules

Planning for Enterprise Voice > Planning for PSTN Connectivity > Planning Outbound Voice Routing >

Topic Last Modified: *2012-09-21*

A dial plan is a named set of normalization rules that translates phone numbers for a named location, individual user, or contact object into a single standard (E.164) format for purposes of phone authorization and call routing.

Normalization rules define how phone numbers expressed in various formats are to be routed for each specified location, user, or contact object. The same dial string may be interpreted and translated differently, depending on the location from which it is dialed and the person or contact object making the call.

Dial Plan Scope

A dial plan's *scope* determines the hierarchical level at which the dial plan can be applied. In Lync Server, a user can be assigned a specific per-user dial plan. If a user dial plan is not assigned, the Registrar pool dial plan is applied. If there is no Registrar pool dial plan, the site dial plan is applied. Finally, if there is no other dial plan applicable to the user, the global dial plan is applied.

Clients obtain dial plan scope levels through in-band provisioning settings that are provided when users log on to Lync Server. As the administrator, you can manage and assign dial plan scope levels by using Lync Server Control Panel.

Note:

The service level public switched telephone network (PSTN) gateway dial plan is applied to the incoming calls from a particular gateway.

Dial plan scope levels are defined as follows:

- **User dial plan:** Can be assigned to individual users, groups, or contact objects. Voice applications can look up a per-user dial plan when a call is received with the phone-context set to user-default. For the purpose of assigning a dial plan, a contact object is treated as an individual user.
- **Pool dial plan:** Can be created at the service level for any PSTN gateway or Registrar in your topology. To define a pool dial plan, you must specify the particular service (PSTN gateway or Registrar pool) to which the dial plan applies.
- **Site dial plan:** Can be created for an entire site, except for any users, groups, or contact objects that are assigned a pool dial plan or user dial plan. To define a site dial plan, you must specify the site to which the dial plan applies.
- **Global dial plan:** The default dial plan installed with the product. You can edit the global dial plan, but you cannot delete it. This dial plan applies to all Enterprise Voice users, groups, and contact objects in your deployment, unless you configure and assign a dial plan with a more specific scope.

Planning for Dial Plans

To plan a dial plan, follow these steps:

- List all the locales in which your organization has an office.
  The list must be up-to-date and complete. It will need to be revised as company organization evolves. In a large, multinational company with numerous small branch offices, this can be a time-consuming task.
- Identify valid number patterns for each site.
  The most time-consuming part of planning your dial plans is identifying the valid number patterns for each site. In some cases, you may be able to copy normalization rules that you have written for one dial plan to other dial plans, especially if the corresponding sites are within the same country/region or even continent. In other cases, small changes to numbers in one dial plan may be enough to use them in other dial plans.
- Develop an organization-wide scheme for naming dial plans.
  Adopting a standard naming scheme assures consistency across an organization and makes maintenance and updates easier.
- Decide whether multiple dial plans are required for a single location.
  If your organization maintains a single dial plan across multiple locations, you may still need to create a separate dial plan for Enterprise Voice users who are migrating from a private branch exchange (PBX) and who need to have their existing extensions retained.

- Decide whether per-user dial plans are required. For example, if you have users at a branch site who are registered with the central site or if you have users who are registered on a Survivable Branch Appliance, you can consider special dialing scenarios for such users using per-user dial plans and normalization rules. For details, see Branch-Site Resiliency Requirements.
- Determine dial plan scope (as previously described in this topic).

To create a dial plan, you specify values in the following fields, as required, by using Lync Server Control Panel or Lync Server Management Shell.

Name and Simple Name

For user dial plans, you should specify a descriptive name that identifies the users, groups, or contact objects to which the dial plan will be assigned. For site dial plans, the Name field is prepopulated with the site name and cannot be changed. For pool dial plans, the Name field is prepopulated with the PSTN gateway or Front End pool fully qualified domain name (FQDN) and cannot be changed.

The dial plan *Simple Name* is prepopulated with a string that is derived from the dial plan name. The Simple Name field is editable, which enables you to create a more descriptive naming convention for your dial plans. The *Simple Name* value cannot be empty and must be unique. A best practice is to develop a naming convention for your entire organization and then use this convention consistently across all sites and users.

Description

We recommend that you type the common, recognizable name of the geographic location to which the corresponding dial plan applies. For example, if the dial plan name is London.Contoso.com, the recommended description would be London.

Dial-in Conferencing Region

If you are deploying dial-in conferencing, you will need to specify a dial-in conferencing region to associate dial-in conferencing access numbers with a dial plan.

External Access Prefix

You can specify an external access prefix of up to four characters (#, *, and 0-9) if users need to dial one or more additional leading digits (for example, 9) to get an external line.

Note:

If you specify an external access prefix, you do not need to create an additional normalization rule to accommodate the prefix.

Normalization Rules

Normalization rules define how phone numbers expressed in various formats are to be routed for the named location. The same number string may be interpreted and translated differently, depending on the locale from which it is dialed. Normalization rules are necessary for call routing because users can, and do, use various formats when entering phone numbers in their Contacts lists.

Normalizing user-supplied phone numbers provides a consistent format that facilitates the following tasks:

- Match a dialed number to the intended recipient's SIP-URI.
- Apply dialing authorization rules to the calling party.

The following number fields are among those that your normalization rules may need to account for:

- Dial plan
- Country code
- Area code
- Length of extension

- Site prefix

Creating Normalization Rules

Normalization rules use .NET Framework regular expressions to specify numeric match patterns that the server uses to translate dial strings to E.164 format for the purpose of performing reverse number lookup. You create normalization rules in the Lync Server Control Panel either by entering the expressions manually, or by entering the starting digits and the length of the dial strings to be matched and letting the Lync Server Control Panel generate the corresponding regular expression for you. Either way, when you finish, you can enter a test number to verify that the normalization rule works as expected.

For details about using .NET Framework regular expressions, see ".NET Framework Regular Expressions" at http://go.microsoft.com/fwlink/p/?linkId=140927.

Sample Normalization Rules

The following table shows sample normalization rules that are written as .NET Framework regular expressions. The samples are examples only and are not meant to be a prescriptive reference for creating your own normalization rules.

Table 1.Normalization Rules Using .NET Framework Regular Expressions

Rule name	Description	Number pattern	Translation	Example
4digitExtension	Translates 4-digit extensions	^(\d{4})$	+1425555$1	0100 is translated to +14255550100
5digitExtension	Translates 5-digit extensions	^5(\d{4})$	+1425555$1	50100 is translated to +14255550100
7digitcallingRedmond	Translates 7-digit numbers to Redmond local numbers	^(\d{7})$	+1425$1	5550100 is translated to +14255550100
7digitcallingDallas	Translates 7-digit numbers to Dallas local numbers	^(\d{7})$	+1972$1	5550100 is translated to +19725550100
10digitcallingUS	Translates 10-digit numbers in the United States	^(\d{10})$	+1$1	2065550100 is translated to +12065550100
LDCallingUS	Translates numbers with long distance prefixes in the United States	^1(\d{10})$	+$1	12145550100 is translated to +2145550100
IntlCallingUS	Translates numbers with international prefixes in the United States	^011(\d*)$	+$1	01191445550100 is translated to +91445550100
RedmondOperator	Translates 0 to Redmond Operator	^0$	+14255550100	0 is translated to +14255550100

RedmondSitePrefix	Translates numbers with on-net prefix (6) and Redmond site code (222)	^6222(\d{4})$	+1425555$1	62220100 is translated to +14255550100
NYSitePrefix	Translates numbers with on-net prefix (6) and NY site code (333)	^6333(\d{4})$	+1202555$1	63330100 is translated to +12025550100
DallasSitePrefix	Translates numbers with on-net prefix (6) and Dallas site code (444)	^6444(\d{4})$	+1972555$1	64440100 is translated to +19725550100

The following table illustrates a sample dial plan for Redmond, Washington, United States, based on the normalization rules shown in the previous table.

Table 2. Redmond Dial Plan Based on Normalization Rules Shown in Table 1

Redmond.forestFQDN
5digitExtension
7digitcallingRedmond
10digitcallingUS
IntlCallingUS
RedmondSitePrefix
NYSitePrefix
DallasSitePrefix
RedmondOperator

Note:

The normalization rules names shown in the preceding table do not include spaces, but this is a matter of choice. The first name in the table, for example, could have been written "5 digit extension" or "5-digit Extension" and still be valid.

1.3.10.5.6.2 Voice Policies

Voice Policies

Planning for Enterprise Voice > Planning for PSTN Connectivity > Planning Outbound Voice Routing >

Topic Last Modified: *2012-09-21*

Lync Server *voice policies* define the following for each user, site, or organization that is assigned the policy:

- A set of calling features that can be enabled or disabled to determine the Enterprise Voice functionality available to users.
- A set of public switched telephone network (PSTN) usage records that define

what types of calls are authorized.

Planning for Voice Policies

The following steps will help you plan the voice policies that you will need for your Enterprise Voice deployment:

- Determine how you will configure your global voice policy (the default voice policy that is installed with the product). This policy will apply to all Enterprise Voice users who are not explicitly assigned a site-level or per-user policy.
- Identify any site-level voice policies that you might need.
- Identify any per-user voice policies that you might need.
- Decide which call features to enable for each voice policy.
- Determine what PSTN usage records to configure for each voice policy.

Voice Policy Scope

Voice policy scope determines the hierarchical level at which the policy can be applied. In Lync Server, you can configure voice policies with the following scope levels (listed from the most specific to the most general).

- **User voice policy** can be assigned to individual users, groups, or contact objects. This is the lowest level policy. User voice policies can be deployed to enable features for certain users or groups at a site, but not for others in the same site. For example, you may want to disable long distance dialing for some employees. For the purpose of assigning a voice policy, a contact object is treated as an individual user.

  Note:

  We recommend that you deploy a user voice policy for branch site Enterprise Voice users who are registered with the central site deployment, or users who are registered on a Survivable Branch Appliance.

- **Site voice policy** applies to an entire site, except for any users, groups, or contact objects that are assigned a user voice policy. To define a site voice policy, you must specify the site to which the policy applies. If a user voice policy is not assigned, the site voice policy is used.
- **Global voice policy** is the default voice policy that is installed with the product. You can edit the global voice policy to meet the specific needs of your organization, but you cannot rename or delete it. This voice policy applies to all Enterprise Voice users, groups, and contact objects in your deployment unless you configure and assign a voice policy with more specific scope. If you want to disable this policy entirely, be sure that all sites and users have custom policies assigned to them.

Call Features

You can enable or disable the following call features for each voice policy:

- **Call forwarding** enables users to forward calls to other phones and client devices. Enabled by default.
- **Delegation** enables users to specify other users to send and receive calls on their behalf. Enabled by default.
- **Call transfer** enables users to transfer calls to other users. Enabled by default.
- **Call park** enables users to park calls and then pick up the call from a different phone or client. Disabled by default.
- **Simultaneous ringing** enables incoming calls to ring on an additional phone (for example, a mobile phone) or other endpoint devices. Enabled by default.
- **Team call** enables users on a defined team to answer calls for other members of the team. Enabled by default.
- **PSTN reroute** enables calls made by users who are assigned this policy to other enterprise users to be rerouted on the public switched telephone network (PSTN) if the WAN is congested or unavailable. Enabled by default.

- **Bandwidth policy override** enables administrators to override call admission control policy decisions for a particular user. Disabled by default.
- **Malicious call tracing** enables users to report malicious calls by using the Lync client, and then flags such calls in the call detail records. Disabled by default.
- **Voicemail escape** prevents calls from being immediately routed to the user's mobile phone voicemail system when simultaneous ringing is configured and the phone is turned off, out of battery, or out of range, and is based on a timer value. This setting enables and disables the timer and sets the value of the timer. It can be configured only by using the Lync Server Management Shell. Disabled by default.
- **Call forwarding and simultaneous ringing PSTN usages** enables administrators to specify the same PSTN usage as the voice policy for call forwarding and simultaneous ringing, restrict call forwarding and simultaneous ringing to internal Lync users only, or specify a custom PSTN usage that is different from the voice policy's PSTN usage. The default is to use the same PSTN usage as the voice policy for call forwarding and simultaneous ringing.

PSTN Usage Records

Each voice policy should have one or more associated PSTN usage records. PSTN usages can be associated with a voice policy for the purpose of simultaneous ringing and call forwarding only. For details about planning PSTN usage records, see PSTN Usage Records.

Note:

PSTN usage order is critical because in matching users to routes, the outbound routing functionality compares PSTN usages from top to bottom. If the first usage matches the call route, that route is used. If not, the outbound routing functionality looks at the next PSTN usage on the list and continues until a match is found. In effect, the subsequent PSTN usages provide backup if the first one on the list is unavailable.

1.3.10.5.6.3 PSTN Usage Records

PSTN Usage Records

Planning for Enterprise Voice > Planning for PSTN Connectivity > Planning Outbound Voice Routing >

Topic Last Modified: *2012-09-23*

Planning PSTN usage records consists mainly of listing all the call permissions that are currently in force in your organization, from the CEO to temporary workers, consultants, and contingent staff. This process also provides an opportunity to reexamine existing call permissions and revise them. You can create PSTN usage records only for those call permissions that apply to your anticipated Enterprise Voice users, but a better long-range solution might be to create PSTN usage records for all call permissions, regardless of whether some may not currently apply to the group of users to be enabled for Enterprise Voice. If call permissions change or new users with different call permissions are added, you will have already created the required PSTN usage records.

The following table shows a typical PSTN usage table.

PSTN Usage Records

Phone attribute	Description
Local	Local calls
Long-Distance	Long distance calls
International	International calls
Delhi	Delhi full-time employees

Redmond	Redmond full-time employees
RedmondTemps	Redmond temporary employees
Zurich	Zurich full-time employees

By themselves, PSTN usage records do not do anything. For them to work, you must associate them with the following:

- Voice policies, which are assigned to users.
- Routes, which are assigned to phone numbers.

For details about voice policies and routes, see Voice Policies and Voice Routes. For details about how to create and configure them, see Configuring Voice Routes for Outbound Calls.

1.3.10.5.6.4 Voice Routes

Voice Routes

Planning for Enterprise Voice > Planning for PSTN Connectivity > Planning Outbound Voice Routing >

Topic Last Modified: *2012-10-22*

Call routes specify how Lync Server handles outbound calls placed by Enterprise Voice users. When a user dials a number, the Front End Server normalizes the dial string to E.164 format, if necessary, and attempts to match it to a SIP URI. If the server cannot make the match, it applies outgoing call routing logic based on the number. The final step in defining that logic is to create a separate named call route for each set of destination phone numbers that are listed in each dial plan.

Before you define outbound call routes, you should complete the following steps:

- Deploy one or more trunks.
- Create dial plans as needed for sites, individuals, and Contact objects.
- Create public switched telephone network (PSTN) usage records.

Additionally, to enable outbound call routing, you must create and assign one or more voice policies. You can do this either before or after you define outbound call routes.

For each route, you must specify:

- A name by which the route can be easily identified.
- An optional description in cases where the name alone may not be sufficient to describe the route.
- The regular expression matching pattern that identifies the destination phone numbers to which the route is applied, along with exceptions to which the matching pattern is not to be applied.
- One or more trunks that you want to assign to the route.
- The PSTN usage records that users must have in order to call numbers matching the destination phone number regular expression.

You can specify call routes in the Lync Server Control Panel. These call routes populate the server routing table, which Lync Server uses to route calls that are destined for the PSTN.

M:N Trunk Support

Lync Server provides flexibility in how calls are routed to the PSTN. A voice route specifies a set of trunks to the PSTN that can be used for a particular voice call. A trunk associates a Mediation Server and a port number with a PSTN gateway and listening port number. This logical association enables a Mediation Server to be associated with multiple gateways and have multiple connections to the same gateway. When defining a call route, you specify the trunks associated with that route, but you do not specify which Mediation Servers are associated with the route. To create trunks by defining the relationships between Mediation Servers and PSTN gateways, IP-PBXs, and Session Border Controllers (SBCs), use the Topology Builder.

Least-Cost Routing

The ability to specify the trunks to which various numbers are routed enables you to determine which routes incur the lowest costs and implement them accordingly. The general rule in selecting trunks is to choose the trunk with the closest gateway to the location of the destination number in order to minimize long-distance charges. For example, if you are in New York and calling a number in Rome, you would carry the call over the IP network to the trunk with the gateway in your Rome office, thereby incurring a charge only for a local call.

For an example of how least-cost routing might be used, consider the following: Fabrikam decides to enable German users to dial U.S. numbers by using the U.S. trunk. Fabrikam also wants to configure the system so that all calls from U.S. Lync Server users to Germany and adjacent countries/regions terminate on the trunk with the gateway in Germany. This routing will save money, because a call from Germany to Austria, for example, is less expensive than a call from the U.S. to Austria.

Translating Outbound Dial Strings

Lync Server 2013, like its immediate predecessors, requires all dial strings to be normalized to E.164 format for the purpose of performing reverse number lookup (RNL). For trunks with gateways or private branch exchanges (PBXs) that require numbers translated in local dialing formats, Lync Server 2013 enables you to create one or more rules that assist in manipulating the called number (i.e. Request URI) prior to routing it to the trunk. For example, you could write a rule to remove +44 from the head of a dial string and replace it with 0144.

With Lync Server 2013, it is possible to create one or more rules that assist in manipulating the calling number prior to routing it to the trunk.

In planning your trunks that associate gateways:port pairs with Mediation Server:port pairs, it may be useful to group trunks with similar local dialing requirements, and therefore reduce the number of required translation rules and the time it takes to write them.

Configuring Caller ID

Lync Server provides a way to manipulate the caller ID for outbound calls. For example, if an organization wants to mask employees' direct-dial extensions and replace them with the generic corporate or departmental number, an administrator can do that by using Lync Server Control Panel to suppress the caller ID and replace it with a specified alternative caller ID. In planning your routing logic, consider which individuals, groups, sites you'll want this option for—perhaps, even, for all employees.

Note:

For calls that are rerouted over the PSTN, the generic caller ID will be presented instead of the original caller ID. This can cause the call to bypass Do Not Disturb or privacy settings that the callee may have configured.

Additional Routing Logic

In creating outbound call routes, you should be aware of the following factors that can affect routing logic:

- Where a call is established over a federated boundary, the domain portion of the URI is used to route the call over to the enterprise that is responsible for applying the outbound routing logic.
- If the domain portion of the request URI does not contain a supported domain for the enterprise, the outbound routing component on the server does not process the call.
- If a user is not enabled for Enterprise Voice, the server applies other routing logic, as appropriate.
- If a call is routed to a gateway that is fully occupied (all trunk lines are busy), the gateway rejects the call and the outbound routing logic redirects the call to the next-least-cost route. Give this careful consideration, because a gateway sized for a small office overseas (for example, Zurich) may actually carry a significant amount of nonlocal traffic for international calls to Switzerland. If the gateway is not correctly sized for this additional traffic, calls to Switzerland may be routed by way of a gateway in Germany, resulting in larger toll charges.

1.3.10.6 Planning for Exchange Unified Messaging Integration

Planning for Exchange Unified Messaging Integration

Microsoft Lync Server 2013 > Planning > Planning for Enterprise Voice >

Topic Last Modified: *2012-10-13*

Lync Server 2013 supports integration with Exchange Unified Messaging (UM) for combining voice messaging and email messaging into a single messaging infrastructure. In Microsoft Exchange Server 2007 Service Pack 1 (SP1) and Microsoft Exchange Server 2010, Exchange Unified Messaging (UM) is one of several Exchange server roles that you can install and configure.

In Microsoft Exchange Server 2013, Exchange UM runs as a service on an Exchange Mailbox server. For Lync Server 2013 Enterprise Voice deployments, Unified Messaging combines voice messaging and email messaging into a single store that is available from a telephone (Outlook Voice Access) or a computer. Unified Messaging and Lync Server 2013 work together to provide call answering, Outlook Voice Access, and auto-attendant services to users of Enterprise Voice.

For more information about the architecture changes in Microsoft Exchange Server 2013, see “Voice Architecture Changes” in the Microsoft Exchange Server 2013 documentation at http://go.microsoft.com/fwlink/p/?LinkId=266730.

For these features to be supported in an on-premises Exchange UM deployment, you must be running one of the following:

- Microsoft Exchange Server 2007 Service Pack 1 (SP1) or latest service pack
- Microsoft Exchange Server 2010 or latest service pack
- Microsoft Exchange Server 2013
- Features of Integrated Unified Messaging and Lync Server 2013
- Components and Topologies for On-Premises Unified Messaging
- Guidelines for Integrating On-Premises Unified Messaging and Lync Server 2013
- Deployment Process for Integrating On-Premises Unified Messaging and Lync Server 2013

Features of Integrated Unified Messaging and Lync Server 2013

Planning > Planning for Enterprise Voice > Planning for Exchange Unified Messaging Integration >

Topic Last Modified: *2012-10-01*

Lync Server 2013, Enterprise Voice uses the Exchange Unified Messaging (UM) infrastructure to provide call answering, call notification, voice access (including voice mail), and auto-attendant services.

Call Answering

Call answering is the receiving of voice messages on behalf of users whose calls are not answered or are busy. It includes playing a personal greeting, recording a message, and submitting the message to be queued for delivery to the user's mailbox, which is stored on the Exchange mailbox server.

If a caller leaves a message, the message is routed to the user's Inbox. If a caller chooses not to leave a message, a missed call notification is stored in the user's mailbox. Users can then access their Inbox by using the Microsoft Outlook messaging and collaboration client, Outlook Web Access, the Exchange ActiveSync technology, or Outlook Voice Access. The subject and priority of calls can be displayed in a way similar to that of email.

Outlook Voice Access

Outlook Voice Access enables an Enterprise Voice user to access not just voice mail, but also the Exchange inbox, including email, calendar, and contacts from a telephony interface. The subscriber access number is assigned by an Exchange UM administrator.

Auto Attendant

Auto attendant is an Exchange UM feature that can be used to configure a phone number that outside users can dial to reach company representatives. In particular, it provides a series of voice prompts that assist an external caller in navigating a menu system. The list of available options is configured on the Exchange UM server by the Exchange UM administrator.

Fax Services

Exchange UM includes fax features, which enable users to receive incoming faxes in their Exchange mailboxes. For details, see "Unified Messaging" in the Microsoft Exchange Server documentation at http://go.microsoft.com/fwlink/p/?linkId=135652.

Note:

Fax services provided by the Exchange UM server are not available in Lync Server deployments that are integrated with Microsoft Exchange Server 2010, Exchange 2010 with the latest service pack, or Exchange 2013.

Components and Topologies for On-Premises Unified Messaging

Server Software and Infrastructure Support > Voice Support > Exchange Unified Messaging (UM) Support >

Topic Last Modified: *2012-09-25*

This topic describes the Microsoft Exchange Server 2013 components required to provide Exchange Unified Messaging (UM) features to Lync Server 2013 deployment. It also describes the supported topologies for on-premises Exchange UM integration.

Exchange Server Components

To provide the Exchange UM features and services described in Features of Integrated Unified Messaging and Lync Server 2013 to Enterprise Voice users in your organization, you must deploy an Microsoft Exchange Mailbox server and Client Access server, which hosts user mailboxes and provides a single storage location for email and voice mail. Exchange UM runs as a service on Exchange Mailbox and Client Access servers.

For details about Exchange UM components in Microsoft Exchange Server 2007 and Microsoft Exchange Server 2010, see Deploying On-Premises Exchange UM to Provide Lync Server 2013 Voice Mail in the Deployment documentation.

Supported Topologies

You can deploy Lync Server 2013 and Exchange Unified Messaging (UM) in the same forest or multiple forests. If the deployment spans multiple forests, you must perform the Exchange integration steps for each Exchange UM forest. Furthermore, you must configure each Microsoft Exchange forest to trust the Lync Server 2013 forest and the Lync Server 2013 forest to trust each Exchange UM forest. In addition to this forest trust, the Exchange UM settings for all users must be set on the user objects in the Lync Server 2013 forest.

Lync Server 2013 supports the following topologies for Exchange UM integration:

- Single forest
- Single domain (that is, a single forest with a single domain). Lync Server 2013, Microsoft Exchange, and users all reside in the same domain.
- Multiple domain (that is, a root domain with one or more child domains). Lync Server 2013, and Microsoft Exchange servers are deployed in different domains from the domain where you create users. Exchange UM servers can be deployed in different domains from the Lync Server 2013 pool they support.
- Multiple forest (that is, resource forest). Lync Server 2013 is deployed in a single forest, and then users are distributed across multiple forests. The users' Exchange UM attributes must be replicated over to the Lync Server 2013 forest.

Note:

Exchange can be deployed in multiple forests. Each Exchange organization can provide Exchange UM to its users, or Exchange UM can be deployed in the same forest as Lync Server 2013.

Guidelines for Integrating On-Premises Unified Messaging and Lync Server 2013

See Also

Planning > Planning for Enterprise Voice > Planning for Exchange Unified Messaging Integration >

Topic Last Modified: *2012-09-25*

The following are guidelines and best practices to consider when you deploy Enterprise Voice:

◆**Important:**
Exchange Unified Messaging (UM) supports IPv6 only if you are also using UCMA 4.

- Deploy a Lync Server 2013 Standard Edition server or a Front End pool. For details about installation, see Deploying Lync Server 2013 in the Deployment documentation.
- Work with Exchange administrators to confirm which tasks each of you will perform to assure a smooth and successful integration.
- Deploy the Exchange Mailbox server roles in each Exchange Unified Messaging (UM) forest where you want to enable users for Exchange UM. For details about installing Exchange server roles, see the Microsoft Exchange Server 2013 documentation.

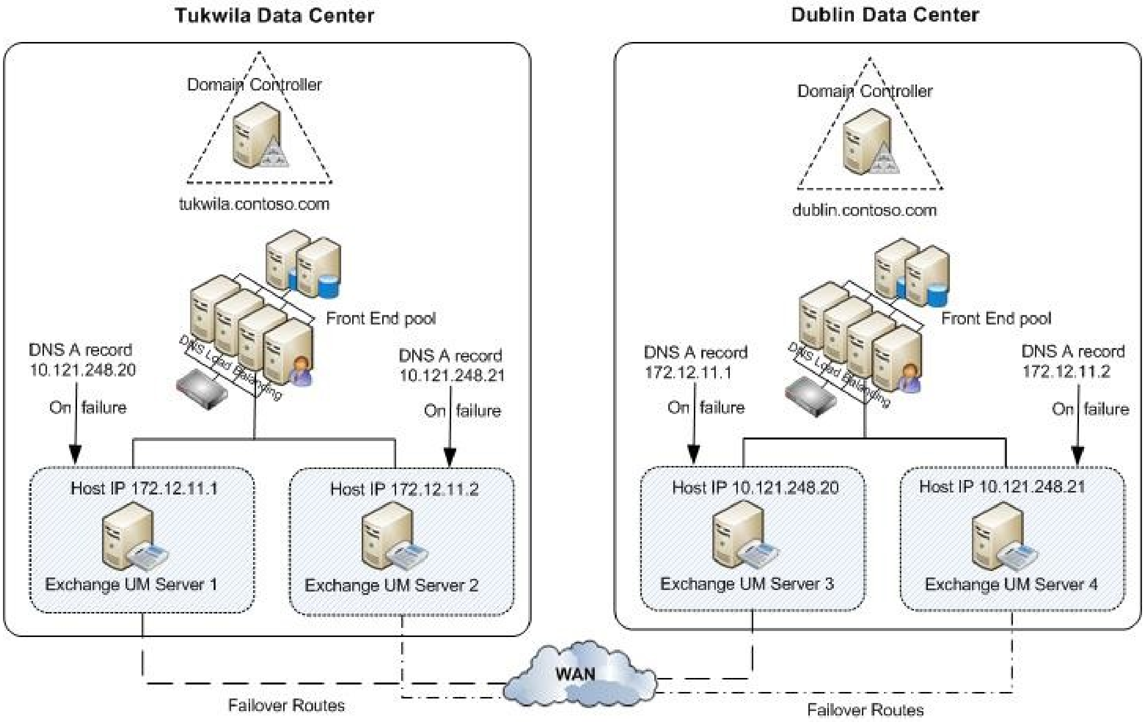
◆**Important:**
When Exchange Unified Messaging (UM) is installed, it is configured to use a self-signed certificate. The self-signed certificate, however, does not enable Lync Server 2013 and Exchange UM to trust each other, which is why it is necessary to request a separate certificate from a certification authority that both servers trust.

- If Lync Server 2013 and Exchange UM are installed in different forests, configure each Exchange forest to trust the Lync Server 2013 forest and the Lync Server 2013 forest to trust each Exchange forest. Also, set the users' Exchange UM settings on the user objects in the Lync Server 2013 forest, typically by using a script or a cross-forest tool, such as Identity Lifecycle Manager (ILM).
- If necessary, install the Exchange Management Console to manage your Unified Messaging servers.
- Obtain valid phone numbers for Outlook Voice Access and auto attendant.
- If you are using a version of Exchange UM earlier than Microsoft Exchange Server 2010 Service Pack 1 (SP1), coordinate names for Exchange UM SIP URI dial plans and Enterprise Voice dial plans.

Deploying Redundant Exchange UM Servers

◆**Important:**
We recommend that you deploy a minimum of two servers on which Exchange UM services is running for each Exchange UM SIP URI dial plan that you configure for your organization. In addition to providing expanded capacity, deploying redundant servers provides high availability. In the event of an server failure, Lync Server 2013 can be configured to fail over to another server.

The following example configurations provide Exchange UM resiliency.

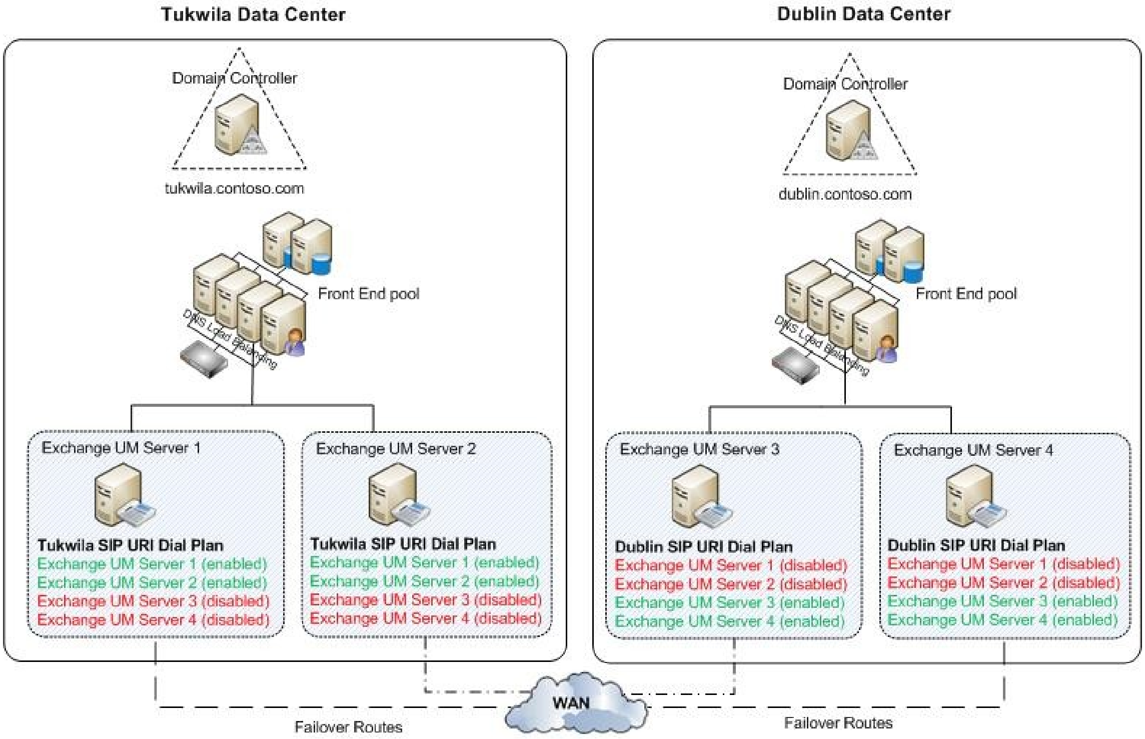


In Example 1, Exchange UM servers 1 and 2 are enabled in the Tukwila data center, and Exchange UM servers 3 and 4 are enabled in the Dublin data center. In the event of an Exchange UM outage in Tukwila, the Domain Name System (DNS) A records for servers 1 and 2 should be configured to point to servers 3 and 4, respectively. In the event of an Exchange UM outage in Dublin, the DNS A records for servers 3 and 4 should be configured to point to servers 1 and 2, respectively.

Note:

For Example 1, you should also assign one of following certificate on each Exchange UM server:

- Use a certificate with a wildcard in the Subject Alternative Name (SAN).
- Put the fully qualified domain name (FQDN) of each of the four Exchange UM servers in the SAN.



Tukwila Data Center
Domain Controller
tukwila.contoso.com
Front End pool
DNS Load Balancing
Exchange UM Server 1
Tukwila SIP URI Dial Plan
Exchange UM Server 1 (enabled)
Exchange UM Server 2 (enabled)
Exchange UM Server 3 (disabled)
Exchange UM Server 4 (disabled)
Exchange UM Server 2
Tukwila SIP URI Dial Plan
Exchange UM Server 1 (enabled)
Exchange UM Server 2 (enabled)
Exchange UM Server 3 (disabled)
Exchange UM Server 4 (disabled)
Dublin Data Center
Domain Controller
dublin.contoso.com
Front End pool
DNS Load Balancing
Exchange UM Server 3
Dublin SIP URI Dial Plan
Exchange UM Server 1 (disabled)
Exchange UM Server 2 (disabled)
Exchange UM Server 3 (enabled)
Exchange UM Server 4 (enabled)
Exchange UM Server 4
Dublin SIP URI Dial Plan
Exchange UM Server 1 (disabled)
Exchange UM Server 2 (disabled)
Exchange UM Server 3 (enabled)
Exchange UM Server 4 (enabled)
WAN
Failover Routes
Failover Routes

In Example 2, under ordinary operating conditions Exchange UM servers 1 and 2 are enabled in the Tukwila data center, and Exchange UM servers 3 and 4 are enabled in the Dublin data center. All four servers are included in the Tukwila users' SIP URI dial plan; however, servers 3 and 4 are disabled. In the event of an Exchange UM outage in Tukwila, for example, Exchange UM servers 1 and 2 should be disabled and Exchange UM servers 3 and 4 should be enabled so the Tukwila Exchange UM traffic will be routed to the servers in Dublin.

For details about how to enable or disable Unified Messaging on Exchange 2013, see “Integrate Exchange 2013 UM with Lync Server” at http://go.microsoft.com/fwlink/p/?LinkId=265372.

For details about how to enable or disable Unified Messaging on Microsoft Exchange Server 2010, see:

- "Enable Unified Messaging on Exchange 2010" at http://go.microsoft.com/fwlink/p/?LinkId=204418.
- "Disable Unified Messaging on Exchange 2010" at http://go.microsoft.com/fwlink/p/?LinkId=204416.

1.3.10.6.4 Deployment Process for Integrating On-Premises Unified Messaging and Lync Server 2013

Deployment Process for Integrating On-Premises Unified Messaging and Lync Server 2013

Planning > Planning for Enterprise Voice > Planning for Exchange Unified Messaging Integration >

Topic Last Modified: *2012-12-17*

If you want to integrate Exchange Unified Messaging (UM) with Lync Server 2013, you must perform the tasks described in this topic. Also be sure that you review the planning and deployment best practices described in Guidelines for Integrating On-Premises Unified Messaging and Lync Server 2013. This topic assumes that you have deployed Lync Server 2013 with a collocated Mediation Server and that you have enabled users for Lync Server 2013, but not necessarily that you have performed all deployment and configuration steps to enable Enterprise Voice, as described in Deploying Enterprise Voice in the Deployment documentation.

Unified Messaging Integration Process

◆**Important:**
It is important that you coordinate with your organization's Exchange administrators to confirm the tasks that each of you will perform to help ensure a smooth, successful integration.

Phase	**Steps**	**Required groups and roles**	**Deployment documentation**
Deploy one of the following: - Microsoft Exchange Server 2007 Service Pack 1 (SP2) or latest service pack - Microsoft Exchange Server 2010 or latest service pack - Microsoft Exchange Server 2013	If you are using Microsoft Exchange Server 2013, install the following Exchange Server roles in either the same forest or a different forest as Lync Server 2013: - Client Access - Mailbox If Microsoft Exchange Server 2013 and Exchange Unified Messaging (UM) are installed in different forests, configure each Exchange forest to trust the Lync Server 2013 forest. If you are using Exchange 2010, install the following Exchange Server roles in either the same forest or a different forest as Lync Server 2013: - Unified Messaging - Hub Transport - Client Access - Mailbox If Lync Server 2013 and Exchange Unified	Enterprise administrators (if this is the first Exchange Server in the organization) -OR- Exchange Organization administrator (if this is not the first Exchange Server in the organization)	See the appropriate documentation for your version of Exchange Server: - Exchange Server 2007 deployment documentation at http://go.microsoft.com/fwlink/p/?LinkId=268694. - Exchange Server 2010 or latest service pack deployment documentation at http://go.microsoft.com/fwlink/p/?LinkId=268695. - Microsoft Exchange Server 2013 Planning and Deployment at http://go.microsoft.com/fwlink/p/?LinkId=266569.

	Messaging (UM) are installed in different forests, configure each Exchange forest to trust the Lync Server 2013 forest.		
Install certificates.	Download and install certificates for each Exchange UM server from a trusted root certificate authority (CA). The certificates are required for mutual Transport Level Security (MTLS) between the servers running Exchange UM and Lync Server 2013.	Administrators	Configure Certificates on the Server Running Microsoft Exchange Server Unified Messaging
Create and configure a new Exchange UM SIP dial plan.	On the Exchange UM server, create a SIP dial plan based on your organization’s specific deployment requirements.	Exchange Organization administrator	For Exchange 2007 SP1 or latest service pack, see "How to Create a Unified Messaging SIP URI Dial Plan" at http://go.microsoft.com/fwlink/p/?linkId=268632. For Exchange 2010 or latest service pack, see "Create a UM Dial Plan" at http://go.microsoft.com/fwlink/p/?linkId=268674. For Exchange 2013, see Unified Messaging at http://go.microsoft.com/fwlink/p/?LinkId=266579.
Configure security settings for the Exchange UM SIP dial plan.	To encrypt Enterprise Voice traffic, configure the security settings on the Exchange UM SIP dial plan as **SIP Secured** or **Secured**. This is an especially important step if you have deployed or plan to deploy Lync Phone Edition devices in your environment. For Lync Phone Edition devices to function in an environment with Exchange UM integration, Lync Server encryption settings must	Exchange Organization administrator	Configure Unified Messaging on Microsoft Exchange For Exchange 2007 SP1 or latest service pack, see also: "How to Configure Security on a Unified Messaging Dial Plan" at http://go.microsoft.com/fwlink/p/?LinkId=268696. For Exchange 2010 or latest service pack, see also:

	align with the Exchange UM dial plan security settings. For details, refer to the Deployment documentation.		"Configure VoIP Security on a UM Dial Plan" http://go.microsoft.com/fwlink/p/?LinkId=268697. For Exchange 2013, see Unified Messaging at http://go.microsoft.com/fwlink/p/?LinkId=266579.
Add Unified Messaging servers to the Exchange UM SIP dial plan.	To enable a newly installed Unified Messaging server to answer and process incoming calls, you must add the Unified Messaging server to a UM dial plan. In this case, add the server to the Exchange UM SIP dial plan.	Administrators Exchange Server administrators	For Exchange 2007 SP1 or latest service pack, see "How to Add Unified Messaging Server to a Dial Plan" at http://go.microsoft.com/fwlink/p/?linkId=268681. For Exchange 2010 or latest service pack, see "View or Configure the Properties of a UM Server" at http://go.microsoft.com/fwlink/p/?linkId=268682. For Exchange 2013, see Unified Messaging at http://go.microsoft.com/fwlink/p/?LinkId=266579.
Configure mailboxes with SIP addresses.	Assign SIP addresses to the mailboxes of Enterprise Voice users who will be using Exchange UM features.	Lync Server 2013 administrator Exchange Recipient administrator	For Exchange 2007 SP1 or latest service pack, see "How to Add, Remove, or Modify a SIP Address for a UM-Enabled User" at http://go.microsoft.com/fwlink/p/?LinkId=268698. For Exchange 2010 or latest service pack, see "Modify a SIP Address for a UM-Enabled User" at http://go.microsoft.com/fwlink/p/?LinkId=268699. For Exchange 2013, see Unified Messaging at http://go.microsoft.com/fwlink/p/?LinkId=266579.
Run the exchucutil.ps1	On the server running Exchange UM services,	Exchange Organization	Configure Unified

script.	open the Exchange Management Shell and run the exchucutil.ps1 script, which does the following: • Grants Lync Server 2013 permission to read Exchange UM Active Directory Domain Services (AD DS) objects, specifically, the SIP dial plans created in the previous task. • Creates a Unified Messaging IP gateway object in Active Directory for each Lync Server 2013 Enterprise Edition pool or Standard Edition server that hosts users who are enabled for Enterprise Voice. • Creates an Exchange UM hunt group for each gateway. The hunt group pilot identifier will be the name of the dial plan that is associated with the corresponding gateway. These need to be mapped 1:1 if there is more than one dial plan.	administrator Exchange Recipient administrator	Messaging on Microsoft Exchange

Configure Lync Server 2013 dial plans.	If you are integrating with Exchange 2007 SP1 or latest service pack, or Exchange 2010, create a new Enterprise Voice dial plan with a name that matches the Exchange UM dial plan fully qualified domain name (FQDN). **Note:** You will need to do this for each UM Dial plan. If you are integrating with Exchange 2010 SP1, ensure that suitable global/site-level or pool-level Enterprise Voice dial plans have been configured. **Note:** If you are integrating with Exchange 2010 SP1, the Lync Server dial plan and Exchange UM SIP dial plan names do not need to match.	RTCUniversalServerAdmins	Configuring Dial Plans
Run the Exchange UM Integration tool.	On the Lync Server 2013, run **ocsumutil.exe**, which: • Creates Subscriber Access and Auto Attendant contact objects. • Validates that there is an Enterprise Voice dial plan with a name that matches the Exchange UM dial plan FQDN. If you are running Exchange 2010 SP1 or later, the dial plan names do not need to match, and you can ignore the	RTCUniversalServerAdmins *and* RTCUniversalUserAdmins **Important:** To run ocsumutil.exe successfully, the user must belong to both of these groups. **Note:** To create Contact objects, the user who runs ocsumutil.exe must have the correct permission to the Active Directory	Configure Lync Server 2013 to Work with Unified Messaging on Microsoft Exchange Server

	tool's warning about this. This tool works by scanning the Active Directory for Exchange UM settings and allowing the Lync Server 2013 administrator to view, create, and edit contact objects.	organizational unit (OU) where the new contact objects are stored. This permission can be granted by running the **Grant-CsOUPermission** cmdlet. For details, see the Lync Server Management Shell documentation.	
If necessary, perform other Enterprise Voice configuration steps.	If you have not already configured Enterprise Voice settings on your servers or users, do one or more of the following: • Deploy and configure Public switched telephone network (PSTN) gateways and Mediation Servers • Define voice policies, PSTN usage records, and outbound call routes. • Enable users for Enterprise Voice. • Optionally, configure specific users with dial plans. Other configuration steps may be required depending on the Enterprise Voice features that you enable.	RTCUniversalServerAdmins RTCUniversalUserAdmins	See topics in the following sections: • Configuring Voice Policies, PSTN Usage Records, and Voice Routes • Deploying Enterprise Voice

Enable Enterprise Voice users for Exchange UM.	On the Exchange UM server, ensure that a Unified Messaging mailbox policy has been created and that each user has a unique extension number assignment, and then enable the user for Unified Messaging.	Exchange Recipient administrato r	For Exchange 2007 SP1 or latest service pack, see "How to Enable a User for Unified Messaging" at http://go.microsoft.com/fwlink/p/?LinkId=268700. For Exchange 2010 or latest service pack, see "Enable a User for Unified Messaging" at http://go.microsoft.com/fwlink/p/?LinkId=268701. For Exchange 2013, see Unified Messaging at http://go.microsoft.com/fwlink/p/?LinkId=266579.

1.3.10.7 Hosted Exchange Unified Messaging Integration

Hosted Exchange Unified Messaging Integration

Microsoft Lync Server 2013 > Planning > Planning for Enterprise Voice >

Topic Last Modified: *2012-09-20*

In addition to the support that previous Lync Server 2013 releases have provided for integration with *on-premises* deployments of Exchange Unified Messaging (UM), Lync Server 2013 introduces support for integration with *hosted* Exchange UM. Hosted Exchange UM enables Lync Server 2013 to provide voice messaging to your users if you transfer some or all of them to a hosted Exchange service provider such as Microsoft Exchange Online.

Lync Server 2013 Enterprise Voice uses the Exchange UM infrastructure to provide call answering, call notification, voice access (including voice mail), and auto attendant services. For details, see Features of Integrated Unified Messaging and Lync Server 2013.

1.3.10.7.1 Hosted Exchange UM Architecture and Routing

Hosted Exchange UM Architecture and Routing

Planning > Planning for Enterprise Voice > Hosted Exchange Unified Messaging Integration >

Topic Last Modified: *2012-03-26*

This section provides an overview of the architecture for on-premises and hosted

Exchange UM integration, including supported modes, shared SIP space, and routing considerations.

- Hosted Exchange UM Integration Architecture
- Hosted Exchange UM Routing

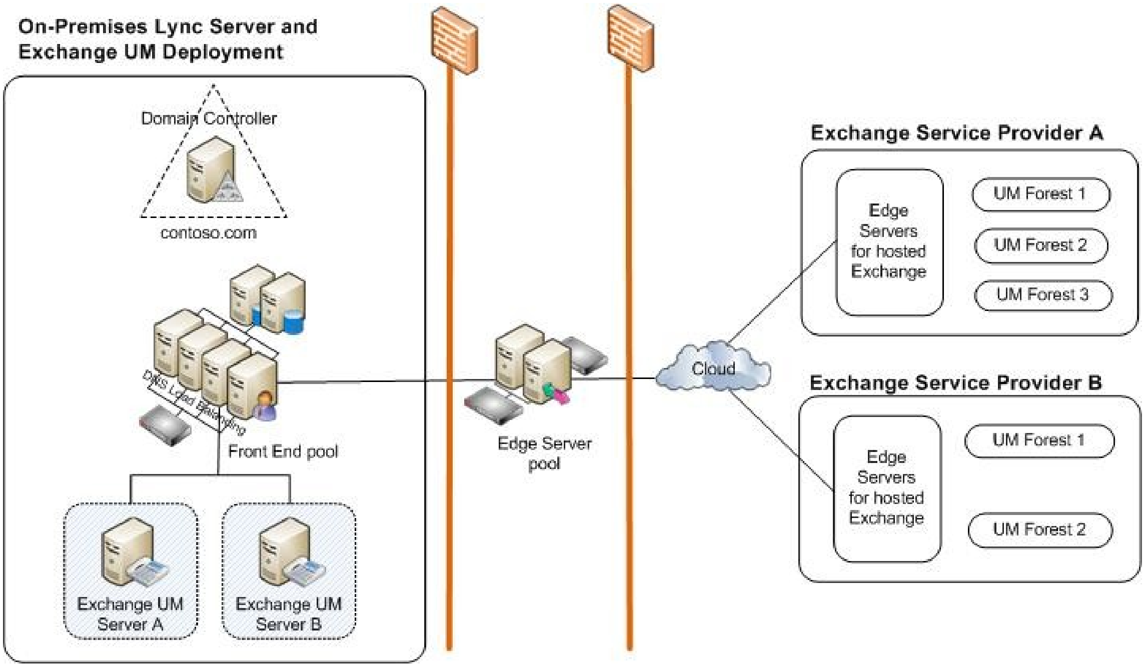
1.3.10.7.1.1 Hosted Exchange UM Integration Architecture

Hosted Exchange UM Integration Architecture

Planning for Enterprise Voice > Hosted Exchange Unified Messaging Integration > Hosted Exchange UM Architecture and Routing >

Topic Last Modified: *2012-09-25*

The Lync Server 2013 ExUM Routing application supports integration with an on-premises Exchange Unified Messaging (UM) deployment, with Exchange UM hosted by a service provider, or with a combination of the two. The following diagram shows all three possibilities.



The following modes are supported:

- **On-premises deployment:** Lync Server 2013 and Exchange UM are both deployed on local servers within your enterprise.
- **Cross-premises deployment:** Lync Server 2013 is deployed on local servers within your enterprise and Exchange UM is hosted in an online service provider’s facility, such as a Microsoft Exchange Online data center.
- **Mixed deployment:** Your Lync Server 2013 deployment has some user mailboxes homed on local Exchange servers within your enterprise and some mailboxes homed in a hosted Exchange service data center.

> **Note:**
> The mixed deployment can be used as a transitional solution during evaluation and phased migration of users to hosted Exchange UM, or a permanent solution if you opt to keep some users’ Exchange UM services on-

premises after transferring others.

Shared SIP Address Space

To integrate Lync Server 2013 with an on-premises Exchange UM deployment, you grant Lync Server 2013 permission to read Exchange UM Active Directory Domain Services objects. This approach does not work for integration with hosted Exchange UM, however, because Lync Server 2013 and Exchange UM are installed in separate forests with no trust between them.

To integrate Lync Server 2013 with hosted Exchange UM, you must configure a *shared SIP address space*. In this configuration, the same SIP domain address space is available to both Lync Server 2013 and the hosted Exchange UM service provider.

Note:

Use of the shared SIP address space is similar to the approach used in a cross-premises Lync Server 2013 environment, in which some users are homed in the on-premises deployment and some are homed in a hosted deployment (such as Lync Online). The SIP domain is split between them. When you integrate Lync Server 2013 with hosted Exchange UM, ensure that you include the Exchange UM service provider in the shared SIP address space.

To configure the shared SIP address space for integrating with an Exchange UM service provider, you need to configure your Edge Server as follows:

1. Configure the Edge Server for federation by running the **Set-CsAccessEdgeConfiguration** cmdlet to set the following parameters:
   - **UseDnsSrvRouting** specifies that Edge Servers will rely on DNS SRV records when sending and receiving federation requests.
   - **AllowFederatedUsers** specifies whether internal users are allowed to communicate with users from federated domains. This property also determines whether internal users can communicate with users in a split domain scenario.
   - **EnablePartnerDiscovery** specifies whether Lync Server 2013 will use DNS records to try to discover partner domains that are not listed in the Active Directory allowed domains list. If False, Lync Server 2013 will federate only with domains that are found on the allowed domains list. This parameter is required if you use DNS service routing. In most deployments, the value is set to false to avoid opening up federation to all partners.
2. Replicate the Central Management store to the Edge Server and verify the replication. For details, see Export Your Topology and Copy It to External Media for Edge Installation in the Deployment documentation.
3. Configure a *hosting provider* on the Edge Server by running the **New-CsHostingProvider** cmdlet to set the following parameters:
   - **Identity** specifies a unique string value identifier for the hosting provider that you are creating, for example, **Hosted Exchange UM**.
   - **Enabled** indicates whether the network connection between your domain and the hosting provider is enabled. Must be set to **True**.
   - **EnabledSharedAddressSpace** indicates whether the hosting provider will be used in a shared SIP address space scenario. Must be set to **True**.
   - **HostsOCSUsers** indicates whether the hosting provider is used to host Lync Server 2013 accounts. Must be set to **False**.
   - **ProxyFQDN** specifies the fully qualified domain name (FQDN) for the proxy server used by the hosting provider, for example, **proxyserver.fabrikam.com**. Contact your hosting provider for this information. This value cannot be modified. If the hosting provider changes its proxy server, you will need to delete and then recreate the entry for that provider.
   - **IsLocal** indicates whether the proxy server used by the hosting provider is contained within your Lync Server 2013 topology. Must be set to **False**.

1.3.10.7.1.2 Hosted Exchange UM Routing

Hosted Exchange UM Routing

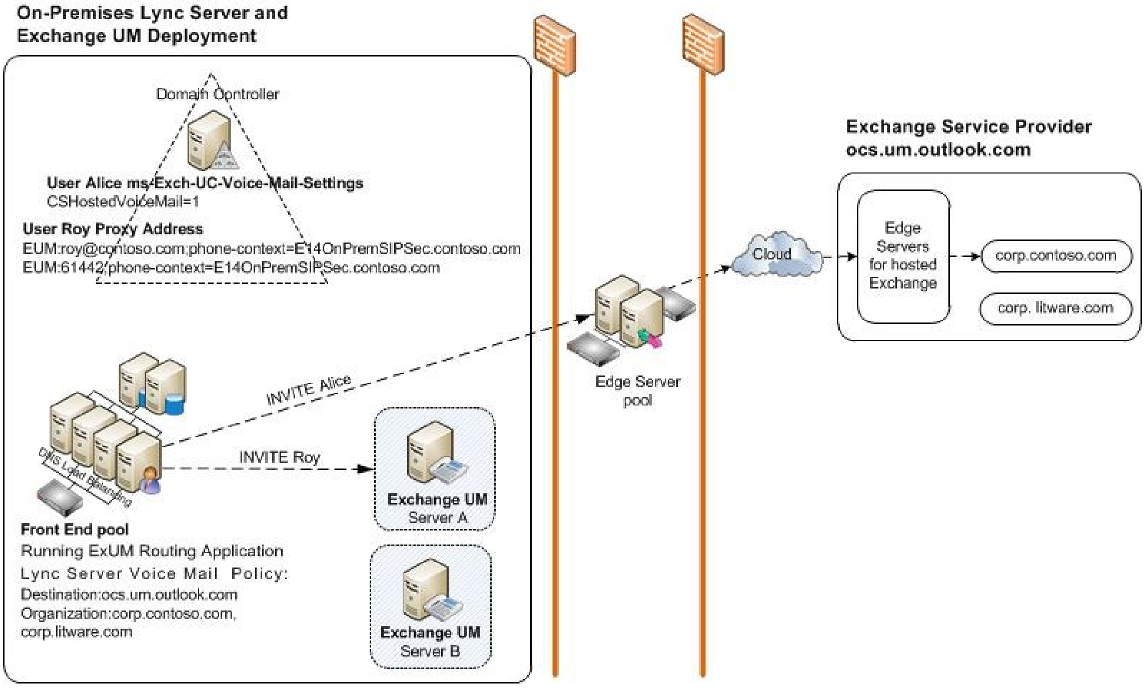
Planning for Enterprise Voice > Hosted Exchange Unified Messaging Integration > Hosted Exchange UM Architecture and Routing >

Topic Last Modified: *2012-10-01*

The Exchange UM Routing application runs on the Front End Server to route calls, either to an on-premises Microsoft Exchange Server Unified Messaging (UM) deployment or to hosted Exchange UM service.

The ExUM Routing Application

The Lync Server 2013 Exchange UM Routing application uses information from user account settings and from hosted voice mail policy parameters to determine how to route calls for hosted voice messaging, as shown in the following diagram.



On-Premises Lync Server and
Exchange UM Deployment
Domain Controller
User Alice ms-Exch-UC-Voice-Mail-Settings
CSHostedVoiceMail=1
User Roy Proxy Address
EUM:roy@contoso.com;phone-context=E14OnPremSIPSec.contoso.com
EUM:61442;phone-context=E14OnPremSIPSec.contoso.com
INVITE Alice
INVITE Roy
DNS Load Balancing
Front End pool
Running ExUM Routing Application
Lync Server Voice Mail Policy:
Destination:ocs.um.outlook.com
Organization:corp.contoso.com,
corp.litware.com
Exchange UM
Server A
Exchange UM
Server B
Edge Server
pool
Cloud
Exchange Service Provider
ocs.um.outlook.com
Edge
Servers
for hosted
Exchange
corp.contoso.com
corp. litware.com

Exchange UM routing can be configured to route calls to users who are enabled for on-premises Exchange UM, to users who are enabled for hosted Exchange UM, or to a combination of the two.

For example, suppose that Roy’s mailbox and Exchange UM service are homed in an on-premises Exchange deployment.

- The proxy address information from Roy’s user account provides the information that the ExUM Routing application uses to route his calls to an on-premises Exchange UM server.

Alice’s mailbox and Exchange UM service are located at a hosted Exchange service provider’s data center. Routing for her Exchange UM calls is configured as follows:

- The values set in the msExchUCVoiceMailSettings attribute of Alice’s user account tell the ExUM Routing application to check for routing details in a hosted voice mail policy.

Note:
The value of the msExchUCVoiceMailSettings attribute can be set by either the Exchange service provider or the Lync Server 2013 administrator. In the example shown in the preceding diagram, the value (CsHostedVoiceMail=1) was set by the Lync Server 2013 administrator to enable hosted voice mail for Alice. For details about this attribute, see Hosted Exchange User Management.

- The hosted voice mail policy that is assigned to Alice's user account provides routing details:
  - Destination is the hosted Exchange UM service provider (ls.ExUm.<*hostedExchangeServer*>.com in this example).
  - Organizations are identified by the tenant IDs, which are the routing FQDNs for SIP messages for Exchange Server tenants that are located on ls.ExUm.<*hostedExchangeServer*>.com (corp.contoso.com and corp.litwareinc.com in this example).

  Note:
  The FQDN for Exchange Online is exap.um.outlook.com.

  For details, see Hosted Voice Mail Policies.

Note:
If both the msExchUCVoiceMailSettings attribute and the UM proxy address settings are present in a user account, the msExchUCVoiceMailSettings attribute takes precedence.

1.3.10.7.2 Hosted Voice Mail Policies

Hosted Voice Mail Policies

Planning > Planning for Enterprise Voice > Hosted Exchange Unified Messaging Integration >

Topic Last Modified: *2012-10-01*

A *hosted voice mail policy* provides information to the Lync Server 2013 ExUM Routing application about where to route calls for users whose mailboxes are located on a hosted Exchange service.

Note:
Hosted voice mail policies are required only for Lync Server 2013 integration with hosted Exchange UM. They are not needed for integration with on-premises Exchange UM.

Hosted Voice Mail Policy Scope

Hosted voice mail policy scope determines the hierarchical level at which the policy applies. You can configure hosted voice mail policies with the following scope levels:

- The *global* policy can potentially affect all users in the Lync Server 2013 deployment. If a user is enabled for hosted Exchange UM access and has not been assigned a per-user policy, and if a site policy has not been assigned to the user's site, the global policy applies. The global policy is installed with Lync Server 2013. You can modify it to meet your needs, but you cannot rename or delete it.
- A *site* policy can affect all users that are homed on the site for which the policy is defined. If a user is configured for hosted Exchange UM access and has not been assigned a per-user policy, the site policy applies.
- A *per-user* policy can affect only individual users or groups. To enforce a per-user policy, you must explicitly assign the policy to individual users, groups, and contact objects.

Note:

In most cases, only one hosted voice mail policy is required. You can often modify the global policy to meet all your needs. If you deploy multiple hosted voice mail policies, all such policies have per-user scope.

Hosted Voice Mail Policy Attributes

A voice mail policy defines two attributes that the Lync Server 2013 ExUM Routing application inserts in the request URI of an INVITE message that is sent to the hosted Exchange UM implementation:

- **Destination:** The fully qualified domain name (FQDN) of the hosted Exchange UM service. This value is used by the on-premises Lync Server Edge Server for routing purposes.

  Note:

  The FQDN for Exchange Online is exap.um.outlook.com.

- **Organization:** The FQDN of the tenant on the hosted Exchange UM service that homes your Lync Server 2013 users' mailboxes. A voice mail policy can contain multiple organizations. If more than one organization is included in the policy, this attribute must be a comma-separated list of the Exchange Server tenants that home your Lync Server 2013 user mailboxes.

Note:

The tenant administrator of your hosted Exchange UM service will provide the necessary values for your Destination and Organization attribute settings. To configure your policy, you must run the New-CsHostedVoicemailPolicy cmdlet or use the Set-CsHostedVoicemailPolicy cmdlet to modify one that exists (for example, the global policy).

For details about managing hosted voice mail policies, see the Lync Server Management Shell documentation for the following cmdlets:

- New-CsHostedVoicemailPolicy
- Set-CsHostedVoicemailPolicy
- Get-CsHostedVoicemailPolicy

Per-User Voice Mail Policy Assignment

If your hosted voice mail policy is defined with per-user scope, you must explicitly assign it. You can run the Grant-CsHostedVoicemailPolicy cmdlet to assign the policy to individual users or groups.

For details about assigning or removing a per-user hosted voice mail policy, see the Lync Server Management Shell documentation for the following cmdlets:

- Grant-CsHostedVoicemailPolicy
- Remove-CsHostedVoicemailPolicy

1.3.10.7.3 Hosted Exchange User Management

Hosted Exchange User Management

Planning > Planning for Enterprise Voice > Hosted Exchange Unified Messaging Integration >

Topic Last Modified: *2012-10-18*

To provide voice mail services for Lync Server 2013 users whose mailboxes are located on a hosted Exchange service, you must enable their user accounts for hosted voice mail.

Note:

Before a Lync Server 2013 user can be enabled for hosted voice mail, a hosted voice mail policy that applies to the corresponding user account must be deployed. The policy can be global, site, or per-user in scope, as long as it applies to the user whom you want to enable. For details, see Hosted Voice Mail Policies.

The msExchUCVoiceMailSettings Attribute

Lync Server 2013 introduces a new user attribute named **msExchUCVoiceMailSettings**, which is created as part of the Lync Server 2013 Active Directory schema preparation. This multivalued attribute holds voice mail settings that are shared by Lync Server 2013 and the hosted Exchange service.

The hosted Exchange service may in some cases set the value of the msExchUCVoiceMailSettings attribute in the process of enabling Exchange UM, or during the process of transferring mailboxes to a hosted Exchange Server. If this attribute is not set by Exchange, the Lync Server 2013 administrator must set it by running the Set-CsUser cmdlet, as described earlier in this topic.

The attribute's key/value pairs and their authors are shown in the following table.

The msExchUCVoiceMailSettings Attribute Key/Value Pairs

Value	Author	Meaning
ExchangeHostedVoiceMail=1	Exchange	User has been enabled for hosted UM access by Exchange Server. The Exchange UM Routing application will check the user's hosted voice mail policy for routing details.
ExchangeHostedVoiceMail=0	Exchange	User has been disabled for hosted UM access by Exchange Server.
CsHostedVoiceMail=1	Lync Server	User has been enabled for hosted UM access by Lync Server 2013. The Lync Server 2013 ExUM Routing application will check the user's hosted voice mail policy for routing details.
CsHostedVoiceMail=0	Lync Server	User has been disabled for hosted UM access by Lync Server 2013.

Note:

If the attribute already has values other than one of the Lync Server 2013 key/value pairs (CSHostedVoiceMail=0 or CSHostedVoiceMail=1), a warning will indicate that the attribute may be managed by a different application. For example, a warning is displayed if the key/value pair ExchangeHostedVoiceMail=0 or ExchangeHostedVoiceMail=1 is already present. In that case, you can change the value by editing it the Active Directory, or run the following cmdlet to set the value to null:

```
Set-CsUser –identity user –HostedVoicemail $null
```

Enabling Users for Hosted Voice Mail

To enable a user's voice mail calls to be routed to hosted Exchange UM, you must run the Set-CsUser cmdlet to set the value of the *HostedVoiceMail* parameter. This parameter also signals Lync Server 2013 to light up the “call voice mail” indicator.

- The following example enables Pilar Ackerman’s user account for hosted voice mail:

  ```
  Set-CsUser -Identity "Pilar Ackerman" -HostedVoiceMail $True
  ```

  The cmdlet verifies that a hosted voice mail policy (global, site-level or per-user) applies to this user. If no policy applies, the cmdlet fails.
- The following example disables Pilar Ackerman’s user account for hosted voice mail:

  ```
  Set-CsUser -Identity "Pilar Ackerman" -HostedVoiceMail $False
  ```

  The cmdlet verifies that no hosted voice mail policy (global, site-level or per-user) applies to this user. If a policy does apply, the cmdlet fails.

For details about using the Set-CsUser cmdlet, see the Lync Server Management Shell documentation.

1.3.10.7.4 Hosted Exchange Contact Object Management

Hosted Exchange Contact Object Management

Planning > Planning for Enterprise Voice > Hosted Exchange Unified Messaging Integration >

Topic Last Modified: *2012-09-25*

You need to configure a Contact object for each auto-attendant number and subscriber access number in your cross-premises deployment.

For integration with hosted Exchange UM, ocsumutil.exe cannot be used to manage Contact objects, because it depends on Active Directory Exchange UM settings. In a cross-premises deployment, Lync Server 2013 and hosted Exchange UM are installed in separate forests with no trust between them. For security reasons, Lync Server 2013 administrators have no direct access to Exchange UM Active Directory settings. As a result, Lync Server 2013 provides a different model for managing Contact objects in a *shared SIP address space* that is accessible to both Lync Server 2013 and the hosted Exchange UM service.

Hosted Contact Object Workflow

The following are the general steps for working with your hosted Exchange tenant administrator to manage contact objects:

1. The Exchange administrator requests phone numbers for the Exchange UM subscriber access and auto-attendant Contact objects.
2. The Lync Server 2013 administrator creates a Contact object for each phone number and assigns a hosted voice mail policy to each Contact object.
3. The Lync Server 2013 administrator provides the phone numbers to the Exchange administrator.
4. The Exchange administrator assigns the phone numbers to appropriate Exchange UM dial plans for auto attendants and subscriber access.

Note:

There is no need to configure any Lync Server 2013 dial plan settings on the Contact objects as there is with on-premises deployments.

Configuring Hosted Contact Objects

Note:

Before Lync Server 2013 Contact objects can be enabled for hosted Exchange UM, a hosted voice mail policy that applies to them must be deployed. The policy can be of global, site-level, or per-user scope, as long as it applies to the contact object you want to enable. For details, see Hosted Voice Mail Policies.

To configure hosted auto-attendant and subscriber access Contact objects in a cross-premises deployment, you must use the following cmdlets:

- **New-CsExUmContact** creates a new Contact object for hosted UM.
- **Set-CsExUmContact** modifies an existing Contact object for hosted Exchange UM.

The following example creates an auto-attendant Contact object:

```
New-CsExUmContact -SipAddress sip:exumaa1@fabrikam.com -RegistrarPool RedmondPool
```

This example creates a new Exchange UM Contact object with the SIP address sip:exumaa1@fabrikam.com. The name of the pool where the Lync Server 2013 Registrar service is running is RedmondPool.litwareinc.com. The Active Directory organizational unit where this information will be stored is OU=ExUmContacts,DC=litwareinc,DC=com. The phone number of the Contact object is 2065554567. The optional -AutoAttendant $True parameter specifies that this object is an auto-attendant Contact object. Setting the -AutoAttendant parameter to False (the default) specifies a subscriber access Contact object.

For details about the New-CsExUmContact and Set-CsExUmContact cmdlets, see the Lync Server Management Shell documentation.

1.3.10.7.5 Deployment Process for Integrating Hosted Exchange UM with Lync Server 2013

Deployment Process for Integrating Hosted Exchange UM with Lync Server 2013

Planning > Planning for Enterprise Voice > Hosted Exchange Unified Messaging Integration >

Topic Last Modified: *2012-09-25*

Effective planning for integrating Lync Server 2013 with hosted Exchange Unified Messaging (UM) requires that you take into account the following:

- Prerequisites for integrating Lync Server 2013 with hosted Exchange UM
- Steps required during the integration process

Deployment Prerequisites for Integrating with Hosted Exchange UM

Before you can begin the integration process, you must already have deployed Lync Server 2013 (at a minimum, a Front End pool or a Standard Edition server), an Edge Server, and Lync 2013 or Lync 2010 clients.

Integration Process

The following table provides an overview of the hosted Exchange UM integration process. For details about deployment steps, see Providing Lync Server 2013 Users Voice Mail on Hosted Exchange UM in the Deployment documentation.

Phase	Steps	Rights and permissions	Deployment documentation
Configure the Edge Server.	1. Configure the Edge Server for federation. 2. Manually replicate data to the Edge Server. 3. Configure the hosting provider on the Edge Server.	RTCUniversalServerAdmins	Configure the Edge Server for Integration with Hosted Exchange UM
Configure hosted voice mail policy.	1. Either modify the global hosted voice mail policy or create a new hosted voice mail policy with Site or Per-User scope. 2. For policies with Per-User scope, assign the policy to users or groups.	RTCUniversalServerAdmins	Manage Hosted Voice Mail Policies
Enable users for hosted voice mail.	- Configure user accounts for users whose mailboxes are on a hosted Exchange service.	RTCUniversalUserAdmins	Enable Users for Hosted Voice Mail
Configure hosted contact objects.	1. Create auto-attendant Contact objects for hosted Exchange UM. 2. Create Subscriber Access contact objects for hosted Exchange UM.	RTCUniversalUserAdmins **Note:** To create, modify or remove contact objects, the user who runs the New-CsExUmContact, Set-CsExUmContact or Remove-CsExUmContact cmdlet must have the correct permission to the Active Directory organizational unit where the new contact objects are stored. This permission can be granted by running the Grant-CsOUPermission cmdlet. For details, see the Lync Server Management Shell documentation.	Create Contact Objects for Hosted Exchange UM

1.3.10.8 Planning for Call Admission Control

Planning for Call Admission Control

Microsoft Lync Server 2013 > Planning > Planning for Enterprise Voice >

Topic Last Modified: *2012-09-21*

For unified communications (UC) applications that are IP-based, such as telephony, video, and application sharing, the available bandwidth of enterprise networks is not generally considered to be a limiting factor within LAN environments. However, on WAN links that interconnect sites, network bandwidth can be limited. When an influx of network traffic oversubscribes a WAN link, current mechanisms such as queuing, buffering, and packet dropping are used to resolve the congestion. The extra traffic is typically delayed until the network congestion eases or, if necessary, the traffic is dropped. For conventional data traffic in such situations, the receiving client can recover. For real-time traffic such as unified communications, network congestion cannot be resolved in this manner, because the unified communications traffic is sensitive to both latency and packet loss. Congestion on the WAN can result in a poor Quality of Experience (QoE) for users. For real-time traffic in congested conditions, it is better to deny calls than to provide connections with poor quality.

Call admission control (CAC) determines whether there is sufficient network bandwidth to establish a real-time session of acceptable quality. In Lync Server 2013, CAC controls real-time traffic only for audio and video, but it does not affect data traffic. If the default WAN path does not have the required bandwidth, CAC can attempt to route the call through an Internet path or the public switched telephone network (PSTN). CAC is available only in Lync Server.

This section describes the call admission control functionality and explains how to plan for CAC.

Note:

Lync Server has three advanced Enterprise Voice features: call admission control (CAC), emergency services (E9-1-1), and media bypass. For an overview of planning information that is common to all three of these features, see Network Settings for the Advanced Enterprise Voice Features.

- Overview of Call Admission Control
- Defining Your Organization's Requirements for Call Admission Control
- Example: Gathering Your Organization's Requirements for Call Admission Control
- Components and Topologies for CAC
- Best Practices for Call Admission Control
- Deployment Checklist for Call Admission Control

1.3.10.8.1 Overview of Call Admission Control

Overview of Call Admission Control

Planning > Planning for Enterprise Voice > Planning for Call Admission Control >

Topic Last Modified: *2012-09-22*

Real-time communications are sensitive to the latency and packet loss that can occur on congested networks. Call admission control (CAC) determines, based on available network bandwidth, whether to allow real-time communications sessions such as voice or video calls to be established. The CAC design in Lync Server 2013 offers four main attributes:

- It is simple to deploy and manage without requiring additional equipment, such as specially configured routers.
- It addresses critical unified communications use cases, such as roaming users and multiple points of presence. CAC policies are enforced according to where the endpoint is located, not where the user is homed.
- In addition to voice calls, it can be applied to other traffic, such as video calls and audio/video conferencing sessions.
- Provides the flexibility to enable representation of various kinds of network topologies. For examples, see Components and Topologies for CAC.

If a new voice or video session exceeds the bandwidth limits that you have set on a WAN link, the session is either blocked or (for phone calls only) rerouted to the PSTN.

CAC controls real-time traffic for voice and video only. It does not control data traffic.

Administrators define CAC policies, which are enforced by the Bandwidth Policy Service that is installed with every Front End pool. CAC settings are automatically propagated to all Lync Server Front End Servers in your network.

For calls that fail because of CAC policies, the order of precedence for rerouting the call is as follows:

1. Internet
2. PSTN
3. Voice mail

Call detail recording (CDR) captures information about calls that are rerouted to the PSTN or to voice mail. CDR does not capture information about calls that are rerouted to the Internet, because the Internet is treated as an alternate path rather than a secondary option.

Note:
Voice mail deposits will not be denied because of bandwidth constraints.

The Bandwidth Policy Service generates two types of log files in comma separated values (CSV) format. The **check failures** log file captures information when bandwidth requests are denied. The **link utilization** log file captures a snapshot of the network topology and the WAN link bandwidth utilization. Both of these log files can assist you in fine-tuning your CAC policies based on utilization.

Call Admission Control Considerations

The administrator selects to install the Bandwidth Policy Service on the first pool configured in the central site. Since there is a single central site per network region, there is only one Bandwidth Policy Service per network region, which manages bandwidth policy for that region, its associated sites and the links to those sites. The Bandwidth Policy Service runs as part of the Front End Servers, and therefore high availability is built-in within that pool. The Bandwidth Policy Service running on each Front End Server synchronizes every 15 seconds. If the Front End pool fails, CAC policies are no longer enforced for that site until the Front End pool and consequently the Bandwidth Policy Service becomes operational again. This implies that all calls will go through for the duration the Bandwidth Policy Service is out of service. Therefore there is the possibility of bandwidth oversubscription of your links during this period

The Bandwidth Policy Service provides high availability within a Front End pool; however, it does not provide redundancy across Front End pools. The Bandwidth Policy Service cannot failover from one Front End pool to another. Once service to the Front End pool is restored, the Bandwidth Policy Service is resumed and can enforce bandwidth policy checks again.

Network Considerations

Although bandwidth restriction for audio and video is enforced by the Bandwidth Policy Service in Lync Server 2013, this restriction is not enforced at the network router (layer 2 and 3). Lync Server 2010 CAC cannot prevent a data application, for example, from consuming the entire network bandwidth on a WAN link, including the bandwidth that is reserved for audio and video by your CAC policy. To protect the necessary bandwidth on your network, you can deploy a Quality of Service (QoS) protocol such as Differentiated Services (DiffServ). Therefore, a best practice is to coordinate the CAC bandwidth policies you define with any QoS settings that you might deploy.

Media and Signaling Paths over VPN

If your enterprise supports media through VPN, ensure that either both the media stream and the signaling stream go through the VPN or both are routed through the internet. By default, the media and signaling streams go through the VPN tunnel.

Call Admission Control of Outside Users

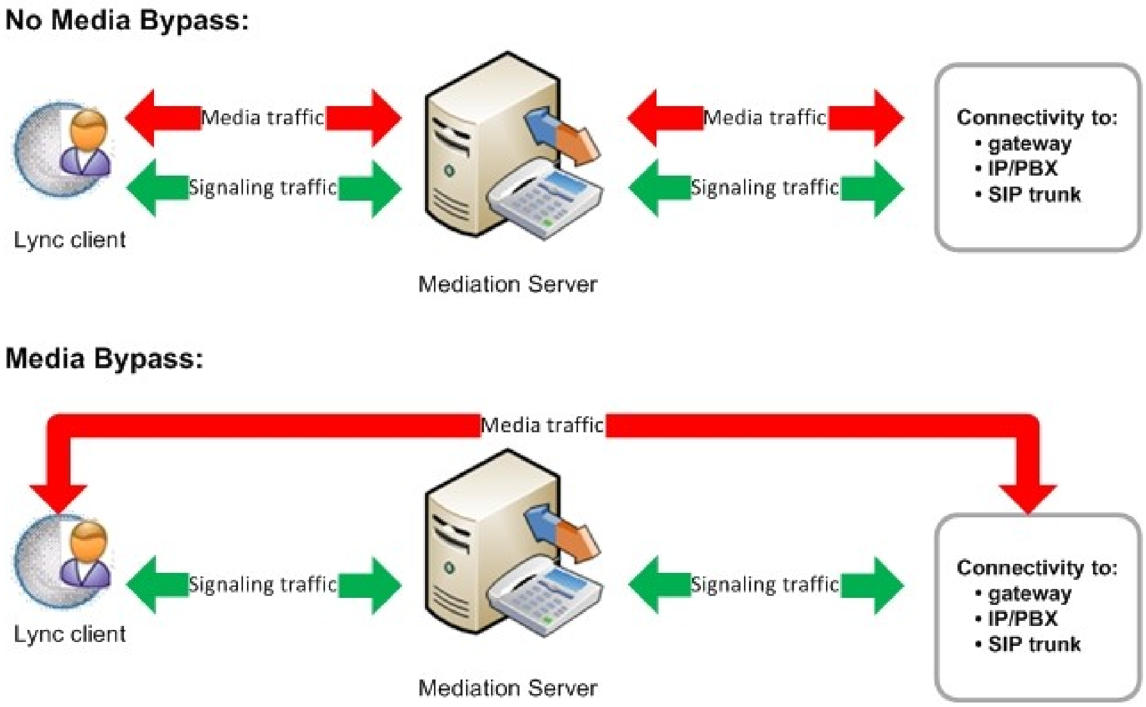
Call admission control is not enforced for remote users where the network traffic flows through the Internet. Because the media traffic is traversing the Internet, which is not managed by Lync Server, CAC cannot be applied. CAC checks will be performed, however, on the portion of the call that flows through the enterprise network.

Call Admission Control of PSTN Connections

Call admission control is enforceable on the Mediation Server regardless of whether it is connected to an IP/PBX, a PSTN gateway, or a SIP trunk. Because the Mediation Server is a back-to-back user agent (B2BUA), it terminates media. It has two connection sides: a side that is connected to Lync Server and a gateway side, which is connected to PSTN gateways, IP/PBXs, or SIP trunks. For details about PSTN connections, see Planning for PSTN Connectivity.

CAC can be enforced on both sides of the Mediation Server unless media bypass is enabled. If media bypass is enabled, the media traffic doesn’t traverse the Mediation Server but instead flows directly between the Lync client and the gateway. In this case, CAC is not needed. For details, see Planning for Media Bypass.

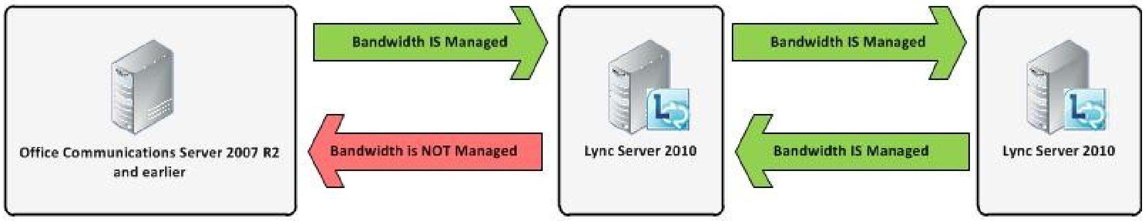
The following figure illustrates how CAC is enforced on PSTN connections with and without media bypass enabled.



Compatibility of Call Admission Control with Earlier Versions of Office Communications Server

Call admission control can be enabled only on endpoints that are enabled for Lync Server 2010 and later.

Call admission control cannot be enabled on endpoints running Office Communicator 2007 R2 or earlier.



1.3.10.8.1.1 Infrastructure Requirements for Call Admission Control

Infrastructure Requirements for Call Admission Control

Planning for Enterprise Voice > Planning for Call Admission Control > Overview of Call Admission Control >

Topic Last Modified: *2012-08-21*

No additional infrastructure requirements, such as special network routers, are necessary. Deploying Lync Server 2013 will automatically install the Bandwidth Policy Service used to enforce call admission control (CAC) policies. Call admission control works only with clients running Lync.

1.3.10.8.2 Defining Your Organization's Requirements for Call Admission Control

Defining Your Organization's Requirements for Call Admission Control

Planning > Planning for Enterprise Voice > Planning for Call Admission Control >

Topic Last Modified: *2012-09-21*

Planning for call admission control (CAC) requires detailed information about your enterprise network topology. To help plan your call admission control policies, follow these steps.

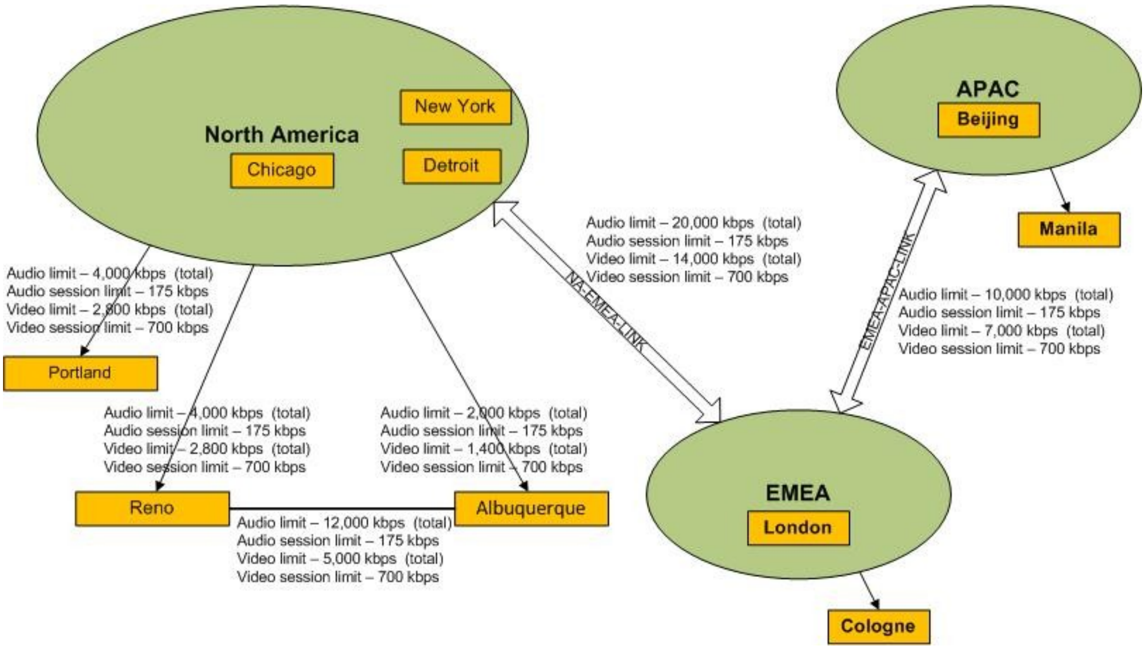
1. Identify the hubs/backbones (called *network regions*) within your enterprise network.
2. Identify the offices or locations (called *network sites*) within each network region.
3. Determine the network route between every pair of network regions.
4. Determine the bandwidth limits for each WAN link.

   Note:

   Bandwidth limits refer to how much of the bandwidth on a WAN link is allocated to Enterprise Voice and audio/video traffic. When a WAN link is described as "bandwidth-constrained," the WAN link has a bandwidth limit that is lower than the expected peak traffic over the link.

5. Identify the IP subnets that are assigned to each network site.

To explain these concepts, we'll use the example network topology shown in the following figure.



North America
New York
Chicago
Detroit
APAC
Beijing
Manila
Audio limit – 20,000 kbps (total)
Audio session limit – 175 kbps
Video limit – 14,000 kbps (total)
Video session limit – 700 kbps
NA-EMEA-LINK
EMEA-APAC-LINK
Audio limit – 10,000 kbps (total)
Audio session limit – 175 kbps
Video limit – 7,000 kbps (total)
Video session limit – 700 kbps
Audio limit – 4,000 kbps (total)
Audio session limit – 175 kbps
Video limit – 2,800 kbps (total)
Video session limit – 700 kbps
Portland
Audio limit – 4,000 kbps (total)
Audio session limit – 175 kbps
Video limit – 2,800 kbps (total)
Video session limit – 700 kbps
Audio limit – 2,000 kbps (total)
Audio session limit – 175 kbps
Video limit – 1,400 kbps (total)
Video session limit – 700 kbps
Reno
Albuquerque
Audio limit – 12,000 kbps (total)
Audio session limit – 175 kbps
Video limit – 5,000 kbps (total)
Video session limit – 700 kbps
EMEA
London
Cologne

Note:

All network sites are associated with a network region. For example, Portland, Reno, and Albuquerque are included in the North America region. In this figure, only WAN links that have CAC policies applied are shown, with bandwidth limits. The network sites of Chicago, New York, and Detroit are shown inside the North America region oval because they are not bandwidth-constrained, and therefore do not require CAC policies.

The components of this example topology are explained in the following sections. For details about how this topology was planned, including the bandwidth limits, see Example: Gathering Your Organization's Requirements for Call Admission Control.

Identify Network Regions

A network region represents a network backbone or a network hub.

A network backbone or hub is a part of computer network infrastructure that interconnects different parts of the network, providing a path for the exchange of information between different LANs or subnets. A backbone can tie together diverse networks from a small location to a wide geographic area. The backbone's capacity is typically greater than that of the networks that connect to it.

Our example topology has three network regions: North America, EMEA, and APAC. A network region contains a collection of network sites (see the definition of network sites later in this topic). Work with your network operations team to identify your network regions.

Associating a Central Site with each Network Region

CAC requires that a Lync Server central site is defined for each network region. The central site is selected with the best network connectivity and highest bandwidth to all the other sites within that network region. The preceding example of network topology shows three network regions, each with a central site that manages CAC decisions. From the preceding example, the appropriate association is shown in the following table.

Note:
Central sites do not necessarily correspond to network sites. In the examples in this documentation, some central sites—Chicago, London, and Beijing—share the same name as the network sites. However, even if a central site and network site share the same name, the central site is an element of the Lync Server topology, whereas the network site is a part of the overall network in which the Lync Server topology resides.

Network regions, central sites, and network sites

Network Region	Central Site	Network Sites
North America	Chicago	Chicago New York Detroit Portland Reno Albuquerque
EMEA	London	London Cologne
APAC	Beijing	Beijing Manila

Identify Network Sites

A network site represents a location where your organization has a physical venue—for example, offices, a set of buildings, or a campus. A physical venue with a LAN and has WAN connectivity to other sites is considered a network site. Start by inventorying all of your organization's offices. In our example topology, the North America network region consists of the following network sites: New York, Chicago, Detroit, Portland, Reno, and Albuquerque.

You must associate every network site with a network region. Depending on whether the network site has a constrained WAN link, a bandwidth policy is associated with the network site. For details about CAC policies and the bandwidth that you allocate by using them, see "Define Bandwidth Policies" later in this topic. To configure CAC, you associate network sites with network regions, and then you create bandwidth-allocating policies to apply to the bandwidth-constrained connections between a given site or region and the WAN connections between the sites and regions.

Identify Network Links

Network links represent connections to the physical WAN that links different regions and sites. In our example topology, there are two regional network links, five network links between regions and sites, and one network link between two sites.

The two regional links are between North America and EMEA, represented as NA-EMEA-LINK, and between APAC and EMEA, represented as EMEA-APAC-LINK.

The site links are indicated by the lines connecting Portland, Reno, and Albuquerque to the North America region, Manila to the APAC region, and Cologne to the EMEA region. The line between Reno and Albuquerque shows a direct network link between these two sites.

Define Bandwidth Policies

Work with your network operations team to determine how much WAN bandwidth is available for real-time audio and video traffic across the WAN links in your organization. Bandwidth policies are typically applied to WAN links if the bandwidth usage is constrained; that is, if it expected to be more than the bandwidth that can be allocated for audio and video modalities.

CAC *bandwidth policies* define the maximum bandwidth that can be reserved for real-time audio and video modalities. Since CAC does not limit the bandwidth of other traffic, it cannot prevent other data traffic such as a large file transfer, music streaming, from using up all of the network bandwidth.

CAC bandwidth policies can define any or all of the following:

- Maximum total bandwidth allocated for audio.
- Maximum total bandwidth allocated for video.
- Maximum bandwidth allocated for a single audio call (session).
- Maximum bandwidth allocated for a single video call (session).

Note:

All CAC bandwidth values represent the maximum *unidirectional* bandwidth limits.

Note:

The Lync Server 2013 Voice Policy features provide the ability to override bandwidth policy checks for incoming calls to the user (not for outgoing calls that are placed by the user). After the session is established, the bandwidth consumption will be accurately accounted for. This setting should be used sparingly. For details, see Create a Voice Policy and Configure PSTN Usage Records or Modify a Voice Policy and Configure PSTN Usage Records in the Deployment documentation.

To optimize bandwidth utilization on a per-session basis, consider the type of audio and video codecs that will be used. In particular, avoid allocating insufficient bandwidth for a codec that you expect to be used frequently. Conversely, if you want to prevent media from using a codec that requires more bandwidth, you should set the maximum bandwidth per session low enough to discourage such use. For audio, not every codec is available for every scenario. For example:

- Peer-to-peer audio calls between Lync endpoints will use either RTAudio (8kHz) or RTAudio (16kHz) when you factor in the bandwidth and prioritization of codecs.
- Conference calls between Lync endpoints and the A/V Conferencing service will use either G.722 or Siren.
- Calls to the public switched telephone network (PSTN) either to or from Lync endpoints will use either G.711 or RTAudio (8kHz).

Use the following table to help optimize the maximum per-session bandwidth settings.

Bandwidth utilization by codecs

Codec	Bandwidth requirement with no forward error correction (FEC)	Bandwidth requirement with forward error correction (FEC)
RTAudio (8kHz)	49.8 kbps	61.6 kbps
RTAudio (16kHz)	67 kbps	96 kbps

Siren	57.6 kbps	73.6 kbps
G.711	102 kbps	166 kbps
G.722	105.6 kbps	169.6 kbps
RTVideo (CIF 15 fps)	260 kbps	Not applicable
RTVideo (VGA 30 fps)	610 kbps	Not applicable

Note:
Bandwidth requirements take into account overhead for the following: Ethernet II, IP, User Datagram Protocol (UDP), RTP (real-time transport protocol), and SRTP (secure real-time transport protocol). They also include 10 kbps for RTCP overhead.

The G.722.1 and Siren codecs are similar, but they offer different bit rates.

G.722, the default codec for Lync Server conferencing, is completely different from the G.722.1 and Siren codecs.

The Siren codec is used in Lync Server in the following situations:

- If the bandwidth policy is set too low for G.722 to be used.
- If a Communications Server 2007 or Communications Server 2007 R2 client connects to a Lync Server conferencing service (because those clients do not support the G.722 codec).

Bandwidth utilization by scenario

Scenario	Bandwidth requirement optimized for quantity (kbps)	Bandwidth requirement for Balanced mode (kbps)	Bandwidth requirement optimized for quality (kbps)
Peer-to-peer audio calls	45 kbps	62 kbps	91 kbps
Conference calls	53 kbps	101 kbps	165 kbps
PSTN calls (between Lync 2013 and PSTN gateway, with media bypass)	97 kbps	97 kbps	161 kbps
PSTN calls (between Lync 2013 and Mediation Server, without media bypass)	45 kbps	97 kbps	161 kbps
PSTN calls (between Mediation Server and PSTN gateway, without media bypass)	97 kbps	97 kbps	161 kbps

Identify IP Subnets

For each network site, you will need to work with your network administrator to determine what IP subnets are assigned to each network site. If your network administrator has already organized the IP subnets into network regions and network sites, then your work is significantly simplified.

In our example, the New York site in the North America region is assigned the following IP subnets: 172.29.80.0/23, 157.57.216.0/25, 172.29.91.0/23, 172.29.81.0/24. Suppose Bob, who typically works in Detroit, travels to the New York office for training. When he turns on his computer and connects to the network, his computer will get an IP address in one of the four ranges reserved for New York, for example 172.29.80.103.

⚠**Warning:**

The IP subnets specified during network configuration on the server must match the format provided by client computers in order to be properly used for media bypass. A Lync client takes its local IP address and masks the IP address with the associated subnet mask. When determining the bypass ID associated with each client, the Registrar will compare the list of IP subnets associated with each network site against the subnet provided by the client for an exact match. For this reason, it is important that subnets entered during network configuration on the server are actual subnets instead of virtual subnets. (If you deploy call admission control, but not media bypass, call admission control will function properly even if you configure virtual subnets.)
For example, if a client signs in on a computer with an IP address of 172.29.81.57 with an IP subnet mask of 255.255.255.0, Lync 2013 will request the bypass ID associated with subnet 172.29.81.0. If the subnet is defined as 172.29.0.0/16, although the client belongs to the virtual subnet, the Registrar will not consider this a match because the Registrar is specifically looking for subnet 172.29.81.0. Therefore, it is important that the administrator enters subnets exactly as provided by Lync clients (which are provisioned with subnets during network configuration either statically or by DHCP.)

1.3.10.8.3 Example: Gathering Your Organization's Requirements for Call Admission Control

Example: Gathering Your Organization's Requirements for Call Admission Control

Planning > Planning for Enterprise Voice > Planning for Call Admission Control >

Topic Last Modified: *2012-09-21*

This example shows you how to plan for and implement call admission control (CAC). At a high level, this consists of the following activities:

1. Identify all of your network hubs and backbones (known as *network regions*).
2. Identify the Lync Server central site that will manage CAC for each network region.
3. Identify and define the *network sites* that are connected to each network region.
4. For each network site whose connection to the WAN is bandwidth-constrained, describe the bandwidth capacity of the WAN connection and the bandwidth limits that to the network administrator has set for Lync Server media traffic, if applicable. You do not need to include sites whose connection to the WAN is not bandwidth-constrained.
5. Associate each subnet in your network with a network site.
6. Map the links between the network regions. For each link, describe its bandwidth capacity and any limits that the network administrator has placed on Lync Server media traffic.
7. Define a route between every pair of network regions.

Gather the Required Information

To prepare for call admission control, gather the information described in the following steps:

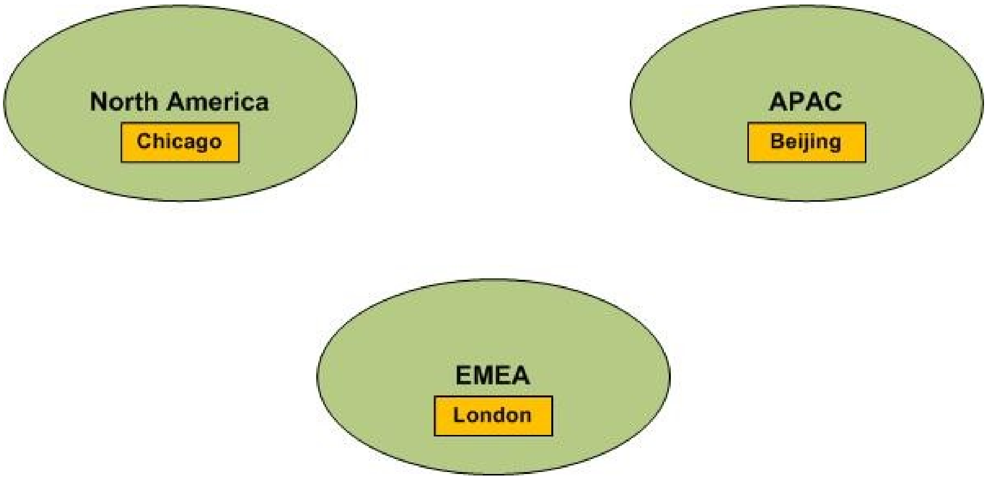
1. Identify your network regions. A network region represents a network

backbone or a network hub.

A network backbone or a network hub is a part of computer network infrastructure that interconnects various pieces of network, providing a path for the exchange of information between different LANs or subnets. A backbone can tie together diverse networks, from a small location to a wide geographic area. The backbone's capacity is typically greater than that of the networks connected to it.

Our example topology has three network regions: North America, EMEA, and APAC. A network region contains a collection of network sites. Work with your network administrator to define the network regions for your enterprise.

2. Identify each network region’s associated central site. A central site contains at least one Front End Server and is the Lync Server deployment that will manage CAC for all media traffic that passes through the network region’s WAN connection.



Note:

A Multiprotocol Label Switching (MPLS) network should be represented as a network region in which each geographic location has a corresponding network site. For details, see the “Call Admission Control on an MPLS Network” topic in the Planning documentation.

In the preceding example network topology, there are three network regions, each with a Lync Server central site that manages CAC. The appropriate central site for a network region is chosen by the geographic vicinity. Because media traffic will be heaviest within network regions, the ownership by geographic vicinity makes it self-contained and will continue to be functional even if other central sites become unavailable.

In this example, a Lync Server deployment named Chicago is the central site for the North America region.

All Lync users in North America are homed on servers in the Chicago deployment. The following table shows central sites for all three network regions.

Network Regions and their Associated Central Sites

Network Region	Central Site
North America	Chicago
EMEA	London
APAC	Beijing

Note:

Depending on your Lync Server topology, the same central site can be assigned to multiple network regions.

3. For each network region, identify all of the network sites (offices or locations) whose WAN connections are not bandwidth-constrained. Because these sites are not bandwidth constrained, you do not need to apply CAC bandwidth policies to them.
   In the example shown in the following table, three network sites do not have bandwidth-constrained WAN links: New York, Chicago, and Detroit.

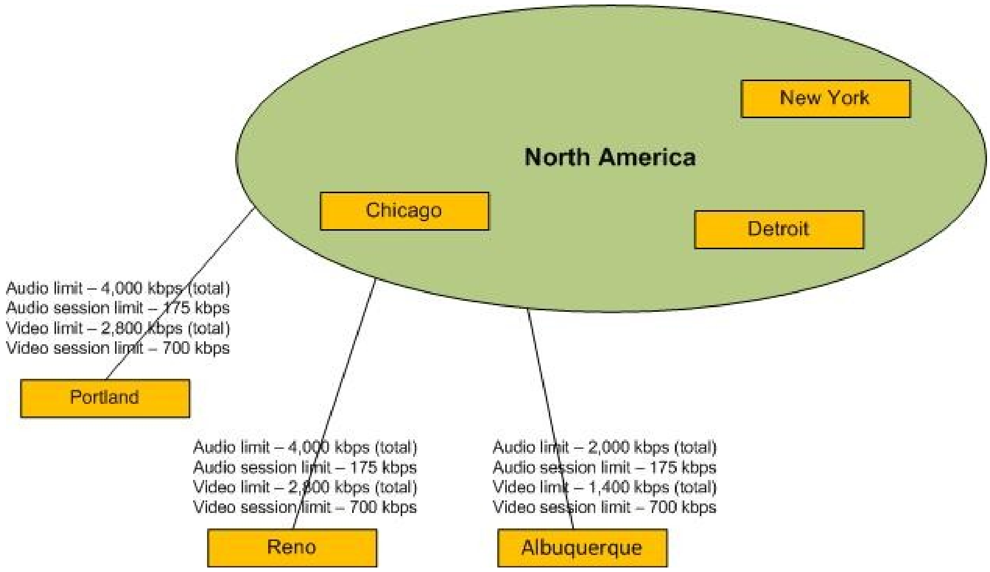
Network Sites not Constrained by WAN Bandwidth

Network Site	Network Region
New York	North America
Chicago	North America
Detroit	North America

4. For each network region, identify all of the network sites that connect to the network region through bandwidth-constrained WAN links.
   To help ensure audio and video quality, we recommend that these bandwidth-constrained network sites have their WANs monitored and CAC bandwidth policies that limit media (voice or video) traffic flow to and from the network region.
   In the example shown in the following table, there are three network sites that are constrained by WAN bandwidth: Portland, Reno and Albuquerque.

Network Sites Constrained by WAN Bandwidth

Network Site	Network Region
Albuquerque	North America
Reno	North America
Portland	North America



New York
North America
Chicago
Detroit
Audio limit – 4,000 kbps (total)
Audio session limit – 175 kbps
Video limit – 2,800 kbps (total)
Video session limit – 700 kbps
Portland
Audio limit – 4,000 kbps (total)
Audio session limit – 175 kbps
Video limit – 2,800 kbps (total)
Video session limit – 700 kbps
Reno
Audio limit – 2,000 kbps (total)
Audio session limit – 175 kbps
Video limit – 1,400 kbps (total)
Video session limit – 700 kbps
Albuquerque

5. For each bandwidth-constrained WAN link, determine the following:
   - Overall bandwidth limit that you want to set for all concurrent audio sessions. If a new audio session will cause this limit to be exceeded, Lync Server does not allow the session to start.
   - Bandwidth limit that you want to set for each individual audio session. The default CAC bandwidth limit is 175 kbps, but it can be modified by the administrator.
   - Overall bandwidth limit that you want to set for all concurrent video sessions. If a new video session will cause this limit to be exceeded, Lync Server does not allow the session to start.

- Bandwidth limit that you want to set for each individual video session. The default CAC bandwidth limit is 700 kbps, but it can be modified by the administrator.

Network Sites with WAN Bandwidth Constraint Information (Bandwidth in kbps)

Network Site	Network Region	BW Limit	Audio Limit	Audio Session Limit	Video Limit	Video Session Limit
Albuquerque	North America	5,000	2,000	175	1,400	700
Reno	North America	10,000	4,000	175	2,800	700
Portland	North America	5,000	4,000	175	2,800	700
New York	North America	(no limit)	(no limit)	(no limit)	(no limit)	(no limit)
Chicago	North America	(no limit)	(no limit)	(no limit)	(no limit)	(no limit)
Detroit	North America	(no limit)	(no limit)	(no limit)	(no limit)	(no limit)

6. For every subnet in your network, specify its associated network site.

Important:

Every subnet in your network must be associated with a network site, even if the network site is not bandwidth constrained. This is because call admission control uses subnet information to determine at which network site an endpoint is located. When the locations of both parties in the session are determined, call admission control can determine if there is sufficient bandwidth to establish a call. When a session is established over a link that has no bandwidth limits, an alert is generated.

If you deploy Audio/Video Edge Servers, the public IP addresses of each Edge Server must be associated with the network site where the Edge Server is deployed. Each public IP address of the A/V Edge Server must be added to your network configuration settings as a subnet with a subnet mask of 32. For example, if you deploy A/V Edge Servers in Chicago, then for each external IP address of those servers create a subnet with a subnet mask of 32 and associate network site Chicago with those subnets. For details about public IP addresses, see Determine External A/V Firewall and Port Requirements in the Planning documentation.

Note:

A Key Health Indicator (KHI) alert is raised, specifying a list of IP addresses that are present in your network but are either not associated with a subnet, or the subnet that includes the IP addresses is not associated with a network site. This alert will not be raised more than once within an 8 hour period. The relevant alert information and an example are as follows:

Source: CS Bandwidth Policy Service (Core)
Event number: 36034
Level: 2
Description: The subnets for the following IP Addresses: <List of IP Addresses> are either not configured or the subnets are not associated to a network site.
Cause: The subnets for the corresponding IP addresses are missing from the network configuration settings or the subnets are not associated to a network site.
Resolution: Add subnets corresponding to the preceding list of IP addresses

into the network configuration settings and associate every subnet to a network site.
For example, if the IP address list in the alert specifies 10.121.248.226 and 10.121.249.20, either these IP addresses are not associated with a subnet, or the subnet that they are associated with does not belong to a network site. If 10.121.248.0/24 and 10.121.249.0/24 are the corresponding subnets for these addresses, you can resolve this issue as follows:

- Be sure that IP address 10.121.248.226 is associated with the 10.121.248.0/24 subnet and IP address 10.121.249.20 is associated with the 10.121.249.0/24 subnet.
- Be sure that the 10.121.248.0/24 and 10.121.249.0/24 subnets are each associated with a network site.

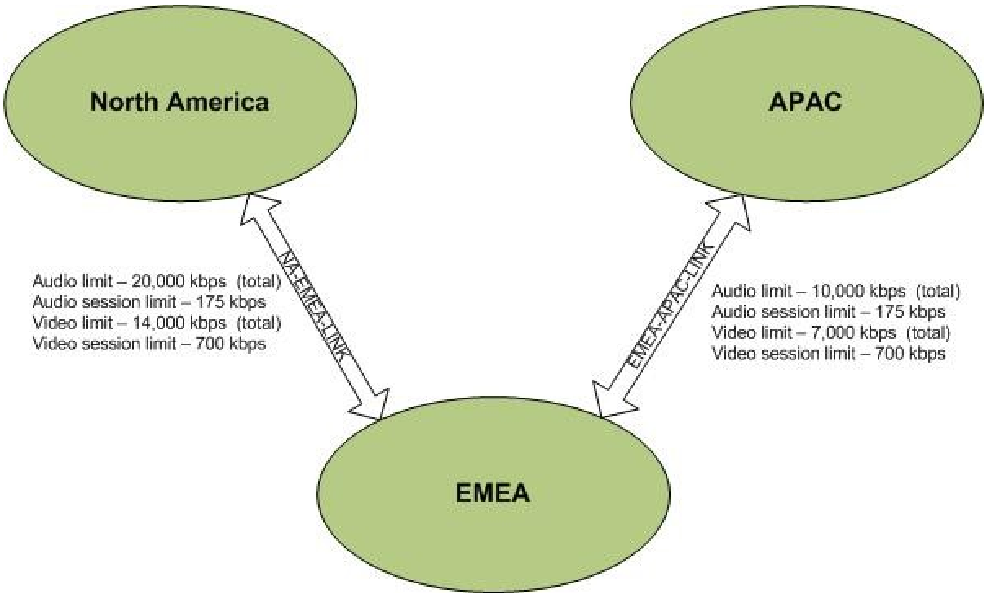
Network Sites and Associated Subnets (Bandwidth in kbps)

Network Site	Network Region	BW Limit	Audio Limit	Audio Session Limit	Video Limit	Video Session Limit	Subnets
Albuquerque	North America	5,000	2,000	175	1,400	700	172.29.79.0/23, 157.57.215.0/25, 172.29.90.0/23, 172.29.80.0/24
Reno	North America	10,000	4,000	175	2,800	700	157.57.210.0/23, 172.28.151.128/25
Portland	North America	5,000	4,000	175	2,800	700	172.29.77.0/24 10.71.108.0/24, 157.57.208.0/23
New York	North America	(no limit)	(no limit)	(no limit)	(no limit)	(no limit)	172.29.80.0/23, 157.57.216.0/25, 172.29.91.0/23, 172.29.81.0/24
Chicago	North America	(no limit)	(no limit)	(no limit)	(no limit)	(no limit)	157.57.211.0/23, 172.28.152.128/25
Detroit	North America	(no limit)	(no limit)	(no limit)	(no limit)	(no limit)	172.29.78.0/24 10.71.109.0/24, 157.57.209.0/23

1. In Lync Server call admission control, the connections between network regions are called *region links*. For each region link, determine the following,

just as you did for the network sites:

- Overall bandwidth limit that you want to set for all concurrent audio sessions. If a new audio session will cause this limit to be exceeded, Lync Server does not allow the session to start.
- Bandwidth limit that you want to set for each individual audio session. The default CAC bandwidth limit is 175 kbps, but it can be modified by the administrator.
- Overall bandwidth limit that you want to set for all concurrent video sessions. If a new video session will cause this limit to be exceeded, Lync Server does not allow the session to start.
- Bandwidth limit that you want to set for each individual video session. The default CAC bandwidth limit is 700 kbps, but it can be modified by the administrator.



North America
APAC
NA-EMEA-LINK
EMEA-APAC-LINK
Audio limit – 20,000 kbps (total)
Audio session limit – 175 kbps
Video limit – 14,000 kbps (total)
Video session limit – 700 kbps
Audio limit – 10,000 kbps (total)
Audio session limit – 175 kbps
Video limit – 7,000 kbps (total)
Video session limit – 700 kbps
EMEA

Region Link Bandwidth Information (Bandwidth in kbps)

Region Link Name	First Region	Second Region	BW Limit	Audio Limit	Audio Session Limit	Video Limit	Video Session Limit
NA-EMEA-LINK	North America	EMEA	50,000	20,000	175	14,000	700
EMEA-APAC-LINK	EMEA	APAC	25,000	10,000	175	7,000	700

2. Define a route between every pair of network regions.

Note:

Two links are required for the route between the North America and APAC regions because there is no region link that directly connects them.

Region Routes

Region Route Name	First Region	Second Region	Region Links
NA-EMEA-ROUTE	North America	EMEA	NA-EMEA-LINK
EMEA-APAC-ROUTE	EMEA	APAC	EMEA-APAC-LINK

NA-APAC-ROUTE	North America	APAC	NA-EMEA-LINK, EMEA-APAC-LINK

3. For every pair of network sites that are directly connected by a single link (called an *inter-site* link), determine the following:
   - Overall bandwidth limit that you want to set for all concurrent audio sessions. If a new audio session will cause this limit to be exceeded, Lync Server does not allow the session to start.
   - Bandwidth limit that you want to set for each individual audio session. The default CAC bandwidth limit is 175 kbps, but it can be modified by the administrator.
   - Overall bandwidth limit that you want to set for all concurrent video sessions. If a new video session will cause this limit to be exceeded, Lync Server does not allow the session to start.
   - Bandwidth limit that you want to set for each individual video session. The default CAC bandwidth limit is 700 kbps, but it can be modified by the administrator.

Bandwidth Information for an Inter-Site Link between Two Network Sites (Bandwidth in kbps)

Inter-Site Link Name	First Site	Second Site	BW Limit	Audio Limit	Audio Session Limit	Video Limit	Video Session Limit
Reno-Albu-Intersite-Link	Reno	Albuquerque	20,000	12,000	175	5,000	700

Next Steps

After you have gathered the required information, you can perform CAC deployment either by using the Lync Server Management Shell or Lync Server Control Panel.

Note:

Although you can perform most network configuration tasks by using Lync Server Control Panel, to create subnets and intersite links, you must use Lync Server Management Shell. For details, see the Lync Server Management Shell documentation for the **New-CsNetworkSubnet** cmdlet and the **New-CsNetworkIntersitePolicy** cmdlet.

1.3.10.8.4 Components and Topologies for CAC

Components and Topologies for CAC

[Planning](#) > [Planning for Enterprise Voice](#) > [Planning for Call Admission Control](#) >

Topic Last Modified: *2012-10-20*

The topics in this section provide information about special considerations for deploying call admission control (CAC) with various types of network topologies.

- [Call Admission Control on an MPLS Network](#)
- [Call Admission Control on a SIP Trunk](#)
- [Call Admission Control with a Third-Party PSTN Gateway or PBX](#)

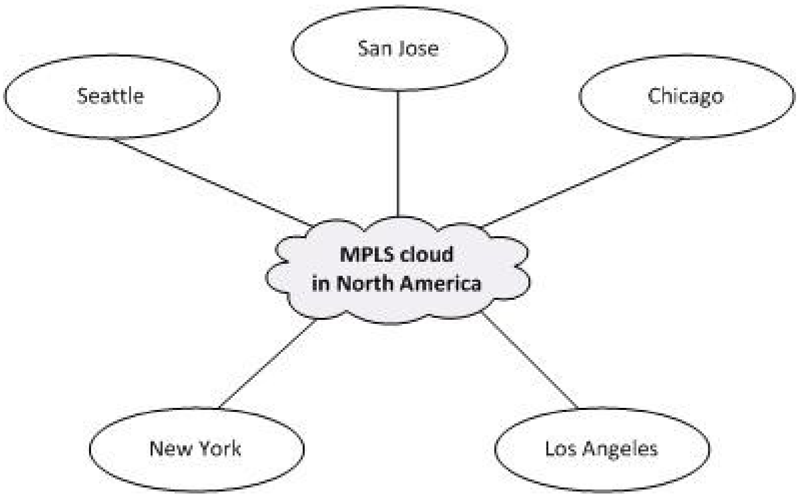
1.3.10.8.4.1 Call Admission Control on an MPLS Network

Call Admission Control on an MPLS Network

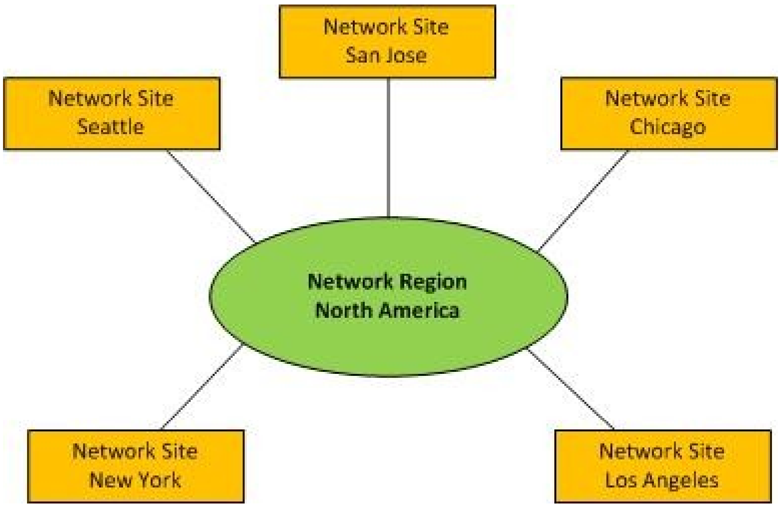
[Planning for Enterprise Voice](#) > [Planning for Call Admission Control](#) > [Components and Topologies for CAC](#) >

Topic Last Modified: *2012-09-22*

In a Multiprotocol Label Switching (MPLS) network, all sites are connected by a full-mesh. That is, all sites are connected directly to the MPLS backbone of the Internet service provider, and each site is provisioned bandwidth to be used across a WAN link to the MPLS cloud. There is no network hub or central site to control IP routing. The following figure shows a simple network based on MPLS technology.



To deploy call admission control (CAC) in an MPLS network, you create a network region to represent the MPLS cloud, and create a network site to represent each MPLS satellite site. The following figure illustrates how the network region and network sites should be configured to represent the example MPLS network in the previous figure. The overall bandwidth limits and bandwidth session limits are then based on the capacity of the WAN link from each network site to the network region that represents the MPLS cloud.



1.3.10.8.4.2 Call Admission Control on a SIP Trunk

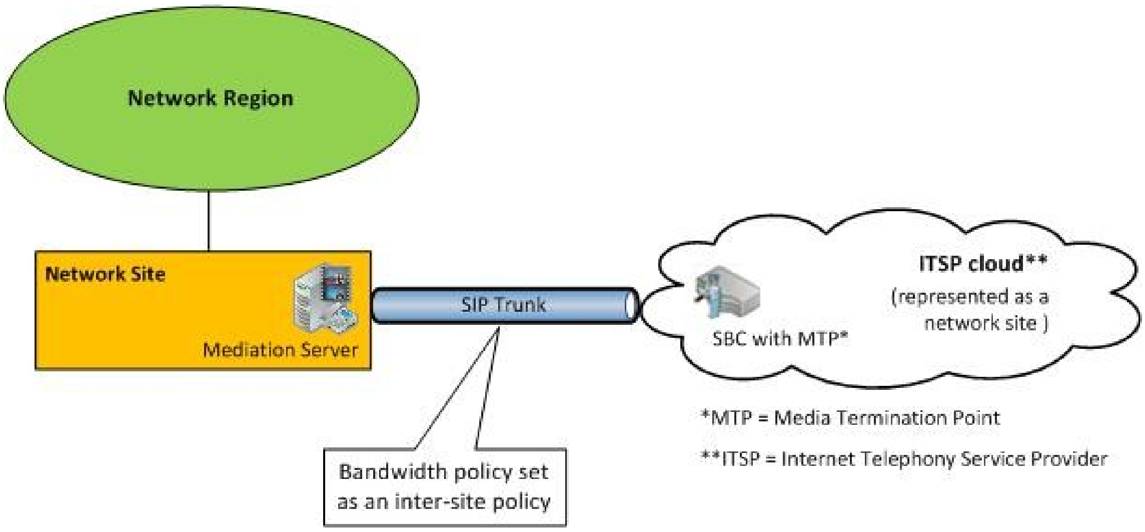
Call Admission Control on a SIP Trunk

Planning for Enterprise Voice > Planning for Call Admission Control > Components and Topologies for CAC >

Topic Last Modified: *2012-09-22*

To deploy call admission control (CAC) on a SIP trunk, you create a network site to represent the Internet telephony service provider (ITSP). To apply bandwidth policy values on the SIP trunk, you create an inter-site policy between the network site in your enterprise and the network site that you create to represent the ITSP.

The following figure shows an example CAC deployment on a SIP trunk.



Network Region
Network Site
Mediation Server
SIP Trunk
SBC with MTP*
ITSP cloud**
(represented as a network site)
*MTP = Media Termination Point
**ITSP = Internet Telephony Service Provider
Bandwidth policy set as an inter-site policy

To configure CAC on a SIP trunk, you will have to perform the following tasks during CAC deployment:

1. Create a network site to represent the ITSP. Associate the network site to an appropriate network region, and allocate bandwidth of zero for audio and video for this network site. For details, see Configure Network Sites for CAC

in the Deployment documentation.

Note:
For the ITSP, this network site configuration is not functional. Bandwidth policy values are actually applied in step 2.

2. Create an inter-site link for the SIP trunk using the relevant parameter values for the site you created in step 1. For example, use the name of the network site in your enterprise as the value of the NetworkSiteID1 parameter, and the ITSP network site as the value of the NetworkSiteID2 parameter. For details, see Create Network Intersite Policies in the Deployment documentation. Also see the Lync Server Management Shell documentation for the New-CsNetworkInterSitePolicy cmdlet.
3. Get the IP address of the Session Border Controller's (SCB) Media Termination Point from your ITSP. Add that IP address with a subnet mask of 32 to the network site that represents the ITSP. For details, see Associate a Subnet with a Network Site.

1.3.10.8.4.3 Call Admission Control w ith a Third-Party PSTN Gatew ay or PBX

Call Admission Control with a Third-Party PSTN Gateway or PBX

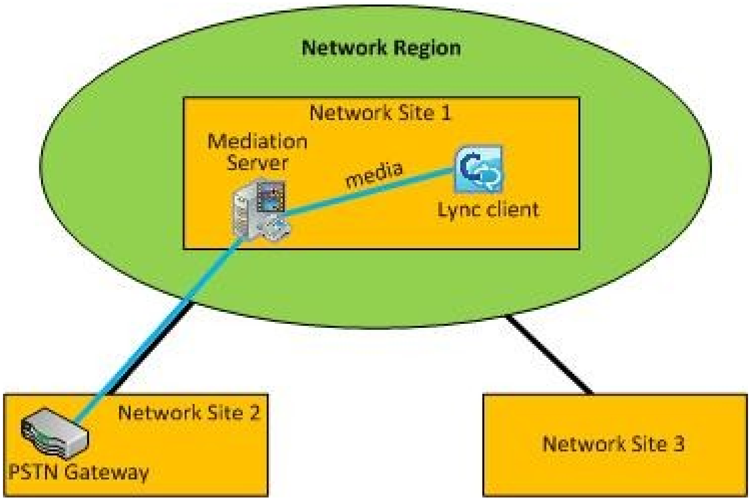
Planning for Enterprise Voice > Planning for Call Admission Control > Components and Topologies for CAC >

Topic Last Modified: *2012-10-20*

This topic describes examples of how call admission control (CAC) can be deployed on the link between the Mediation Server's gateway interface and a third-party public switched telephone network (PSTN) gateway or private branch exchange (PBX).

Case 1: CAC between the Mediation Server and a PSTN gateway

CAC can be deployed on the WAN link from the Mediation Server's gateway interface to a third-party PBX or PSTN gateway.



In this example, CAC is applied between the Mediation Server and a PSTN gateway. If a Lync client user at Network Site 1 places a PSTN call through the PSTN gateway in

Network Site 2, the media flows through the WAN link. Therefore, two CAC checks are performed for each PSTN session:

- Between the Lync client application and the Mediation Server
- Between the Mediation Server and the PSTN gateway

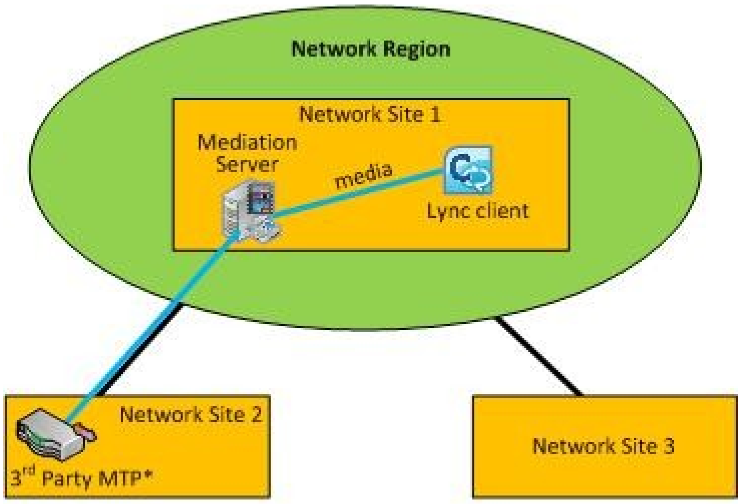
This works for both incoming PSTN calls to a client in Network Site 1, and for outgoing PSTN calls originating from a client application in Network Site 1.

Note:

Make sure that the IP subnet that the PSTN gateway belongs to is configured and associated with Network Site 2.
Make sure that the IP subnet that both interfaces of the Mediation Server belong to is configured and associated with Network Site 1.
For details, see Associate a Subnet with a Network Site.

Case 2: CAC between the Mediation Server and a third-party PBX with Media Termination Point

This configuration is similar to Case 1. In both the cases, the Mediation Server knows what device terminates media at the opposite end of the WAN link, and the IP address of the PSTN gateway or PBX with Media Termination Point (MTP) is configured on the Mediation Server as the next hop.



*MTP = Media Termination Point

In this example, CAC is applied between the Mediation Server and the PBX/MTP. If a Lync client user at the Network Site 1 places a PSTN call through the PBX/MTP located in Network Site 2, the media flows through the WAN link. Therefore, for each PSTN session two CAC checks are performed:

- Between the Lync client application and the Mediation Server
- Between the Mediation Server and the PBX/MTP

This works for both incoming PSTN calls to a client in Network Site 1, and outgoing PSTN calls originating from a client in Network Site 1.

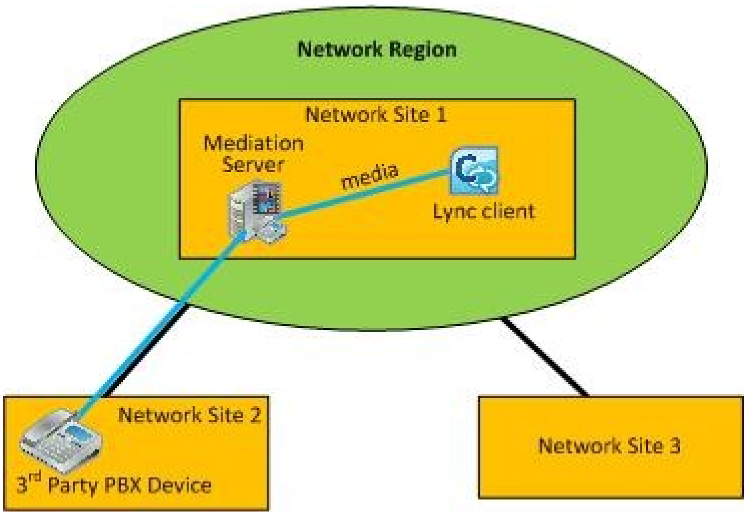
Note:

Make sure that the IP subnet that the MTP belongs to is configured and associated with Network Site 2.

Make sure that the IP subnet that both interfaces of the Mediation Server belong to is configured and associated with Network Site 1.
For details, see Associate a Subnet with a Network Site.

Case 3: CAC between the Mediation Server and a third-party PBX without a Media Termination Point

Case 3 is slightly different from the first two cases. If there is no MTP on the third-party PBX, for an outgoing session request to the third-party PBX the Mediation Server does not know where media will terminate in the PBX boundary. In this case, the media flows directly between the Mediation Server and the third-party endpoint device.



In this example, if a Lync client user at Network Site 1 places a call to a user through the PBX, the Mediation Server is able to perform CAC checks only on the proxy leg (between the Lync client application and Mediation Server). Because the Mediation Server does not have information about the endpoint device while the session is being requested, CAC checks cannot be performed on the WAN link (between the Mediation Server and the third-party endpoint) prior to call establishment. After the session is established, however, the Mediation Server facilitates in accounting for the bandwidth used on the trunk.

For calls that originate from the third-party endpoint, the information about that endpoint device is available at the time of session request and CAC check can be performed on both the sides of the Mediation Server.

Note:

Make sure that the IP subnet that the endpoint devices belong to is configured and associated with Network Site 2.
Make sure that the IP subnet that both interfaces of the Mediation Server belong to is configured and associated with Network Site 1.
For details, see Associate a Subnet with a Network Site.

1.3.10.8.5 Best Practices for Call Admission Control

Best Practices for Call Admission Control

Planning > Planning for Enterprise Voice > Planning for Call Admission Control >

Topic Last Modified: *2012-09-22*

To enhance performance and facilitate deployment, apply the following best practices when you deploy call admission control:

- Ensure that WANs are adequately provisioned for current and anticipated media traffic.

> **Note:**
> We recommend that you factor in a buffer to your bandwidth limits. There are scenarios such as race conditions that affect the total bandwidth used and can result in situations where the bandwidth limit is exceeded. For example, if two calls try to start while media traffic is approaching a bandwidth limit, one of them may be denied because the other managed to start first.

- Monitor network usage and call detail records so that you can choose optimal CAC settings and update CAC settings as network usage changes.
- Use CAC bandwidth policies to complement QoS settings.
- If you want to re-route blocked calls onto the PSTN, verify PSTN functionality and capacity. For details, see Planning Outbound Voice Routing.

> **Note:**
> Capacity refers to the number of ports you need to open to support potential PSTN re-routing.

1.3.10.8.6 Deployment Checklist for Call Admission Control

Deployment Checklist for Call Admission Control

Planning > Planning for Enterprise Voice > Planning for Call Admission Control >

Topic Last Modified: *2012-10-08*

To plan effectively for call admission control (CAC), you need to consider the following:

- Prerequisites for deploying CAC.
- Information required for CAC and configuration decisions that you must make in advance of deployment.

Deployment Prerequisites for Call Admission Control

Before you deploy call admission control, you must already have deployed your Lync Server 2013 internal servers, including either a Front End pool or a Standard Edition server.

Information Requirements for Call Admission Control

The following table summarizes the required information for deploying call admission control.

Information Requirements for Call Admission Control Deployment

Information	Summary of Information Required	Documentation
Lync Server capabilities required by your organization	• Capabilities to be supported by your organization • Capabilities to be enabled for individual users	Defining Your Organization's Requirements for Call Admission Control
Topologies and components to be deployed	• CAC related components are automatically installed as part of Lync Server 2013	Defining Your Organization's Requirements for Call Admission Control
System requirements	• Hardware requirements • Software requirements • Collocation requirements	Determining Your System Requirements
Infrastructure requirements	• No specific infrastructure requirements are necessary for CAC	Infrastructure Requirements for Call Admission Control
Network interface requirements	• Internal and external interface information • Routing information (including information on the NextHop blog at http://go.microsoft.com/fwlink/p/?LinkId=203149, Microsoft Lync Server team's customer response channel)	Deploying External User Access
Deployment strategy	• Deployment sequence • Workgroup or domain • Security • Monitoring and auditing • Hardware considerations	Best Practices for Call Admission Control
Deployment process	• Prerequisites • Information requirements • Process and procedures	Configure Call Admission Control

1.3.10.9 Planning for Emergency Services (E9-1-1)

Planning for Emergency Services (E9-1-1)

Microsoft Lync Server 2013 > Planning > Planning for Enterprise Voice >

Topic Last Modified: *2012-10-17*

Lync Server 2013 supports Enhanced 9-1-1 (E9-1-1) services within the United States as part of an Enterprise Voice deployment. E9-1-1 is an emergency dispatch feature that associates a 9-1-1 call with an Emergency Response Location (ERL) that consists of civic (that is, street) addresses and other more specific location information, such as floor numbers, for calls from office buildings and other multitenant facilities. By using the provided ERL, a Public Safety Answering Point (PSAP) can immediately dispatch first responders to the caller in distress with reduced risk of inadvertently directing the responder to an incorrect or ambiguous location.

Note:
Lync Server has three advanced Enterprise Voice features: call admission control, emergency services (E9-1-1), and media bypass. For an overview of planning information that is common to all three of these features, see Network Settings for the Advanced Enterprise Voice Features.

- Overview of E9-1-1
- Defining Your Requirements for Emergency Calls
- Deployment Checklist for E9-1-1

1.3.10.9.1 Overview of E9-1-1

Overview of E9-1-1

Planning > Planning for Enterprise Voice > Planning for Emergency Services (E9-1-1) >

Topic Last Modified: *2012-10-29*

Microsoft Lync Server 2013 supports Enhanced 9-1-1 (E9-1-1) calling from Lync clients and Lync Phone Edition devices. When you configure Lync Server for E9-1-1, emergency calls placed from Lync 2013 or Lync Phone Edition include Emergency Response Location (ERL) information from the Location Information service database. ERLs consist of civic (that is, street) addresses and other information that helps to identify a more precise location in office buildings and other multitenant facilities. When a user makes an emergency call, Lync Server routes the call audio, along with the location and callback information, through a Mediation Server to an E9-1-1 service provider. The E9-1-1 service provider uses the civic address of the caller to route the call to the Public Safety Answering Point (PSAP) that serves the caller's location, and sends along an Emergency Service Query Key (ESQK) that the PSAP uses to look up the caller's ERL.

Lync Server supports two methods for routing emergency calls to an E9-1-1 service provider:

- A Session Initiation Protocol (SIP) trunk connection to a qualified E9-1-1 service provider
- An Emergency Location Identification Number (ELIN) gateway to a public switched telephone (PSTN)-based E9-1-1 service provider

When you use a SIP trunk E9-1-1 service provider, you add ERLs to the Location Information service database, and then validate the locations against a Master Street Address Guide (MSAG) that is maintained by the E9-1-1 service provider. If an E9-1-1 service provider receives a call that doesn't have location information or has a location that has not been validated against the MSAG, the E9-1-1 service provider routes the call to a national/regional Emergency Call Response Center (ECRC), which is staffed with specially trained personnel who verbally obtain the caller's location, if possible, and manually route the call to the appropriate PSAP. (Some SIP trunk E9-1-1 service providers also provide customers with a PSTN direct inward dialing (DID) number to the ECRC, which provides an alternate means of routing 9-1-1 calls, if the SIP trunk fails for any reason.)

Unlike time division multiplexing (TDM) and IP-based private branch exchange (PBX) phones, which have fixed locations, a Lync endpoint can be very mobile. When you deploy the E9-1-1 feature, Lync Server helps to ensure that no matter where a caller is located, the emergency call can be routed to the PSAP that serves the caller's location. For example, if a user's main office is located in Redmond, Washington, but the user places an emergency call from a computer in a branch office in Wichita, Kansas, the SIP trunk or PSTN-based E9-1-1 service provider will route the call to the PSAP in Wichita, not to the PSAP in Redmond.

When you use an ELIN gateway, you also add ERLs to the Location Information service database, but you include also an ELIN number for each location. The ELIN number becomes the emergency calling number during the emergency call. You must then make sure that your PSTN carrier uploads the ELINs to the Automatic Location Identification (ALI) database.

Note:

Lync-connected analog devices cannot receive location information from the Location Information service or transmit location to the E9-1-1 service provider. If you use the SIP trunk E9-1-1 service provider option and need to support E9-1-1 from analog phones, you have two options:

- **Traditional PS-ALI option** If you have local PSTN gateways at each site where analog phones are deployed and each analog phone has a DID, you can provision the analog device’s location directly with a Private Switch/ Automatic Location Identification (PS-ALI) service provider. In this case, you configure specially-crafted Lync voice policies and assign them to the analog device contact objects so that E9-1-1 calls from those phones route directly through the local gateway to the PSTN provider that services the site (instead of routing the call to an E9-1-1 service provider SIP trunk). When an emergency call is placed, a database at a PS-ALI provider that is associated with the PSTN trunk maps the DID of each analog phone to a physical location and provides this location to the PSAP. These records must be updated with the PS-ALI service provider every time phones are moved to different ERLs.
- **E9-1-1 service provider option** You can register the analog phone DIDs and their corresponding ERLs with the E9-1-1 service provider, if this is supported by the E9-1-1 service provider. If the provider receives a call from Lync Server that doesn’t include PIDF-LO data, the provider can see if there is a database match on the calling party’s DID number. By using the ERL retrieved from its database, the provider can automatically route the emergency call to the correct PSAP, and the PSAP will receive the DID of the analog device and an ESQK record that allows the dispatcher to lookup the caller’s location.

If you use the ELIN gateway option and need to support E9-1-1 from analog phones, you can provision the analog device's location directly with the PS-ALI service provider, as described in the first option above.

From a Lync Server perspective, the E9-1-1 process can be separated into two stages:

- Stage 1: Acquiring a location
- Stage 2: Routing the emergency call to an E9-1-1 service provider

This section describes how these stages work.

If you plan to configure your infrastructure to automatically detect client location, first you need to decide which network elements you will use to map callers to locations. For details about the possible options, see Defining the Network Elements Used to Determine Location.

In This Section

- Acquiring a Location
- Routing E9-1-1 Calls by Using a SIP Trunk
- Routing E9-1-1 Calls by Using an ELIN Gateway

1.3.10.9.1.1 Acquiring a Location

Acquiring a Location

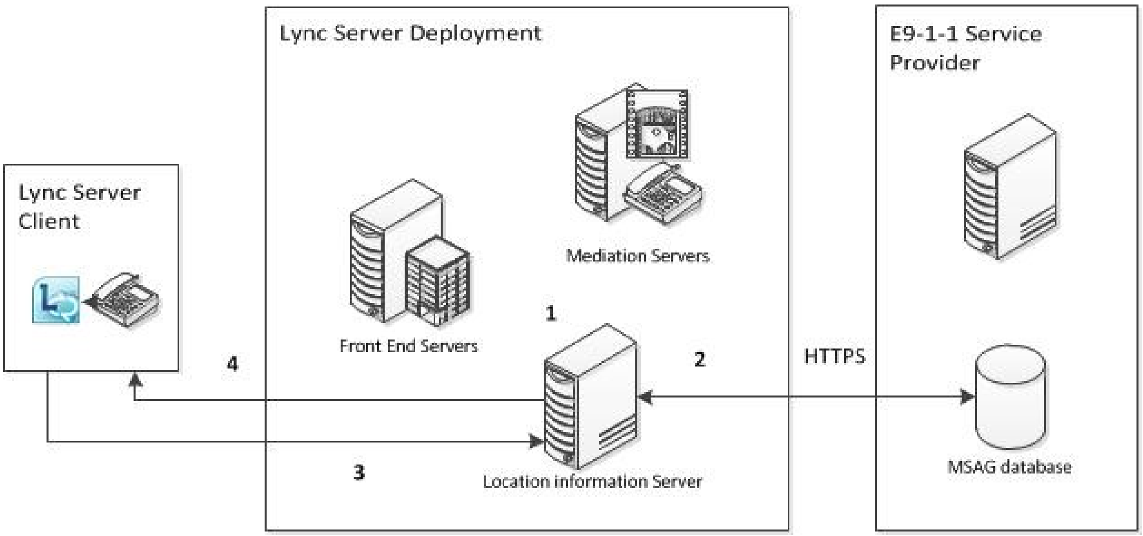
Planning for Enterprise Voice > Planning for Emergency Services (E9-1-1) > Overview of E9-1-1 >

Topic Last Modified: *2012-06-06*

In a Lync Server 2013 E9-1-1 deployment, each internally-connected Lync or Lync Phone Edition client actively acquires its own location. After SIP registration, the client furnishes all the network connectivity information that it knows about itself it in a location request to the Location Information service, which is a web service backed by a replicated SQL Server database. Each central site pool has a Location Information service, which uses the network information to query its records for a matching location. If there is a match, the Location Information service returns a location to the client. If there is not a match, the user may be prompted to enter a location manually (depending on location policy settings). The location data are transmitted back to the client in an Internet Engineering Task Force (IETF) standardized XML format called Presence Information Data Format Location Object (PIDF-LO).

The Lync Server client includes the PIDF-LO data as part of an emergency call, and this data is used by the E9-1-1 service provider to determine the appropriate PSAP and route the call to that PSAP along with the correct ESQK, which allows the PSAP dispatcher to obtain the caller’s location.

The following diagram shows how a Lync Server client acquires a location (except for the third-party client MAC address–based location method):



For a client to acquire a location, the following steps must take place:

1. The administrator populates the Location Information service database with the network wiremap (tables that map various types of network addresses to corresponding Emergency Response Locations (ERLs)).
2. If you use a SIP trunk E9-1-1 service provider, the administrator validates the civic address portions of the ERLs against a Master Street Address Guide (MSAG) database maintained by the E9-1-1 service provider. If you use an ELIN gateway, the administrator ensures that the PSTN carrier uploads the ELINs to the Automatic Location Identification (ALI) database.
3. During registration or whenever a network change occurs, an internally-connected client sends a location request that contains the client's discovered network addresses to the Location Information service.
4. The Location Information service queries its published records for a location, and, if a match is found, returns the ERL to the client in PIDF-LO format.

1.3.10.9.1.2 Routing E9-1-1 Calls by Using a SIP Trunk

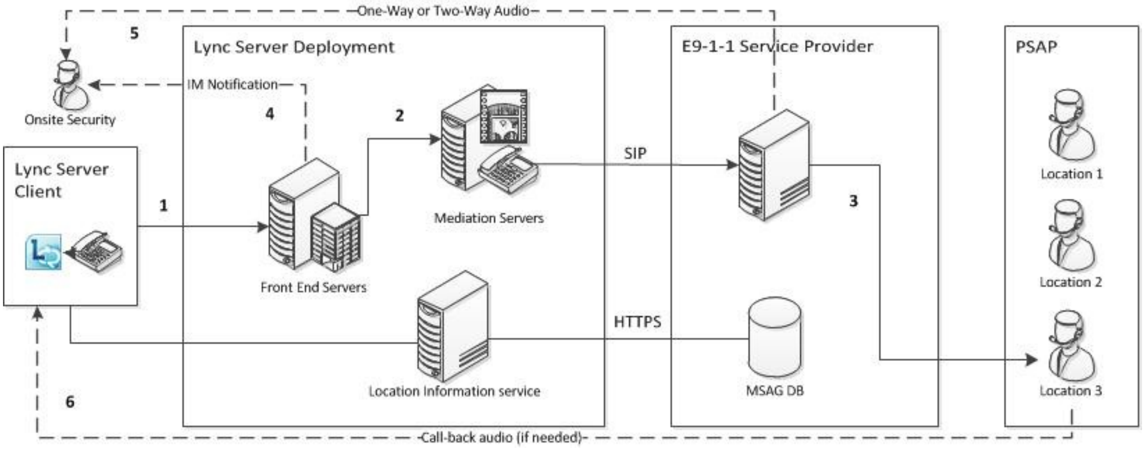
Routing E9-1-1 Calls by Using a SIP Trunk

Planning for Enterprise Voice > Planning for Emergency Services (E9-1-1) > Overview of E9-1-1 >

Topic Last Modified: *2012-09-29*

Using a SIP trunk to connect to a qualified E9-1-1 service provider is one way that you can deploy E9-1-1. For details about using an ELIN gateway to connect to a public switched telephone network (PSTN)-based E9-1-1 service provider, see Routing E9-1-1 Calls by Using an ELIN Gateway.

The following diagram shows how an emergency call is routed from Lync Server to the Public Safety Answering Point (PSAP) when you use a SIP trunk and qualified E9-1-1 service provider.



When an emergency call is placed from a compatible Lync Server client:

1. A SIP INVITE that contains the location, the caller's callback number, and the (optional) Notification URL and conference callback number is routed to Lync Server.
2. Lync Server matches the emergency number and routes the call (based on the **PSTN Usage** value that is defined in the applicable location policy) to a Mediation Server, and from there, over a SIP trunk to the E9-1-1 service provider.
3. The E9-1-1 service provider routes the emergency call to the correct PSAP based on the location that is provided with the call. When the client includes a validated Emergency Response Location (ERL) with the emergency call, the provider automatically routes the call to the appropriate PSAP. If the location was manually entered by the user, the Emergency Call Response Center (ECRC) first verbally verifies the accuracy of the location with the caller before routing the emergency call to the PSAP.
4. If you configured the location policy for notifications, one or more of your organization’s security officers are sent a special Lync emergency notification instant message. This message always pops up on the security officers’ screen(s) and contains the caller’s name, phone number, time, and location, enabling security personnel to quickly respond to the emergency caller by using an instant message or voice.
5. If you configured the location policy for conferencing and it is supported by the E9-1-1 service provider, an internal Security Desk is conferenced into the call with either one-way audio or two-way audio.
6. If the call is broken prematurely, the PSAP uses the callback number to contact the caller directly.

Routing E9-1-1 Calls by Using an ELIN Gateway

Planning for Enterprise Voice > Planning for Emergency Services (E9-1-1) > Overview of E9-1-1 >

Topic Last Modified: *2013-02-05*

Some partners in the Unified Communications Open Interoperability Program provide qualified Emergency Location Identification Number (ELIN)-capable gateways, which can serve as an alternative to a SIP trunk connection to a qualified E9-1-1 service provider. ELIN gateways support ISDN or Centralized Automatic Message Accounting (CAMA) connectivity to public switched telephone network (PSTN)-based E9-1-1 services. For details about partners who provide ELIN gateways and links to their documentation, see http://go.microsoft.com/fwlink/p/?LinkId=248425.

Like SIP trunk connections to E9-1-1 service providers, ELIN gateways also provide the means of routing an emergency call to the caller's most appropriate Public Safety Answering Point (PSAP), but these gateways use an ELIN as the location identifier. You define ELINs for each Emergency Response Location (ERL) in your organization (for details, see Managing Locations for ELIN Gateways).

When you use an ELIN gateway for emergency calls, you use the same Lync Server E9-1-1 infrastructure that you would use for a SIP trunk connection. That is, the Location Information service database provides the location to the Lync Server client, and the location policy enables the feature and defines the routing. With an ELIN gateway, however, you need to add the ELINs to the Location Information service database and have your PSTN carrier upload them to the Automatic Location Identification (ALI) database.

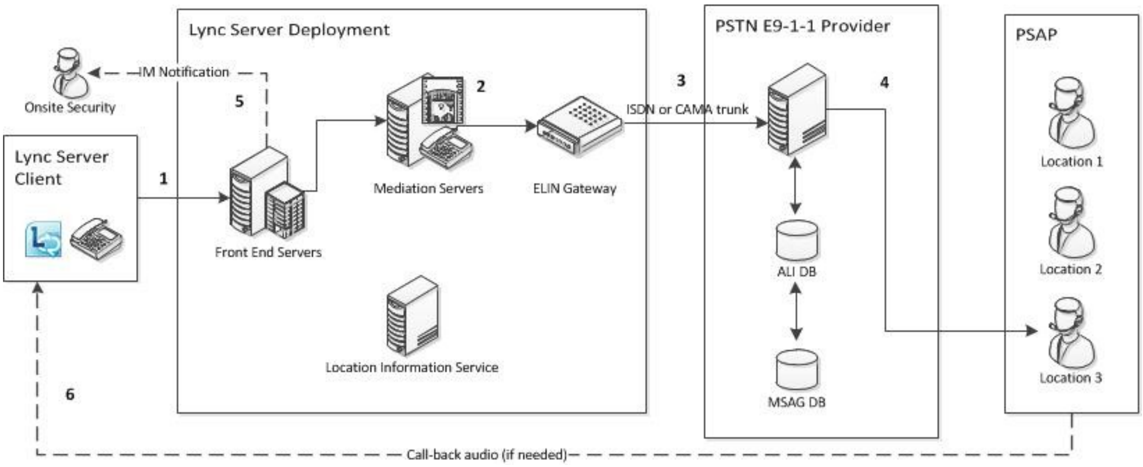
When a Lync client obtains its location from the Location Information service, the location includes the ELIN. During an emergency call, the ELIN is included with the location sent to the ELIN gateway. The ELIN gateway identifies the call as an emergency call and swaps the calling party's number with the ELIN. The ELIN gateway then routes the call to the PSTN with the ELIN as the calling number. The PSTN E9-1-1 provider looks up the ELIN in the ALI database, which is a companion database to the Master Street Address Guide (MSAG) database. The PSTN then sends the call to the most appropriate PSAP based on the ALI lookup, and the PSAP sends first responders to the caller's location based on the ALI lookup. The calling number is cached on the ELIN gateway for a predefined amount of time for callbacks. During a callback, the PSAP reaches the ELIN gateway, which swaps the ELIN for the caller's direct inward dialing (DID) number.

ELIN gateways support emergency calls only from within your organization's network. They do not support emergency calls made from outside your network.

Note:

For details about using a SIP trunk connection for emergency calls, see Routing E9-1-1 Calls by Using a SIP Trunk.

The following diagram shows how an emergency call is routed from Lync Server to the PSAP when you use an ELIN gateway.



1. A SIP INVITE containing the location, the caller's callback number, and the (optional) Notification URL and conference callback number is routed to Lync Server.
2. Lync Server matches the emergency number and then routes the call (based on the **PSTN Usage** value defined in the applicable location policy) to a Mediation Server, and from there to an ELIN gateway.
3. The ELIN gateway routes the call over an ISDN or CAMA trunk to the PSTN.
4. The PSTN identifies the call as an emergency call and routes it to an E9-1-1 selective router in the network. The E9-1-1 selective router looks up the caller's number in the ALI database to obtain the geographical location. The E9-1-1 selective router sends the call to the most appropriate PSAP based on the location information that was retrieved from the ALI database.
5. If you configured the location policy for notifications, one or more of your organization's security officers are sent a special Lync emergency notification instant message. This message always pops up on the security officers' screen(s) and contains the caller's name, phone number, time, and location, enabling security personnel to quickly respond to the emergency caller by using an instant message or voice.
6. If the call is broken prematurely, the PSAP uses the ELIN to contact the caller directly. The ELIN gateway swaps the ELIN for the caller's DID.

Before you begin a Microsoft Lync Server 2013 E9-1-1 deployment, you should first be able to answer the questions detailed in the following sections. The planning you need to do depends on the type of E9-1-1 solution that you choose to deploy—a SIP trunk E9-1-1 service provider or an Emergency Location Identification Number (ELIN) gateway. The following table identifies the sections in this planning workbook that you'll need to review for each of those solutions.

Planning Steps by Type of E9-1-1 Solution

Defining the Scope of the E9-1-1 Deployment

Planning for Enterprise Voice > Planning for Emergency Services (E9-1-1) > Defining Your Requirements for Emergency Calls >

Topic Last Modified: *2012-06-06*

Before you configure Microsoft Lync Server 2013 for E9-1-1, you need to plan your E9-1-1 deployment. Some of the questions to consider include:

What are your organization’s policy and legal obligations with regard to E9-1-1?

E9-1-1 legal requirements for PBXs (called Multi-line Telephone Systems, or MLTS, in E9-1-1 parlance) differ from state to state. You should consult with your legal team to understand the obligations that may apply to your deployment of Lync Server in your relevant geographies.

What areas within your enterprise need to be enabled for E9-1-1?

You can enable E9-1-1 for the entire enterprise or for selected locations. For example, you may have varying E9-1-1 requirements for offices in different states, or you may want to exclude sites outside the U.S.

How will you deploy E9-1-1 to branch sites?

Voice resiliency is an important concept to understand when deploying E9-1-1 at a branch site. If you have centralized E-9-1-1 SIP trunks and a WAN outage occurs, clients signing in may not be able to obtain a location from Location Information service or to connect to the emergency services service provider. Lync Server provides several strategies for handling voice resiliency in branch offices, including: having resilient data networks, deploying a SIP trunk at each branch, or pushing emergency calls out to the local gateway during outages. For details, see Planning for Branch-Site Voice Resiliency.

Will you enable E9-1-1 for users working outside the network?

Automatic location acquisition is available only for clients located inside the organization’s network, so your organization needs to decide whether it will support E9-1-1 calls made from Lync clients while off-premises. For example, will you enable users to place emergency calls if they are working from home or from a customer site? If a client is located outside the enterprise network, the client can be configured to prompt the user for a location. However, because these user-provided locations cannot be prevalidated against the Master Street Address Guide (MSAG), the emergency services service provider dispatcher will need to confirm the validity of the location verbally with the caller before routing the call to the Public Safety Answering Point (PSAP).

Note:

Lync clients of users who connect to your organization’s network by using VPN can pick up internal IP address information, but because these addresses cannot be used to identify the user’s actual location, it is essential that VPN subnets are excluded from the Location Information service.

Do you want to provide emergency call routing to sites outside the U.S.?

You may want to provide emergency routing to areas of your company not served by an emergency services service provider (for example, international locations). To do this, create a new site, and then assign voice policies to the sites that refer to a PSTN usage that routes the call through the local PSTN gateway.

1.3.10.9.2.2 Defining the Network Elements Used to Determine Location

Defining the Network Elements Used to Determine Location

Planning for Enterprise Voice > Planning for Emergency Services (E9-1-1) > Defining Your Requirements for Emergency Calls >

Topic Last Modified: *2012-10-29*

If you are setting up your Lync Server infrastructure to support automatic client location detection, you first need to decide which network elements you are going to use to map callers to locations. In Lync Server 2013, you can associate the following Layer 2 and Layer 3 network elements with locations:

- Wireless access point (WAP) Basic Service Set Identification (BSSID) addresses (Layer 2)
- LLDP switch port (Layer 2)
- LLDP switch chassis IDs (Layer 2)
- IP subnets (Layer 3)
- Client MAC addresses (Layer 2)

The network elements are listed in order of precedence. If a client can be located by using more than one network element, Lync Server uses the order of precedence to determine which mechanism to use.

The following sections provide more details for using each network element.

Important:

When you use network elements to map callers to locations, it is of utmost importance that you keep the Location Information service database up-to-date. For example, if you add or change a network element, such as adding a WAP, you must delete the old entry and add the new entry in the location database.

Wireless Access Point

When a client connects to the network wirelessly, the location request uses the BSSID address of the WAP to determine its location. If the client is roaming, the WAP indicated may not be the closest one, and it’s even possible to pick up a WAP that is on a different floor of the building. To indicate that the location is approximate, you can prepend the location value with a **Near** or **Close to** descriptor.

This location method assumes that the BSSID of each WAP is static. However, if your WAP vendor uses dynamically-assigned BSSIDs, the BSSID that is obtained from a WAP could change (this can happen following a WAP configuration change), and wireless clients could be left in a situation where they don’t receive a location. To prevent this possibility, you need to populate the Location Information service database with ERLs for all possible BSSID addresses used by each WAP.

LLDP Ports and Switches

Managed Ethernet switches that support Link Layer Discovery Protocol-Media Endpoint Discover (LLDP-MED) can advertise their identity and port information to LLDP-MED compatible clients, which then can be queried against the location database to provide the location of the device. You can associate ERLs solely on the switch chassis ID, or you can map them down to the port level.

Note:

Lync Server 2013 supports using LLDP-MED for determining locations only of Lync Phone Edition devices and Lync 2013 running on Windows 8. If you need to use switch-level Layer 2 data to determine the location of other wired PC-based Lync clients, you need to use the client MAC address method.

Subnet

Layer 3 IP subnets provide a mechanism supported by all Lync Server clients that can be used to automatically detect client location. Using IP subnets is the easiest location method to configure and manage wired clients. Before you decide to use subnets, however, use the following questions to help determine if the location specificity of the subnet is sufficiently fine to accurately locate a client:

- Do one or more client subnets cover multiple floors?
- Do one or more subnets cover more than one building?
- How much floor space is covered by each client subnet?

If the subnet covers too broad an area, you may need to use another mechanism to locate clients. However, if at all practical, we recommend that customers reorganize their IP subnetting to meet the ERL location specificity requirements rather than incurring the cost and complexity of third-party SNMP-based solutions.

Client MAC Address

To use a client computer's MAC address to locate a caller, you need managed Ethernet switches, and you must deploy a third-party SNMP solution that can discover the MAC addresses of Lync clients connected to (or through) those switches. The SNMP solution continually polls the managed switches to get the current mappings of the endpoint MAC addresses connected to each port and obtains the corresponding port IDs. During a Lync client's request to the Location Information service, the Location Information service queries the third-party application by using the client's MAC address, and then returns any matching switch IP addresses and port IDs. The Location Information service uses this information to query its published Layer 2 wiremap for a matching record and returns the location to the client. If you use this option, make sure that the switch port identifiers are consistent between the SNMP application and the published location database records.

Note:

Some third-party SNMP solutions can support unmanaged access switches; if the switch that services the Lync client is unmanaged but has an uplink to a managed distribution switch, the managed switch can report back to the SNMP application the MAC addresses of the clients connected to the access switch. This information enables the Location Information service to identify the location of the user. However, it is possible to assign only a single ERL to all ports on the unmanaged switch, so the location specificity is available only at the chassis level of the access switch, not the port level.

1.3.10.9.2.3 Enabling Users for E9-1-1

Enabling Users for E9-1-1

Planning for Enterprise Voice > Planning for Emergency Services (E9-1-1) > Defining Your Requirements for Emergency Calls >

Topic Last Modified: *2012-06-06*

During client registration, Lync Server uses a location policy to configure the E9-1-1 properties for Enterprise Voice-enabled users. This policy contains the settings that define how E9-1-1 is implemented. For example, the location policy contains information such as the emergency dial string, and whether or not a user is required to manually enter a location if the Location Information service does not automatically provide one. For a complete definition of a location policy, see Defining the Location Policy.

Lync Server can assign a location policy to clients based on subnet, or to users based on a global, per-site, or per-user policy. To help decide how you will enable users, you should first answer the following questions.

Do you plan to enable all users, or limit support to specific geographic areas of the enterprise?

You can assign a location to all users in your enterprise by using a global location policy. However, by assigning a location policy to a Lync Server network site and then adding subnets to the site, you can limit E9-1-1 support to selected locations within the enterprise and specify E9-1-1 routing behavior on a per-site basis.

Do you plan to enable individual users through a user policy?

You can assign location policies directly to specific users or common area phone contact objects if you want to customize their E9-1-1 support.

When clients roam outside the network or connect from an undefined subnet, should the clients still be enabled for E9-1-1?

If users are assigned a global, site, or per-user location policy, they can be required to manually enter a location into the client if the client is not located within a defined subnet or no location has been found by the Location Information service. For details, see Defining the User Experience for Manually Acquiring a Location.

Managing Locations for SIP Trunk Service Providers

Planning for Enterprise Voice > Planning for Emergency Services (E9-1-1) > Defining Your Requirements for Emergency Calls >

Topic Last Modified: *2012-10-02*

To configure Lync Server to automatically locate clients within a network, you need to either populate the Location Information service database with a network wiremap and publish the locations, or link to an external database that already contains the correct mappings. As part of this process, you need to validate the civic addresses of the locations with your E9-1-1 service provider. For details, see Configure the Location Database in the Deployment documentation.

You populate the Location Information service database with an Emergency Response Location (ERL), which consists of a civic address and the specific address within a building. The Location Information service **Location** field, which is the specific location within a building, has a maximum length of 20 characters (including spaces). Within that limited length, try to include the following:

- An easy-to-understand name that identifies the location of the 911 caller to help ensure that emergency responders find the specific location promptly when they arrive at the civic address. This location name may include a building number, floor number, wing designator, room number, and so on. Avoid nicknames known only to employees, which might cause emergency responders to go to the wrong location.
- A location identifier that helps users to easily see that their Lync client picked up the correct location. The Lync client automatically concatenates and displays the discovered **Location** and **City** fields in its header. A good practice is to add the street address of the building to each location identifier (for example, "1st Floor <street number>"). Without the street address, a generic location identifier such as "1st Floor" could apply to any building in the city.
- If the location is approximate because it’s determined by a wireless access point, you can add the word **Near** (for example, "Near 1st Floor 1234").

Note:

Locations added to the central location database are not available to the client until they are published by using a Lync Server Management Shell command and are replicated to the pool's local stores. For details, see Publish the Location Database in the Deployment documentation.

The following sections discuss considerations that you need to take into account when populating and maintaining the location database.

Populating the Location Database

The following questions can help you determine how to populate the location database.

What process will you use to populate the location database?

Where does the data exist, and what steps do you need to take to convert the data into the format required by the location database? Will you add locations individually, or in bulk, by using a CSV file?

Do you have a third party database that already contains a mapping of locations?

By using Lync Server's Secondary Location Information service option to connect to a third-party database, you can group and manage locations by using an offline platform. A benefit to this approach is that in addition to associating locations to network identifiers, you can associate locations to a user. This means that the Location Information service can return multiple addresses, originating from the

Secondary Location Information service, to a Lync Server client. The user can then choose the most appropriate location.

To integrate with the Location Information service, the third-party database must follow the Lync Server Location Request/Response schema. For details, see "[MS-E911WS]: Web Service for E911 Support Protocol Specification" at http://go.microsoft.com/fwlink/p/?linkid=213819. For details about deploying a Secondary Location Information service, see Configure a Secondary Location Information Service in the Deployment documentation.

For details about populating the location database, see Configure the Location Database in the Deployment documentation.

Maintaining the Location Database

After you populate the location database, you need to develop a strategy for updating the database as the network configuration changes. The following questions will help you determine how to maintain the location database.

How will you update the location database?

There are several scenarios that require an update to the location database, including adding WAPs, office recabling (resulting in different switch assignments), and subnet expansion. Will you directly update each individual location, or will you perform a bulk update of all the locations by using a CSV file?

Will you use an SNMP application to match Lync client MAC addresses to port and switch identifiers?

If you use an SNMP application, you need to develop a manual process for keeping the switch chassis and port information consistent between the SNMP application and the location database. If the SNMP application returns a chassis IP address or port ID that is not included in the database, the Location Information service will not be able to return a location to the client.

1.3.10.9.2.5 Managing Locations for ELIN Gateways

Managing Locations for ELIN Gateways

Planning for Enterprise Voice > Planning for Emergency Services (E9-1-1) > Defining Your Requirements for Emergency Calls >

Topic Last Modified: *2012-10-02*

To have Lync Server automatically provide locations for clients within a network, you need to perform the following tasks:

- Populate the Location Information service database with a network wiremap, and include the Emergency Location Identification Numbers (ELINs) in the CompanyName field.
- Publish the locations so that they are available for clients in your network.
- Upload the ELINs to your public switched telephone network (PSTN) carrier's Automatic Location Identification (ALI) database.

For details about how to perform these tasks, see Configure the Location Database in the Deployment documentation.

Note:

Locations added to the central location database are not available to the client until they have been published by using a Lync Server Management Shell command and are replicated to the pool's local stores. For details, see Publish the Location Database in the Deployment documentation.

This section describes things to consider as you plan to update and maintain the location database.

Planning Emergency Locations

When you use ELIN gateways, you populate the Location Information service database with the civic address, a specific location within a building, and at least one ELIN for each location . During the planning phase, it is a good idea to decide how you want to name the locations and how you want to assign ELINs.

Planning Location Names

The Location Information service **Location** field, which holds the specific location within a building, has a maximum length of 20 characters (including spaces). Within that limited length, try to include the following:

- An easy-to-understand name that identifies the location of the 911 caller to help ensure that emergency responders find the specific location promptly when they arrive at the civic address. This location name may include a building number, floor number, wing designator, room number, and so on. Avoid nicknames that are known only to employees, which might cause emergency responders to go to the wrong location.
- A location identifier that helps users to easily see that their Lync client picked up the correct location. The Lync client automatically concatenates and displays the discovered **Location** and **City** fields in its header. A good practice is to add the street address of the building to each location identifier (for example, "1st Floor <street number>"). Without the street address, a generic location identifier such as "1st Floor" could apply to any building in the city.
- If the location is approximate because it’s determined by a wireless access point, you may want to add the word **Near** (for example, "Near 1st Floor 1234").

Planning ELINs

After you decide how you want to divide your building space into locations, you need to decide how many ELINs to assign to each location. For example, in a multifloor or multitenant building, different areas in the building can be assigned different emergency zones. Typically, each floor in a building is designated as a location. Each location is then assigned one or more ELINs, which are used as the calling number(s) during an emergency call. Contact your PSTN carrier for phone numbers that you can use for ELINs. The following table provides an example of locations for a specific street address.

Sample Location and ELIN Assignments

Building Area	Location	ELIN
First floor	1	425-555-0100
Second floor	2	425-555-0111
Third floor	3	425-555-0123

The locations you define should meet the following requirements:

- Comply with local and national/regional regulations in terms of maximum area per location and number of locations per street address.
- Are specific enough to make it easy to locate the emergency caller.

Populating the Location Database

The following questions will help you determine how to will populate the location database.

What process will you use to populate the location database?

Where does the data exist, and what steps do you need to take to convert the data into the format required by the location database? Will you add locations individually, or in bulk, by using a CSV file?

Do you have a third party database that already contains a mapping of locations?

By using Lync Server's Secondary Location Information service option to connect to a third-party database, you can group and manage locations by using an offline platform. A benefit to this approach is that in addition to associating locations to network identifiers, you can associate locations to a user. This means that the Location Information service can return multiple addresses, originating from the Secondary Location Information service, to a Lync Server client. The user can then choose the most appropriate location.

To integrate with the Location Information service, the third-party database must follow the Lync Server Location Request/Response schema. For details, see http://go.microsoft.com/fwlink/p/?linkid=213819. For details about deploying a Secondary Location Information service, see Configure a Secondary Location Information Service in the Deployment documentation.

For details about populating the location database, see Configure the Location Database in the Deployment documentation.

Maintaining the Location Database

After you populate the location database, you need to develop a strategy for updating the database as the network configuration changes. The following questions will help you determine how to maintain the location database.

How will you update the location database?

There are several scenarios that require an update to the location database, including adding wireless access points (WAPs), office recabling (resulting in different switch assignments), and subnet expansion. Will you directly update each individual location, or will you perform a bulk update of all the locations by using a CSV file?

Will you use an SNMP application to match Lync client MAC addresses to port and switch identifiers?

If you use an SNMP application, you need to develop a manual process for keeping the switch chassis and port information consistent between the SNMP application and the location database. If the SNMP application returns a chassis IP address or port ID that is not included in the database, the Location Information service will not be able to return a location to the client.

1.3.10.9.2.6 Defining the User Experience for Manually Acquiring a Location

Defining the User Experience for Manually Acquiring a Location

Planning for Enterprise Voice > Planning for Emergency Services (E9-1-1) > Defining Your Requirements for Emergency Calls >

Topic Last Modified: *2012-10-03*

If a client is located outside the network, or in an undefined subnet, the user can manually enter a location. But during an emergency call, the call will first be routed to a national/regional E9-1-1 Emergency Call Response Center (ECRC) dispatcher before being routed to a Public Safety Answering Point (PSAP). The ECRC will verbally query the caller for a location and then forward the call to the appropriate PSAP, based on the information provided.

Should users be prompted to enter a location when one is not automatically provided by the Location Information service?

For example, if a client is located in an undefined subnet, at home, in a hotel, or anywhere else outside the network, should the user be required to enter a location?

You can configure the **Location Required** setting in the location policy to define the client behavior. Setting this value to No means that the user will not be prompted for a location. Setting this value to Yes means that the user will be prompted for a location, but can dismiss the prompt. Setting this value to Disclaimer means that the user will be prompted for a location, and will be shown a disclaimer if they try to dismiss the prompt. In all cases, the user can continue to use the client as usual.

When a user manually enters a location, the location is mapped to the MAC address of the default gateway of the client's network, and is stored in a per-user table located on the client. When the user returns to any previously stored location, the Lync client automatically sets itself to that location.

Note:

You can modify only the current location of your client, but you can also delete any location stored in the local user's table.

1.3.10.9.2.7 Designing the SIP Trunk for E9-1-1

Designing the SIP Trunk for E9-1-1

Planning for Enterprise Voice > Planning for Emergency Services (E9-1-1) > Defining Your Requirements for Emergency Calls >

Topic Last Modified: *2012-10-03*

Lync Server uses SIP trunks to connect an emergency call to the E9-1-1 service provider. You can set up emergency service SIP trunks for E9-1-1 at one central site, at multiple central sites, or at each branch site. However, if the WAN link between the caller's site and the site that hosts the emergency service SIP trunk is unavailable, then a call placed by a user at the disconnected site will need a special phone usage record in the user's voice policy that will route the call to the ECRC through the local public switched telephone network (PSTN) gateway. The same is true if call admission control concurrent call limits are in effect.

Note:

There are two ways to implement a SIP trunk in a Lync Server environment:

- Use multihomed Mediation Servers that use their outward-facing publicly-routed interfaces to communicate with the SIP trunk provider.
- Use an on-premises Session Border Controller (SBC) to provide a secure demarcation point between the Mediation Servers and the SIP trunk provider's services.

If you choose the latter method, be sure that the SBC make and model that you choose has been certified and supports passing Presence Information Data Format Location Object (PIDF-LO) location data as part of its SIP INVITE. Otherwise, the calls will arrive at the emergency services service provider stripped of their location information. For details about certified SBCs, see "Infrastructure Qualified for Microsoft Lync" at http://go.microsoft.com/fwlink/p/?LinkId=248425.

E9-1-1 service providers supply you with access to a pair of SBCs for redundancy. You need to make several decisions regarding the Mediation Server topology and call routing configuration. Will you treat both SBCs as equal peers and use round-robin routing for calls between them, or will you designate one SBC as primary and the other as secondary?

For details about deploying a SIP trunk in Lync Server, see How Do I Implement SIP Trunking?. The following questions will help you decide how to deploy the SIP trunks for

E9-1-1.

Should you deploy the SIP trunk over a dedicated leased or a shared internet connection?

It is important that emergency calls always connect. A dedicated line provides a connection that will not be preempted by other traffic on the network, and gives you the ability to implement Quality of Service (QoS). Remember that if you are connecting to emergency services service providers over the public Internet and you need to guarantee the confidentiality of emergency calls, IPSec encryption is required.

Is your E9-1-1 deployment designed for disaster tolerance?

Because this is an emergency solution, resiliency is important. Deploy your primary and secondary Mediation Servers and SIP trunks in disaster tolerant locations. It is a good idea to deploy your primary Mediation Server closest to the users that it is supporting, and route failover calls through the secondary Mediation Server (located in a different geographic location).

Should you deploy a separate SIP trunk for each branch office?

Lync Server provides several strategies for handling voice resiliency in branch offices, including: having resilient data networks, deploying a SIP trunk at each branch, or pushing calls out to the local gateway during outages. For details, see Branch Site SIP Trunking.

Is call admission control (CAC) enabled?

Lync Server does not handle emergency calls any differently than an ordinary call. For this reason, bandwidth management, or call admission control (CAC), can have a negative impact on an E9-1-1 configuration. Emergency calls will be blocked or routed to the local PSTN gateway if a CAC is enabled and the configured limit is exceeded on a link where emergency calls are being routed. As indicated earlier in this topic, such calls will not have location data and must be manually routed to the ECRC.

1.3.10.9.2.8 Including the Security Desk

Including the Security Desk

Planning for Enterprise Voice > Planning for Emergency Services (E9-1-1) > Defining Your Requirements for Emergency Calls >

Topic Last Modified: *2012-10-02*

Your company may require the security desk to become involved in an emergency call. To help decide how to integrate the Security Desk into you E9-1-1 deployment, you should answer the following questions.

Do you want the security desk to be notified when there is an emergency call?

You can configure the location policy so that Lync Server sends instant messaging (IM) alerts to the Lync SIP addresses of one or more security personnel. These alerts contain the name, number, and location of the person placing the emergency call, and facilitate security personnel in assisting with the emergency situation.

Do you want to conference the security desk in on each emergency call?

If supported by the emergency services service provider, you can configure the location policy to include a callback number with each emergency call. This number is then used by the provider to conference your organization's security personnel into emergency calls. This conferencing can be configured in the location policy to be one-way (listen-only) or two-way (bidirectional).

Note:

If desired, you can configure different emergency personnel for each location policy. This allows you to customize the response for different areas within your company, or create different behavior for emergency calls that originate from inside as opposed to outside the network. You can use distribution groups to specify the personnel you want to notify.

1.3.10.9.2.9 Choosing an E9-1-1 Service Provider

Choosing an E9-1-1 Service Provider

Planning for Enterprise Voice > Planning for Emergency Services (E9-1-1) > Defining Your Requirements for Emergency Calls >

Topic Last Modified: *2012-06-06*

The E9-1-1 service provider routes emergency calls originating from Lync Server to the correct Public Safety Answering Point (PSAP) based on the location information contained within the call.

To support E9-1-1 as part of a Lync Server deployment, you must obtain E9-1-1 routing service from a Lync Open Interoperability Program qualified E9-1-1 service provider. Choose the provider that best fits your organizational requirements.

1.3.10.9.2.10 Defining the Location Policy

Defining the Location Policy

Planning for Enterprise Voice > Planning for Emergency Services (E9-1-1) > Defining Your Requirements for Emergency Calls >

Topic Last Modified: *2012-10-29*

Each location policy contains the following information:

Emergency Services Enabled

When this value is **Yes**, the client is enabled for E9-1-1. When a client registers, it attempts to acquire a location from the Location Information service and will include the location information as part of an emergency call.

Location Required

This setting is used only when **Emergence Services Enabled** is set to **Yes**.

You can configure the **Location Required** setting to define the client behavior. Setting the value to **No** means that the user will not be prompted for a location. Setting the value to **Yes** means that the user will be prompted for a location, but can dismiss the prompt. Setting the value to **Disclaimer** means that the user will be prompted for a location and also will be shown a disclaimer if they try to dismiss the prompt. In all cases, the user can continue to use the client.

Note:

The disclaimer text will not appear if a user manually entered a location before being enabled for E9-1-1. Updates to the disclaimer text will not be viewed by users that have already viewed the disclaimer.

Enhanced Emergency Service Disclaimer

This setting specifies the disclaimer that users see if they dismiss the prompt for a location. In Lync Server 2013, you can use location policy to set different disclaimers for different locales or different sets of users.

Note:

This location policy setting differs from Lync Server 2010, where you used the **Set-**

CsEnhancedEmergencyServiceDisclaimer cmdlet to set a global disclaimer for the entire organization. If a global disclaimer already exists, you need to specify that disclaimer in location policy. That is, Lync Server 2013 uses only disclaimers specified in location policy.

Emergency Dial String

This dial string (less the leading "+", but including any normalization done by the Lync user's Dial Plan) signifies that a call is an emergency call. The **Emergency Dial String** causes the client to include location and callback information with the call.

Note:

If your organization does not use an external line access prefix, you do not need to create a corresponding Dial Plan normalization rule that adds a "+" to the 911 string prior to sending the call to Outbound Routing on a Lync pool server; the "+" will be automatically prepended by the Lync client as a result of the location policy. However, if your site uses an external access prefix, you need to add a normalization rule to the applicable Dial Plan policy that strips the external access prefix and adds the "+". For example, if your location uses an external access prefix of 9 and a user dials 9 911 to place an emergency call, the client will use its Dial Plan policy to normalize this to +911 before the the dialed number is evaluated by the routes in the caller's location profile.

Emergency Dial String Masks

A semicolon-separated list of dial strings that is translated into the specified **Emergency Dial String**. For example, you may want to add 112, which is the emergency service number for most of Europe. A visiting Lync user from Europe may not know that 911 is the U.S. emergency number, but they can dial 112 and get the same result. As with the Emergency Dial String, do not include a "+" before each number, and if you use external line access codes, be sure there are normalization rules in the user's Dial Plan policy to strip off the access code digit.

PSTN Usage

The name of the PSTN Usage that contains the routing paths that determine which SIP trunk, PSTN gateway, or ELIN gateway emergency calls will go to.

Note:

Only one usage can be assigned to a location policy. This PSTN Usage overrides the PSTN Usages assigned to the user's voice policy, but applies only to calls placed to the Emergency Dial String or to one of the Emergency Dial String Masks.

Notification URI

Specifies one or more SIP URIs of the security personnel who receive an instant messaging (IM) notification when an emergency call is placed. Distribution groups are supported.

Conference URI

Specifies a direct inward dialing (DID) number (typically, a security desk number) that should be conferenced in when an emergency call is placed.

Conference Mode

Specifies if the conference URI will be conferenced into the emergency call by using one-way or two-way communication.

Location Refresh Interval

Specifies the amount of time (in hours) between client requests for a location update from the Location Information service. The value can be set to any value between 1 and 12. The default value is 4.

1.3.10.9.2.11 Assigning Location Policy Scope

Assigning Location Policy Scope

Planning for Enterprise Voice > Planning for Emergency Services (E9-1-1) > Defining Your Requirements for Emergency Calls >

Topic Last Modified: *2012-06-06*

As with other Lync Server policies, location policies can be assigned at multiple scope levels: global, site, and user. However, the scope of user-level location policies behaves a bit differently than with other Lync Server policies. Not only can per-user location policies be applied to endpoint objects (such as Users and Common Area Phone contact objects), they can also be applied to Lync Server network sites. Network sites are groupings of client subnets associated with a geographical location (but may not necessarily be all subnets in an entire central site or branch site). Any clients connected to the subnets in a network site automatically pick up the location policy assigned to that network site. In cases where a user-level location policy is assigned both to a user and to a network site, the network site-based location policy overrides any per-user policy setting.

Each network site has a location policy assigned to it, and each policy will have different PSTN Usages, Notification URIs, and Conference URIs values assigned to it.

Note:
The reason for this special policy scoping behavior is so that when a user homed on a pool at one office site visits another site and has to make an emergency call, the E9-1-1 call routing settings appropriate to that network site will apply no matter what pool or site the user is assigned to.

1.3.10.9.3 Deployment Checklist for E9-1-1

Deployment Checklist for E9-1-1

Planning > Planning for Enterprise Voice > Planning for Emergency Services (E9-1-1) >

Topic Last Modified: *2012-10-03*

To plan effectively for Enhanced 9-1-1 (E9-1-1), be sure to include the following deployment requirements:

- Prerequisites for deploying E9-1-1.
- Steps that are required to deploy E9-1-1.

Deployment Prerequisites for E9-1-1

Before you deploy E9-1-1, you must already have deployed your Lync Server internal servers, including a Central Management store, a Front End pool or a Standard Edition server, one or more Mediation Servers or Mediation Server pools, and Lync Server clients. In addition, an E9-1-1 deployment requires a SIP trunk to a qualified E9-1-1 service provider or an Emergency Location Identification Number (ELIN) gateway to your public switched telephone network (PSTN). Lync Server supports using E9-1-1 service providers only inside the United States.

Deployment Process

The following table provides an overview of the E9-1-1 deployment process. For details about deployment steps, see Configure Enhanced 9-1-1 in the Deployment documentation.

Phase	Steps	Roles	Deployment documentation
Configure voice usages, routes, and trunk configurations	1. Create a new PSTN usage record. This is the same name that is used for the **PSTN Usage** setting in the location policy. 2. Create or assign a voice route to the PSTN usage record created in the previous step and then point the gateway attribute to the E9-1-1 SIP trunk or ELIN gateway. 3. For a SIP trunk E9-1-1 service provider, set the trunk that will be handling E9-1-1 calls over the SIP to pass PIDF-LO data by using the **Set-CsTrunkConfiguration –EnablePIDFLOSupport** cmdlet. 4. Optionally, for a SIP trunk E9-1-1 service provider, create or assign a local PSTN route for calls that are not handled by the E9-1-1 service provider's SIP trunk. This route will be used if the connection to the E9-1-1 service provider is not available. If supported by your E9-1-1 service provider, assign a trunk configuration rule to the gateway that translates the 911 dial string into the direct inward dialing (DID) number of the national/ regional Emergency Call Response Center (ECRC).	CSVoiceAdmin	Configure an E9-1-1 Voice Route
Create location	1. Review the global	CSVoiceAdmin	Create Location

policies and assign them to users and subnets	location policy. 2. Create a location policy with a user-level scope; or, if the organization has more than one site with different emergency usages, create a location policy with a network-level scope. 3. Assign the location policy to network sites. 4. Add the appropriate subnets to the network site. 5. (Optional) Assign the location policy to user policies.	CSLocationAdmin (except for creating Location Policies)	Policies Add a Location Policy to a Network Site Associate Subnets with Network Sites for E9-1-1
Configure the location database	1. Populate the database with a mapping of network elements to locations. 2. For ELIN gateways, add the ELINs to the <CompanyName> column. 3. Configure the connection to the E9-1-1 service provider for validating addresses. 4. Validate the addresses with the E9-1-1 service provider. 5. Publish the updated database. 6. For ELIN gateways, upload the ELINs to your PSTN carrier's Automatic Location Identification (ALI) database.	CSVoiceAdmin CSLocationAdmin	Configure the Location Database
Configure Advanced Features (optional)	1. Configure the URL for the SNMP application. 2. Configure the URL for the location of the Secondary Location Information service.	CSVoiceAdmin	Configure an SNMP Application Configure a Secondary Location Information Service

1.3.10.10 Planning for Media Bypass

Planning for Media Bypass

See Also

Microsoft Lync Server 2013 > Planning > Planning for Enterprise Voice >

Topic Last Modified: *2012-09-21*

Media bypass refers to removing the Mediation Server from the media path whenever possible for calls whose signaling traverses the Mediation Server.

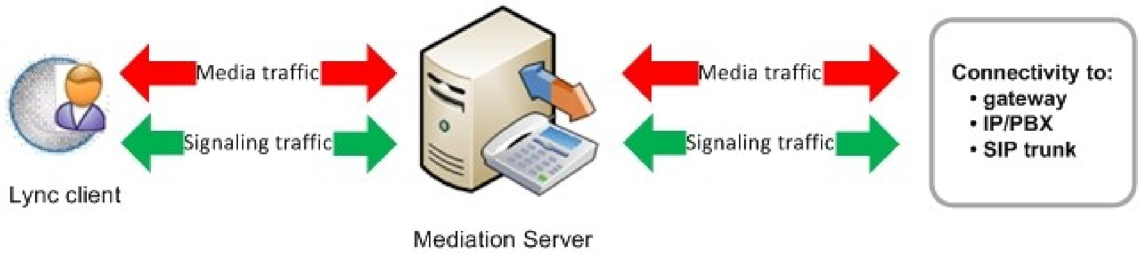
Media bypass can improve voice quality by reducing latency, needless translation, possibility of packet loss, and the number of points of potential failure. Scalability can be improved, because elimination of media processing for bypassed calls reduces the load on the Mediation Server. This reduction in load complements the ability of the Mediation Server to control multiple gateways.

Where a branch site without a Mediation Server is connected to a central site by one or more WAN links with constrained bandwidth, media bypass lowers the bandwidth requirement by allowing media from a client at a branch site to flow directly to its local gateway without first having to flow across the WAN link to a Mediation Server at the central site and back.

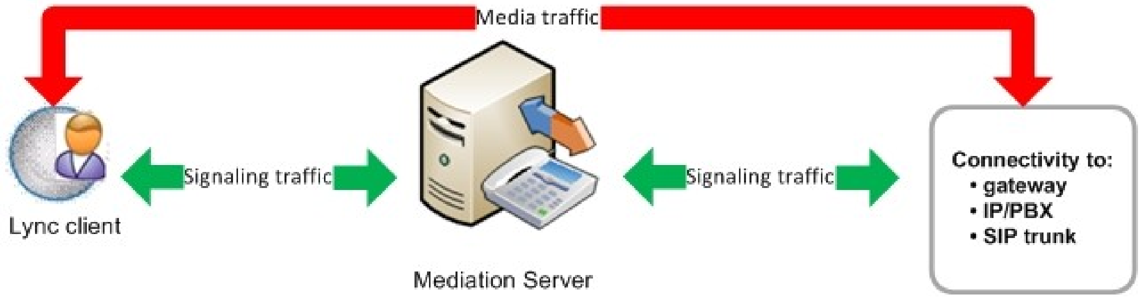
By relieving the Mediation Server from media processing, media bypass may also reduce the number of Mediation Servers that an Enterprise Voice infrastructure requires.

The following figure shows basic media and signaling pathways in topologies with and without media bypass.

No Media Bypass:



Media Bypass:



As a general rule, enable media bypass wherever possible.

1.3.10.10.1 Overview of Media Bypass

Overview of Media Bypass

See Also

Planning > Planning for Enterprise Voice > Planning for Media Bypass >

Topic Last Modified: *2012-09-21*

Media bypass is useful when you want to minimize the number of Mediation Servers deployed. Typically, a Mediation Server pool will be deployed at a central site, and it will control gateways at branch sites. Enabling media bypass allows media for public switched telephone network (PSTN) calls from clients at branch sites to flow directly through the gateways at those sites. Lync Server 2013 outbound call routes and Enterprise Voice policies must be properly configured so that PSTN calls from clients at a branch site are routed to the appropriate gateway.

Wi-Fi networks typically experience more packet loss than wired networks. Recovery from this packet loss is not typically something that can be accommodated by gateways. Therefore, we recommend that you evaluate the quality of a Wi-Fi network before determining whether bypass should be enabled for a wireless subnet. There is a tradeoff in latency reduction versus recovery from packet loss to consider, as well. RTAudio, a codec which is available for calls that do not bypass the Mediation Server, is better suited for handling packet loss.

After your Enterprise Voice structure is in place, planning for media bypass is straightforward.

- If you have a centralized topology without WAN links to branch sites, you can enable global media bypass, because fine-tuned control is unnecessary.
- If you have a distributed topology that consists of one or more network regions and their affiliated branch sites, determine the following:
    - Whether your Mediation Server peers are able to support the capabilities required for media bypass.
    - Which sites in each network region are well-connected.
    - Which combination of media bypass and call admission control is appropriate for your network.

When you enable media bypass, a unique bypass ID is automatically generated for a network region, and for all network sites without bandwidth constraints within that region. Sites with bandwidth constraints within the region and sites connected to the region over WAN links with bandwidth constraints are each assigned their own unique bypass IDs.

When a user makes a call to the PSTN, the Mediation Server compares the bypass ID of the client subnet with the bypass ID of the gateway subnet. If the two bypass IDs match, media bypass is used for the call. If the bypass IDs do not match, media for the call must flow through the Mediation Server.

When a user receives a call from the PSTN, the user’s client compares its bypass ID to that of the PSTN gateway. If the two bypass IDs match, media flows directly from the gateway to the client, bypassing the Mediation Server.

Only Lync 2010 or above clients and devices support media bypass interactions with a Mediation Server.

◆**Important:**
In addition to enabling media bypass globally, you must enable media bypass individually on each PSTN trunk. If bypass is enabled globally, but is not enabled for a particular PSTN trunk, media bypass will not be invoked for any calls involving that PSTN trunk. In addition, when media bypass is set to **Use Site and Region Information**, you must associate all routable subnets with the sites in which they are located. If there are routable subnets within a site for which bypass is not wanted, these subnets should be grouped within a new site before you enable media bypass. Doing so will assure that the unroutable subnets are assigned a different bypass ID.

Technical Requirements for Media Bypass

1.3.10.10.2 Media Bypass Modes

Media Bypass Modes

See Also

Planning > Planning for Enterprise Voice > Planning for Media Bypass >

Topic Last Modified: *2012-10-05*

You must configure media bypass both globally and for each individual PSTN trunk. When enabling media bypass globally, you have two choices: **Always Bypass** and **Use Site and Region Information**.

As the name suggests, **Always Bypass** means that bypass will be attempted for all PSTN calls. **Always Bypass** is used for deployments where there is no need to enable call admission control, nor is there a need to specify detailed configuration information regarding when to attempt media bypass. Furthermore, **Always Bypass** is used when there is full connectivity between clients and PSTN gateways. In this configuration, all subnets are mapped to one and only one bypass ID, which is computed by the system.

With **Use Site and Region Information**, the bypass ID associated with site and region configuration is used to make the bypass decision. This configuration provides the flexibility to configure bypass for most common topologies, as it gives you fine-grained control over when bypass happens, in addition to supporting interactions with call admission control (CAC). The system tries to ease your task by automatically assigning bypass IDs as follows.

- The system automatically assigns a single unique bypass ID to each region.
- Any site connected to a region over a WAN link without bandwidth constraints inherits the same bypass ID as the region.
- A site associated with the region over a WAN link with constrained bandwidth is assigned a different bypass ID from that of the region.
- Subnets associated with each site inherit the bypass ID for that site.

Planning > Planning for Enterprise Voice > Planning for Media Bypass >

Topic Last Modified: *2012-10-05*

Media bypass and call admission control (CAC) work together to manage bandwidth control for call media. Media bypass facilitates media flow over well-connected links; CAC manages traffic on links with bandwidth constraints. Because Media Bypass and CAC are mutually exclusive, you must be mindful of one when planning for the other. The following combinations are supported:

- CAC and Media Bypass are both enabled. Media Bypass must be set to **Use Site and Region Information**. This site and region information is the same as that used for CAC.

  If you enable CAC, you cannot select **Always Bypass**, and vice-versa, because the two configurations are mutually exclusive. That is, only one of the two will apply to any given PSTN call. First, a check is made to determine if media bypass applies to the call. If it does, then CAC is not used. This makes sense, because if a call is eligible for bypass, it is by definition using a connection where CAC is not needed. If bypass cannot be applied to the call (that is, if the client’s and gateway’s bypass IDs do not match), then CAC is applied to the call.

- CAC not enabled and Media Bypass set to **Always Bypass**.

  In this configuration, both client and trunk subnets are mapped to one and only one bypass ID, which is computed by the system.

- CAC not enabled and Media Bypass set to **Use Site and Region Information**.

  Where **Use Site and Region Information** is enabled, bypass determination works essentially the same way, regardless of whether CAC is enabled or not. That is, for any given PSTN call, the client’s subnet is mapped to a particular site, and the bypass ID for that subnet is extracted. Similarly, the gateway’s subnet is mapped to a particular site, and the bypass ID for that subnet is extracted. Only if the two bypass IDs are identical will bypass happen for the call. If they are not identical, media bypass will not occur.

  Even though CAC is disabled globally, bandwidth policy needs to be defined for each site and link if you want to use site-and-region configuration to control the bypass decision. The actual value of the bandwidth constraint or its modality doesn’t matter. The ultimate goal is to have the system automatically calculate different bypass IDs to associate with different locales that are not well connected. Defining a bandwidth constraint by definition means a link is not well connected.

- CAC is enabled and media bypass is not enabled. This would apply only where all gateways and IP-PBXs are not well connected or do not meet other requirements for media bypass. For details about requirements for media bypass, see Technical Requirements for Media Bypass.

Planning > Planning for Enterprise Voice > Planning for Media Bypass >

Topic Last Modified: *2012-09-21*

For each call to the PSTN, the Mediation Server determines whether media from the Lync endpoint of origin can be sent directly to a Mediation Server peer without traversing the Mediation Server. The peer can be a PSTN gateway, IP-PBX, or Session Border Controller (SBC) at an Internet telephony service provider (ITSP) that is associated with the trunk between the Mediation Server where the call is routed.

Media bypass can be employed when the following requirements are met:

- A Mediation Server peer must support the necessary capabilities for media bypass, the most important being the ability to handle multiple forked responses (known as “early dialogs”). Contact the manufacturer of your gateway or PBX, or your ITSP, to obtain the value for the maximum number of early dialogs that the gateway, PBX, or SBC can accept.
- The Mediation Server peer must accept media traffic directly from Lync endpoints. Many ITSPs allow their SBC to receive traffic only from the Mediation Server. Contact your ITSP to determine whether its SBC accepts media traffic directly from Lync endpoints.
- Lync clients and a Mediation Server peer must be well connected, meaning that they are either located in the same network region or at network sites that connect to the region over WAN links that have no bandwidth constraints

Media Bypass and Call Admission Control

1.3.10.11 Planning for Private Telephone Lines

Planning for Private Telephone Lines

Microsoft Lync Server 2013 > Planning > Planning for Enterprise Voice >

Topic Last Modified: *2013-02-11*

Lync Server 2013 introduces the ability to give users a second, private telephone line in addition to their primary telephone line. Private telephone lines are often assigned to executives and others who want an unlisted telephone number at which they can be reached directly.

Private telephone lines can only be configured with the Lync Server Management Shell. You cannot configure private telephone lines with the Lync Server Control Panel. Private telephone lines should be configured only in deployments of Lync Server and not in mixed deployments.

Characteristics of Private Telephone Lines

Although the concept of a second, private telephone line is fundamentally simple, it is important to understand the characteristics of private lines and the ways in which they are similar to and different from users’ primary telephone lines.

General Characteristics of Private Telephone Lines

- A user can have only one private telephone line.
- A user with a private telephone line has only one voice mailbox and receives missed call notifications at a single email address.
- A user with a private telephone line does not have a second SIP address, and a second, private telephone line does not give a user a second presence on the network (such as a second instant messaging identity).
- Private telephone lines are available for on-premises deployments only. They are not available with hosted deployments of Lync Server.

How Private Telephone Lines Differ from Primary Telephone Lines

- The telephone numbers for private telephone lines do not appear in the telephone directories or Contacts lists that are derived from Active Directory Domain Services.
- None of the following features are available with a private telephone line: call forwarding, team call, delegation, team ring, Group Call Pickup, and Response Group application.
- Calls to a private telephone line have a special ring, and the system notification for the call tells the user that the incoming call is on his or her private line.
- Calls to the private telephone line always ring through. They do not follow "do not disturb" rules.
- Private telephone lines are inbound only and cannot be used to make outgoing calls. When a user with a private telephone line makes a call, the call originates from the user’s primary telephone line and does not hide the user’s name or the user’s primary telephone number from the person called.

How Private Telephone Lines Are Similar to Primary Telephone Lines

- Unanswered calls to a private telephone line are routed to the same voice mail inbox as for the primary telephone line (if voice mail is enabled).
- Call park and call pickup work with private telephone lines in exactly the same manner as they do with the user’s primary telephone line.
- When simultaneous ringing is enabled on a user’s primary telephone line, it is also enabled on the private telephone line.
- The telephone number for a private telephone line is recorded in the call detail record in the same manner as the telephone number for a user’s primary telephone line, but with an indication that it is a private telephone number.
- After a user answers a call on a private telephone line, the call is treated the same as a call on the user’s primary telephone line. For example, if a user who receives a call on a private telephone line forwards the call or invites others to a conference call, the user’s name appears in Lync 2013, and the telephone number for the user’s primary telephone line appears in caller ID.
- A user can deflect a call (redirect the call to another destination, such as a mobile phone or home phone, before answering) from the private telephone line in the same manner as with a primary telephone line.

Note:

When a call to a private line is routed to an alternate telephone number, the telephone number for the private telephone line is made available to the alternate telephone number and can be displayed in the logs for that number.

Note:

Calls from a conference to the private telephone line will not have a *private-line* indication in the incoming system notification.

Administering Private Telephone Lines

In addition to the technical aspects of creating and managing private telephone lines, you will need to establish administrative procedures for them. This includes determining policies for who in the organization is eligible for a private line, creating and maintaining lists of people and their telephone lines, possibly creating a private telephone directory for executives, arranging for user training, and related tasks.

Note:
The private telephone line is stored in Active Directory as an msRTCSIP-PrivateLine attribute on the user object. By default any member of the Authenticated Users group has read access to this attribute.

Assigning Telephone Numbers

Accounts for new users who need private telephone lines are created in the same manner as accounts without private telephone lines, using Lync Server Control Panel or Lync Server Management Shell.

Use the **Set-CsUser** cmdlet in the Lync Server Management Shell to assign a telephone number to a private telephone line for a user, for example, **Set-CsUser -Identity "sip:joe@contoso.com" -PrivateLine "Tel:+14255551212"**.

Telephone numbers for private telephone lines can be between 3 and 15 numbers in length and must be preceded with the "TEL:" prefix. They can have any area code and any country/region code as long as your organization has direct inward dialing for that area code and country/region code.

For details about cmdlets and Lync Server Management Shell, see the Lync Server Management Shell documentation.

Private Telephone Lines in Mixed Deployments

Private telephone lines should be configured only for deployments of Lync Server. In a deployment in which there are both Lync Server and Office Communications Server 2007 or Office Communications Server 2007 R2 servers, when a user on earlier version attempts to call a private telephone line, routing of the call fails because the server cannot perform a reverse number lookup on a private telephone line.

The information in this topic pertains to Cumulative Updates for Lync Server 2013: February 2013.

Location-Based Routing makes it possible to restrict the routing of calls between VoIP endpoints and PSTN endpoints based on the location of the parties in the call. Location-Based Routing is part of the Lync Server 2013 Enterprise Voice infrastructure. Location-Based Routing is a call management feature that controls how calls are routed by Lync Server 2013 CU1. It enforces call authorization rules on whether calls can be routed to PBX or PSTN endpoints based on the Lync caller’s geographic location.

Topic Last Modified: *2013-02-21*

Location-Based Routing introduces a new set of rules that modifies the routing of national and international PSTN calls to prevent toll bypass. Location-Based Routing provides the flexibility to scope these rules to specific regions, specific gateways or to specific set of users only.

The following scenarios illustrate the main types of restrictions Location-Based Routing can enforce:

- Egress calls – Location-Based Routing can enforce outgoing calls to egress from a PSTN gateway that is located in the same region as where the caller is to prevent PSTN toll bypass, which prevents calls to egress from a PSTN gateway located in a different region as the caller.
- Ingress calls – Location-Based Routing can prevent incoming PSTN calls to ring Lync endpoints if the PSTN gateway routing the incoming call is not located in the same region as the called Lync user.
- Unknown regions – Location-Based Routing restricts incoming and outgoing PSTN calls to and from users that are located in undetermined locations (i.e. remote users connecting from the Internet or located in unknown regions).
- International regions – Location-Based Routing enforces routing of outgoing calls through international PSTN gateways if a gateway local to the user’s location cannot be found.

Topic Last Modified: *2013-03-09*

Location-Based Routing leverages the same network regions, sites and subnets as defined in Lync Server used by E9-1-1, CAC and Media Bypass to apply call routing restrictions to prevent PSTN toll bypass. A user’s location is determined by the IP subnet of the user’s Lync endpoint(s) are connected from. Each IP subnet is associated to a network site, which are aggregated into network regions defined by the administrator. Location-Based Routing is enforced based on the user’s network site.

Location-Based Routing rules are applied on a per network site basis, meaning that a given set of rules will be applied to all endpoints enabled for Location-Based Routing that are located within the same network site. Administrators can apply Location-Based Routing to network sites that require it.

Voice routing policies can be defined on a per network site basis to define a particular PSTN gateway that should be used by all users located in the network site to call PSTN phone numbers. Such voice routing policies will take precedence over the routing defined by the user’s voice policy when the user is located in a network site enabled for Location-Based Routing, and it will prevent the routing of calls via other PSTN gateways that are enabled for Location-Based Routing. When a Lync user places a PSTN call, the user’s voice policy determines whether the user can be authorized to place the call. If the user’s voice policy allows the user to place the call, Location-Based Routing determines which PSTN gateway the call should egress from. Location-Based Routing makes this determination based on the user’s location.

A user location can be categorized in the following ways:

- The user is located in a known network site enabled for Location-Based Routing and his DID (Direct Inward Dial) number terminates on a PSTN gateway placed in the same network site (i.e. office). The routing of outbound calls will be through the voice routing policy of the network site in which the user is located. Incoming PSTN calls to the user are routed to endpoints that are located in the same network site as the PSTN gateway.
- The user is located in a known network site that is in different from the network site where the PSTN gateway is located. (i.e. the user traveled to another corporate office). The routing of outbound calls will be using the voice routing policy of the network site in which the user is located. Incoming PSTN calls to the user will not be routed to endpoints that are located in different sites than the PSTN gateway to prevent PSTN toll bypassing.
- When a user is located in a network site that is unknown to the Lync Server deployment, the routing of outbound calls will be based on the voice policy assigned to the user to PSTN gateways not bound to Location-Based Routing restrictions. Incoming PSTN calls will not be routed to endpoints that are located in unknown network sites to prevent PSTN toll bypassing.

Calls routed via PSTN gateways and PBXs might require Location-Based Routing restrictions depending on the location of such systems. Location-Based Routing can be enabled at the granularity on a per trunk basis.

Location-Based Routing introduces the following set of rules when enabled on a trunk:

- When Location-Based Routing is enabled on a per trunk basis, the rules define on that trunk will be applied only to calls routed through that trunk.
- To prevent PSTN tolls bypass where calls originate from a network site different that the network site where the PSTN gateway is located, Location-Based Routing introduces the association of a network site to a given trunk. This defines the network site that allows calls to be routed to a given trunk.

Trunks can be enabled for Location-Based Routing in two ways:

- The trunk is defined for a PSTN gateway that egresses calls to the PSTN. Incoming calls routed by a trunk of this type will be routed only to endpoints located within the same network site as the trunk.
- The trunk is defined for a Mediation Server peer that doesn’t egress calls to the PSTN and services users with legacy phones in a static locations (i.e. PBX phones). For this particular configuration, all incoming calls routed by a trunk of this type will be considered to be originating from the same network site as the trunk. Calls from PBX users will have the same Location-Based Routing enforcement as Lync users who are located in the same network site as the trunk. If two PBX systems located in separate network sites are connected through Lync Server, Location-Based Routing will allow routing from one PBX endpoint in one network site to another PBX endpoint in the other network site. This scenario will not be blocked by Location-Based Routing. In addition to this scenario and in a similar way as a Lync user in the same location, endpoints connected to a Mediation Server peer with this configuration will be able to make or receive calls to and from other Mediation Server peer that do not route calls to the PSTN (i.e. an endpoint connected to a different PBX) regardless of the network site to which the Mediation Server peer is associated. All inbound calls, outbound calls, call transfers and call forwards involving PSTN endpoints will be subject to Location Based Routing to use only PSTN gateways that are defined as local to such Mediation Server peer.

The routing of outbound calls of users enabled for Location-Based Routing is affected by the network location of the user's endpoint. The following table illustrates how Location-Based Routing affects the routing of outbound calls depending on the location of the caller's endpoint.

Caller placing an outbound call to the PSTN

	User endpoint located in a network site enabled for Location-Based Routing	User endpoint located in unknown network site or not enabled for Location-Based Routing
Authorization of outbound calls	Call is authorized based on user's voice policy	Call is authorized based on user's voice policy
Routing of outbound call	Call is routed according to the network site's voice routing policy	Call is routed according to user's voice policy and only through trunks not enabled for Location-Based Routing (if available)

Scenarios for Location-Based Routing

1.3.10.12.3.2 Incoming calls

Incoming calls

See Also

Planning for Enterprise Voice > Planning for Location Based Routing > Scenarios for Location-Based Routing >

Topic Last Modified: *2013-03-09*

The routing of incoming calls to users enabled for Location-Based Routing depends on the location of the user's endpoint. The routing of incoming calls is affected in the following way. If a user has an incoming call to an endpoint located in a Location-Based Routing enabled network site, and the endpoint is located in the same network site as the PSTN gateway, the call will be routed. If a user has an incoming call to an endpoint located in a Location-Based Routing enabled network site, and the endpoint is located in a different network site than the PSTN gateway, the call will not be routed. When a user has no endpoints located in the same network site as the PSTN gateway where the incoming call is originating from, the incoming call will be routed directly to the user's voicemail and a missed call notification will be sent to the called party.

The call forwarding settings of a user that is enabled for Location-Based Routing will continue to be enforced, however, calls forwarded will be subject to Location-Based Routing restrictions of the user.

The following table illustrates how Location-Based Routing affects the routing of inbound calls depending on the location of the callee's endpoint. The network site of the PSTN gateway is enabled for Location-Based Routing, and Location-Based Routing only permits routing of PSTN calls to endpoints within the same network site.

Callee receiving an inbound call from the PSTN

	Callee's endpoint located in the same network site as PSTN gateway	**Callee's endpoint not located in the same network site as PSTN gateway**	**Callee's endpoint located in unknown network site or not enabled for Location-Based Routing**
Routing of inbound PSTN call	Incoming call is routed to callee's endpoints	Incoming call is not routed to callee's endpoints	Incoming call is not routed to callee's endpoints

When a PSTN endpoint is involved, Location-Based Routing analyzes the location of the calle's endpoint and the endpoint where the call will be transferred or forwarded to (i.e. transfer/forward target). Location-Based Routing determines whether the call should be transferred or forwarded depending on the location of both endpoints.

The following table illustrates the scenario of a Lync user in a call with a PSTN endpoint, and the Lync user transfers the call to another Lync user. Depending on the network site location of the transferee's endpoint, Location-Based Routing affects the routing of the call transfer or forward.

Initiating call transfer or forward

User initiating the call transfer/ forward	**Target endpoint is in same network site as user initiating call transfer or forward**	**Target endpoint is in different network site as user initiating call transfer or forward**	**Target endpoint is in unknown network site or network site not enabled for Location-Based**

			Routing
Lync user	Call forward or transfer is allowed	Call forward or transfer is not allowed	Call forward or transfer is not allowed

For example: a Lync user in a call with a PSTN endpoint transfers the call to another Lync user that is in the same network site. In this case, the call transfer is allowed.

The following table illustrates the scenario of a Lync user in a call with another Lync user, and one of the users transfers the call to a PSTN endpoint. Depending on the location of the user the call is being transferred to, the table details how Location-Based Routing affects the call.

Call transfer or forward to PSTN endpoint

Call transfer/ forward endpoint target	**Lync users in same network site**	**Lync users in different network sites**	**One or both Lync users in unknown network site or network site not enabled for Location-Based Routing**
PSTN endpoint	Call forward or transfer allowed by the transferred user's site voice routing policy	Call forward or transfer allowed by the transferred user's site voice routing policy	Call forward or transfer allowed by the transferred user's voice policy only through trunks not enabled for Location-Based Routing

For example: a Lync user in a call with another Lync user that is in the same network site transfers the call to a PSTN endpoint and the call transfer is allowed.

Planning for Enterprise Voice > Planning for Location Based Routing > Scenarios for Location-Based Routing >

Topic Last Modified: *2013-03-09*

When the called party has simultaneous ringing enabled, Location-Based Routing analyzes the location of the calling party and the endpoints of the called parties to determine whether the call should be routed.

The following table illustrates a user configured with simultaneous ringing, and the simultaneous ringing target is a user in the same network site, in a different network site, or in an unknown network site.

Incoming PSTN call for	**Located in the same network site as**	**Located in different network site than**	**Located in unknown network site or not**

	callee	callee	enabled for Location-Based Routing
Lync user	Simultaneous ring allowed	Simultaneous ring not allowed	Simultaneous ring not allowed

The following table illustrates a call from a Lync user (i.e. Lync caller) in the same network site, in a different network site, or from an unknown network site. The callee has a PSTN endpoint (i.e. cellphone) configured as a simultaneous ring target. In this scenario, Location-Based Routing will determine whether the call should be routed to the simultaneous ring target (i.e. cellphone) of the callee or not.

Simultaneous ring target	Located in the same network site as callee	Located in different network site than callee	Located in unknown network site or not enabled for Location-Based Routing
PSTN endpoint	Simultaneous ring allowed through the caller's site voice routing policy	Simultaneous ring allowed through the caller's site voice routing policy	Simultaneous ring allowed through the caller's voice policy to trunks not enabled for Location-Based Routing

1.3.10.12.3.5 Delegation

Delegation

See Also

Planning for Enterprise Voice > Planning for Location Based Routing > Scenarios for Location-Based Routing >

Topic Last Modified: *2013-03-09*

The delegation capabilities in Lync are affected by Location-Based Routing in the following manner:

- When a delegate enabled for Location-Based Routing places a call on behalf of a manager, the delegate's voice policy is used to authorize the call and the delegate's site voice routing policy will be used to route the call
- For incoming PSTN calls to a manager, the same rules applicable for call forwarding or simultaneously ringing will apply as described in the Call transfers and forwarding and Simultaneous ringing topics.
- When a delegate sets a PSTN endpoint as a simultaneous ring target, for an incoming call to the manager, the voice routing policy of the site that is associated to the incoming trunk will be used to route the call to the delegate's PSTN endpoint.
- For delegation, it's recommended that the manager and his associated delegates to be usually located in the same network site.

Scenarios for Location-Based Routing

1.3.10.12.4 Technical Considerations for Location-Based Routing

Technical Considerations for Location-Based Routing

See Also

Planning > Planning for Enterprise Voice > Planning for Location Based Routing >

Topic Last Modified: *2013-03-09*

When planning Location-Based Routing, you should consider the impact to the following scenarios.

Disaster Recovery

During a failover from the primary pool to a backup pool as well as when restoring normal operations to the primary pool, Location-Based Routing remains enforced at all times during a disaster and recovery procedure.

Survivable Branch Appliance

Configuring Location-Based Routing impacts the planning of where you deploy the gateways associated to your Survivable Branch Appliances. The gateway associated to your SBA must be located in the same network site as your Survivable Branch Appliance; otherwise, users homed on your Survivable Branch Appliance will not be permitted to place outbound calls if Location-Based Routing is configured. When the WAN connection between your Survivable Branch Appliance and the central site is down, Location-Based Routing restrictions remains enforced.

Planning for Location Based Routing

1.3.10.12.5 Client and Server Support for Location-Based Routing

Client and Server Support for Location-Based Routing

See Also

Planning > Planning for Enterprise Voice > Planning for Location Based Routing >

Topic Last Modified: *2013-03-09*

Location-Based Routing is enforced by Lync Server. Lync Server can identify the network sites where users are connecting from within the corporate network. Since remote users are outside the corporate network, their location is considered to be unknown.

Lync Server Support

Location-Based Routing requires that Lync Server 2013 CU1 is deployed on all Front End pools and Standard Edition servers in a given topology. If Lync Server 2013 CU1 is not installed on certain Lync components in the topology, Location-Based Routing restrictions cannot be fully enforced.

The following table identifies the combination of server roles and versions that is supported for Location-Based Routing.

Pool version	Mediation Server version	Supported
Lync Server 2013 CU1	Lync Server 2013 CU1	yes
Lync Server 2013 CU1	Lync Server 2013	no
Lync Server 2013 CU1	Lync Server 2010	no
Lync Server 2013 CU1	Office Communications Server 2007 R2	no
Lync Server 2013	any	no
Lync Server 2010	any	no
Office Communications Server 2007 R2	any	no

Lync Client Support

The following table identifies the clients that Location-Based Routing supports.

Client type	Supported	Details
Lync 2013	yes	Including Lync 2013 CU1
Lync 2010	yes	
Office Communicator 2007 R2	no	
Lync Phone Edition	yes	
Lync Attendant	yes	
Lync for Windows 8	yes	
Lync Mobile 2013	no	VoIP must be disabled for Lync Mobile 2013 clients if used by users with Location-Based Routing enabled.
Lync Mobile 2010	yes	

Note:

To disable VoIP for Lync Mobile 2013 clients, assign a mobility policy with the setting, IP Audio/Video, disabled for all users enabled for Location Based Routing. For more details about mobility policy, see New-CsMobilityPolicy.

Planning > Planning for Enterprise Voice > Planning for Location Based Routing >

Topic Last Modified: *2013-03-09*

This topic provides an overview of the process involved in configuring Location-Based Routing. You must deploy Lync Server Enterprise Edition or Standard Edition with Enterprise Voice before you configure Location-Based Routing. The components required by Location-Based Routing are already installed and enabled when you deploy Enterprise Voice.

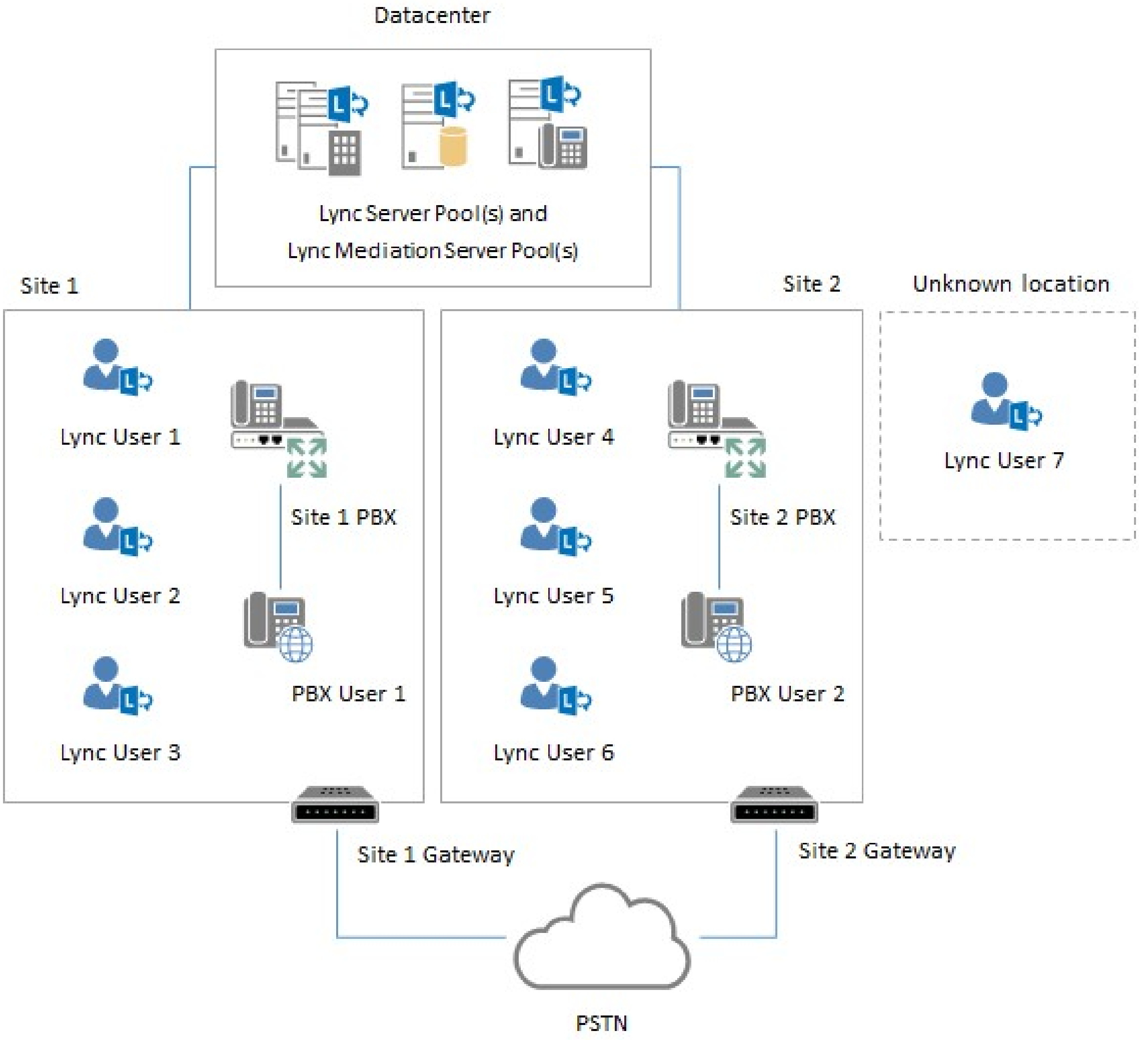
Location-Based Routing Deployment Process

Phase	Steps	Required groups and roles	Deployment documentation
Deploy Enterprise Voice	• Configure Trunks • Create Voice Policies • Define Voice Routes	CSVoiceAdmins CsAdministrator CsServerAdministrator	Deploying Enterprise Voice
Verify your Enterprise Voice deployment		CSVoiceAdmins CsAdministrator CsServerAdministrator	
Configure network regions, sites, and subnets	• Create network regions • Create network sites • Associates subnets with network sites	CSVoiceAdmins CsAdministrator CsServerAdministrator	About Network Regions, Sites, and Subnets Create or Modify a Network Region Create or Modify a Network Site Associate a Subnet with a Network Site

Configure Location-Based Routing	• Create voice routing policies • Define separate trunk configuration per trunk • Modify voice policies • Enable Location-Based Routing configuration	CSVoiceAdmins CsAdministrator CsServerAdministrator	

Sample Deployment

The following deployment is used to illustrate further the mechanisms enabled by Location-Based Routing.



Incoming PSTN calls

An administrator can enable the trunk defined to route calls to "Site 1 Gateway" for Location-Based Routing and associate the "Site 1 Gateway" to site 1. Once enabled, calls that are routed through "Site 1 Gateway" will only be routed to users that are located in site 1. All calls routed through the "Site 1 Gateway" trunk destined to users in a different site, such as site 2 will be blocked to prevent PSTN toll bypass.

All incoming PSTN calls through "Site 1 Gateway" will only be allowed to route to endpoints located in site 1. For example, when "Lync user 1" travels to site 2, all incoming PSTN calls through "Site 1 Gateway" will not be routed to "Lync user 1" endpoints located in site 2. The same routing rule applies if "Lync user 1" travels to an unknown network site where the user's location can't be determined.

The following table outlines the user experience of "Lync user 1" in this context.

	Lync user 1 endpoints located in network site 1	**Lync user 1 endpoints located in network site 2**	**Lync user 1 endpoints located in unknown network site**
Inbound PSTN calls to Lync user 1	Calls are routed to endpoints in this location	Calls are not routed to endpoints in this location	Calls are not routed to endpoints in this location

Outgoing PSTN calls

Voice routes are referenced in both Voice Policies assigned directly to users, and Voice Routing Policies assigned to network sites. Both policies contain references to routes, which can be used to route a call differently. For example, an administrator can define a Voice Routing Policy for all users located in network site 1 to route all outbound calls through the "Site 1 Gateway" while the Voice Policy of some users define a route for all outbound calls through the "Site 2 Gateway". While these users are located in network site 1, their outbound calls will be routed through the "Site 1 Gateway".

When a user is located in a network site configured for Location-Based Routing, the network site's Voice Routing Policy route overrides the user's Voice Policy route. This rule is particularly useful for users that temporarily move to a different site. In this particular case a user will always use a gateway that is local to his location; if "Lync user 3" is located at "Site 2", all his outbound calls will be routed via "Site 2 Gateway", but if he travels to site 1, all his outbound calls placed while he's at site 1 will be routed through "Site 1 Gateway".

The following table illustrates the user experience of Lync user 1 placing an outbound call from the following network sites.

	Network site 1	**Network site 2**	**Unknown network site or not enabled for Location-Based Routing**
Authorization of outbound calls	Lync user 1 voice policy	Lync user 1 voice policy	Lync user 1 voice policy
Routing of outbound calls	Site 1 voice routing policy	Site 2 voice routing policy	User's voice policy and only to systems not enabled for Location-Based Routing

Call transfers and forwards

When calls are transferred or forwarded, the routing of calls is affected by Location-Based Routing.

The following table depicts Lync user 1 transferring or forwarding a PSTN call to another Lync user.

User initiating call transfer or forward	**Lync user 2**	**Lync user 4**	**Lync user in network site not enabled for Location-Based Routing**

Lync user 1	Call forward or transfer is allowed	Call forward or transfer is not allowed	Call forward or transfer is not allowed

The following table illustrates how Location-Based Routing affects how the call is routed based on the location of the Lync user being transferred (Lync user 2, Lync user 4, etc) to a PSTN endpoint

Endpoint where call is transferred or forwarded to	**Lync user 2**	**Lync user 4**	**Lync user in network site not enabled for Location-Based Routing**
PSTN endpoint	Call forward or transfer is routed through site 1 voice routing policy and egress via Site 1 Gateway	Call forward or transfer is routed through site 2 voice routing policy and egress via Site 2 Gateway	Call forward or transfer is routed through the Lync user voice policy and egress via a gateway not enabled for location-based routing (if available)

Simultaneous ringing

Once location-based routing is configured in the sample topology, the following interactions are enforced.

The following table illustrates whether Location-Based Routing allows simultaneous ringing for different Lync users (i.e. Lync user 2, Lync user 4, etc).

Incoming PSTN call target	**Lync user 2**	**Lync user 4**	**Lync user in network site not enabled for Location-Based Routing**
Lync user 1	Simultaneous ring is allowed	Simultaneous ring is not allowed	Simultaneous ring is not allowed

The following table illustrates whether Location-Based Routing allows simultaneous ringing to a PSTN endpoint from different Lync users (i.e. Lync user 2, Lync user 4, etc).

Simultaneous ring target	**Lync user 2**	**Lync user 4**	**Lync user in network site not enabled for Location-Based Routing**
Lync user 1 mobile phone (PSTN endpoint)	Call routed through network site 1's voice routing policy and egress via site 1 gateway	Call routed through network site 2's voice routing policy and egress via site 2 gateway	Call routed through the caller voice policy and will egress via a PSTN gateway not enabled for Location-Based Routing

1.3.10.13 Planning for Call Management Features

Planning for Call Management Features

Microsoft Lync Server 2013 > Planning > Planning for Enterprise Voice >

***Topic Last Modified:** 2012-12-17*

Enterprise Voice call management features control how incoming calls are routed and answered. Lync Server 2013 provides the following call management features:

- **Call Park**: Enables voice users to temporarily park a call and then pick it up from the same or another phone.
- **Group Pickup**: Enables voice users to pick up calls that are ringing for other voice users who are assigned to call pickup groups.

  Note:
  Group Pickup is new with Cumulative Updates for Lync Server 2013: February 2013.
- **Response Group**: Routes incoming calls to groups of agents by using hunt groups or interactive voice response (IVR) questions and answers.
- **Announcement:** Plays a message for calls made to an unassigned number, or routes the call elsewhere, or both.

If you plan to deploy Enterprise Voice, you can choose to implement any or all of these call management features.

- Deployment Process for Call Park

1.3.10.13.1.1 Overview of Call Park

Overview of Call Park

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Call Park >

***Topic Last Modified:** 2012-10-29*

The Lync Server 2013 Call Park application lets Enterprise Voice users do any of the following:

- Put a call on hold and then retrieve the call from the same phone or another phone.
- Put a call on hold to transfer it to a department or general area (for example, to a sales department or a warehouse where there is a common area phone).
- Put a call on hold and keep the original answering phone free for other calls.

When a user parks a call, Lync Server transfers the call to a temporary number, called an *orbit*, where the call is held until it is retrieved or it times out. Lync Server sends the orbit to the user who parked the call. To retrieve the parked call, the user can dial the orbit number or click the orbit link or button in the Conversation window.

The user who parked a call can notify someone to retrieve the call by using an external mechanism, such as instant messaging (IM) or a paging system, to communicate the orbit number to someone else. The user who parked the call can leave the Conversation window open to receive notification when the call is retrieved.

Because orbit ranges are globally unique, it is possible to retrieve calls from any Lync Server site or PBX phone if routing is configured appropriately. If no one retrieves the call within a configurable amount of time, the call rings back to the person who parked it. If that person does not answer the ringback, the call is transferred to a fallback destination, such as to an operator, if so configured. You can configure the number of times the call rings back before being transferred from one to ten times. If no one answers a transferred call, the call is disconnected. The orbit is freed when the call is retrieved or disconnected.

When you deploy Call Park, you need to reserve ranges of extension numbers for parking calls. These extensions need to be virtual extensions: extensions that have no user or phone assigned to them. You then configure the call park orbit table with the ranges of extension numbers and specify which Application service hosts the Call Park application that handles each range. Each Front End pool has a Call Park table on the corresponding Back End Server that is used to manage calls that are parked on the pool. The list of orbit ranges is stored in Central Management store and is used to route orbits to the destination pool. Each Lync Server pool where the Call Park application is deployed and configured can have one or more orbit ranges. Orbit ranges must be globally unique across the Lync Server deployment.

You also configure other Call Park settings, such as where calls are redirected if they time out and whether the person on the phone hears music while parked. You can also specify the music file to play while the call is on hold.

Note:

Customized music-on-hold files for Call Park are not backed up as part of the Lync Server 2013 disaster recovery process and will be lost if the files uploaded to the pool are damaged, corrupted, or erased. Always keep a separate backup copy of the customized music-on-hold files that you have uploaded for Call Park.

The Call Park application is a component of Enterprise Voice. When you deploy Enterprise Voice, the Call Park application is installed and activated automatically. Before you can use Call Park, however, the Enterprise Voice administrator must configure it and enable it for users through voice policy.

1.3.10.13.1.2 Components Used by Call Park

Components Used by Call Park

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Call Park >

Topic Last Modified: *2012-09-13*

The Call Park application is automatically installed when you deploy Enterprise Voice. You enable Call Park by configuring voice policy. The following Lync Server 2013 components support the Call Park application:

- **Application service** Application service provides a platform for deploying, hosting, and managing unified communications applications, such as the Call Park application. Application service is automatically installed on every Front End Server in a Front End pool and on every Standard Edition server.
- **Call Park application** The Call Park application is one of the unified communications applications that are hosted by Application service. It is included automatically when you deploy Enterprise Voice. Call Park parks and retrieves calls and manages call park orbits.
- **Music-on hold-file** If music in enabled, the music file is played while a call is parked. A default music file is included when the Call Park application is installed.
- **File Store** The Call Park application uses File Store to hold custom audio files.
- **Lync Server Control Panel** You can use Lync Server Control Panel to configure the call park orbit table and to enable Call Park for users.
- **Lync Server Management Shell** All Call Park application configuration can be performed by using Lync Server Management Shell cmdlets.

1.3.10.13.1.3 Technical Requirements for Call Park

Technical Requirements for Call Park

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Call Park >

Topic Last Modified: *2012-09-30*

This section describes the following technical requirements for Call Park:

- Hardware requirements
- Software requirements
- Port requirements
- Audio file requirements

Hardware Requirements

The Call Park application has the same hardware requirements as Front End Servers. For details about hardware requirements, see Server Hardware Platforms in the Supportability documentation.

Software Requirements

The Call Park application has the same operating system requirements and software prerequisites as Front End Servers. For details about software requirements, see Server and Tools Operating System Support in the Supportability documentation.

All Front End Servers and Standard Edition servers where the Call Park application is deployed must have the Windows Media Format Runtime installed for servers running

Windows Server 2008 R2, or Microsoft Media Foundation for servers running Windows Server 2012. For Windows Server 2008 R2, Windows Media Format Runtime is installed as part of Windows Desktop Experience. Windows Media Format Runtime or Microsoft Media Foundation is required for Windows Media Audio (.wma) files that Call Park plays for music on hold.

Port Requirements

The Call Park application uses the following port:

- **Port 5075** Used for SIP listening requests.

Note:

This port is a default setting that you can change by using the **Set-CsApplicationServer** cmdlet. For details about this cmdlet, see the Lync Server Management Shell documentation.

Audio File Requirements

The Call Park application supports only Windows Media Audio (.wma) files for music on hold. You can use the Microsoft Expression Encoder 4 to customize files for music on hold. To download Expression Encoder 4, see "Expression Encoder 4" at http://go.microsoft.com/fwlink/p/?linkId=202843. Use the tool to convert the file to a .wma format. The recommended format for Call Park music-on-hold files is Media Audio 9, 44 kHz, 16 bits, Mono, CBR, 32 kbps.

Note:

The converted file plays over the phone only at 16 kHz, even if it was recorded at 44 kHz.

1.3.10.13.1.4 Clients Supported for Call Park

Clients Supported for Call Park

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Call Park >

Topic Last Modified: *2012-09-13*

This section identifies the clients that can be used to park calls and the clients that can be used to retrieve parked calls.

Clients Supported for Parking Calls

Calls from any IP, private branch exchange (PBX), public switched telephone network (PSTN), or mobile phone can be parked.

Note:

Only audio calls can be parked. Instant messages and conferences cannot be parked.

The following clients can use Call Park to park calls:

- Lync 2013
- Lync 2010
- Lync 2010 Attendant
- Lync Phone Edition

Note:

Mobile phones cannot use Call Park to park calls.

Clients Supported for Retrieving Calls

Orbit ranges are configured as blocks of virtual extensions (extensions without an assigned user or phone). When you configure orbits as virtual extensions, mobile phones and PSTN phones cannot retrieve parked calls.

Federated users cannot retrieve parked calls.

The following clients can retrieve calls that are parked on Call Park:

- Lync 2013
- Lync 2010
- Lync 2010 Attendant
- Lync Phone Edition
- IP common area phones
- Non-IP phones that are connected to the Lync Server 2013 infrastructure, including common area phones and private branch exchange (PBX) phones

1.3.10.13.1.5 Capacity Planning for Call Park

Capacity Planning for Call Park

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Call Park >

Topic Last Modified: *2012-09-13*

The following table describes the Call Park user model that you can use as the basis for capacity planning requirements.

◆**Important:**
Keep in mind that, for disaster recovery capacity planning, each pool of a paired pool should be able to handle the workloads for Call Park services in both pools.

Call Park User Model

Metric	**Per Front End pool (with 8 Front End Servers)**	**Per Standard Edition server**
Park rate	8 per minute	1 per minute
Retrieve parked call rate	8 per minute	1 per minute
Average park duration	60 seconds	60 seconds

1.3.10.13.1.6 Deployment Process for Call Park

Deployment Process for Call Park

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Call Park >

Topic Last Modified: *2013-02-25*

This section provides an overview of the steps involved in deploying the Call Park application. You must deploy Enterprise Edition or Standard Edition with Enterprise Voice before you configure Call Park. The components required by Call Park are installed and enabled when you deploy Enterprise Voice.

Call Park Deployment Process

Phase	**Steps**	**Required groups**	**Deployment**

		and roles	documentation
Configure the call park orbit ranges in the orbit table	Use Lync Server Control Panel or the **New-CSCallParkOrbit** cmdlet to create the orbit ranges in the call park orbit table and associate them with the Application service that hosts the Call Park application. **Note:** For seamless integration with existing dial plans, orbit ranges are typically configured as a block of virtual extensions. Assigning Direct Inward Dialing (DID) numbers as orbit numbers in the call park orbit table is not supported.	RTCUniversalServerAdmins CsVoiceAdministrator CsServerAdministrator CsAdministrator	Create or Modify a Call Park Orbit Range
Configure Call Park settings	Use the **Set-CsCpsConfiguration** cmdlet to configure Call Park settings. At a minimum, we recommend that you configure the **OnTimeoutURI** option to configure the fallback destination to use when a parked call times out. You can also configure the following settings: • (Optional) **EnableMusicOnHold** to enable or disable music on hold. • (Optional) **MaxCallPickupAttempts** to determine the number of times a parked call rings back to the answering phone before forwarding the call to the fallback Uniform Resource Identifier (URI). • (Optional) **CallPickupTimeoutThreshold** to determine the amount of time that elapses after a call has been parked before it rings back to the phone where the call was answered.	RTCUniversalServerAdmins CsVoiceAdministrator CsServerAdministrator CsAdministrator	Configure Call Park Settings
Optionally, customize the	Use the **Set-CsCallParkServiceMusicOnHol**	RTCUniversalServerAdmins	Customize Call Park Music on Hold

music on hold	**dFile** cmdlet to customize and upload an audio file, if you don't want to use the default music on hold.	CsVoiceAdministrator CsServerAdministrator CsAdministrator	
Configure voice policy to enable Call Park for users	Use Lync Server Control Panel or the **Set-CSVoicePolicy** cmdlet with the **EnableCallPark** option to enable Call Park for users in voice policy. **Note:** By default, Call Park is disabled for all users. **Note:** If you have multiple voice policies, make sure the EnableCallPark property is set for each voice policy, not just for the default policy.	RTCUniversalServerAdmins CsVoiceAdministrator CsUserAdministrator CsAdministrator	Enable Call Park for Users
Verify normalization rules for Call Park	Call park orbits must not be normalized. Verify that your normalization rules do not include any of your orbit ranges. If necessary, create additional normalization rules to prevent orbits being normalized.	RTCUniversalServerAdmins CsVoiceAdministrator CsServerAdministrator CsAdministrator	Verify Normalization Rules for Call Park
Verify your Call Park deployment	Test parking and retrieving calls to make sure that your configuration works as expected.	-	(Optional) Verify Call Park Deployment

1.3.10.13.2 Planning for Group Call Pickup

Planning for Group Call Pickup

Planning > Planning for Enterprise Voice > Planning for Call Management Features >

Topic Last Modified: *2013-02-01*

Cumulative update for Lync Server 2013: February 2013 introduces Group Call Pickup as a new Enterprise Voice feature. Group Call Pickup lets users pick up calls that are ringing for another user by dialing a call pickup group number. This section includes planning information that is specific to Group Call Pickup.

- Overview of Group Call Pickup
- Components Used by Group Call Pickup
- Technical Requirements for Group Call Pickup
- Clients Supported for Group Call Pickup
- Deployment Process for Group Call Pickup

1.3.10.13.2.1 Overview of Group Call Pickup

Overview of Group Call Pickup

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Group Call Pickup >

Topic Last Modified: *2013-02-12*

Group Call Pickup, a new feature in Cumulative Updates for Lync Server 2013: February 2013, lets users answer incoming calls to their colleagues from their own phones. This new feature increases the availability of a user's line by enabling other users to answer an incoming call by dialing a call pickup group number. When Group Call Pickup is deployed, the number of incoming calls that are routed to voice mail can be significantly reduced, which is particularly useful for calls from customers who are external to your organization.

The Group Call Pickup feature is designed in particular for business units in open office environments. Incoming calls are not disruptive because they ring only at the intended destination. Other users who hear the ring, however, can still pick up the call simply by dialing the group number.

In environments where users are not located in an open office layout, or where users who share a common responsibility are geographically distributed, team call presents the most suitable solution. The primary difference between Group Call Pickup and team call is that, with Group Call Pickup, an incoming call rings only at the intended destination, but anyone can still choose to answer it by dialing a group number. With team call, the call rings at all the team members' phones, and any user in the team can pick up the phone to answer the call. An additional difference between Group Call Pickup and team call is that Group Call Pickup is managed by an administrator, through Lync Server. With team call, end users manage the feature by using the Lync client. With Group Call Pickup, therefore, this aspect of call management can be centralized.

Group Call Pickup is built on the Call Park application. When you deploy Group Call Pickup, you configure the call park orbit table with separate ranges of extension numbers that are designated as call pickup group numbers. Like call park orbit numbers, call pickup group numbers must be virtual extensions that have no user or phone assigned to them. Each Front End pool where you deploy Group Call Pickup can have one or more ranges of call pickup group numbers. The group number ranges must be globally unique across the Lync Server deployment.

Note:

Number ranges that are designated as Group Call Pickup numbers in the call park orbit table cannot be managed or viewed by using the Lync Server Control Panel. The only way to see all the number ranges in the call park orbit table is to use Lync Server Management Shell. Similarly, the only way to add, modify, or remove Group Call Pickup numbers is to use Lync Server Management Shell.

After you configure the call pickup group numbers, you assign users to a call pickup group. Any user who is assigned to a call pickup group can have their calls answered by other users. When a call comes in to a user who is assigned to a call pickup group, any other user who notices the call can answer it by manually dialing the call pickup group number. The user who picks up the call does not need to be a member of the group. When a call is picked up by another user, a notification is sent to the number originally called.

Note:

A user can be a member of only one call pickup group.

Note:

Although any user in the Lync Server deployment can answer a call to a call pickup group member, the person answering the call must know the correct call pickup group number to dial.

If a user dials a call pickup group number to answer a call when multiple phones in the group are ringing, the user answers the call that has been ringing the longest.

Simultaneous ringing settings will work for users who have group call pickup. That is, a call made to a user who has Group Call Pickup will ring for all the configured destinations, and another user can answer the call. The exception to this rule is when the user configures simultaneous ringing to call all the team members.

Group Call Pickup cannot be used to answer the following types of calls:

- Calls to a private line
- Calls from a contact who has been assigned the Friends and Family privacy relationship

  Tip:

  A user who is a member of a call pickup group can prevent certain calls from being retrieved through Group Call Pickup by marking the contact as a personal contact in the Lync client. To mark a contact as a personal contact, set the Privacy Relationship for the contact to Friends and Family. Any incoming call from contacts with the Privacy Relationship set to Friends and Family cannot be retrieved by using Group Call Pickup.
- Video portion of audio/video calls

  Note:

  If a user answers an audio/video call, the user receives only the audio. Either the person calling or the person answering the call can escalate the call to add video.
- Simultaneous ringing calls that are routed to team call members
- Calls routed to a delegate
- Calls routed to a response group

The following types of users cannot participate in Group Call Pickup. That is, they should not be included in a Group Call Pickup group, and they cannot pick up calls for users who have Group Call Pickup enabled.

- Users who are homed online in a hybrid deployment
- Users who are not homed on a Lync Server 2013 pool with Cumulative Updates for Lync Server 2013: February 2013 in an on-premises deployment

If no one answers a call to a member of a call pickup group, the call is routed as specified in the client settings. That is, the call goes to voicemail or is forwarded to a different destination, as specified in the client settings.

1.3.10.13.2.2 Components Used by Group Call Pickup

Components Used by Group Call Pickup

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Group Call Pickup >

Topic Last Modified: *2013-01-30*

Group Call Pickup is automatically deployed when you deploy Enterprise Voice and the Call Park application. You enable Group Call Pickup by configuring the Call Park orbit table with separate ranges of numbers designated as call pickup group numbers, and then by assigning users to call pickup groups and enabling the users for Group Call Pickup. The following Lync Server components support Group Call Pickup:

- **Application service** Application service provides a platform for deploying, hosting, and managing unified communications applications, such as the Call Park application. Application service is automatically installed on every Front End Server in a Front End pool and on every Standard Edition server.
- **Call Park application** The Call Park application is one of the unified communications applications that are hosted by Application service. Group Call Pickup is based on the Call Park application.
- **Lync Server Management Shell** You use Lync Server Management Shell to manage Group Call Pickup groups.
- **SEFAUtil resource kit tool** You use the secondary extension feature activation utility (SEFAUtil) to assign users to a call pickup group and to enable or disable call pickup for users.

1.3.10.13.2.3 Technical Requirements for Group Call Pickup

Technical Requirements for Group Call Pickup

See Also

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Group Call Pickup >

Topic Last Modified: *2013-01-30*

Group Call Pickup has the same hardware, software, and port requirements as the Call Park application. Group Call Pickup does not use audio files.

Concepts

Technical Requirements for Call Park

1.3.10.13.2.4 Clients Supported for Group Call Pickup

Clients Supported for Group Call Pickup

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Group Call Pickup >

Topic Last Modified: *2013-02-12*

Any of the following clients can be used to answer calls to Group Call Pickup members:

- Lync 2013
- Lync 2010
- Lync Phone Edition

Note:

Users can use any of these clients to answer calls to Group Call Pickup members, but the users must be homed on a Lync Server 2013 pool with Cumulative Updates for Lync Server 2013: February 2013.

In Cumulative Updates for Lync Server 2013: February 2013, the following clients and devices are not supported for picking up calls to Group Call Pickup members:

- Lync Mobile
- Lync app for Windows 8 and Windows RT
- Lync for iPad
- Analog phones
- Phones with public switched telephone network (PSTN) numbers

1.3.10.13.2.5 Capacity Planning for Group Call Pickup

Capacity Planning for Group Call Pickup

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Group Call Pickup >

Topic Last Modified: *2013-02-12*

The following table describes the Group Call Pickup user model that you can use as the basis for capacity planning requirements.

Important:

Group Call Pickup is based on the Call Park application. Keep in mind that, for disaster recovery capacity planning, each pool of a paired pool should be able to handle the workloads for Call Park services, including Group Call Pickup, in both pools.

Group Call Pickup User Model

Metric	Per Front End pool (with 8 Front End Servers)	Per Standard Edition server
Recommended number of users per group	50	50
Recommended number of groups	500	60
Maximum number of users per pool enabled for Group Call Pickup	25,000	3,000
Maximum rate of incoming calls to total users enabled for Group Call Pickup per pool per minute	500	60
Maximum rate of calls retrieved by users with Group Call Pickup per pool per minute	200	25

Note:

- For Front End pools that have fewer than eight Front End Servers, calculate the metrics linearly. For example, if your Front End pool has one Front End Server, calculate the maximum load as 1/8 of the values shown in the table.
- You can increase or decrease the recommended number of users per group and number of groups as long as you do not exceed the maximum number of users per pool. For example, your Standard Edition server can have 120 groups with 25 users per group because the number of users enabled for Group Call Pickup is still within the user model maximum (that is, 120 groups times 25 users is 3,000 users enabled for Group Call Pickup).

1.3.10.13.2.6 Deployment Process for Group Call Pickup

Deployment Process for Group Call Pickup

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Group Call Pickup >

Topic Last Modified: *2013-02-25*

This section provides an overview of the steps involved in deploying Group Call Pickup. You must deploy Enterprise Edition or Standard Edition with Enterprise Voice before you configure Group Call Pickup. The components required by Group Call Pickup are installed and enabled when you deploy Enterprise Voice.

Group Call Pickup Deployment Process

Phase	Steps	Required groups and roles	Deployment documentation
Enable the SEFAUtil resource kit tool in the topology	1. Use the **New-CsTrustedApplicationPool** cmdlet to create a new trusted application pool. 2. Use the **New-CsTrustedApplication** cmdlet to specify the SEFAUtil tool as trusted application. 3. Run the **Enable-CsTopology** cmdlet to enable the topology. 4. Install the resource kit tools on a Front End Server that is in the trusted application pool created in step 1. 5. Verify that SEFAUtil is running correctly by running it to display the call forwarding settings of a user in the deployment.	RTCUniversalServerAdmins	Deploy the SEFAUtil tool
Configure call pickup number ranges in the call park orbit table	Use the **New-CSCallParkOrbit** cmdlet to create call pickup number ranges in the call park orbit table and assign the call pickup ranges the type GroupPickup. **Note:** You must use Lync Server Management Shell to create, modify, remove, and view Group Call Pickup number ranges in the call park orbit table. Group Call Pickup number ranges are not available in Lync Server Control Panel. **Note:** For seamless integration with existing dial plans, number ranges are typically configured as a block of virtual extensions.	RTCUniversalServerAdmins CsVoiceAdministrator CsServerAdministrator CsAdministrator	Configure Call Pickup Group Numbers

	Assigning Direct Inward Dialing (DID) numbers as range numbers in the call park orbit table is not supported.		
Assign a call pickup number to users, and enable Group Call Pickup for the users	Use the /enablegrouppickup parameter in the SEFAUtil resource kit tool to enable Group Call Pickup and assign a call pickup number for users.	-	Enable Group Call Pickup for Users and Assign a Group Number
Notify users of their assigned call pickup number and any other number of interest	Because any user can retrieve a call made to a Group Call Pickup user, users may want to monitor more than one group.	-	Communicate Group Call Pickup Assignment to Users
Verify your Group Call Pickup deployment	Test placing and retrieving calls to make sure that your configuration works as expected.	-	(Optional) Verify the Group Call Pickup Deployment

1.3.10.13.3 Planning for Response Groups

Planning for Response Groups

Planning > Planning for Enterprise Voice > Planning for Call Management Features >

Topic Last Modified: *2012-06-19*

If your organization has groups of people who answer and manage certain types of calls, such as for customer service, an internal help desk, or general telephone support for a department, you can deploy the Lync Server Response Group application to manage these types of calls. The Response Group application routes and queues incoming calls to designated persons, who are known as agents. You can increase the use of telephone support services and reduce the overhead of running these services by using response groups. This section describes planning considerations for Response Group.

- Overview of Response Groups
- Components Used by Response Group
- Technical Requirements for Response Groups
- Clients Supported for Response Group
- Capacity Planning for Response Group
- Deployment Process for Response Group

1.3.10.13.3.1 Overview of Response Groups

Overview of Response Groups

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Response Groups >

Topic Last Modified: *2012-09-11*

When a caller calls a response group, the call is routed to an agent based on a hunt group or the caller's answers to interactive voice response (IVR) questions. The Response Group application uses standard response group routing methods to route the call to the next available agent. Call routing methods include serial, longest-idle, parallel, round robin, and Attendant routing (that is, all agents are called at the same time for every incoming call, regardless of their current presence). If no agents are available, the call is held in a queue until an agent is available. While in the queue, the caller hears music until an available agent accepts the call. If the queue is full, or if the call times out while in the queue, the caller might hear a message and then is either disconnected or transferred to a different destination. When an agent accepts the call, the caller might or might not be able to see the agent's identity, depending on how the administrator configures the response group. Agents can either be formal, which means that they must sign in to the group before they can accept calls routed to the group, or informal, which means that they do not sign into and out of the group to accept calls.

Note:

Only on-premises users can be agents. If an agent is moved from on-premises to online, Response Group calls will not be routed to that agent.

Note:

The Response Group application uses an internal service, called Match Making, to queue calls and find available agents. Each computer that runs the Response Group application runs the Match Making service, but only one Match Making service per Lync Server pool is active at a time--the others are passive. If the active Match Making service becomes unavailable during an unplanned outage, one of the passive Match Making services becomes active. The Response Group application does its best to make sure that call routing and queuing continues uninterrupted. However, when a Match Making service transition occurs, any calls that are in transfer at the time are lost. For example, if the transition is due to the Front End Server going down, any calls currently being handled by the active Match Making service on that Front End Server are also lost.

In Lync Server 2013, two management roles are available for managing response groups: Response Group Manager and Response Group Administrator. Response Group Administrators can manage any aspect of any response group. Response Group Managers can manage only certain aspects, and only for the response groups that they own. The new Manager role can help reduce administration costs, because you can delegate limited responsibilities for specific response groups to any user who is enabled for Enterprise Voice.

To accommodate the new Manager role, Lync Server 2013 Response Group application introduces a **Workflow Type** of Managed or Unmanaged. The following table describes Managed and Unmanaged response groups.

Managed and Unmanaged Response Groups

Response group type	Description
Unmanaged	• Unmanaged response groups have no assigned Managers. Only the Response Group Administrator can configure these response groups. • Multiple unmanaged response groups can share a queue or agent group. • When you migrate response groups from a prior version to Lync Server 2013, the type is set to Unmanaged.
Managed	• Response Group Administrators can configure any aspect of managed response groups. • Response Group Managers cannot view or modify response groups that are not explicitly assigned to them. • Response Group Managers can configure only some settings for the response groups that are explicitly

	assigned to them. - Managed response groups can't share any queues or agent groups with any other response group, managed or unmanaged.

The following table describes the actions that Response Group Managers can and cannot perform for the response groups assigned to them.

Response Group Manager Capabilities

Can configure:	Can create, delete, or configure:	Cannot:
- Agents - Welcome message - Response Group name - Description - Display number - Business hours - Music on hold - Status (active/ inactive) - Hunt group workflows or Interactive voice response (IVR) workflows	- Agent Groups - Queues - Holiday sets	- Create or delete any type of workflow - Modify core response group settings, such as: **SIP URI**, **Telephone Number**, or **Workflow Type**.

Response Group Managers can use the following tools to manage their designated response groups.

- Lync Server Control Panel

✎**Note:**
Response Group Managers can only manage Response Group settings with this tool. Other Lync Server settings are not available to Managers.

- Response Group Configuration Tool
- Lync Server Management Shell

Response Group scales well to departmental or workgroup environments (for details, see Capacity Planning for Response Group) and can be deployed in entirely new telephony installations. It supports incoming calls from the Enterprise Voice deployment and from the local carrier network. Agents can use Lync 2013, Lync 2010, Lync 2010 Attendant, or Lync Phone Edition to take the calls routed to them.

The Response Group application is a component of Enterprise Voice. When you deploy Enterprise Voice, the Response Group application is installed and activated automatically.

1.3.10.13.3.2 Components Used by Response Group

Components Used by Response Group

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Response Groups >

Topic Last Modified: *2012-09-11*

The Response Group application is automatically enabled when you deploy Enterprise Voice. This section describes the components that support the Response Group application.

Response Group Components

The following Microsoft Lync Server 2013 components support the Response Group application:

- **Application service** Application service provides a platform for deploying, hosting, and managing unified communications applications, such as Response Group. The Application service is automatically installed on every Front End Server in a Front End pool and on every Standard Edition server.
- **Response Group application** The Response Group application is one of the unified communications applications that are hosted by Application service. It is included automatically when you deploy Response Group. The Response Group application routes and queues incoming calls to groups of agents.
- **Language pack** A language pack is required to support text-to-speech and speech recognition. These speech technologies are used when you configure messages, such as the welcome message and other prompts, and interactive voice response (IVR) questions and answers. By default, the 26 supported language packs are installed when you deploy Lync Server 2013.
- **Audio files** Audio files are used for messages and on-hold music.
- **File Store** Response Group uses File store to store audio files. Multiple Response Group pools can use the same instance of File store.
- **Response Group Configuration Tool** The Response Group Configuration Tool is a web-based tool that is used to create and configure response groups. The Response Group Configuration Tool is included when you install Web Services.
- **Microsoft Lync Server 2013 Control Panel** You can use Lync Server Control Panel to setup and configure agent groups and queues for response groups.
- **Lync Server Management Shell** All Response Group settings can be configured by using Lync Server Management Shell cmdlets.
- **Microsoft Lync 2013** Formal agents (agents who are required to sign in to the group before they can accept calls for the group) use Lync 2013 to sign in to and sign out from the group. If an agent group is configured for formal agents, the agents click a menu item in Lync 2013 to open Internet Explorer and display a webpage console for signing in and out of the group.
- **Web Services** Web Services is required for Response Group Configuration Tool, the agents' sign-in and sign-out console, Lync Server Control Panel, and Response Group client web service.
- **Response Group Client Web Service** Response Group application provides a client web service, which can be used by third-party applications to retrieve information about agents, agent group membership, agent sign-in status, call status for groups, and the groups that support anonymous calls. Lync 2013 and Lync 2010 Attendant use Response Group Client Web service to retrieve the list of response groups that agents can use to make anonymous calls. The client web service is included when you install Web Services.

1.3.10.13.3.3 Technical Requirements for Response Groups

Technical Requirements for Response Groups

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Response Groups >

Topic Last Modified: *2012-09-12*

This section describes the following technical requirements for the Response Group application:

- Hardware requirements
- Software requirements
- Port requirements
- Audio file requirements
- Response Group configuration tool requirements

Hardware Requirements

The Response Group application has the same hardware requirements as Front End Servers. For details about hardware requirements, see Server Hardware Platforms in the Supportability documentation.

Software Requirements

The Response Group application has the same operating system requirements and software prerequisites as Front End Servers. For details about software requirements, see Server and Tools Operating System Support in the Supportability documentation.

If you use Windows Media Audio (.wma) files for Response Group music and announcements, all Front End Servers or Standard Editions servers that run the Response Group application must have the Windows Media Format Runtime installed for servers running Windows Server 2008 R2, or Microsoft Media Foundation for servers running Windows Server 2012. For Windows Server 2008 R2, Windows Media Format Runtime is installed as part of Windows Desktop Experience.

For more details about audio requirements, see "Audio File Requirements" later in this section.

Port Requirements

The Response Group application uses the following ports:

- **Port 5071** Used for SIP listening requests
- **Port 8404** Used for interserver communications

  Note:

  This port is used for the Match Making service and is required when the Response Group application is deployed in a pool that has more than one Front End Server.

Note:

These ports are default settings that you can change by using the **Set-CsApplicationServer** cmdlet. For details about this cmdlet, see the Lync Server Management Shell documentation.

Audio File Requirements

The Response Group application supports wave (.wav) file format and Windows Media audio (.wma) file format for Response Group messages, on-hold music, or interactive voice response (IVR) questions.

The Windows Media audio file format requires that the Windows Media Format Runtime is installed on Front End Servers running Windows Server 2008 R2 and Windows Server 2008. For more details, see "Software Requirements" earlier in this section.

Supported Wave File Formats

All wave files must meet the following requirements:

- 8-bit or 16-bit file
- Linear pulse code modulation (LPCM), A-Law, or mu-Law format
- Mono or stereo
- 4MB or less

For the best performance of wave files, a 16 kHz, mono, 16-bit Wave file is recommended.

Supported Windows Media Audio File Formats

If you use a Windows Media audio file, consider using low bit rates, and verify the performance of your system under load.

You can use the Microsoft Expression Encoder 4 to convert a file to the Windows Media Audio format. To download Expression Encoder 4, see http://go.microsoft.com/fwlink/p/?linkId=202843.

Response Group Configuration Tool Requirements

The Response Group Configuration Tool supports the combinations of operating systems and web browsers described in the following table.

Note:
32-bit or 64-bit versions of the operating systems are supported. Only 32-bit versions of Internet Explorer are supported.

Supported Operating Systems and Web Browsers

Operating system	**Web browser**
Windows Vista with Service Pack (SP) 2	Internet Explorer 7 Internet Explorer 8 (native mode) Internet Explorer 9 (native mode)
Windows 7 Windows 7 with Service Pack 1	Internet Explorer 8 (native mode) Internet Explorer 9 (native mode)
Windows Server 2008 with Service Pack 2	Internet Explorer 7 Internet Explorer 8 (native mode) Internet Explorer 9 (native mode)
Windows Server 2008 R2 Windows Server 2008 R2 with Service Pack 1	Internet Explorer 8 (native mode) Internet Explorer 9 (native mode)

Response Group Agent Console

The agent console supports the combinations of operating systems and web browsers described in the following table.

Note:
32-bit or 64-bit versions of the operating systems are supported. Only 32-bit versions of Internet Explorer are supported.

Supported Operating Systems and Web Browsers

Operating system	Web browser
Windows Vista with Service Pack (SP) 2	Internet Explorer 7 Internet Explorer 8 (native mode) Internet Explorer 9 (native mode)
Windows 7 Windows 7 with Service Pack 1	Internet Explorer 8 (native mode) Internet Explorer 9 (native mode) Firefox 10.0 Chrome 18.0
Windows Server 2008 with Service Pack 2	Internet Explorer 7 Internet Explorer 8 (native mode) Internet Explorer 9 (native mode)
Windows Server 2008 R2 Windows Server 2008 R2 with Service Pack 1	Internet Explorer 8 (native mode) Internet Explorer 9 (native mode) Firefox 10.0 Chrome 18.0

1.3.10.13.3.4 Clients Supported for Response Group

Clients Supported for Response Group

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Response Groups >

Topic Last Modified: *2012-12-04*

The Response Group application supports the following clients:

- Lync 2013
- Lync 2010
- Lync 2010 Attendant
- Office Communications Server 2007 R2 Attendant
- Lync Phone Edition

◆**Important:**

For details about new features, see New Response Group Application Features in the Getting Started documentation.

The specific client that you can use depends on the type of Response Group user that you are:

- **Callers** can call a response group by using any of the clients listed previously, and by using a standard telephone over the public switched telephone network (PSTN).

- **Informal agents** (agents who do not sign into and out of their groups to accept calls) can accept calls by using Attendant, Lync, or Lync Phone Edition. Informal agents are automatically signed into their groups when they sign in to Lync Server 2013 by using one of these clients.
- **Formal agents** (agents who must sign into and out of their groups to accept calls) can accept calls by using Lync 2013 and accessing the agent console from the menu item, or by using Attendant and accessing the agent console directly from Internet Explorer.

1.3.10.13.3.5 Capacity Planning for Response Group

Capacity Planning for Response Group

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Response Groups >

Topic Last Modified: *2012-10-29*

The following table describes the Response Group user model that you can use as the basis for capacity planning requirements.

Note:

The numbers in the following table assume that you use 16 kHz, mono, 16-bit Wave (.wav) files for all response group audio files. If you use other file formats, such as Windows Media Audio (.wma), the numbers may vary.

Important:

Keep in mind that for disaster recovery capacity planning, each pool of a paired pool should be able to handle the workloads for all the response groups in both pools.

Response Group User Model

Metric	Per Enterprise Edition pool (With 8 Front End Servers)	Per Standard Edition server
Incoming calls per second	16	2
Concurrent calls connected to IVR or MoH	480	60
Concurrent anonymous sessions (without IM)	224	28
Concurrent anonymous sessions (with IM)	64	8
Active agents (formal and informal)	1200	1200
Number of hunt groups	400	400
Number of IVR groups (use speech recognition)	200	200

1.3.10.13.3.6 Deployment Process for Response Group

Deployment Process for Response Group

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Response Groups >

Topic Last Modified: *2012-09-27*

This section provides an overview of the phases and steps involved in deploying the Response Group application.

Response Group Deployment Process

Phase	Steps	Permissions	Deployment documentation
Install the Response Group application	The Response Group application is installed and activated by default when you deploy Enterprise Voice.	RTCUniversalServerAdmins	Deploying Enterprise Voice
Install components for Response Group	Lync Server cmdlets, the Lync Server Control Panel, Response Group Configuration Tool, agents' sign-in and sign-out console, and Response Group Client Web service are installed as part of Web Services. Web Services is installed when you deploy an Enterprise Edition pool or a Standard Edition server.	RTCUniversalServerAdmins	Deploying Lync Server 2013
Enable users for Lync 2013 and for Enterprise Voice	Enable users who will be agents for Lync Server and Enterprise Voice. Users must be enabled before you can add them to agent groups. Typically, users are enabled for Lync Server during the Enterprise Edition or Standard Edition server deployment. Users are enabled for Enterprise Voice during the Enterprise Voice deployment.	RTCUniversalUserAdmins CsUserAdministrator CsAdministrator	Disable or Re-Enable User Account for Lync Server Enable Users for Enterprise Voice
Create and configure response groups, which consist of agent groups, queues, and workflows	1. Use the Lync Server Control Panel or Lync Server Management Shell to do the following: 1.a. Create and configure agent groups. 1.b. Create and configure queues. 2. Optionally, use Lync Server Management Shell to create predefined response group business hours and holidays. 3. Use the Response Group Configuration	RTCUniversalServerAdmins CsResponseGroupAdministrator CsVoiceAdministrator CsServerAdministrator CsAdministrator CsResponseGroupManager	Create Response Group Agent Groups Create Response Group Queues (Optional) Define Response Group Business Hours (Optional) Define Response Group Holiday Sets Create or Modify a Workflow

	Tool or Lync Server Management Shell to create workflows (hunt groups or interactive voice response (IVR) call flows), including custom response group business hours and holidays. **Note:** You can access the Response Group Configuration Tool through Lync Server Control Panel.		
(Optional) Customize application-level settings	Use Lync Server Management Shell to customize the default music-on-hold configuration, the default music-on-hold audio file, the agent ringback grace period, and the call context configuration.	RTCUniversalServerAdmins CsResponseGroupAdministrator CsVoiceAdministrator CsServerAdministrator CsAdministrator	Managing Application-Level Response Group Settings
(Optional) Delegate management of response groups	Assign users the CsResponseGroupManager role to delegate configuration of response groups. Response Group Managers can then configure the response groups assigned to them.	RTCUniversalServerAdmins CsResponseGroupAdministrator CsVoiceAdministrator CsServerAdministrator CsAdministrator	Planning for Role-Based Access Control
Verify your Response Group deployment	Test answering calls to your hunt group and interactive voice response workflows to ensure that your configuration works as expected.	-	-

1.3.10.13.4 Planning for Announcements

Planning for Announcements

Planning > Planning for Enterprise Voice > Planning for Call Management Features >

Topic Last Modified: *2012-09-13*

The Lync Server Announcement application lets you configure the handling of incoming phone calls when the dialed number is valid for your organization, but is not assigned to a user or a phone. You can transfer these calls to a predetermined destination (phone number, SIP URI, or voice mail), or play an audio announcement, or both. The Announcement application helps you avoid the situations in which a caller misdials and hears a busy tone or the SIP client receives an error message. This section includes planning information that is specific to the Announcement application.

- Overview of Announcements
- Components Used by Announcements
- Technical Requirements for Announcements
- Deployment Process for Announcements

1.3.10.13.4.1 Overview of Announcements

Overview of Announcements

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Announcements >

Topic Last Modified: *2012-09-13*

When you deploy the Announcement application, you need to configure an unassigned number table that determines the action to be taken when someone dials an unassigned number. The unassigned number table contains ranges of phone numbers that are valid for the organization and specifies which Announcement application handles each range. When a caller dials a telephone number that is valid for your organization but is not assigned to anyone, Lync Server looks up the number in the unassigned number routing table, identifies which range the number falls in, and routes the call to the Announcement application specified for that range. The Announcement application answers the call and plays an audio message (if you configured it to do so) and then either disconnects the call or transfers it to a predetermined destination, such as to an operator. You can use Lync Server Management Shell cmdlets to configure multiple audio messages or to transfer destinations.

How you configure the unassigned number table depends on how you want to use it. If you have specific numbers that are no longer in use and you want to play messages that are tailored for each number, you can enter those specific numbers in the unassigned number table. For example, if you changed the number for your customer service desk, you can enter the old customer service number and associate it with an announcement that gives the new number. If you want to play a general message to anyone who calls a number that is not assigned, such as for employees who have left your organization, you can enter ranges for all the valid extensions in your organization. The unassigned number table is invoked whenever the caller dials a number that is not currently assigned.

In Lync Server 2013, the Announcement application is automatically installed with the Response Group application. The Announcement and Response Group applications are standard components of an Enterprise Voice deployment: When you deploy Enterprise Voice, both of these applications are automatically deployed.

1.3.10.13.4.2 Components Used by Announcements

Components Used by Announcements

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Announcements >

Topic Last Modified: *2012-09-13*

In Lync Server 2013, the Announcement application is a component of the Response Group application. When you deploy Enterprise Voice, the Announcement application is automatically installed and activated along with the Response Group application. This section describes the components that support the Announcement application.

Announcement Application Components

The following Lync Server components support the Announcement application:

- **Application service** Application service provides a platform for deploying, hosting, and managing unified communications applications. Application service is automatically installed on every Front End Server in a Front End pool and on every Standard Edition server.
- **Response Group application** The Response Group application is one of the unified communications applications that are hosted by Application service. When an unassigned phone number range is configured to route to an announcement, the Response Group application is required to route the calls made to the phone number. (Response Group application is not required if all the ranges are configured to route to Exchange Unified Messaging (UM).)
- **Audio files** Audio files are used for the announcements.
- **File Store** The Announcement application uses File Store to store its audio files.
- **Lync Server Control Panel** You can use Lync Server Control Panel to configure the unassigned number table.
- **Lync Server Management Shell** You can use Lync Server Management Shell cmdlets to configure Announcement settings and the unassigned number table.

1.3.10.13.4.3 Technical Requirements for Announcements

Technical Requirements for Announcements

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Announcements >

***Topic Last Modified:** 2012-09-13*

This section describes the following technical requirements for the Announcement application:

- Hardware requirements
- Software requirements
- Port requirements
- Audio file requirements

Hardware Requirements

The Announcement application has the same hardware requirements as Front End Servers. For details about hardware requirements, see Server Hardware Platforms in the Supportability documentation.

Software Requirements

The Announcement application has the same operating system requirements and software prerequisites as Front End Servers. For details about software requirements, see Server and Tools Operating System Support in the Supportability documentation.

All Front End Servers or Standard Edition servers that run the Announcement application must have the Windows Media Format Runtime installed for servers running Windows Server 2008 R2, or Microsoft Media Foundation for servers running Windows Server 2012. For Windows Server 2008 R2, the Windows Media Format Runtime is installed as part of Windows Desktop Experience. Windows Media Format Runtime or Microsoft Media Foundation is required for Windows Media Audio (.wma) files that the Announcement application plays for announcements and music.

Port Requirements

The Announcement application uses the following port:

- **Port 5071** Used for SIP listening requests

Note:

This port is the default setting, which you can change by using the **Set-CsApplicationServer** cmdlet. For details about this cmdlet, see the Lync Server Management Shell documentation.

Audio File Requirements

The Announcement application supports Wave (.wav) file format and Windows Media audio (.wma) file format for music and announcements. Audio file requirements for the Announcement application are the same as for the Response Group application. For details, see Technical Requirements for Response Groups.

1.3.10.13.4.4 Deployment Process for Announcements

Deployment Process for Announcements

Planning for Enterprise Voice > Planning for Call Management Features > Planning for Announcements >

Topic Last Modified: *2012-09-12*

This section provides an overview of the steps involved in deploying the Announcement application. You must deploy Enterprise Voice before you configure announcements. The components required by the Announcement application are installed and enabled when you deploy Enterprise Voice.

1.3.10.14 Planning for Enterprise Voice Resiliency

Planning for Enterprise Voice Resiliency

Microsoft Lync Server 2013 > Planning > Planning for High Availability and Disaster Recovery >

Topic Last Modified: *2012-09-22*

Voice resiliency refers to the ability of users to continue making and receiving calls if a central site that hosts Microsoft Lync Server 2010 becomes unavailable, whether through a wide area network (WAN) failure or another cause. If a central site fails, Enterprise Voice service must continue uninterrupted through seamless failover to a backup site. In the event of WAN failure, branch site calls must be redirected to a local PSTN gateway. This section discusses planning for voice resiliency in the event of central-site or WAN failure.

- Planning for Central Site Voice Resiliency
- Planning for Branch-Site Voice Resiliency

1.3.10.14.1 Planning for Central Site Voice Resiliency

Planning for Central Site Voice Resiliency

See Also

Planning > Planning for High Availability and Disaster Recovery > Planning for Enterprise Voice Resiliency >

Topic Last Modified: *2012-09-28*

Increasingly, enterprises have multiple sites spread across the globe. Maintaining emergency services, access to help desk, and the ability to conduct critical business tasks when a central site is out of service is essential for any Enterprise Voice resiliency solution. When a central site becomes unavailable, the following conditions must be met:

- Voice failover must be provided.
- Users who ordinarily register with the Front End pool at the central site must be able to register with an alternative Front End pool. This can be done by creating multiple DNS SRV records, each of which resolves to a Director pool or Front End pool in each of your central sites. You can adjust the priority and weights of the SRV records so that users who are served by that central site get the corresponding Director and Front End pool ahead of those in other SRV records.
- Calls to and from users located at other sites must be rerouted to the PSTN.

This topic describes the recommended solution for securing central site voice resiliency.

Architecture and Topology

Planning for voice resiliency at a central site requires a basic understanding of the central role played by the Lync Server 2013 Registrar in enabling voice failover. The Lync Server Registrar is a server role that enables client registration and authentication and provides routing services. It resides along with other components on a Standard Edition server, Front End Server, Director, or Survivable Branch Appliance. A Registrar pool consists of Registrar Services running on the Front End pool and residing at the same site. The Front End pool must be load balanced. DNS load balancing is recommended, but hardware load balancing is acceptable. A Lync client discovers the Front End pool through the following discovery mechanism:

1. DNS SRV record
2. Autodiscovery Web Service (new in Lync Server 2013)
3. DHCP option 120

After the Lync client connects to the Front End pool, it is directed by the load balancer to one of the Front End Servers in the pool. That Front End Server, in turn, redirects the client to a preferred Registrar in the pool.

Each user enabled for Enterprise Voice is assigned to a particular Registrar pool, which becomes that user’s primary Registrar pool. At a given site, hundreds or thousands of users typically share a single primary Registrar pool. To account for the consumption of central site resources by any branch site users that rely on the central site for presence, conferencing, or failover, we recommend that you consider each branch site user as though the user were a user registered with the central site. There are currently no limits on the number of branch site users, including users registered with a Survivable Branch Appliance.

To assure voice resiliency in the event of a central site failure, the primary Registrar pool must have a single designated backup Registrar pool located at another site. The backup can be configured by using Topology Builder resiliency settings. Assuming a resilient WAN link between the two sites, users whose primary Registrar pool is no longer available are automatically directed to the backup Registrar pool.

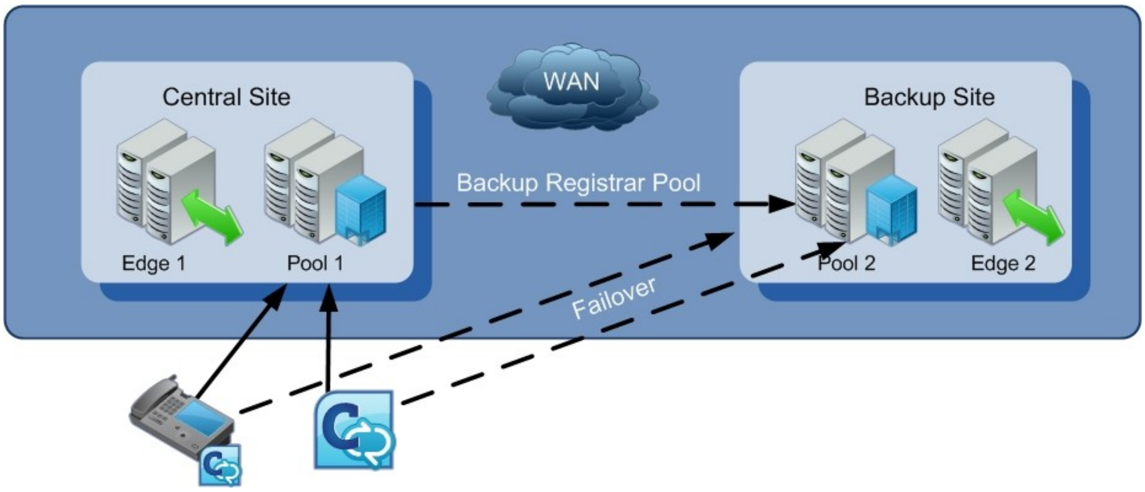
The following steps describe the client discovery and registration process:

1. A client discovers Lync Server through DNS SRV records. In Lync Server 2013, DNS SRV records can be configured to return more than one FQDN to the DNS SRV query. For example, if enterprise Contoso has three central sites (North America, Europe, and Asia-Pacific) and a Director pool at each central site, DNS SRV records can point to the Director pool FQDNs in each of the three locations. As long as the Director pool in one of the locations is available, the client can connect to the first hop Lync Server.

   Note:
   Using a Director pool is optional. A Front End pool can be used instead.

2. The Director pool informs the Lync client about the user’s primary Registrar pool and backup Registrar pool.
3. The Lync client attempts to connect to the user’s primary Registrar pool first. If the primary Registrar pool is available, the Registrar accepts the registration. If the primary Registrar pool is unavailable, the Lync client attempts to connect to the backup Registrar pool. If the backup Registrar pool is available and has determined that the user’s primary Registrar pool is unavailable (by detecting a lack of heartbeat for a specified failover interval) the backup Registrar pool accepts the user’s registration. After the backup Registrar detects that the primary Registrar is again available, the backup Registrar pool will redirect failover Lync clients to their primary pool.

The following figure shows the recommended topology for assuring central site resiliency. The two sites are connected by a resilient WAN link. If the central site becomes unavailable, users who are assigned to that pool are directed to the backup site for registration.



Requirements and Recommendations

The following requirements and recommendations for implementing central site voice resiliency are appropriate for most organizations:

- The sites in which the primary and backup Registrar pools reside should be connected by a resilient WAN link.
- Each central site must contain a Registrar pool consisting of one or more Registrars.
- Each Registrar pool must be load-balanced by using DNS load balancing or hardware load balancing.
- Each user must be assigned to a primary Registrar pool by using either the Lync Server Management Shell **set-CsUser** cmdlet or the Lync Server Control Panel.
- The primary Registrar pool must have a single backup Registrar pool located in a different central site.
- The primary Registrar pool must be configured to fail over to the backup Registrar pool. By default, the primary Registrar is set to fail over to the backup Registrar pool after an interval of 300 seconds. You can change this interval by using the Lync Server 2013 Topology Builder.
- Configure a failover route, as described in the "Configuring a Failover Route" topic in the Planning documentation. When configuring the route, specify a gateway that is located at a different site from the gateway specified in the primary route.
- If the central site contained your primary management server and the site is likely to be down for an extended period, you will need to reinstall your management tools at the backup site; otherwise, you won't be able to change any management settings.

Dependencies

Lync Server depends on the following infrastructure and software components to assure voice resiliency:

Component	**Functional**
DNS	Resolving SRV records and A records for server-server and server-client connectivity
Exchange and Exchange Web Services (EWS)	Contact storage; calendar data

Exchange Unified Messaging and Exchange Web Services	Call logs, voice mail list, voice mail
DHCP Options 120	If DNS SRV is unavailable, the client will attempt to use DHCP Option 120 to discover the Registrar. For this to work, either a DHCP server must be configured or Lync Server 2013 DHCP must be enabled. For details, see Hardware and Software Requirements for Branch-Site Resiliency in Branch-Site Resiliency Requirements section.

Survivable Voice Features

If the preceding requirements and recommendations have been implemented, the following voice features will be provided by the backup Registrar pool:

- Outbound PSTN calls
- Inbound PSTN calls, if the telephony service provider supports the ability to fail over to a backup site
- Enterprise calls between users at both the same site and between two different sites
- Basic call handling, including call hold, retrieval, and transfer
- Two-party instant messaging and sharing audio and video between users at the same site
- Call forwarding, simultaneous ringing of endpoints, call delegation, and team call services, but only if both parties to call delegation, or all team members, are configured at the same site.
- Existing phones and clients continue to work.
- Call detail recording (CDR)
- Authentication and authorization

Depending on how they are configured, the following voice features may or may not work when a primary central site is out of service:

- Voice mail deposit and retrieval
  If you want to make Exchange UM available when the primary central site is out of service, you must do one of the following:
  - Change DNS SRV records so that the Exchange UM servers at the central site point to backup Exchange UM servers at another site.
  - Configure each user’s Exchange UM dial plan to include Exchange UM servers at both the central site and the backup site, but designate the backup Exchange UM servers as disabled. If the primary site becomes unavailable, the Exchange administrator has to mark the Exchange UM servers at the backup site as enabled.

  If neither of the preceding solutions is possible, then Exchange UM will not be available in the event the central site becomes unavailable.
- Conferencing of all types
  A user who has failed over to a backup site can join a conference that is created or hosted by an organizer whose pool is available but cannot create or host a conference on his or her own primary pool, which is no longer available. Similarly, others users cannot join conferences that are hosted on the affected user’s primary pool.

The following voice features do not work when a primary central site is out of service:

- Conference Auto-Attendant
- Presence and DND-based routing
- Updating call forwarding settings
- Response Group service and Call Park

- Provisioning new phones and clients
- Address Book Web Search

Planning for Branch-Site Voice Resiliency

1.3.10.14.2 Planning for Branch-Site Voice Resiliency

Planning for Branch-Site Voice Resiliency

Planning > Planning for High Availability and Disaster Recovery > Planning for Enterprise Voice Resiliency >

Topic Last Modified: *2012-09-21*

If you want to provide branch-site resiliency, that is, high-availability Enterprise Voice service, you have three options for doing so:

- Survivable Branch Appliance
- Survivable Branch Server
- A full Lync Server deployment at the branch site

This guide will help you evaluate which resiliency solution is best for your organization and, based on your resiliency solution, which PSTN-connectivity solution to use. It will also help you prepare to deploy the solution that you choose by describing prerequisites and other planning considerations.

- Branch-Site Resiliency Features
- Branch-Site Resiliency Solutions
- Branch-Site Resiliency Requirements

1.3.10.14.2.1 Branch-Site Resiliency Features

Branch-Site Resiliency Features

Planning for High Availability and Disaster Recovery > Planning for Enterprise Voice Resiliency > Planning for Branch-Site Voice Resiliency >

Topic Last Modified: *2012-10-10*

If you provide branch-site resiliency, if a branch site's WAN connection to a central site fails or if the central site is unreachable, the following voice features should continue to be available:

- Inbound and outbound public switched telephone network (PSTN) calls
- Enterprise calls between users at both the same site and between two different sites
- Basic call handling, including call hold, retrieval, and transfer
- Two-party instant messaging
- Call forwarding, simultaneous ringing of endpoints, call delegation, and team call services, but only if the delegator and delegate (for example, a manager and the manager's administrator), or all team members, are configured at the same site
- Call detail records (CDRs)
- PSTN dial-in conferencing with Conferencing Auto-Attendant
- Voice mail capabilities, if you configure voice mail rerouting settings. (For details, see Branch-Site Resiliency Requirements.)
- User authentication and authorization

The following features will be available only if your resiliency solution is a full-scale Lync Server deployment at the branch site:

- IM, web, and A/V conferencing
- Presence and Do Not Disturb (DND)-based routing (where calls are prevented from ringing on extensions that have DND activated)
- Updating call forwarding settings
- Response Group application and Call Park application
- Provisioning new phones and clients, but only if Active Directory Domain Services (AD DS) is present at the branch site.
- Enhanced 9-1-1 (E9-1-1)
  If E9-1-1 is deployed, and the SIP trunk at the central site is not available because the WAN link is down, then the Survivable Branch Appliance will route E9-1-1 calls to the local branch gateway. To enable this feature, the branch-site users' voice policies should route calls to the local gateway in the event of WAN failure.

1.3.10.14.2.2 Branch-Site Resiliency Solutions

Branch-Site Resiliency Solutions

See Also

Planning for High Availability and Disaster Recovery > Planning for Enterprise Voice Resiliency > Planning for Branch-Site Voice Resiliency >

Topic Last Modified: *2012-09-23*

There are obvious advantages to providing branch-site resiliency to your organization. Specifically, if you lose the connection to the central site, branch site users will continue to have Enterprise Voice service and voice mail (if you configure voice mail rerouting settings; for details, see Branch-Site Resiliency Requirements). However, for sites with fewer than 25 users, a resiliency solution may not provide a sufficient return on investment.

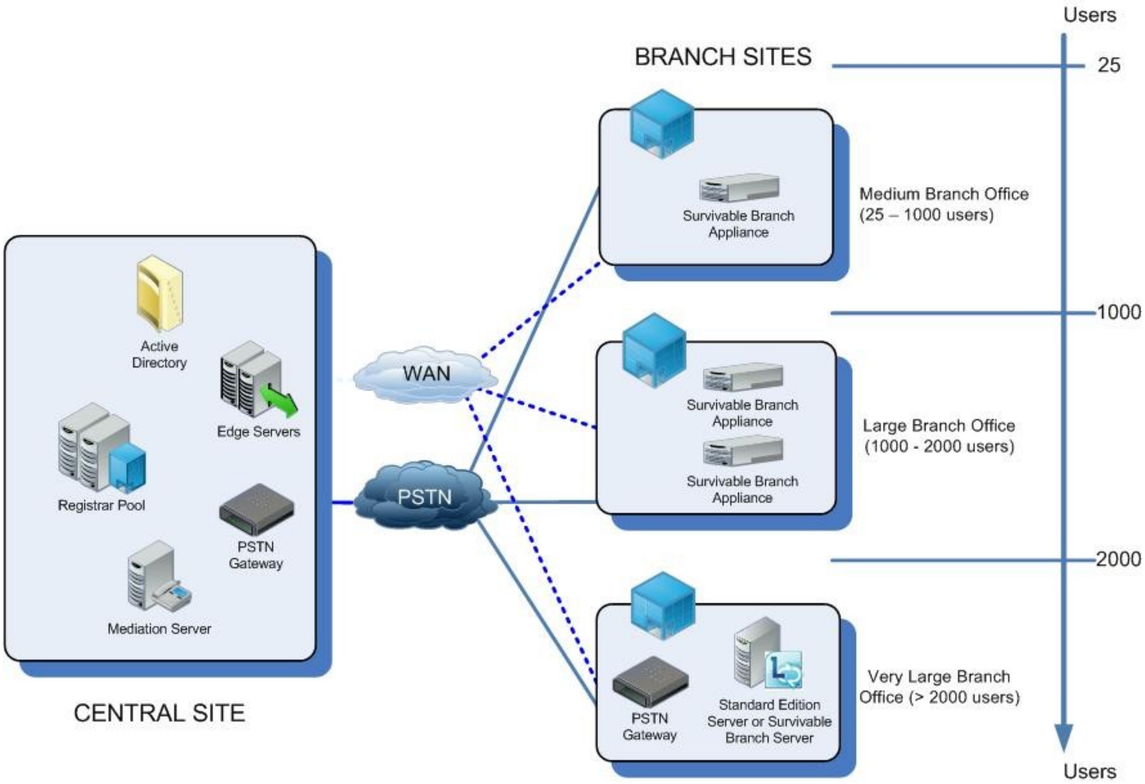
If you decide to provide branch-site resiliency, you have three options. The following table can help you determine the best option for your organization.

If you...	We recommend that you use a...
Host between 25 and 1000 users at your branch site, and if the return on investment does not support a full deployment or where local administrative support is unavailable	Survivable Branch Appliance The Survivable Branch Appliance is an industry-standard blade server with a Lync Server Registrar and Mediation Server running on Windows Server 2008 R2. The Survivable Branch Appliance also contains a public switched telephone network (PSTN) gateway. Qualified third-party devices (developed by Microsoft partners in the Survivable Branch Appliance (SBA) qualification/certification program) provide a continuous PSTN connection in the event of WAN failure, but this approach does not provide resilient presence and conferencing because these features depend on Front End Servers at the central site. For details about Survivable Branch Appliances, see "Survivable Branch Appliance Details," later in this topic.

	Note: If you decide to also use a SIP trunk with your Survivable Branch Appliance, contact your Survivable Branch Appliance vendor to learn about which service provider is best for your organization.
Host between 1000 and 2000 users at your branch site, lack a resilient WAN connection, and have trained Lync Server administrators available	Survivable Branch Server or two Survivable Branch Appliances. The Survivable Branch Server is a Windows Server meeting specified hardware requirements that has Lync Server Registrar and Mediation Server software installed on it. It must connect to either a PSTN gateway or a SIP trunk to a telephone service provider. For details about Survivable Branch Servers, see "Survivable Branch Server Details," later in this topic.
If you require presence and conferencing features in addition to voice features for up to 5000 users, and have trained Lync Server administrators available	Deploy as a central site with a Standard Edition server rather than as a branch site. A full-scale Lync Server deployment provides a continuous PSTN connection and resilient presence and conferencing in the event of WAN failure. For details about preparing for this solution, see Planning Primer: Planning for Your Organization, Determining Your System Requirements, Determining Your Infrastructure Requirements, and other relevant sections of the Planning documentation.

Resiliency Topologies

The following figure shows the recommended topologies for branch-site resiliency.



Users
BRANCH SITES
25
Survivable Branch Appliance
Medium Branch Office (25 – 1000 users)
1000
Survivable Branch Appliance
Survivable Branch Appliance
Large Branch Office (1000 - 2000 users)
2000
PSTN Gateway
Standard Edition Server or Survivable Branch Server
Very Large Branch Office (> 2000 users)
Users
Active Directory
Edge Servers
Registrar Pool
PSTN Gateway
Mediation Server
WAN
PSTN
CENTRAL SITE

Survivable Branch Appliance Details

The Lync Server Survivable Branch Appliance includes the following components:

- A Registrar for user authentication, registration and call routing
- A Mediation Server for handling signaling between the Registrar and a PSTN gateway
- A PSTN gateway for routing calls to the PSTN as a fallback transport in the event of a WAN outage
- SQL Server Express for local user data storage

The Survivable Branch Appliance also includes PSTN trunks, analog ports, and an Ethernet adapter.

If the branch site’s WAN connection to a central site becomes unavailable, internal branch users continue to be registered with the Survivable Branch Appliance Registrar and obtain uninterrupted voice service by using the Survivable Branch Appliance connection to the PSTN. Branch site users who connect from home or other remote locations will be able to register with a Registrar server at a central site if the WAN link to the branch site is unavailable. These users will have full unified communications functionality, with the one exception that inbound calls to the branch site will go to voice mail. When the WAN connection becomes available, full functionality should be restored to branch site users. Neither the failover to the Survivable Branch Appliance nor the restoration of service requires the presence of an IT administrator.

Lync Server supports up to two Survivable Branch Appliance at a branch site.

Survivable Branch Appliance Deployment Overview

The Survivable Branch Appliance is manufactured by original equipment manufacturers in partnership with Microsoft and deployed on their behalf by value-added retailers. This deployment should occur only after Lync Server has been deployed at the central site, a WAN connection to the branch site is in place, and branch site users are enabled for Enterprise Voice.

For details about these phases, see Deploying a Survivable Branch Appliance or Server in the Deployment documentation.

Phase	Steps	User Rights
Set up Active Directory Domain Services for the Survivable Branch Appliance	**At the central site:** 1. Create a domain user account (or enterprise identity) for the technician who will install and activate the Survivable Branch Appliance at the branch site. 2. Create a computer account (with the applicable fully qualified domain name (FQDN)) for Survivable Branch Appliance in Active Directory Domain Services. 3. In Topology Builder, create and publish the Survivable Branch Appliance.	The technician user account must be a member of RTCUniversalSBATechnicians. The Survivable Branch Appliance must belong to the RTCSBAUniversalServices group, which happens automatically when you use Topology Builder.
Install, and activate the Survivable Branch Appliance.	**At the branch site:** 1. Connect the Survivable Branch Appliance to an Ethernet port and PSTN port. 2. Start the Survivable Branch Appliance. 3. Join the Survivable Branch Appliance to the domain, using the domain user account created for the Survivable Branch Appliance at the central site. Set the FQDN and IP address to match the FQDN created in the computer account. 4. Configure the Survivable Branch Appliance using the OEM user interface. 5. Test PSTN connectivity.	The technician user account must be a member of RTCUniversalSBATechnicians.

Survivable Branch Server Details

In Topology Builder create the branch site, add the Survivable Branch Server to that site, and then run the Lync Server Deployment Wizard on the computer where you want to install the role.

1.3.10.14.2.3 Branch-Site Resiliency Requirements

Branch-Site Resiliency Requirements

Planning for High Availability and Disaster Recovery > Planning for Enterprise Voice Resiliency > Planning for Branch-Site Voice Resiliency >

Topic Last Modified: *2012-10-18*

This topic will help you to prepare users for branch-site resiliency and voice mail survivability, and also specifies the relevant hardware and software requirements.

Preparing Branch Users for Branch-Site Resiliency

Prepare users for branch-site resiliency by setting their Registrar pool as the Survivable Branch Appliance (SBA) or Survivable Branch Server.

Registrar Assignments for Branch Users

Regardless of which branch-site resiliency solution you choose, you will need to assign a primary Registrar to each user. Branch site users should always register with the Registrar at the branch site, regardless of whether that Registrar resides in the Survivable Branch Appliance, Survivable Branch Server, or stand-alone Lync Server 2013 Standard or Enterprise Edition server. A domain name system (DNS) service (SRV) resource record is required so that a client can discover its Registrar pool. If the Survivable Branch Appliance becomes unavailable, this is how branch site clients will automatically discover the backup Registrar.

If a branch site does not have a DNS server, there are two alternative ways to configure discovery of the Survivable Branch Appliance or Survivable Branch Server:

- Configure DHCP option 120 on the branch site’s Dynamic Host Configuration Protocol (DHCP) server to point to the fully qualified domain name (FQDN) of the Survivable Branch Appliance or Survivable Branch Server.
- Configure the Survivable Branch Appliance or Survivable Branch Server to respond to DHCP 120 queries.

Voice Routing for Branch Users

We recommend that you create a separate user-level Voice over Internet Protocol (VoIP) policy for users in a branch site. This policy should include a primary route that uses the Survivable Branch Appliance or branch server gateway, and one or more backup routes that use a trunk with a public switched telephone network (PSTN) gateway at the central site. If the primary route is unavailable, the backup route that uses one or more central site gateways is used instead. This way, regardless of where a user is registered—on the branch site Registrar or the backup Registrar pool at the central site—the user’s VoIP policy is always in effect. This is an important consideration for failover scenarios. For example, if you need to rename the Survivable Branch Appliance or reconfigure the Survivable Branch Appliance to connect to a backup Registrar pool at the central site, then you must move branch site users to the central site for the duration. (For details about renaming or reconfiguring a Survivable Branch Appliance, see Appendix B: Managing a Survivable Branch Appliance in the Deployment documentation.) If those users do not have user-level VoIP policies or user-level dial plans, when the users are moved to another site, the site-level VoIP policies and site-level dial plans of the central site apply to the users by default, instead of the branch site site-level VoIP policies and dial plans,. In this scenario, unless the site-level VoIP policies and site-level dial plans used by the backup Registrar pool can also apply to the branch site users, their calls will fail. For example, if users from a branch site located in Japan are moved to a central site in Redmond, then a dial plan with normalization rules that prepend +1425 to all 7-digit calls is unlikely to appropriately translate calls for those users.

Important:

When you create a branch office backup route, we recommend that you add two PSTN phone usage records to the branch office user policy and assign separate routes to each one. The first, or primary, route would direct calls to the gateway associated with the Survivable Branch Appliance (SBA) or branch server; the second, or backup, route would direct calls to the gateway at the central site. In directing calls, the SBA or branch server will attempt all routes assigned to the first PSTN usage record before attempting the second usage record.

To help ensure that inbound calls to branch site users will reach those users when the branch gateway or the Windows component of the Survivable Branch Appliance site is unavailable (which would happen, for example, if the Survivable Branch Appliance or branch gateway were down for maintenance), create a failover route on the gateway (or work with your Direct Inward Dialing (DID) provider) to redirect incoming calls to the backup Registrar pool at the central site. From there, the calls will be routed over the WAN link to branch users. Be sure that the route translates numbers to comply with the PSTN gateway or other trunk peer's accepted phone number formats. For details about creating a failover route, see Configuring a Failover Route. Also create service-level dial plans for the trunk associated with the gateway at the branch site to normalize incoming calls. If you have two Survivable Branch Appliances at a branch site, you can create a site-level dial plan for both unless a separate service-level plan for each is necessary.

Note:

To account for the consumption of central site resources by any branch site users that rely on the central site for presence, conferencing, or failover, we recommend that you consider each branch site user as if the user were registered with the central site. There are currently no limits on the number of branch site users, including users registered with a Survivable Branch Appliance.

We also recommend that you create a user-level dial plan and voice policy, and then assign it to branch site users. For details, see Create a Dial Plan and Create the VoIP Routing Policy for Branch Users in the Deployment documentation.

Routing Extension Numbers

When preparing dial plans and voice policies for branch site users, be sure to include normalization rules and translation rules that match the strings and number format used in the msRTCSIP-line (or Line URI) attribute, so that Lync 2013 calls enabled between branch site users and central site users will be routed correctly—particularly when calls must be rerouted over the PSTN because the WAN link is unavailable. Additionally, there are special considerations for dialed numbers that include extension numbers, rather just phone numbers.

Normalization rules and translations rules that match Line URIs that contain an extension number, whether exclusively or in addition to a full E.164 phone number, have additional requirements. This section describes several example scenarios to route calls for Line URIs with an extension number.

If your organization does not have Direct Inward Dial (DID) phone numbers configured for individual users and the Line URI of each user is configured with *only* an extension number, internal users can call one another by dialing only an extension number. However, you must configure normalization rules that can apply to calls from a branch site user to a central site user, that match the extension numbers.

In a scenario where the WAN link between a branch site and a central site is available, calls from branch site users to central site users do not require the matching normalization rule to translate the number because the call is not routed over the PSTN. For example:

Rule name	Description	Number pattern	Translation	Example

5digitExtensions	Does not translate 5-digit numbers	^(\d{5})$	$1	10001 is not translated

You must also accommodate extension numbers for specific scenarios, such as when the WAN link between a branch site and central site is unavailable and a call from a branch site must be routed over the PSTN. During a WAN outage, if a branch site user calls a central site user only by dialing the central site user's extension, you must have an outbound translation rule that adds the central site user's full phone number. If a user's Line URI contains your organization's full phone number and the user's unique extension number instead of a full phone number that is unique to the user, then you must have an outbound translation rule that adds your organization's full phone number instead. For example:

Description	Matching pattern	Translation	Example
Translates 5-digit numbers to a user's phone number and extension	^(\d{5})$	+14255550123;ext=$1	10001 is translated to +14255550123;ext=10001
Translates 5-digit numbers to your organization's phone number and a user's extension	^(\d{5})$	+14255550100;ext=$1	10001 is translated to +14255550100;ext=10001

In this scenario, if the trunk peer that handles rerouting to the PSTN does not support extension numbers, then the outbound translation rule must also remove the extension number. For example:

Description	Matching pattern	Translation	Example
Removes extension from phone numbers with extensions	^\+(\d*);ext=(\d*)$	+$1	+14255550123;ext=10001 is translated to +14255550123

Whether or not a WAN link is available, if your organization does not have DID numbers configured for individual users and the Line URI for a user contains your organization's phone number and the user's unique extension number, then you must configure your organization's phone number Line URI with a number that is reachable by the trunk peer or PSTN gateway at the branch site. You must also configure your organization's phone number Line URI to include its own unique extension for calls to be routed to that number.

For details about calls from a central site user to a branch site user when the WAN link between the sites is unavailable, see "Preparing for Voice Mail Survivability" later in this topic. For details about dial plans and normalization rules, including other sample rules, see Dial Plans and Normalization Rules in the Planning documentation and Configuring Dial Plans in the Deployment documentation. For details about outbound translation rules, see Translation Rules in the Planning documentation and Defining Translation Rules in the Deployment documentation.

Preparing for Voice Mail Survivability

Exchange Unified Messaging (UM) is usually installed only at a central site and not at branch sites. A caller should be able to leave a voice mail message, even if the WAN link between branch site and central site is unavailable. As a result, configuring the Line URI for the Exchange UM Auto Attendant phone number that provides voice mail for branch site users requires special considerations, in addition to the voice policy, dial plan, and normalization rules applicable to that voice mail number.

Survivable Branch Appliances (SBAs) and Survivable Branch Servers provide voice mail survivability for branch users during a WAN outage. Specifically, if you are using a Survivable Branch Appliance or Survivable Branch Server and the WAN becomes unavailable, the SBA or Survivable Branch Server reroutes unanswered calls over the PSTN to Exchange UM at the central site. With a SBA or Survivable Branch Server, users can also retrieve voice mail messages through the PSTN during a WAN outage. Finally, during a WAN outage the Survivable Branch Appliance or Survivable Branch Server queues missed-call notifications and then uploads them to the Exchange UM server when the WAN is restored. To help ensure that voice mail rerouting is resilient, be sure that you add an entry for the central site pool’s FQDN and an entry for the Edge Server FQDN to the hosts file on the Survivable Branch Server. Otherwise, DNS resolution can time out if you do not have a DNS server at the branch site.

We recommend the following configurations for voice mail survivability for branch site users:

- An Microsoft Exchange administrator should configure Exchange UM Auto Attendant (AA) to accept messages only. This configuration disables all other generic functionality, such as transfer to a user or transfer to an operator, and limits the AA to only accepting messages. Alternatively, the Exchange administrator can use a generic AA or an AA customized to route the call to an operator.
- The Lync Server administrator should take the AA phone number and use that phone number as the **exchange um auto attendant** number in the voice mail rerouting settings for the Survivable Branch Appliance or branch server.
- The Lync Server administrator should get the Exchange UM subscriber access phone number and use that number as the **subscriber access** number in the voice mail rerouting settings for the Survivable Branch Appliance or Survivable Branch Server.
- The Lync Server administrator should configure Exchange UM so that only one dial plan is associated with all branch users who need access to voice mail during a WAN outage.
- When the WAN link is unavailable, calls to branch site users can be routed to the user’s Exchange Unified Messaging (UM) voice mailbox, but only if the voice policy applied to the call specifies a voice mail phone number that is unique and does not include an extension number.

Hardware and Software Requirements for Branch-Site Resiliency

The hardware and software requirements vary, depending on your resiliency solution.

Requirements for Survivable Branch Appliances

Required hardware and software is built into the Survivable Branch Appliance. However, we also recommend that each branch site deploy a DHCP server to obtain client IP addresses; otherwise, when the DHCP lease expires, clients will not have IP connectivity.

If the enterprise DNS servers are located only in central sites, branch site users will be unable to access them during a WAN outage, and therefore Lync Server discovery that uses DNS SRV (service (SRV) resource record) will fail. To assure prompt rerouting during a WAN outage, DNS records must be cached at the branch site. If the branch router supports it, turn on DNS caching. Or, you can deploy a DNS server at the branch. This can be a stand-alone server or a version of the Survivable Branch Appliance that supports DNS capabilities. For details, contact your Survivable Branch Appliance provider.

Note:

It is not necessary to have a domain controller at a branch site. The Survivable Branch Appliance authenticates clients by using a special certificate that it sends the client in response to the client’s certificate request when it signs in.

Lync clients can discover the Lync Server by using DHCP Option 120 (SIP Registrar Option). This can be configured in one of two ways:

- Configure the DHCP server at the branch site to reply to DHCP 120 queries, which return the FQDN of the Registrar on the Survivable Branch Appliance or Survivable Branch Server.
- Turn on Lync Server DHCP. When this is turned on, the Lync Server Registrar responds to DHCP Option 120 queries. Note that the Registrar does not respond to any DHCP queries other than DHCP Options 120.

Additionally, for larger branch sites that have multiple subnets, DHCP relay agents should be enabled to forward DHCP Option 120 queries to the DHCP Server (configuration 1) or to the Registrar (configuration 2).

Finally, branch site users must be configured for Enterprise Voice and provisioned with an appropriate unified communications endpoint.

Requirements for Survivable Branch Servers

The requirements for Survivable Branch Servers are the same as the requirements for any Lync Server server role. For details, see Determining Your Infrastructure Requirements in the Planning documentation.

Requirements for Full-Scale Lync Server Branch-Site Deployments

For details, see Determining Your Infrastructure Requirements in the Planning documentation.

Configuring a Failover Route

Planning for Enterprise Voice Resiliency > Planning for Branch-Site Voice Resiliency > Branch-Site Resiliency Requirements >

Topic Last Modified: *2012-09-21*

The following example shows how an administrator can define a failover route for use if the Dallas-GW1 is down for maintenance or is otherwise unavailable. The following tables illustrate the required configuration change.

Table 1. User Policy

User policy	Phone usage
Default Calling Policy	Local GlobalPSTNHopoff
Redmond Local Policy	RedmondLocal
Dallas Calling Policy	DallasUsers GlobalPSTNHopoff

Table 2. Routes

Route name	Number pattern	Phone usage	Trunk	Gateway
Redmond Local Route	^\+1(425|206|253)(\d{7})$	Local RedmondLocal	Trunk1 Trunk2	Red-GW1 Red-GW2

Dallas Local Route	^\+1(972|214|469)(\d{7})$	Local	Trunk3	Dallas-GW1
Universal Route	^\+?(\d*)$	GlobalPSTNHopoff	Trunk1 Trunk2 Trunk3	Red-GW1 Red-GW2 Dallas-GW1
Dallas Users Route	^\+?(\d*)$	DallasUsers	Trunk3	Dallas-GW1

In Table 1, a phone usage of GlobalPSTNHopoff is added after the DallasUsers phone usage in the Dallas Calling Policy. This enables calls with the Dallas Calling policy to use routes that are configured for the GlobalPSTNHopoff phone usage if a route for the DallasUsers phone usage is unavailable.

1.3.10.15 Deployment Guidelines for Enterprise Voice

Deployment Guidelines for Enterprise Voice

Microsoft Lync Server 2013 > Planning > Planning for Enterprise Voice >

Topic Last Modified: *2012-09-21*

This topic describes prerequisites and other guidelines to consider when you are planning to deploy Lync Server 2013 and the Enterprise Voice workload.

Deployment Prerequisites

For an optimum experience when deploying Enterprise Voice, make sure that your IT infrastructure, network, and systems meet the following prerequisites:

- Lync Server 2013 Standard Edition or Enterprise Edition is installed and operational on your network.
- All Edge Servers are deployed and operational in your perimeter network, including Edge Servers with Access Edge service, A/V Edge service, Web Conferencing Edge service, and a reverse proxy.
- One or more users have been created and enabled for Lync Server.
- Microsoft Exchange Server 2007 Service Pack 1 (SP1) or latest service pack, or Microsoft Exchange Server 2010 is installed. One of these is required for integrating Exchange Unified Messaging (UM) with Lync Server and to provide rich notifications and call log information to client endpoints.
- A unique primary phone number has been designated, normalized, and copied to the **msRTCSIP-line** attribute for each user who is to be enabled for Enterprise Voice.

> **Note:**
>
> Lync Server supports E.164 numbers and non-Direct Inward Dialing (DID) numbers. Non-DID numbers can be represented in the format **<E.164>;ext=<extension>** or as a string of digits, with the requirement that the private extension is unique across the enterprise. For example, a private number of 1001 can be represented as **+1425550100;ext=1001**, or as **1001**. When represented as **1001**, the expectation is that this private number is unique across the enterprise.

- Administrators who deploy Enterprise Voice should be members of the RTCUniversalServerAdmins group.

- At a minimum, Office Communicator 2007 is successfully deployed. To use features new to this release, Lync 2013 is deployed.
- Managed key infrastructure (MKI) is deployed and configured, using either a Microsoft or a third-party certification authority (CA) infrastructure.
- Each computer on which you install Mediation Server must be:
  - A member server of a domain, and prepared for Active Directory Domain Services (AD DS). For Active Directory Domain Services (AD DS) preparation procedures, see Preparing Active Directory Domain Services for Lync Server 2013 in the Deployment documentation.
  - Running one of the following operating systems:
    - The 64-bit edition of the Windows Server 2008 Standard operating system
    - The 64-bit edition of the Windows Server 2008 Enterprise operating system
- If the connection to the public switched telephone network (PSTN) or private branch exchange (PBX) is by means of a Time Division Multiplexing (TDM) connection, one or more PSTN gateways are available for deployment. (If the connection is by means of a SIP trunk, a PSTN gateway is not required.)

Power, Network, or Telephone Service Outages

If there is an outage, disruption, or other degradation of the power, network, or telephone services at your location, the voice, instant messaging, presence, and other features of Lync Server and any device connected to Lync Server may not work properly.

Enterprise Voice Depends on Server Availability and Voice Client and Hardware Operability

Voice communications with Lync Server depend upon the availability of the server software and the proper functioning of the voice clients or the hardware phone devices connecting to the server software.

Alternative Means of Accessing Emergency Services

For those locations where you install a voice client (for example, a PC running Lync client or an Lync Phone Edition device), we recommend that you maintain a backup option for users to call emergency services (for example, 911 or 999) in case of a power failure, network connectivity degradation, telephone service outage, or other issue that may inhibit operation of Lync Server, Lync, or Lync Phone Edition devices. Such alternative options could include a telephone connected to a standard public switched telephone network line or a cell phone.

Emergency Calls and Multi-Line Telephone Systems

The use of a multiline telephone system (MLTS) may be subject to U.S state or federal laws or the laws of other countries/regions that require the MLTS to provide a caller's telephone number, extension, and/or physical location to applicable emergency services when a caller is placed to emergency services (for example, when dialing an emergency access number such as 911 or 999). In this release, Lync Server can be configured to provide a caller's physical location to an emergency services provider, as described in Planning for Emergency Services (E9-1-1). Compliance with MLTS laws is the sole responsibility of the purchaser of Lync Server, Lync client, and Lync Phone Edition devices.

1.3.10.16 Deployment Process Overview for Enterprise Voice

Deployment Process Overview for Enterprise Voice

Microsoft Lync Server 2013 > Planning > Planning for Enterprise Voice >

Topic Last Modified: *2012-09-22*

The deployment and configuration steps that you need to follow are dependent on the Enterprise Voice feature or functionality you are adding to your Lync Server 2013 environment.

Feature Deployment Overviews

For an overview of deploying PSTN connectivity, see the following:

- SIP Trunk Deployment Checklist
- Direct SIP Deployment Options
- Planning Outbound Voice Routing

For an overview of deploying Exchange Unified Messaging (UM), see the following:

- Deployment Process for Integrating On-Premises Unified Messaging and Lync Server 2013

For an overview of deploying call admission control, see the following topics:

- Deployment Checklist for Call Admission Control

For an overview of the deployment process for Emergency Services, see the following:

- Defining Your Requirements for Emergency Calls
- Choosing an E9-1-1 Service Provider
- Deployment Checklist for E9-1-1

For an overview of deploying private telephone lines, see the "Private Telephone Lines in Mixed Deployments" section of Planning for Private Telephone Lines.

- Deployment Process for Call Park
- Deployment Process for Announcements

1.3.10.17 Moving Users to Enterprise Voice

Moving Users to Enterprise Voice

Microsoft Lync Server 2013 > Planning > Planning for Enterprise Voice >

Topic Last Modified: *2012-10-18*

If you are moving users from an existing PBX telephony infrastructure to Enterprise Voice, the deployment process includes some steps that are not part of the planning process already described in Planning for Enterprise Voice. For information about migrating users from an earlier Enterprise Voice deployment, see the migration documents that were included with your installation media.

The process of moving users from an existing telephony infrastructure to Enterprise Voice consists of the following steps:

1. Designate primary phone numbers.
2. Enable users for Enterprise Voice.
3. Prepare dial plans for users.
4. Plan user voice policies.
5. Plan call routes.
6. Configure PBX or SIP Trunk to reroute calls for users enabled for Enterprise Voice.
7. Move users to Exchange Unified Messaging (UM) (recommended).

This topic describes the planning that is necessary for each of these steps.

Step 1. Designate primary phone numbers

Enterprise Voice integrates voice with other messaging media, such that when an incoming call arrives at the server, the server maps the number to the user's SIP-URI and then forks the call to all the client endpoints associated with that SIP-URI. This process requires that each user be associated with a primary phone number.

A primary phone number must be:

- Globally unique or, in the case of internal extensions, unique in the enterprise.
- Owned by and routable in the enterprise. Personal numbers should not be used.

Enterprise users can have two or more telephone numbers listed for them in Active Directory Domain Services (AD DS). All the telephone numbers associated with a particular user can be viewed or changed on the property sheet for that user in the Active Directory Users and Computers snap-in.

The **Telephone number** box on the **General** tab of the **User Properties** dialog box should contain the user's main work number. This number will usually be designated as the user's Primary Phone Number.

Some users may have special requirements (for example, an executive who wants all incoming calls routed through an administrative assistant), but such exceptions should be limited only to those where the need is clear and critical.

After a primary number is chosen, it must be:

- Normalized to E.164 format, wherever possible.
- Copied to the Active Directory **msRTCSIP-line** attribute.

Note:

Coexisting with remote call control (RCC)

RCC is the ability to use Lync Server to monitor and control a desktop PBX phone. Control is routed through the server, which acts as a gateway to the PBX. Although you cannot configure a user for both RCC and Enterprise Voice, the Line URI setting designates a user's primary phone number in either case.

If you have an existing PBX infrastructure that you want selected users to continue using, you can introduce Enterprise Voice incrementally into your organization. For details about this deployment scenario, see Direct SIP Deployment Options in the Planning documentation.

In previous releases, you could enable both RCC and Enterprise Voice for a user, but only if you also configured the user for dual forking, a feature in which an incoming call will ring a user's PBX phone and Communicator simultaneously. In Lync Server 2010, dual-forking is not supported.

There are three methods for populating the **msRTCSIP-line** attribute:

- Microsoft Identity Integration Server (recommended)
- The **Users** page in the Lync Server Control Panel

Where many phone numbers must be processed, a script custom developed by your organization is the better choice. Depending on how your organization represents telephone numbers in Active Directory Domain Services, the script may have to normalize primary phone numbers to E.164 format before copying them to the **msRTCSIP-line** attribute.

- If your organization maintains all telephone numbers in Active Directory Domain Services in a single format, and if that format is E.164, your script only needs to write each Primary Telephone Number to the **msRTCSIP-line** attribute.
- If your organization maintains all telephone numbers in Active Directory Domain Services in a single format, but that format is not E.164, your script should define an appropriate normalization rule to convert Primary Telephone Numbers from their existing format to E.164 before writing them to the **msRTCSIP-line** attribute.
- If your organization does not enforce a standard format for telephone numbers in Active Directory Domain Services, your script should define appropriate normalization rules to convert Primary Phone Numbers from their various formats to E.164 compliance before writing the Primary Telephone Numbers to the **msRTCSIP-line** attribute.

Your script will also have to insert the prefix **Tel:** before each primary number before writing it to the **msRTCSIP-line** attribute.

The expected format of the number specified in this attribute is:

- Tel:+14255550100;ext=50100.
- Tel:5550100 (for unique enterprise wide extensions)

Important:

The normalization performed by the Address Book Service (ABS) does not replace or otherwise eliminate the need to normalize each user's primary phone number in Active Directory Domain Services because ABS does not have access to Active Directory Domain Services and therefore cannot copy primary numbers to the **msRTCSIP-line** attribute.

Step 2. Enable users for Enterprise Voice

Other than identifying which users are to be enabled, no special planning is required to complete this step.

Step 3. Prepare dial plans for users.

Users who are enabled for Enterprise Voice will not be able to make calls to the PSTN without dial plans in place. A dial plan is a named set of normalization rules that translates phone numbers for a named location, individual user, or contact object into a single standard (E.164) format for purposes of phone authorization and call routing. Normalization rules define how phone numbers expressed in various formats are to be routed for each specified location, user, or contact object.

For information about preparing dial plans, see Dial Plans and Normalization Rules.

Step 4. Plan user voice policies

User class-of-service settings on a legacy PBX, such as the right to make long-distance or international calls from company phones, must be reconfigured as VoIP policies for users moved to Enterprise Voice. For details about planning and creating policies for Enterprise Voice, see Voice Policies.

Step 5. Plan outbound call routes

Call routes specify how Lync Server handles outbound calls placed by Enterprise Voice users. When a user dials a number, the server, if necessary, normalizes the dial string to E.164 format and attempts to match it to a SIP URI. If the server is unable to make the match, it applies outgoing call routing logic based on the number. The final step in defining that logic is creating a separate named call route for each set of destination phone numbers that are listed in each dial plan.

For details about planning call routes, see Voice Routes.

Step 6. Configure PBX or SIP Trunk to reroute calls for Enterprise Voice users

Users who formerly were hosted on a traditional PBX or on a SIP Trunk connection to an Internet Telephony Service Provider (ITSP) retain their phone numbers after the move. The only requirement is that after the move, the PBX or SIP Trunk must be reconfigured to route incoming calls for Enterprise Voice users to the Mediation Server.

Step 7. Move users to Exchange Unified Messaging (recommended)

Moving users to Exchange Unified Messaging consists of the following tasks:

- Configure Exchange Unified Messaging and Lync Server to work together.
- Enable users for Exchange Unified Messaging call answering and Outlook Voice Access. This task is performed on the Exchange Unified Messaging server. For details, see the Exchange Server 2010 TechNet Library at http://go.microsoft.com/fwlink/p/?linkID=139372.

1.3.11 Planning for Monitoring

Planning for Monitoring

Microsoft Lync Server 2013 > Planning >

Topic Last Modified: *2012-09-05*

The monitoring service in Microsoft Lync Server 2013 provides a way for administrators to collect usage, trend, and quality of service data for the communication sessions that take place in their organization. Monitoring in Lync Server 2013 no longer requires a separate server role; instead, the monitoring service is built into each Front End server. However, by default monitoring is not enabled in Lync Server 2013. This document will help you determine whether or not monitoring should be enabled in your organization.

- Overview of Monitoring
- Defining Your Organizations's Requirements for Monitoring
- Enabling Monitoring

- Accessing Monitoring Data
- Components and Topologies for Monitoring
- Deployment Checklist for Monitoring

1.3.11.1 Overview of Monitoring

Overview of Monitoring

Microsoft Lync Server 2013 > Planning > Planning for Monitoring >

Topic Last Modified: *2012-09-05*

In Microsoft Lync Server 2013, monitoring is used to collect usage information and Quality of Experience (QoE) data about the communication sessions that your users are involved in. A session is a generic term that covers a user’s connection to a:

- Conference
- Conferencing modality (such as Audio/Video or Application Sharing)
- Another user via a peer-to-peer conversation such as instant messaging or an audio call

Note:

Lync Server 2013 keeps track of information about each session: who called who; which endpoints were used in the session; how long did the session last; what was the perceived quality of the session; and so on. However, Lync Server does not record and store the actual call itself. That includes instant messaging sessions as well: although Lync Server records information about instant messaging sessions, it does not maintain a record of each instant message that was sent during the session.

The call detail information collected by Lync Server can be employed for any number of uses, including:

- **Return on Investment (ROI)**. Administrators can compare the usage data collected by Monitoring Server to similar data collected for their previous telephony system in order to show cost savings and help justify the deployment of Lync Server.
- **Device Inventory Management**. Asset management information helps administrators identify old devices still in use that need to be replaced, as well as identify expensive devices that do not appear to be getting used at all.
- Help Desk. Troubleshooting data enables support engineers to determine why a user’s call failed, and to do so without having to collect server or client side logs. This information can be readily accessed and understood by support personnel who do not have a deep technical knowledge of Microsoft Lync 2013 and Lync Server 2013.
- **System Troubleshooting**. Enables administrators to detect major issues that might prevent end users from performing basic tasks like joining a conference, establishing a call, or sending an instant message.

In addition to this basic call information, the Monitoring Server also provides a mechanism that allows SIP endpoints (such as Lync 2013) to provide troubleshooting information that the server would not otherwise have access to:

- **Media Metrics that Impact Quality**. These metrics deal with the actual transmission of the call itself; that is, they provide a sort of travel log as the call journeys across the network. These metrics (which include such things as packet loss, jitter, and round trip times) provide information on what happened to the call from the time it left your endpoint to the time it arrived at the other person's endpoint.
- **Issues Reported to the End User**. These metrics include poor quality notifications that Lync 2013 presents to end users in cases where they are too far from a microphone, speaking too softly, have a poor network connection, or are experiencing poor quality because another program on the

computer is consuming the available resources.

- **Environment Information**. These metrics detail call quality factors such as the type of microphone and speakers being used, whether the user is connected through a VPN connection, and whether the user is on a wireless connection.

At the end of each call, SIP-compliant endpoints automatically transmit this information to the Front End server that facilitated the call. You don't have to do anything to get endpoints to transmit that information; that behavior is built into the SIP protocol. However, if you want to collect and store that information, then you need to install and enable monitoring. If you do install and enable monitoring, then call information is gathered by agents running on the Front End server and relayed to a pair of SQL Server databases.

Note that the process of installing and configuring monitoring has been simplified in Lync Server 2013. In prior versions of the software, monitoring required a separate Monitoring Server role, which typically meant a separate computer set aside for use as the Monitoring Server. In Lync Server 2013, however, the Monitoring Server role has been eliminated. Instead, the monitoring service (in the form of "unified data collection agents") has been collocated into all Front End servers. This has at least two major benefits. Collocation of the monitoring service:

- Decreases the number of server roles required when implementing Lync Server 2013. Decrementing the Monitoring Server role also helps reduce costs by eliminating the need to maintain dedicated servers for monitoring.
- Reduces the complexity of Lync Server 2013 setup and administration. By collocating the monitoring services on each Front End server you no longer have to install, configure, and manage the Monitoring Server role.

For more information see the topic Deploying Monitoring in the Lync Server 2013 2013 deployment guide.

1.3.11.2 Defining Your Organizations's Requirements for Monitoring

Defining Your Organizations's Requirements for Monitoring

Microsoft Lync Server 2013 > Planning > Planning for Monitoring >

Topic Last Modified: *2012-09-05*

Streamlining the deployment and installation of monitoring in Microsoft Lync Server 2013 has also streamlined the processes involved in defining your organization's requirements for monitoring. Nevertheless, there are still several key issues that should be addressed before you begin to install and configure Lync Server 2013:

What type of data do you want to monitor? Lync Server 2013 enables you to monitor two different types of data: call detailing recording (CDR) data and Quality of Experience (QoE) data. Call detail recording provides a way for you to track the usage of Lync Server features such as Voice over IP (VoIP) phone calls; instant messaging (IM); file transfers; audio/video (A/V) conferencing; and application sharing sessions. This information helps you know which Lync Server features are being used (and which ones are not) and also provides information as to when these features are being used. Quality of Experience data allows you to maintain a record of the quality of audio and video calls made in your organization, including such things as the number of network packets lost, background noise, and the amount of "jitter" (differences in packet delay).

If you choose to enable monitoring in Lync Server 2013 you can enable both CDR monitoring and QoE monitoring, or you can choose to enable one type of monitoring while leaving the other type disabled. For example, suppose your users only use instant messaging and file transfers, and do not make audio or video calls. In that case, there might be little reason to enable QoE monitoring. Likewise, Lync Server makes it easy to enable and disable monitoring after monitoring has been deployed. For example, you might choose to deploy monitoring but initially leave QoE monitoring disabled. If your users begin to experience problems with audio or video calls you could then enable QoE monitoring and use that data to help you troubleshoot and resolve those problems.

There is no particular advantage (or disadvantage) to installing monitoring at the same time you install Lync Server vs. installing monitoring after Lync Server has been installed. The one point to keep in mind is that, before you install monitoring, you must select a computer to host the backend monitoring store, and a supported version of SQL Server must be installing and configured on that computer before that computer can be used for monitoring. If you have already installed SQL Server on a computer and that computer is ready for use then you can install monitoring at the same time you install Lync Server. If you do not have a backend computer ready then you can proceed to install Lync Server by itself, then install monitoring whenever the backend computer is ready for use.

When do you want to install monitoring? Monitoring can be installed and configured at the same time you install and configured Lync Server 2013; the Lync Server Deployment Wizard will provide you with the opportunity to associate your Front End pools with a monitoring database during setup. Alternatively, you can install monitoring after Lync Server itself has been installed; this can be done by using Topology Builder to associate your Front End pools and servers with a monitoring database, and then publishing the revised topology.

How many backend monitoring databases do you need? A single monitoring database can support tens of thousands of users (for Microsoft Lync Server 2010, it was estimated that a collocated database for both monitoring and archiving could support 240,000 users). In addition, a single monitoring database can be used by multiple Front End pools; if you have three Front End pools in your organization then you could associate all three of those pools with the same backend store.

This simply means that, for many organizations, database capacity will not be the deciding factor when determining the number of backend monitoring databases that will be required. Instead, a more important consideration could be network speed. Suppose you have three Front End pools, but one of those pools is located across a slow network connection. In that case, you might want to use two monitoring databases: one database to service the two pools with the good network connection, and a separate database to service the pool with the slower network connection.

When planning your monitoring infrastructure you should also take into account that Lync Server 2013 supports the use of mirror databases. "Database mirroring" provides a way for you to simultaneously maintain two copies of a database, with each database residing on a different server. Any time data is written to a primary database that same data is also written to the mirror database. If the primary database should fail or otherwise become unavailable, you can "fail over" to the mirror database by using a simple Lync Server PowerShell command. For example:

```
Invoke-CsDatabaseFailover -PoolFqdn atl-cs-001.litwareinc.com -DatabaseType "Moni
```

This is important for planning purposes simply because mirroring will require you to double your required number of databases: in addition to each primary database you will need a second database to act as the mirror.

Do your Lync Server sites need their own custom monitoring configurations? When you install Lync Server 2013 you also install global collections of CDR and QoE configuration settings; these global collections give you the ability to apply the same CDR and QoE settings to your entire organization. In many cases, this will be sufficient: often-times you will want, say, to have CDR monitoring enabled for all of your users.

However, there might also be times when you want to apply different settings to different sites. For example, perhaps you want to use both CDR and QoE monitoring in your Redmond site, but only use CDR monitoring in your Dublin site. Likewise, you might want to retain monitoring data for 60 days in the Redmond site but only need to maintain this type of data for 30 days in the Dublin site. Lync Server 2013 allows you to create separate collections of CDR and QoE configuration settings at the site scope; that enables you to manage each site differently. (This includes both enabling and disabling monitoring as well as configuring management settings such as how long data is to be retained.)

Note that you can make this decision before you deploy monitoring or after you deploy monitoring. For example, you can deploy monitoring and then manage the entire organization by using the global settings. If you later change your mind, you can create a separate collection of settings for, say, the Redmond site, and then use those settings to manage monitoring for Redmond. (Settings applied at the site scope always take precedence over settings applied at the global scope.) If you change your mind again, you can simply delete the configuration settings applied to the Redmond site. When a collection of site settings is removed then the global collection of settings will automatically be applied to that site.

1.3.11.3 Enabling Monitoring

Enabling Monitoring

Microsoft Lync Server 2013 > Planning > Planning for Monitoring >

Topic Last Modified: *2012-10-17*

Although the unified data collection agents are automatically installed and activated on each Front End server, that does not mean that you will automatically begin to collect monitoring data the moment you finish installing Microsoft Lync Server 2013. Instead, you must do two things: you must associate your Front End servers/Front End pools with a monitoring database, and you must enable call detail recording (CDR) and/or Quality of Experience (QoE) monitoring at the global scope and/or the site scope.

For step-by-step instructions on associating Front End servers or Front End pools with a monitoring database, see the topic Associating a Monitoring Store with a Front End Pool in the Deployment guide. After these associations have been made, and after your new Lync Server topology has been published, you will still not be able to collect monitoring data. That's because, by default, both CDR and QoE data collection is disabled when you install Lync Server 2013.

In order to begin data collection you will need to enable CDR and/or QoE monitoring. (Note that you do not have to enable both CDR and QoE monitoring; if you prefer, you can enable one type of monitoring while leaving the other type disabled.) To enable CDR monitoring at the global scope run the following command from within the Lync Server Management Shell:

```
Set-CsCdrConfiguration -Identity "global" -EnableCDR $True
```

Alternatively, you can enable CDR monitoring from within the Lync Server 2013 Control Panel. From within the Lync Server Control Panel, complete the following procedure:

1. Click **Monitoring**.
2. On the **Call Detail Recording** tab, double-click the **Global** setting.
3. In the **Edit Call Detail Recording (CDR) Setting** pane, select **Enable monitoring of CDRs** and then click **Commit**.

To enable QoE monitoring at the global scope, run this command from within the Lync Server Management Shell:

```
Set-CsQoEConfiguration -Identity "global" -EnableQoE $True
```

If you prefer, you can also enable QoE monitoring from within the Lync Server Control Panel. From within the Control Panel, complete the following procedure:

1. Click **Monitoring**.
2. On the **Quality of Experience Data** tab, double-click the **Global** setting.
3. In the **Edit Quality of Experience (QoE) Setting** pane, select **Enable monitoring of QoE data** and then click **Commit**.

As noted, the preceding examples enable monitoring at the global scope; that is, they enable CDR and QoE monitoring throughout your organization. Alternatively, you can create separate CDR and QoE configuration settings at the site scope, and then selectively enable or disable monitoring for each site. For example, you could enable CDR monitoring for your Redmond site, yet disable CDR monitoring for your Dublin site. For more information on managing your monitoring configuration settings, see the Deployment guide topic Configuring Call Detail Recording and Quality of Experience Settings.

1.3.11.4 Accessing Monitoring Data

Accessing Monitoring Data

Microsoft Lync Server 2013 > Planning > Planning for Monitoring >

Topic Last Modified: *2012-09-05*

Monitoring data is stored in a pair of SQL Server databases: LcsCdr for call detail recording data, and QoEMetrics for Quality of Experience data. There is nothing special about these two databases; that means that the data stored in those databases can be accessed using any of the tools you typically use for accessing and analyzing SQL Server data.

One tool you should consider for accessing and analyzing monitoring data is the Lync Server Monitoring Reports. Monitoring Reports are a set of standard reports that are published by Microsoft SQL Server Reporting Service. These reports, which are accessible by using a web browser, provide usage, call diagnostic information, and media quality information, all based on call detail recording (CDR) and Quality of Experience (QoE) records stored in the CDR and QoE databases. Monitoring Reports ship with Lync Server 2013 and can be installed from the Lync Server Deployment Wizard after Lync Server has been installed and monitoring has been configured.

As noted, Monitoring Reports requires the use of SQL Server Reporting Service. SQL Server Reporting Service can be installed at the same time you install SQL Server or can be installed any time after SQL Server itself has been installed.

For more information, see the topic Installing Lync Server 2013 Monitoring Reports in the Lync Server 2013 deployment guide.

1.3.11.5 Components and Topologies for Monitoring

Components and Topologies for Monitoring

See Also

Microsoft Lync Server 2013 > Planning > Planning for Monitoring >

Topic Last Modified: *2012-09-05*

Because the unified data collection agents are automatically installed and activated on each Front End server you do not need to configure a server to act as the Monitoring server; each Front End server already functions as a Monitoring server. However, you will need to install and configure a database to act as the backend data store for your monitoring data. Microsoft Lync Server 2013 can use any of the following databases as the backend store for monitoring:

- Microsoft SQL Server 2008 R2 Enterprise Edition
- Microsoft SQL Server 2008 R2 Standard Edition
- Microsoft SQL Server 2012 Enterprise Edition
- Microsoft SQL Server 2012 Standard Edition

Note that you must use the 64-bit editions of these databases; 32-bit versions of SQL Server cannot be used as the backend store for monitoring. Likewise, Lync Server 2013 does not support the Express Editions of SQL Server 2008 or SQL Server 2012. For more information on database requirements for Lync Server 2013 see the topic Database Software Support in the Lync Server 2013 Supportability guide.

Keep in mind that SQL Server must be installed and configured before you deploy and configure monitoring. However, you only need to deploy SQL Server itself; you do not have to setup the monitoring databases in advance. Instead, those databases will automatically be created for you when you publish your Lync Server topology.

Monitoring data can share a SQL Server instance with other types of data. Typically, the call detail recording database (LcsCdr) and the Quality of Experience database (QoEMetrics) share the same SQL instance; it is also common for the two monitoring databases to be in the same SQL instance as the archiving database (LcsLog). About the only real requirement with SQL Server instances is that any one instance of SQL Server is limited to the following:

- One instance of the Lync Server 2013 backend database. (As a general rule, it is not recommended that your monitoring database be collocated in the same SQL instance, or even on the same computer, as the backend database. Although technically possible, you run the risk of the monitoring database using up disk space needed by the backend database.)
- One instance of the call detail recording database.
- One instance of the Quality of Experience database.
- One instance of the archiving database.

In other words, you cannot have two instances of the LcsCdr database in the same instance of SQL Server. If you need multiple instances of the LcsCdr database then you will need to configure multiple instances of SQL Server.

1.3.11.6 Deployment Checklist for Monitoring

Deployment Checklist for Monitoring

Microsoft Lync Server 2013 > Planning > Planning for Monitoring >

Topic Last Modified: *2012-09-05*

Although monitoring is already installed and activated on each Front End server, there are still several steps that you must undertake before you can actually being to collect monitoring data for Microsoft Lync Server 2013. These steps are outlined in the following checklist:

Phase	Steps	Role and group	Documentation

		membership	
Install prerequisite hardware and software	Install a supported version of Microsoft SQL Server on the computer that will act as the backend data store for monitoring.	Domain user who is also a member of the local administrators group.	Supported Hardware in the Supportability guide Server Software and Infrastructure Support in the Supportability Guide
Create the appropriate internal topology to support monitoring	Use Lync Server 2013 Topology Builder to add monitoring databases to the topology, then published the updated topology.	To define a topology, a user who is a member of the local users group. To publish the topology, a user who is a member if the domain administrators group and the RTCUniversalServerAdmins group.	Associating a Monitoring Store with a Front End Pool in the Deployment guide
Enable the appropriate monitoring settings	Enable call detail recording (CDR) and/or Quality of Experience (QoE) monitoring at the global and/or the site scopes.	A user who is a member of the RTCUniversalServerAdmins group or who has been assigned an RBAC role that provides access to the CsCdrConfiguration and CsQoEConfiguration cmdlets.	Configuring Call Detail Recording and Quality of Experience Settings in the Operations guide

1.3.12 Planning for Archiving

Planning for Archiving

Microsoft Lync Server 2013 > Planning >

Topic Last Modified: *2012-09-28*

Corporations and other organizations are subject to an increasing number of industry and government regulations that require the retention of specific types of communications. If your organization has such requirements, you can use Archiving in Lync Server 2013 to archive instant messaging (IM) and conferencing (meeting) communications sent through Lync Server to help support some of your compliance requirements.

- Overview of Archiving
- How Archiving Works
- Defining Your Organization's Requirements for Archiving
- Components and Topologies for Archiving
- Technical Requirements for Archiving
- Deployment Checklist for Archiving

1.3.12.1 Overview of Archiving

Overview of Archiving

Microsoft Lync Server 2013 > Planning > Planning for Archiving >

Topic Last Modified: *2012-10-10*

Archiving in Lync Server 2013 provides a way for you to archive communications that are sent through Lync Server 2013.

You can implement Archiving as part of your initial Lync Server 2013 deployment, or you can add it to an existing deployment. To use Lync Server 2013 Archiving databases (SQL Server databases) for storage of archiving data, you use Topology Builder to add the databases to your topology, and then publish the topology again. If all your users are homed on Exchange 2013 and have their mailboxes put on In-Place Hold, you do not have to update your topology, but only need to enable Microsoft Exchange integration to store archived data in Exchange 2013.

When you implement Archiving, you configure it to specify what is archived. By default, nothing is archived. You configure and manage Archiving by using Lync Server 2013 Control Panel. You can implement Archiving for internal communications, external communications, or both. You can configure archiving settings your entire organization and, optionally, for specific sites, specific pools, and specific users and user groups. For details about determining the appropriate options for your organization, see Defining Your Organization's Requirements for Archiving in the Planning documentation. For details about how Archiving policies and configurations are implemented, see How Archiving Works in the Planning documentation, Deployment documentation, or Operations documentation.

1.3.12.2 How Archiving Works

How Archiving Works

Microsoft Lync Server 2013 > Planning > Planning for Archiving >

Topic Last Modified: *2013-01-22*

Lync Server 2013 Archiving provides options to help you meet your compliance needs. To implement and maintain it in a way that most effectively meets your organization’s requirements, you should understand:

- What information can be archived.
- How to enable and disable Archiving in your deployment.
- The archiving options that you can configure to control how Archiving is implemented.

What Information Can Be Archived?

The following types of content can be archived:

- Peer-to-peer instant messages
- Conferences (meetings), which are multiparty instant messages
- Conference content, including uploaded content (for example, handouts) and event-related content (for example, joining, leaving, uploading sharing, and changes in visibility)
- Whiteboards and polls shared during a conference

The following types of content are not archived:

- Peer-to-peer file transfers
- Audio/video for peer-to-peer instant messages and conferences

- Desktop and application sharing for peer-to-peer instant messages and conferences

Lync Server also does not archive Persistent Chat conversations. To archive Persistent Chat conversations, you must enable and configure the compliance service, which is a component that can be deployed with Microsoft Lync Server 2013, Persistent Chat Server. For details, see Planning for Persistent Chat Server in the Planning documentation.

How Do I Start Using Archiving?

Archiving is automatically installed on each Front End Server when you deploy the server, but Archiving is not enabled until you configure it. How you configure it is determined by how you deploy Archiving:

- **Archiving using Microsoft Exchange integration.** If you have users who are homed on Exchange 2013 and their mailboxes have been put on In-Place Hold, you can select the option to integrate Lync Server 2013 storage with Exchange storage. If you choose the Microsoft Exchange integration option, you use Exchange 2013 policies and configurations to control the archiving of Lync Server 2013 data for those users.
- **Archiving using Lync Server Archiving databases.** If you have users who are not homed on Exchange 2013 or who have not had their mailboxes put on In-Place Hold, or if you don’t want to use Microsoft Exchange integration for any or all users in your deployment, you can deploy Lync Server Archiving databases using SQL Server to store Archiving data for those users. In this case, Lync Server 2013 Archiving policies and configurations determine whether Archiving is enabled and how it is implemented. To use Lync Server 2013, you must add the appropriate SQL Server databases to your topology and publish the topology.

Archiving Setup When Using Microsoft Exchange Integration

If your users are homed on Exchange 2013 and their mailboxes have been put on In-Place Hold, you can choose the **Microsoft Exchange integration** option (as described later in this section) to archive Lync Server 2013 for those users, and then you control archiving for those users by specifying Exchange In-Place Hold policies and settings, as well as Lync Server configurations to control the following:

- Whether to archive IM, conferencing, or both.
- Whether to implement critical mode for your Lync Server deployment.
- Selection of the Microsoft Exchange integration option to use Exchange 2013 for storage of archived data.

These Lync Server 2013 Archiving configuration options are described later in this section. For information about how to configure Exchange In-Place Hold policies and settings to support archiving, see the Exchange 2013 product documentation.

Archiving Setup When Using Lync Server Archiving Database Storage

If you want to use Lync Server Archiving databases (using SQL Server databases) to archive data for any users in your deployment, you can configure Lync Server Archiving policies to control whether Archiving is enabled for those users. In each Archiving policy, you can enable or disable Archiving for either or both of the following:

- Internal communications
- External communications

By default, archiving is not enabled for internal communications or external communications in any Lync Server Archiving policy. You enable and disable communications using Lync Server 2013 Control Panel or using cmdlets in the Lync Server 2013 Management Shell.

Lync Server 2013 Archiving policies include the following:

- **Global Archiving policy**. This is the default Archiving policy and applies to your entire deployment. It is created when you deploy Lync Server 2013 and, by default, disables Archiving for both internal and external communications. You cannot delete this policy. If you choose the delete option, the global policy is reset to the default settings.
- **Site Archiving policy**. Optionally, you can enable or disable Archiving for one or more specific sites by creating and configuring a site-level Archiving policy for the site. When you create a site-level Archiving policy, by default, archiving is not enabled. You can delete any site-level Archiving policy that you create. A site-level Archiving policy overrides the global policy, but only for the site specified in the policy. For example, if you enable Archiving for internal and external communications in your global policy and create a site policy in which you disable Archiving for external communications, only internal communications would be archived for that site.
- **User Archiving policy**. Optionally, you can enable or disable Archiving for one or more specific users and group of users by creating, configuring, and applying a user-level Archiving policy for the specified users and user groups. When you create a user-level Archiving policy, by default, archiving is not enabled. You can delete any user-level Archiving policy that you create, and you can change which users and group of users the Archiving policy applies to. A user-level Archiving policy overrides the global policy and any site policies, but only for the users and user groups to whom the policy is applied. For example, if you disable Archiving for internal and external communications in your global policy, create a site-level policy in which you enable Archiving for internal and external communications, and then create a user-level policy in which you disable Archiving for external communications, the communications would be archived for both external and internal communications for all site users except that, for the users to whom you apply the user-level policy, only internal communications would be archived.

For details about how to set up initial Archiving policies when you deploy Archiving, see Configuring and Assigning Archiving Policies in the Deployment documentation. For details about using Archiving policies to enable and disable communications after deployment, see Managing the Archiving of Internal and External Communications in the Operations documentation.

Note:

If you implement both Lync Server 2013 Archiving databases and enable Microsoft Exchange integration, Exchange 2013 policies override Lync Server Archiving policies, but only for users who are homed on Exchange 2013 and have had had their mailboxes put on In-Place Hold. Lync Archiving depends on Microsoft Exchange In-Place Hold policy only.

What Options Do I Have for Configuring Archiving?

In addition to using policies and to enable and disable Archiving, you have other Archiving options that can be configure for your entire deployment and, optionally, for specific sites and pools. You control most Archiving options by using one or more Archiving configurations, which are available in Lync Server 2013 Control Panel, but also have another option that is only available for configuration using Lync Server 2013 Management Shell.

Archiving Configuration Options Available in Lync Server 2013 Control Panel

Each archiving configuration provides the following options:

The global-level configuration is created automatically when you deploy archiving and can be configured, but not deleted. If you select the option to delete the global configuration, the settings are reset to the default values. You can create multiple site and pool configurations that, together with the global configuration, control archiving settings. For the global configuration and each site and pool configuration, you have the following options:

- Disable archiving, enable archiving only for instant messaging (IM), or enable archiving of both IM and conferencing.
- Configure critical mode to block IM and conferencing sessions in the event of a Lync Server failure. Failures include the following:
  - **IM**. A problem with the Lync Server storage service. In this case, IM is blocked for users who are enabled for Archiving.
  - **Conferencing**. A failure could be an unavailable file share or a problem with the storage service. In this case, all active conferences hosted in the pool at the time of failure are switched to restricted mode and new conferences cannot be activated.

  Both IM and conferencing automatically recover after the failures are corrected.
- Specify the use of Microsoft Exchange Server 2013 integration to use Exchange 2013 for storage of archived data, instead of setting up separate SQL Server databases for storage of Lync Server 2013 archiving data.
- Configure purging options for archived data. This includes specifying when to purge archived data, which can be either of the following:
  - After a specific number of days that you specify
  - After the archiving data has been exported (which includes data that has been uploaded to Exchange, if you enable Microsoft Exchange integration).

  Note:

  If you enable Microsoft Exchange integration, purging for users homed on Exchange 2013 and with their mailboxes put on In-Place Hold is controlled by Exchange. The only qualification is for conferencing files, which are stored on the Lync Server file share. These files are purged from the file share only after the files have been exported (uploaded to Exchange), if you select the option to purge data after the archiving data has been exported, or after the specified maximum number of days, if you specify a maximum number of days for retention.

By default, no archiving options are enabled. You can manage Archiving configurations using Lync Server 2013 Control Panel.

You can specify the following Archiving configurations:

- **Global Archiving configuration**. This is the default Archiving configuration and applies to your entire deployment. It is created when you deploy Lync Server 2013 and, by default, does not enable archiving functionality. You can modify the global configuration, but you cannot delete it. If you choose the delete option for the configuration, the global configuration is reset to the default settings.
- **Site Archiving configuration**. Optionally, you can configure Archiving for one or more specific sites by creating and configuring a site-level Archiving configuration for an individual site. A site-level Archiving configuration exists only if you create it. You can modify or delete any site-level Archiving configuration. A site-level Archiving configuration overrides the global configuration, but only for the site specified in the site-level configuration. For example, if you enable Archiving for only IM in your global configuration and create a site configuration in which you enable Archiving for both IM and conferencing, conferencing would only be archived for the site, not for the remainder of your organization.
- **Pool Archiving configuration**. Optionally, you can specify Archiving settings for one or more specific pools by creating and configuring a pool-level configuration for the individual pool. A pool-level Archiving configuration exists only if you create it. You can modify and delete any pool-level Archiving configuration. A pool-level Archiving configuration overrides the global configuration and any site archiving configuration you may have created. For example, if you enable Archiving for only IM in your global configuration, create a site-level configuration in which you enable Archiving for both IM and conferencing for the site, and then create a pool-level configuration in which

you enable Archiving only for IM, the communications would be archived for both IM and conferencing for all users of the site except the users homed in the pool specified in the pool-level configuration. For all other users in your organization, Archiving would be enabled only for IM.

For details about how to set up initial Archiving configurations when you deploy Archiving, see Configuring Archiving Options in the Deployment documentation. For details about using Archiving policies to enable and disable communications after deployment, see Managing Archiving Configuration Options for Your Organization, Sites, and Pools in the Operations documentation.

Archiving Options Available Only in Windows PowerShell

Using Lync Server 2013 Management Shell, you can use cmdlets to implement options that are not available in Lync Server 2013 Control Panel. These options include the following:

- **Archive duplicate messages**. For details, see New-CsArchivingConfiguration and Set-CsArchivingConfiguration in the Operations documentation.
- **Export archived data**. For details, see Export-CsArchivingData

How Do I Access Archived Data?

Access to archived data is dependent on where the data is stored:

- **Microsoft Exchange storage**. If you choose the SharePoint integration option, Lync Server deposits the archiving content in the Exchange 2013 store for all users who are homed on Exchange 2013, and who have had their mailboxes put on In-Place Hold. Archived data is stored in user mailboxes Recoverable items folder, which is generally invisible to users, and can only be searched by users with an Exchange **Discovery Management** role. Exchange enables federated search and discovery, along with SharePoint, if it is deployed. For more details about storage, retention, and discovery of data stored in Exchange, see the Exchange 2013 and SharePoint documentation.
- **Lync Server storage**. If you set up Lync Server 2013 Archiving databases for storage of Lync Server data, Lync Server deposits archiving content in the Lync Server Archiving databases (SQL Server databases) for any users not homed on Exchange 2013, and who have not had their mailboxes put on In-Place Hold. This data is not searchable, but it can be exported to formats that are searchable using other tools. For details about exporting data stored in Archiving databases, see Exporting Archived Data in the Operations documentation.

For more details about how Lync Server 2013 and Exchange 2013 work together, see Exchange Server and SharePoint Integration Support in the Supportability documentation.

1.3.12.3 Defining Your Organization's Requirements for Archiving

Defining Your Organization's Requirements for Archiving

Microsoft Lync Server 2013 > Planning > Planning for Archiving >

***Topic Last Modified:** 2012-10-09*

If your organization must follow compliance regulations, you can deploy Archiving to enable archiving support for Lync Server 2013 instant messaging (IM) and conferencing (meetings). For details about the type of content that can be archived, see Overview of Archiving in the Planning documentation.

To implement Archiving, you need to first decide how to meet your organization’s requirements for Archiving. This requires determining the following:

- **When to deploy Archiving**. You can deploy Archiving as part of your initial Lync Server 2013 deployment, or you can add it to an existing deployment. You deploy Archiving by using Topology Builder to add it to your topology, and then publishing the topology.
- **Whether to archive internal or external communications**. You can enable archiving for internal communications (communications between internal users), external communications (communications that include at least one user outside your internal network), or both. You can specify these options for your entire organization, or you can specify them for specific sites and pools. By default, neither option is enabled.

  Note:

  If you use Microsoft Exchange integration to store archived data, your Exchange settings control whether Lync communications are archived. If your deployment includes multiple forests, you must synchronize the settings between Lync Server and Exchange. Controlling archiving for internal or external communications is only available for Lync Policy. For Exchange-integrated archiving, both of them will be archived or not archived.
- **Why enable Archiving**. You can enable and disable Archiving for your entire deployment at a global level, and you can enable and disable Archiving for specific sites and users. At each of these levels, you specify whether to enable archiving of IM sessions (peer-to-peer), conferences (meetings, which are multiparty sessions), or both. By default, Archiving is disabled.
- **How critical Archiving is to users in your organization**. If archiving is mission-critical in your organization, you can specify that Lync Server 2013 run in critical mode, which blocks IM and conferencing sessions if archiving fails. For example:
  - If the Archiving service is temporarily unable to send a message to the database queue or insert a message into the database), both IM and conferencing functionality are blocked in the deployment until archiving support is restored.
  - If a conferencing user uploads a file, but the file cannot be copied to the archiving file store, conferencing functionality is blocked in the deployment until the problem is resolved, but IM functionality is not blocked.

  You can configure this option at the global level, site level, and pool level. By default, critical mode is not enabled.
- **Whether to use Microsoft Exchange integration**. This option integrates Archiving storage with your Exchange 2013 storage, so that your Lync Server archived data and Exchange 2013 archived data are stored together in Exchange. You can use Microsoft Exchange integration for storage of archiving data for users who are homed on Exchange 2013, if their mailboxes have been put on In-Place Hold. If you do not have an Exchange 2013 deployment, or if you prefer not to integrate with it, or if you have any Lync users who are not homed on Exchange 2013, you can deploy separate Archiving databases by using SQL Server to store archived data from Lync communications. You can configure the Microsoft Exchange integration option at the global level, site level, and pool level. By default, Microsoft Exchange integration is not enabled.
- **How archived data is to be managed**. The archiving database is not intended for long-term retention and Lync Server 2013 does not provide an e-discovery (search) solution for archived data, so data needs to be moved to other storage. Lync Server does provide a session export tool that you can use to export archived data, and which creates searchable transcripts of the archived data. For the global policy, and for each site and user policy that you create, you can enable data purging and specify one of the following options:
  - Purge both exported archiving data and stored archiving data after a specific number of days. The minimum number of days that you can specify is one day. The maximum number of days that you can specify is 2562 days.
  - Purge exported archiving data only. This option purges all records that have been exported and marked as safe to delete by the session export tool.

  You can configure this option at the global level, site level, and pool level. By default, purging is not enabled.

You control Archiving by using the following methods:

- **Archiving policies**. You use one or more Archiving policies to enable and disable archiving of internal and external communications. By default, no archiving is enabled. You enable or disable Archiving for internal communications, external communications, or both in your deployment by using the default global policy. You cannot delete the global policy. You can specify one or more optional site policies to enable or disable Archiving for internal and external communications for specific sites. You can also specify one or more user policies to enable or disable Archiving for specific users and user groups. User-level policies override site policies. Site-level policies override the global-level policies. User-level policies are implemented only for the specific users who are configured to use the policy. Group instant messages and conferences are archived only if a policy for at least one of the participants is configured to enable archiving.

  Note:
  If you use Microsoft Exchange integration, Exchange 2013 policies override Lync Server Archiving policies for all users homed on the Exchange 2013 servers.

- **Archiving configurations**. You use one or more Archiving configurations to specify most of the Archiving options that are described previously in this topic, except for enabling archiving of internal and external communications (configured using Archiving policies, as described in the previous bullet). Archiving configurations include the default global configuration and optional site and pool configurations. You cannot delete the global configuration. Pool-level configurations override site-level configurations. Site-level configurations override the global-level configuration.

As part of your requirements analysis, you need to determine how to configure the global Archiving configuration and global Archiving policy. You also need to determine your requirements for any site-level Archiving configurations, pool-level Archiving configurations, site-level Archiving policies, and user-level Archiving policies.

If you deploy Archiving for one Front End pool or Standard Edition server, you should then enable it for all other Front End pools and Standard Edition servers in your deployment. You need to do this because users whose communications are required to be archived can be invited to a group IM conversation or meetings hosted on a different pool. If archiving is not enabled on the pool where the conversation or meeting is hosted, all conference data may not be archived. Archiving will still work for archiving enabled users and all IM messages, but conferencing content and events may not be archived.

Note:
To enable delegation of administrative tasks while maintaining your organization's security standards, Lync Server 2013 uses role-based access control (RBAC). With RBAC, administrative privilege is granted by assigning users to predefined administrative roles. To configure Lync Archiving policies and Archiving configurations, the user must be assigned to the CsArchivingAdministrator role (unless the configuration is done directly on the server where Archiving is deployed, instead of remotely from another computer). For details about RBAC, see Planning for Role-Based Access Control in the Planning documentation. For a list of the user rights, permissions, and roles required for archiving deployment, see Deployment Checklist for Archiving, which is available in both the Planning documentation and the Deployment documentation.
If you use Microsoft Exchange integration, configuration of Exchange policies requires appropriate administrator rights and permissions. For details, see the Exchange 2013 documentation.

1.3.12.4 Components and Topologies for Archiving

Components and Topologies for Archiving

Microsoft Lync Server 2013 > Planning > Planning for Archiving >

Topic Last Modified: *2012-10-09*

If you want to archive Lync Server 2013 IM and conferencing content, you can implement Archiving in Lync Server.

Archiving Components

The Archiving feature includes the following components:

- **Archiving agents**. Archiving agents (also known as unified data collection agents) are installed and activated automatically on every Front End pool and Standard Edition server. Although archiving agents are activated automatically, no messages are actually captured until Archiving is enabled and appropriately configured.
- **Archiving data storage**. Data storage for Lync Server 2013 can be either of the following:
  - Exchange 2013 storage. If you enable the Microsoft Exchange integration option, user mailboxes homed on the Exchange 2013 server use Exchange 2013 storage for archived data, but only if the mailboxes have been put on In-Place Hold.
  - SQL Server storage. If you have users in your deployment who are homed on Lync Server 2013, you can set up Archiving databases that run a supported version of SQL Server to enable archiving for those users.

Archiving also requires file storage, but Archiving uses the same file storage as the Front End Servers or Standard Edition server.

For a list of hardware and software requirements for Archiving, see Supported Hardware and Server Software and Infrastructure Support in the Supportability documentation.

Supported Topologies

You deploy Archiving in each pool that has users that require archiving support. Archiving runs on Front End Servers in Enterprise Edition pools and on Standard Edition servers. Archiving data storage can be the following:

- Integrated with Exchange 2013 storage
- Deployed using separate SQL Server databases

If your Exchange 2013 deployment does not include all users in your Lync Server deployment, you must use Microsoft Exchange integration for the users whose mailboxes are home on Exchange 2013 servers, and you must deploy separate SQL Server databases for all other Lync users to use for archiving.

Supported Collocation

Lync Server 2013 supports a variety of collocation scenarios, allowing you flexibility to save hardware costs by running multiple components on one server (if you have a small organization), or to run individual components on different servers (if you have a larger organization that needs scalability and performance). Scalability factors should certainly be considered before you decide whether to collocate components.

Archiving is deployed on the Front End Servers of a pool or Standard Edition servers. For details about components that can be collocated there, see Supported Server Collocation in the Supportability documentation.

If you use separate SQL Server databases for Archiving, instead of or in addition to integrating storage with Exchange 2013 storage, you can collocate the Archiving database with any of the following:

- Monitoring database
- Back-end database of an Enterprise Edition Front End pool

Note:

The server hosting the Archiving database can host other databases. However, when you consider collocating the Archiving database with other databases, be aware that if you are archiving the messages of more than a few users, the disk space needed by the Archiving database can grow very large. For this reason, we do not recommend collocating the Archiving database with the back-end database.

If you collocate the Archiving database with the Monitoring database, back-end database, or both of these databases, you can either use a single SQL instance for any or all of the databases, or you can use a separate SQL instance for each database, with the following limitation:

- Each SQL instance can contain only a single back-end database, single Monitoring database, and single Archiving database.

For details about collocation of all server roles and databases, see Supported Server Collocation in the Supportability documentation.

1.3.12.5 Technical Requirements for Archiving

Technical Requirements for Archiving

Microsoft Lync Server 2013 > Planning > Planning for Archiving >

Topic Last Modified: *2012-10-09*

Lync Server 2013 technical requirements include the following:

- Infrastructure requirements.
- Prerequisite software that must be installed for Archiving.
- Data storage requirements for Archiving.
- Scaling requirements and considerations for your Archiving deployment.
- Performance requirements and considerations for your Archiving databases.

Note:

Scaling and performance information is not available in this Lync Server 2013 release.

Infrastructure Requirements

Lync Server 2013 Archiving infrastructure requirements are the same as for deployment of Lync Server 2013. For details, see Determining Your Infrastructure Requirements in the Planning documentation.

Archiving Prerequisites

Lync Server 2013 streamlines prerequisites for Archiving because of the following:

- Archiving Server is no longer a server role. Instead, Unified Data Collection

Agents run on the Front End Servers in a pool and Standard Edition servers to capture data for Archiving, so you do not set up separate system platforms for Archiving.

- Archiving uses the Lync Server 2013 file storage for temporary storage of meeting content files, so you do not set up a separate file store for archiving.
- In Lync Server 2013, Message Queuing is not required.

Data Storage Requirements for Archiving

Additionally, you need to set up the infrastructure for Archiving storage. This includes one or both of the following:

- **Microsoft Exchange storage**. Meeting content files, such as PowerPoint presentations, are archived as attachments. If you want to use Microsoft Exchange integration so that Lync archive data is stored with Exchange compliance data, you must use Exchange 2013 for your Exchange deployment and ensure that the maximum storage size supports storage of the meeting content files. If you deploy Archiving using the Microsoft Exchange integration option, Lync archive data is stored with Exchange 2013 compliance data only for the users who are homed on your Exchange 2013 servers. You must deploy Exchange 2013 prior to deploying and enabling Archiving using the Microsoft Exchange integration option. If you choose to use Exchange 2013 storage, you do not need to deploy separate SQL Server databases for Archiving, unless you have Lync users who are not homed on your Exchange 2013 servers.
- **SQL Server database storage for Archiving**. To support users who are not homed on Exchange 2013 servers, or if you do not want to use the Microsoft Exchange integration option, you must deploy Archiving storage using a SQL Server database. Lync Server 2013 supports the following 64-bit versions of SQL Server:
  - Microsoft SQL Server 2008 R2 Enterprise
  - Microsoft SQL Server 2008 R2 Standard
  - Microsoft SQL Server 2012 Enterprise
  - Microsoft SQL Server 2012 Standard

  Note:

  Microsoft SQL Server 2008 R2 Express and Microsoft SQL Server 2012 Express are not supported for Archiving. 32-bit versions of SQL Server are not supported. For additional SQL Server requirements and restrictions, see Database Software Support in the Planning documentation or in the Supportability documentation.

  You must set up the SQL Server platforms prior to deploying and enabling Archiving. If the account to be used to publish the topology has the appropriate administrator rights and permissions, you can create the Archiving database (LcsLog) when you publish your topology. You can also create the database later, including as part of the installation procedure. For details about SQL Server, see the SQL Server TechCenter at http://go.microsoft.com/fwlink/p/?linkID=129045.

1.3.12.6 Deployment Checklist for Archiving

Deployment Checklist for Archiving

Microsoft Lync Server 2013 > Planning > Planning for Archiving >

Topic Last Modified: *2012-10-18*

Archiving is automatically installed on each Front End Server in your Lync Server 2013 deployment, but you still need to set it up before you can use it. The steps required to set it up, as summarized in this section, constitute the deployment of Archiving.

Deployment Sequence

How you set up Archiving depends on which storage option you choose:

- If you use Microsoft Exchange integration for all users in your deployment, you don’t need to configure Lync Server 2013 Archiving policies for your users. Instead, configure your Exchange In-Place Hold policies to support archiving for users homed on Exchange 2013, with their mailboxes put on In-Place Hold. For details about configuring these policies, see the Exchange 2013 product documentation.
- If you do not use Microsoft Exchange integration for all users in your deployment, you need to add Lync Server Archiving databases (SQL Server databases) to your topology and then publish it, as well as configure policies and settings for your users, before you can archive data for those users. You can deploy Archiving databases at the same time that you deploy your initial topology or after you have deployed at least one Front End pool or Standard Edition server. This document describes how to deploy Archiving databases by adding them to an existing deployment.

If you enable archiving in one Front End pool or Standard Edition server, you should enable it for all other Front End pools and Standard Edition servers in your deployment. This is because users whose communications are required to be archived can be invited to a group IM conversation or meetings hosted on a different pool. If archiving is not enabled on the pool where the conversation or meeting is hosted, the complete session may not be archived. In these cases, IMs with archiving-enabled users still can be archived, but not for conferencing content files, and conference join or leave events.

Important:

If archiving is critical in your organization for compliance reasons, be sure to deploy Archiving, configure policies and other options at the appropriate level, and enable it for all appropriate users, before you enable those users for Lync Server 2013.

Archiving Deployment Process

The following table provides an overview of the steps required to deploy archiving in an existing topology.

Phase	Steps	Roles and group memberships	Documentation
Install prerequisite hardware and software	• To use Microsoft Exchange integration (using Exchange 2013 for archiving storage for some or all users), you need an existing Exchange 2013 deployment. • To use separate Archiving databases (using SQL Server databases) for archiving storage for some or all users, SQL Server on the server that will store archiving data.	Domain user who is a member of the local administrators group.	Supported Hardware in the Supportability documentation. Server Software and Infrastructure Support in the Supportability documentation. Technical Requirements for Archiving in the Planning documentation. Setting Up

	Note: Archiving runs on Front End Servers of an Enterprise pool and Standard Edition servers. It has no additional hardware or software requirements beyond what is required to install those servers.		Systems and the Infrastructure for Archiving in the Deployment documentation. Exchange Server and SharePoint Integration Support in the Supportability documentation.
Create the appropriate internal topology to support archiving (only if not using Microsoft Exchange integration for all users in your deployment)	Run Topology Builder to add Lync Server 2013 Archiving databases (SQL Server databases) to the topology, and then publish the topology.	To define a topology to incorporate Archiving databases, an account that is a member of the local users group. To publish the topology, an account that is a member of the domain admins group and RTCUniversalServerAdmins group, and that has full control permissions (read/write/modify) on the file share to be used for the Lync Server 2013 file store (so that Topology Builder can configure the required DACLs).	Adding Archiving Databases to an Existing Lync Server 2013 Deployment in the Deployment documentation.
Configure server-to-server authentication (only if using Microsoft Exchange integration)	Configure servers to enable authentication between Lync Server 2013 and Exchange 2013. We recommend running **Test-CsExchangeStorageConnectivity testuser_sipUri –Folder Dumpster** to validate Exchange Archiving storage connectivity before enabling archiving.	An account with the appropriate permissions for managing certificates on the servers.	Managing Server-to-Server Authentication (Oauth) and Partner Applications in the Deployment documentation or the Operations documentation.
Configure archiving policies and configurations	Configure archiving, including whether to use Microsoft Exchange integration, the global policy and any site and user policies (when not using Microsoft Exchange integration	RTCUniversalServerAdmins group (Windows PowerShell only) or assign users to	Configuring Support for Archiving in the Deployment documentation.

	for all data storage), and specific archiving options, such as critical mode and data export and purging. If using Microsoft Exchange integration, configure Exchange In-Place Hold policies as appropriate.	the CSArchivingAdministrator or CSAdministrator role.	Exchange product documentation (if using Microsoft Exchange integration).

Deploying Lync Server and Microsoft Exchange in Different Forests

If Microsoft Exchange Server is not deployed in the same forest as Lync Server, you must make sure that the following Exchange Active Directory attributes are synchronized to the forest where Lync Server is deployed:

1. msExchUserHoldPolicies
2. proxyAddresses

This is a multi-value attribute. When synchronizing this attribute, you need to merge the values, not replace them to ensure the existing values are not lost.

1.3.13 Planning for Persistent Chat Server

Planning for Persistent Chat Server

Microsoft Lync Server 2013 > Planning >

Topic Last Modified: *2012-10-11*

You can use Lync Server 2013, Persistent Chat Server to enable multiple users to participate in conversations in which they post and access content about specific topics, including text, links, and files. Although users can communicate in real time during a session, the content of each session is persistent, which means it continues to be available after a session ends.

This section describes planning considerations in a Lync Server 2013, Persistent Chat Server deployment, including defining requirements, identifying components and supported topologies, and deployment recommendations.

- Overview of Persistent Chat Server
- How Persistent Chat Server Works
- Defining Your Organization's Requirements for Persistent Chat Server
- Components and Topologies for Persistent Chat Server
- Technical Requirements for Persistent Chat Server
- Setting Up Systems and the Infrastructure for Persistent Chat Server
- Deployment Checklist for Persistent Chat Server

1.3.13.1 Overview of Persistent Chat Server

Overview of Persistent Chat Server

Microsoft Lync Server 2013 > Planning > Planning for Persistent Chat Server >

Topic Last Modified: *2012-10-29*

Lync Server 2013, Persistent Chat Server enables users to participate in multiparty, topic-based conversations that persist over time. Persistent Chat Server can help your organization do the following:

- Improve communication between geographically dispersed and cross-functional teams. By using Persistent Chat, teams can efficiently share information, ideas, and decisions with one another. The messages posted to chat rooms (discussion forums) can persist (that is, can be available over time), so that people from different locations and departments can participate, even when they are not simultaneously online. When a user connects to a chat room, backchat (a configurable number of chat-history messages) is automatically loaded in the chat room to give the user a context for the conversation.
- Improve information awareness. By using client-side filters, users can define conditions—such as keywords in message content, or the value of the "from" field in a message—to receive notification when those conditions are met in Persistent Chat instant messages or chat room messages. This way, users can stay up-to-date with the content that interests them most.
- Improve communication with their extended organization. By making it easy to collaborate over long-running topics with others in the organization, and by providing a persistent place to share information, Persistent Chat helps improve communication.
- Reduce information overload. Users can follow chat rooms and messages of most interest by using client-side filters, and can add chat rooms they want to follow to their contact list.
- Increase dispersion of important knowledge and information. Documents and links can be included within conversations for access by all the team. By posting questions to a broader team, users can benefit from responses by subject matter experts. Integration with other information systems enables important organizational data to be easily communicated to large groups.

To enable chat rooms in Lync Server 2013, deploy Lync Server 2013 Persistent Chat. For information about enabling chat rooms, see the Persistent Chat Help at http://go.microsoft.com/fwlink/p/?linkid=270945. If users are enabled for Lync Server, and Lync Server support is deployed, users can install and use Lync 2013 Persistent Chat to provide chat room support.

If your organization is required to follow compliance regulations, you can optionally deploy Persistent Chat Compliance service.

1.3.13.2 How Persistent Chat Server Works

How Persistent Chat Server Works

Microsoft Lync Server 2013 > Planning > Planning for Persistent Chat Server >

Topic Last Modified: *2012-11-21*

Lync Server 2013, Persistent Chat Server enables you to participate in multiparty, topic-based conversations that persist over time. Persistent Chat Server can help your organization do the following:

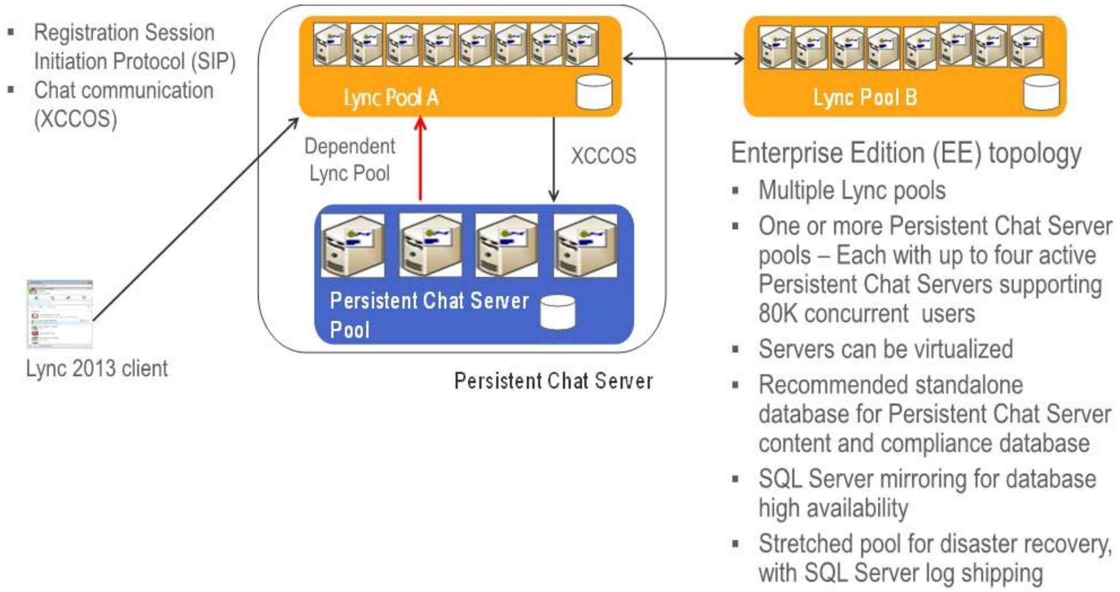
- Improve communication between geographically dispersed and cross-functional teams
- Broaden information awareness and participation
- Improve communication with your extended organization

- Reduce information overload
- Improve information awareness
- Increase dispersion of important knowledge and information

You can deploy Persistent Chat Server as an optional role with Lync Server 2013. Persistent Chat services run on a dedicated pool, and a Persistent Chat Server pool depends on a Lync Server pool to route messages to it. Clients use eXtensible Chat Communication Over SIP (XCCOS). The Lync Server Front End Servers are configured to route the traffic to a Persistent Chat Server pool.

High-Level Architecture

The following diagrams provide high-level perspectives of the Persistent Chat Server architecture and services.

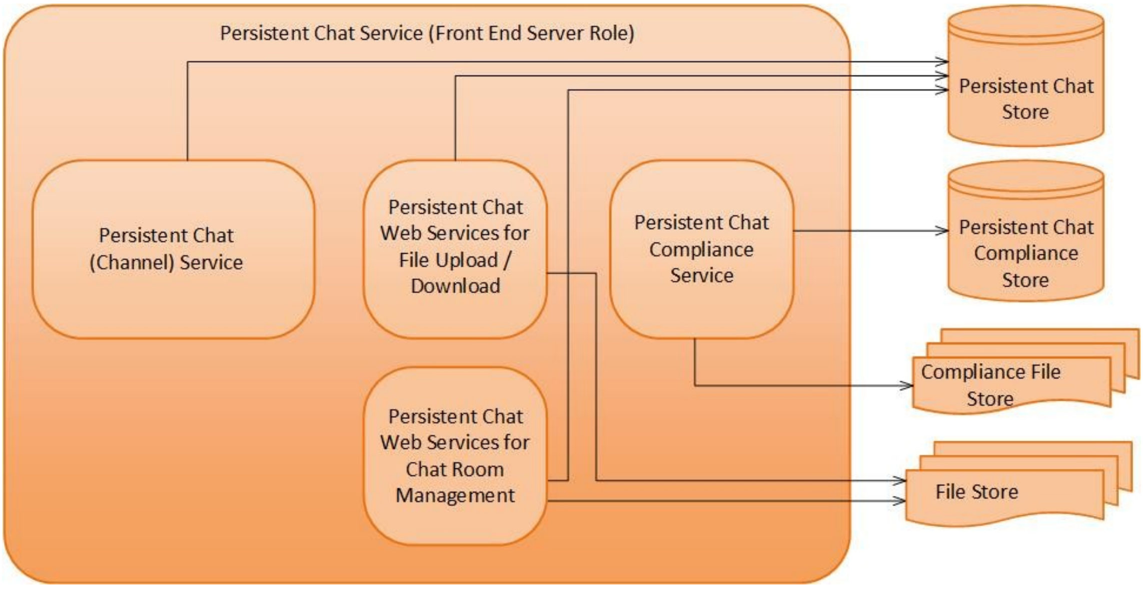


- Registration Session Initiation Protocol (SIP)
- Chat communication (XCCOS)

Enterprise Edition (EE) topology

- Multiple Lync pools
- One or more Persistent Chat Server pools – Each with up to four active Persistent Chat Servers supporting 80K concurrent users
- Servers can be virtualized
- Recommended standalone database for Persistent Chat Server content and compliance database
- SQL Server mirroring for database high availability
- Stretched pool for disaster recovery, with SQL Server log shipping

Lync Pool A
Lync Pool B
Dependent Lync Pool
XCCOS
Persistent Chat Server Pool
Persistent Chat Server
Lync 2013 client



Persistent Chat Service (Front End Server Role)
Persistent Chat (Channel) Service
Persistent Chat Web Services for File Upload / Download
Persistent Chat Compliance Service
Persistent Chat Web Services for Chat Room Management
Persistent Chat Store
Persistent Chat Compliance Store
Compliance File Store
File Store

Two services run on the Persistent Chat Server Front End Servers:

- Persistent Chat (Channel)
- Compliance

Persistent Chat (Channel) Service

The Persistent Chat (Channel) service is the core service responsible for Persistent Chat Server. This service provides the following functions:

- Accepts incoming messages
- Registers and lists online participants within a Persistent Chat room
- Retransmits messages to other channel subscribers
- Implements logic for channel management, chat room invitation, search, and new content notifications

The Persistent Chat (Channel) service stores and accesses chat room content and other system metadata (authorization rules, and so on) by using the Persistent Chat Store. This service stores files that are uploaded into chat rooms in the Persistent Chat File Store.

Compliance Service

The Compliance service is an optional component of Persistent Chat Server and is responsible for archiving chat content and events to the Persistent Chat Compliance Store. If your organization has regulations that require Persistent Chat activity to be archived, you can deploy the optional Persistent Chat Compliance service. The Compliance service is installed on each Persistent Chat Server in a Persistent Chat pool. When configured, Persistent Chat Server compliance records user activity such as joining and leaving rooms, and posting and reading of messages. The Compliance service stores files that need to be archived in the Persistent Chat Compliance File Store.

Persistent Chat Web Services

On the Lync Server Front End Servers, two services run that depend on Internet Information Services (IIS), and are implemented as web components:

- **Persistent Chat Web Services for File Upload/Download** Responsible for posting and retrieving files from chat rooms.
- **Persistent Chat Web Services for Chat Room Management** Responsible for providing users the ability to manage their chat rooms, and create new chat rooms.

How Do I Start Using Persistent Chat Server?

Persistent Chat Server is an optional server role within the Lync Server 2013 infrastructure. If you install the Persistent Chat Server role, any users who have been enabled through policy by an administrator can use Persistent Chat with the Lync 2013 client.

For details about how to deploy Persistent Chat Server and enable users to leverage the capabilities by policy, see Deploying Persistent Chat Server.

For details about how to configure settings on your Persistent Chat Server deployment, see Deploying Persistent Chat Server and Managing Lync Server 2013, Persistent Chat Server.

For details about how to enable users by policy such that they can leverage Persistent Chat functionality in Lync 2013 client, see Deploying Persistent Chat Server and Managing Lync Server 2013, Persistent Chat Server.

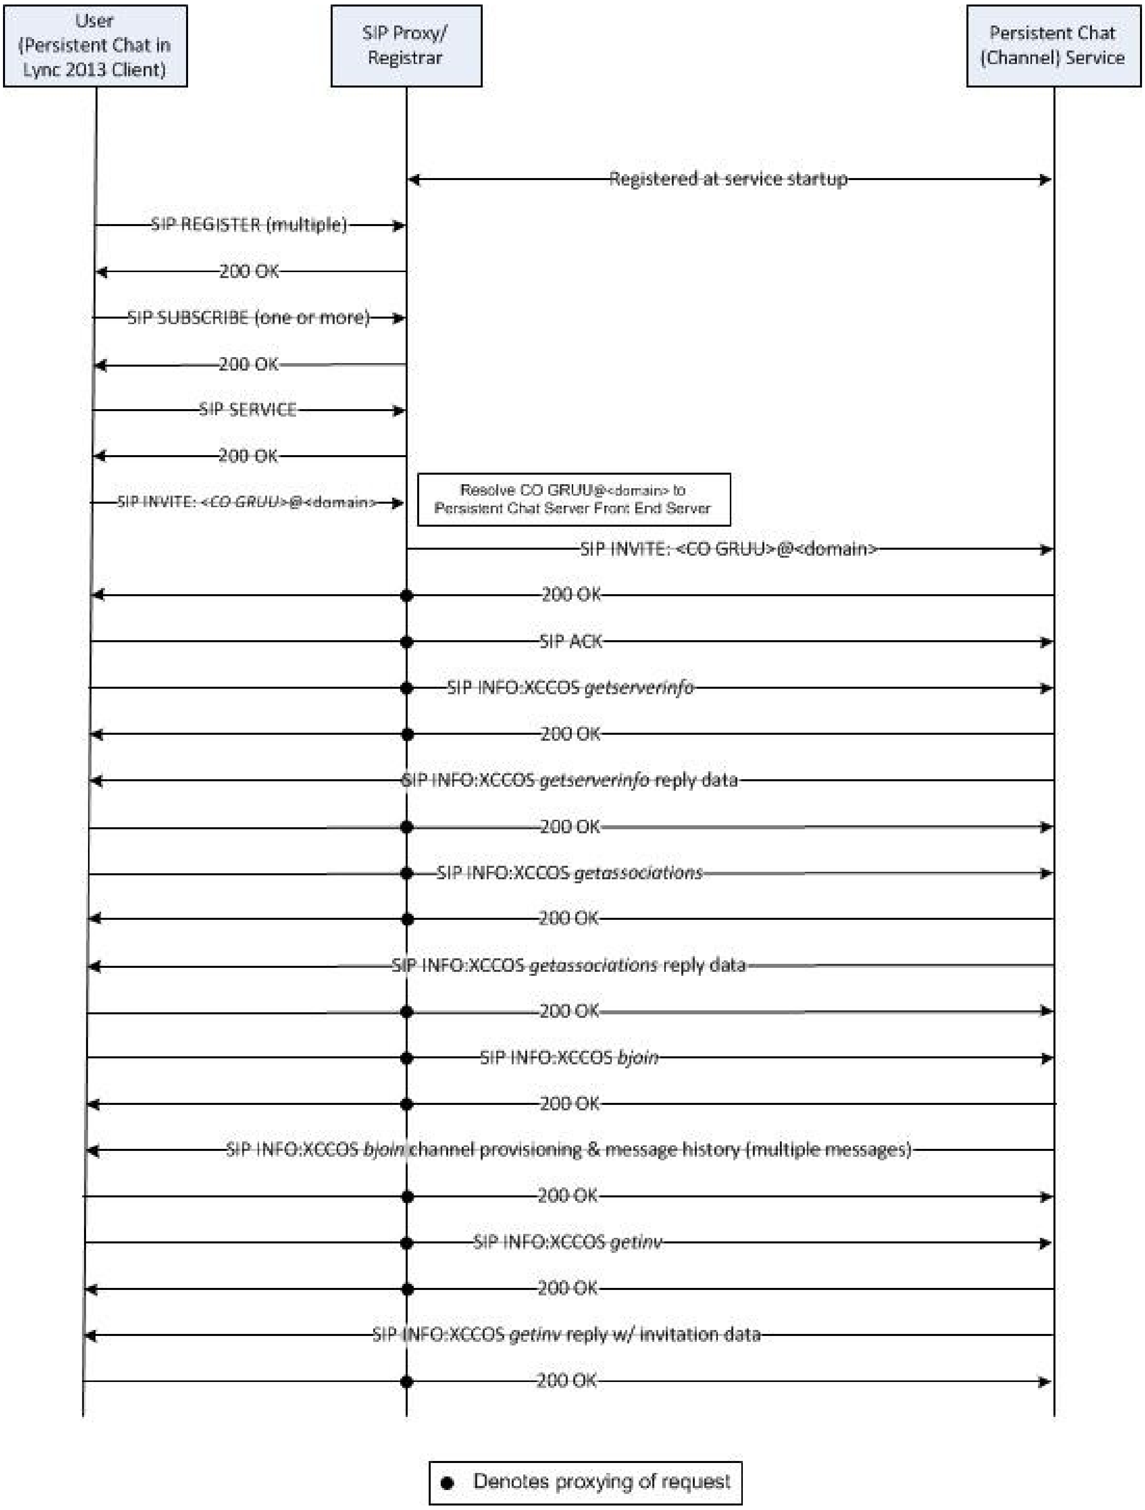
If you deployed Persistent Chat compliance, see Managing Lync Server 2013, Persistent Chat Server for details about how to configure settings for compliance.

Persistent Chat Call Flows

The Persistent Chat client communicates with the Persistent Chat service by using XCCOS. The following sequences describe the sign-in process and a typical room subscription and message post scenario.

Sign-in

The following call flow diagram and steps describe the sign-in process.



User (Persistent Chat in Lync 2013 Client)
SIP Proxy/ Registrar
Persistent Chat (Channel) Service
Registered at service startup
SIP REGISTER (multiple)
200 OK
SIP SUBSCRIBE (one or more)
200 OK
SIP SERVICE
200 OK
SIP INVITE: <CO GRUU>@<domain>
Resolve CO GRUU@<domain> to Persistent Chat Server Front End Server
SIP INVITE: <CO GRUU>@<domain>
200 OK
SIP ACK
SIP INFO:XCCOS getserverinfo
200 OK
SIP INFO:XCCOS getserverinfo reply data
200 OK
SIP INFO:XCCOS getassociations
200 OK
SIP INFO:XCCOS getassociations reply data
200 OK
SIP INFO:XCCOS bjoin
200 OK
SIP INFO:XCCOS bjoin channel provisioning & message history (multiple messages)
200 OK
SIP INFO:XCCOS getinv
200 OK
SIP INFO:XCCOS getinv reply w/ invitation data
200 OK
● Denotes proxying of request

1. The Persistent Chat client first sends a SIP SUBSCRIBE to retrieve the in-band provisioning document from the server. This document indicates if Persistent Chat is enabled or disabled for the user and the list of SIP URIs for the Persistent Chat Server pool.
2. The Persistent Chat client sends a SIP INVITE message to the SIP URI of the Persistent Chat Server that it obtained in the previous step. The INVITE sequence is followed by 200 OK and ACK, and the Persistent Chat client has

now opened a SIP session with a Persistent Chat Server endpoint. Consequently, the Persistent Chat client communicates with Persistent Chat Server by sending SIP INFO messages that contain either chat messages or commands requesting the server to take an action. All of these messages are acknowledged with either 200 OK or 503 Service Unavailable (that is, in the event of heavy server load). If the client receives a 503 response, it will retry the message. (This example does not include a 503 response.) If the server accepts the message or command and sends 200 OK, it provides a response to the client in the form of a separate SIP INFO message. This response includes a reference to the originating command.

3. The Persistent Chat client sends a SIP INFO message that contains the XCCOS **getserverinfo** command. Persistent Chat Server replies with a new SIP INFO message that contains information about the Persistent Chat service configuration.
4. The Persistent Chat client sends a SIP INFO message that contains the XCCOS **getassociations** command. Persistent Chat Server replies with a new SIP INFO message that contains the list of rooms of which the user is a member. The Persistent Chat client repeats the command to retrieve the list of rooms of which the user is a manager.
5. The Persistent Chat client gets the list of followed rooms from the "presence" document, where each followed room is represented by a "roomSetting" category. All followed rooms are joined by a single SIP INFO message that contains the XCCOS **bjoin** command that contains the list of room URIs. Because the list of followed rooms is kept on the server, any client on any computer has the same list of followed rooms for the specified user URI. The Persistent Chat client also keeps the list of opened rooms (if this option is enabled by the user) in the local computer registry, and joins each of these rooms at sign-in by sending a SIP INFO message that contains the XCCOS **join** command for each opened room. Because this list is kept in the registry, it can be different on two Persistent Chat clients running on different computers.
6. For each room joined, the Persistent Chat client sends a SIP INFO message that contains the XCCOS **bccontext** command. Persistent Chat Server replies with a new SIP INFO message that contains the most recent chat message in the room.
7. The Persistent Chat client sends a SIP INFO message that contains a XCCOS **getinv** (that is, get invitation) command to request any new room invitations that the client has not yet seen. In a separate SIP INFO message, Persistent Chat Server returns a list of those rooms.

Subscribe to a Room and Post a Message

The following call flow diagram and steps describe a typical room subscription and message post scenario.

1. From the Persistent Chat client, User1 clicks **Join a Chat Room**, clicks **Search**, and then enters some search criteria. The Persistent Chat client sends a SIP INFO message that contains the XCCOS **chansrch** (room search) command, along with the search criteria. Persistent Chat Server queries the back-end database and replies in a new SIP INFO message that contains a list of available rooms that meet the search criteria.
2. User1 selects the chat room that he or she wants to join, and then clicks **Follow this room**. The Persistent Chat client sends Persistent Chat Server a SIP INFO message that contains the XCCOS **join** command and the room ID of the chat room that the user selected. Persistent Chat Server replies with a SIP INFO message that contains the provisioning data.
3. The Persistent Chat client sends Persistent Chat Server a SIP INFO message that contains the XCCOS **bccontext** (backchat context) command. Persistent Chat Server retrieves the chat history, and returns it to the Persistent Chat client in a separate SIP INFO message. At this point, the user enters the chat

room and is ready to participate.
4. User1 enters a new message, and then clicks **Send**. The Persistent Chat client posts the message to the chat room in a SIP INFO XCCOS **grpchat** command. Persistent Chat Server stores a copy of this new message in the Persistent Chat back-end database.
5. Persistent Chat Server sends a separate copy of the SIP INFO XCCOS **grpchat** message to User2, who has already entered the chat room.

Persistent Chat Compliance Call Flows

Persistent Chat Server uses Message Queuing (also known as MSMQ) and an additional compliance database (mgccomp) to process compliance data. As an example of how compliance events are processed, the following sequence of events describes how a message post event is processed.

1. A user posts a message to a room.
2. Persistent Chat Server places information pertaining to the event in a private Message Queuing queue.
3. Persistent Chat Compliance server reads this event from the queue, and places it into the mgccomp database for processing later.
4. Periodically, the Persistent Chat Compliance server processes a set of events in the database, and sends them to the Persistent Chat Compliance adapter for processing.
5. If the adapter successfully processes the data, Persistent Chat Compliance server deletes the events from the mgccomp database.

1.3.13.3 Defining Your Organization's Requirements for Persistent Chat Server

Defining Your Organization's Requirements for Persistent Chat Server

Microsoft Lync Server 2013 > Planning > Planning for Persistent Chat Server >

***Topic Last Modified:** 2012-09-30*

Before you deploy Persistent Chat Server for your organization, it’s essential to consider the following key questions to optimize your deployment:

- Who (user profile) should be enabled for Persistent Chat Server? Persistent Chat Server is enabled by a policy that can be set at a Global, Site, Pool or User level.
- How many users (scale) should be enabled for Persistent Chat Server? Persistent Chat Server supports 150,000 provisioned users (enabled by policy), and a maximum of 80,000 concurrent users using Persistent Chat Server. A single Persistent Chat Server can support 20,000 connected users, and a single Persistent Chat Server pool can have up to 4 active servers for a total of 80,000 concurrently connected users.
- Are you migrating from a previous version of Group Chat Server, or are you deploying Persistent Chat Server for the first time?
- Are there compliance requirements? Persistent Chat Server supports compliance. The compliance service runs collocated on the Persistent Chat Server Front End Server, as opposed to the requirement for a separate computer in previous Group Chat Server deployments. Compliance is optional, and if chosen, requires a compliance database that must be configured to store compliance data and events. You may want to also configure an adapter to take the data from the compliance database and convert to another format (such as XML files or Exchange-hosted archives).
- How do you want to control scopes, ethical boundaries, and access? You can define **Categories** to segregate these boundaries, and choose who is allowed to be in rooms that are created in each of these categories.

- How do you want to control who can create rooms? You can configure **Creators**, appropriate to your categories, who can create rooms. Creators can assign other members as **Chat Room Managers** for ongoing management of the rooms (adding or removing additional members), according to the scope for **AllowedMembers/DeniedMembers** configured by the category.
- How do you want to create rooms? Persistent Chat Server provides a web-based feature for room creation and management. This can be launched from the Lync 2013 client. You can choose to define a custom solution (by using the Persistent Chat Server Software Development Kit (SDK)) that implements your business requirements and workflows, and configures Persistent Chat Server to direct users to your custom solution.
- What kind of add-ins do you want to provision? **Add-ins** enhance the in-room experience by leveraging the extensibility pane in the Lync 2013 client to provide context that is relevant to the room. You can choose what general add-ins might be most useful (for example, your company website, internal collaboration documents, and so on). Chat room managers can choose one of the registered add-ins and associate it with their rooms, if desired.
- What kind of high availability and disaster recovery requirements do you have? Persistent Chat Server supports SQL Server mirroring for high availability and supports up to 8 servers (4 active and 4 standby) in a stretched pool with SQL Server log shipping for disaster recovery.
- Are there regulatory requirements? If your company is in a country/region where data needs to be kept globally, you may need to deploy multiple Persistent Chat Server pools, each local to a specific geography. A room, category, or add-in does not span pools—it belongs to only one Persistent Chat Server pool. Users can be configured to have access to rooms in one or more pools, depending on how you design your categories.

Important:
Having multiple Persistent Chat Server pools does not give you more scale (you can still have only 80,000 concurrently connected users across all your Persistent Chat Server pools).

1.3.13.4 User Roles in Persistent Chat Server

User Roles in Persistent Chat Server

Microsoft Lync Server 2013 > Planning > Planning for Persistent Chat Server >

Topic Last Modified: *2012-10-05*

Persistent Chat Server provides the concept of Allowed/Denied members, which applies to Persistent Chat categories and controls who can access rooms in a particular category.

Important:
Allowed/Denied members in a Category is not the same as a **Member** role, which applies to a Persistent Chat room. Searches display all open and closed chat rooms for which the user performing the search is in the Allowed/Denied member list. Secret rooms are not displayed unless the user who performs the search is a member of the secret room. The user can search only for rooms that he or she is already a member of, or those for which they can request membership.

The primary rationale for the concept of Allowed/Denied Members is ethical walls. For example, it is common in banking and financial institutions to have ethical boundaries that prevent traders and analysts from sharing communications while implementing policies and conventions. To address this requirement, an administrator can create categories so that one category allows rooms to be created and used by traders, and another category allows rooms to be created and used by analysts. With this constraint is designed into the system prohibits adding a user as a member of the room if the parent category prevents it.

Following are the four user roles Persistent Chat Server:

- **Creator:** Users who have permissions to create chat rooms. These users are in the Creators list of certain categories: they can create chat rooms in that category, and they can also assign membership according to the category, and assign managers to manage the chat room. The user who creates a chat room is automatically added as a manager of the room.

  Note:

  Being a Creator simply provides rights for creating chat rooms. It is the automatic promotion to Manager that enables the Creator to further refine memberships, managers, and so on, on the created chat services.

  This role exists to give you the option of controlling who creates chat rooms in your organization, particularly if you want to centrally manage creating chat rooms to enforce policies and conventions, and subsequently delegate the chat room management to other users in the organization.
- **Manager:** Users who manage properties of a chat room. Chat room managers can modify the member list (add and remove members), and modify the chat room managers list (add and remove managers). Chat room managers can add themselves to the members or presenters list (for auditorium rooms) so they can participate in the chat room. Chat room managers can also disable chat rooms (administrators can query for disabled chat rooms and can permanently delete them). Managers can change all the properties of a chat room, except the category of the chat room. Only the Persistent Chat Administrator can change the category after the chat room has been created.

  Important:

  If the manager is also a Creator in another category, he or she can change the category to one where they are authorized to create rooms.
- **Member:** Users who are members of a chat room. These users can see the chat rooms in the directory (even if the chat room is secret), as well as subscribe to the chat room (including metadata options such as unread messages, ego filters, and keyword filters), and participate in the chat room (can post, unless the room is an auditorium room where only presenters can post, get content, and search). Users who aren't members of the chat room can search for the chat room if they are in the Allowed Members list of the category, but need to request access to join these chat rooms to access content. (There is no request access or approvals built into the system; these are done externally by email, phone, or other forms of contact.)
- **Presenter:** Users who can post to an auditorium room.

The following roles are administrator roles for Persistent Chat Server:

- **Persistent Chat Administrator (CsPersistentChatAdministrator):** This is a new Role-Based Access Control (RBAC) role to administer and manage Persistent Chat Server. Users or security groups designated as CsPersistentChatAdministrator are able administer Persistent Chat Server by using Windows PowerShell cmdlets remotely (that is, from a computer other than the Persistent Chat Server). Persistent Chat Server checks that the Persistent Chat Administrator is member of the RTC Local administrator local group on the Persistent Chat Server Front End Server.
  The CsPersistentChatAdministrator role can manage chat rooms (modify all properties including membership, managers, categories, mark rooms as disabled), as well as create and manage chat room categories that define who can create and access chat rooms. Administrators can also mark chat rooms as disabled and clean up chat rooms that are no longer active. Administrators are not subject to the Creators or Allowed Members restrictions. Administrators can create any kind of chat room and add themselves as a member to any chat room. Administrators can also modify and manage Persistent Chat

configuration (pool properties, global settings, and compliance configuration) and can also plan and implement migration from an older Group Chat Server deployment to Lync Server 2013 Persistent Chat Server.

- **Lync Administrator:** Overall enterprise administrator for Lync Server 2013 responsible for deployment.
- **Operations Manager:** User responsible for managing day-to-day operations.
- **Third-party developers and partners:** Third-party developers extend the system, in particular providing an ethical wall solution for group conversations, compliance support and tools, web/mobile clients, and a framework for Bot development.

1.3.13.5 Components and Topologies for Persistent Chat Server

Components and Topologies for Persistent Chat Server

Microsoft Lync Server 2013 > Planning > Planning for Persistent Chat Server >

Topic Last Modified: *2012-10-05*

Persistent Chat Server supports both single-server configurations and multiple-server configurations. Persistent Chat Server can also run on a Lync Server 2013 Standard Edition server. These configurations consist of the following Persistent Chat Server components and topologies.

Persistent Chat Server Components

Installing the latest version of Persistent Chat Server requires the following components:

- One or more computers running Persistent Chat Server and providing the following services:
  - Persistent Chat service
  - Compliance service, which is turned on if compliance is enabled

  Important:

  In Lync Server 2013, the Persistent Chat Web Services for File Upload/Download is now collocated with Lync Server 2013 Front End Server. The Persistent Chat Web Services for Chat Room Management is also collocated with Lync Server 2013 Front End Server.

- Server(s) (more than one server if mirroring is used) that host the SQL Server back-end database for hosting the Persistent Chat content database where chat room content, rooms, and categories are stored.

  Note:

  The back-end database stores chat history data, including information about categories and Persistent Chat rooms that are created.

- If compliance was enabled, a server(s) (more than one server if mirroring is used) that host the SQL Server back-end database for hosting the Persistent Chat Compliance database, where compliance events and chat content for the purpose of compliance are stored.

To administer Persistent Chat Server from a separate computer (such as an administrative console), use the Lync Server Control Panel on the computer. This computer must then be deployed in an Active Directory Domain Services (AD DS) domain, with at least one global catalog server in the forest root.

For details about hardware and software requirements for Persistent Chat Server, see Technical Requirements for Persistent Chat Server, Supported Hardware, and Server Software and Infrastructure Support in the Supportability documentation.

Supported Collocation

Lync Server 2013 supports a variety of collocation scenarios, providing you the flexibility to save hardware costs by running multiple components on one server (if you have a small organization), or to run individual components on different servers (if you have a larger organization that needs scalability and performance). Scalability factors should certainly be considered before you decide whether to collocate components.

The Persistent Chat Compliance service, if compliance is enabled, is collocated with the Lync Server 2013 Front End Server.

Persistent Chat Server can be deployed on the Standard Edition server. The Persistent Chat Server Back End Server and the Persistent Chat Compliance database can be collocated on the Standard Edition server on the local SQL Server Express Back End Server. For details about components that can be collocated there, see Supported Server Collocation in the Supportability documentation.

For Lync Server 2013 Enterprise Edition, Persistent Chat Servers cannot be collocated on the Enterprise Edition server. The SQL Server database for Persistent Chat Server can be collocated with the Back End Server database of an Enterprise Edition Front End pool. The SQL Server database for Persistent Chat compliance can also be collocated with the Back End Server database of an Enterprise Edition pool.

Important:

The server hosting the Persistent Chat database can host other databases. However, when you consider collocating the Persistent Chat database with other databases, be aware that if you are storing the messages of more than a few users, the disk space needed by the Persistent Chat database can grow very large. For this reason, we do not recommend collocating the Persistent Chat database with the back-end database.

If you collocate the Persistent Chat database with the back-end database, you can either use a single instance of SQL Server for any or all of the databases, or you can use a separate instance of SQL Server for each database, with the following limitation:

- Each instance of SQL Server can contain only a single back-end database and a single Persistent Chat database.

For details about collocation of all server roles and databases, see Supported Server Collocation in the Supportability documentation.

Persistent Chat Server Topologies

Persistent Chat Server supports the following topologies:

- Lync Server 2013 Enterprise Edition single server Persistent Chat Server Front End Server
- Lync Server 2013 Enterprise Edition multiple server Persistent Chat Server Front End Server
- Lync Server 2013 Standard Edition server using SQL Server Express
- Lync Server 2013 Standard Edition server and Persistent Chat Server on a separate server using Standard Edition server as the next hop server.

You can add Persistent Chat Server to your Lync Server 2013 deployment by using Topology Builder. You can add a single server or a multiple server Persistent Chat Server pool to your topology.

Important:

After you create a Persistent Chat Server pool with a single server by using Topology Builder, you cannot add additional servers to the pool.

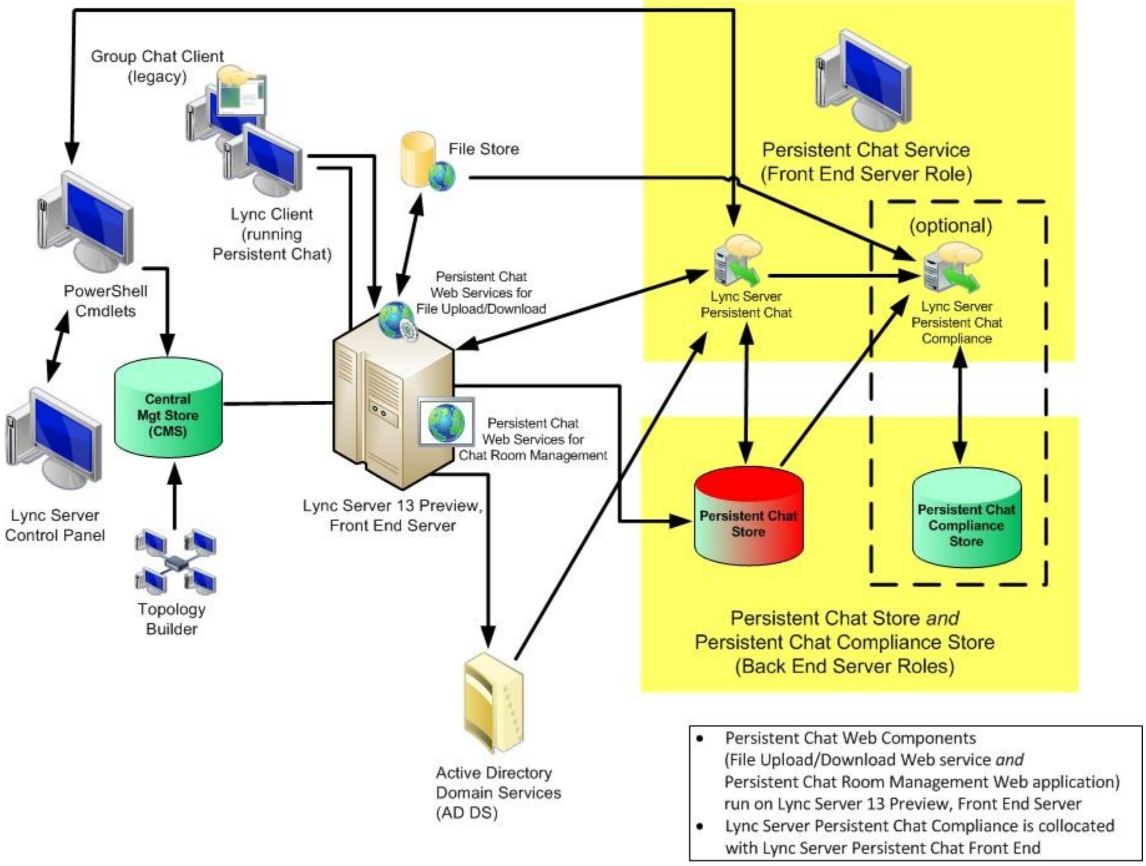
Single-Server Topology

The minimum configuration and simplest deployment for Persistent Chat Server is a single Persistent Chat Server Front End Server topology. This deployment requires a single server that runs Persistent Chat Server (which optionally runs the Compliance service, if compliance is enabled), a server that hosts both the SQL Server database, and if compliance is required, the SQL Server database to store the compliance data.

Important:

You cannot add additional servers to a Persistent Chat Server pool that is started as a single-server deployment in Topology Builder. We recommend using the multiple-server pool topology, even if you're using a single server, so that you can add more servers later, if needed..

The following figure shows all required and optional components of a topology for a single Persistent Chat Server Front End Server with compliance.

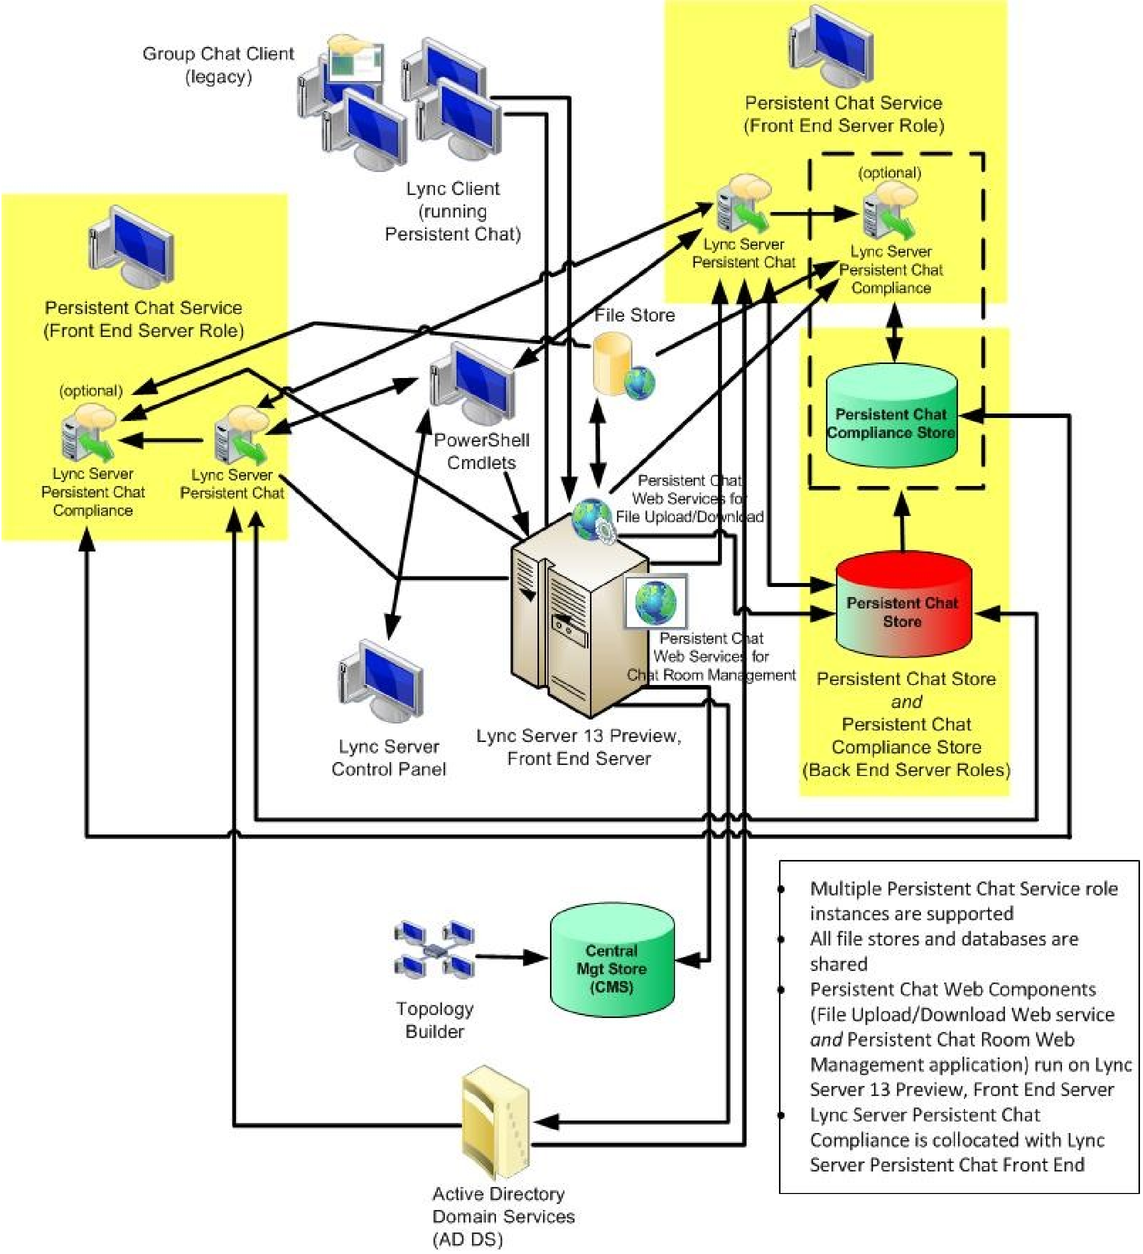


- Persistent Chat Web Components (File Upload/Download Web service *and* Persistent Chat Room Management Web application) run on Lync Server 13 Preview, Front End Server
- Lync Server Persistent Chat Compliance is collocated with Lync Server Persistent Chat Front End

Multiple-Server Topology

To provide greater capacity and reliability, you can deploy a multiple-server topology, as described in Planning for Persistent Chat Server. The multiple-server topology can include as many as four active computers running Persistent Chat Server (high availability and disaster recovery configurations will allow up to eight, but only four can be active and the remaining four on standby). Each server can support as many as 20,000 concurrent users, for a total of 80,000 concurrent users connected to a Persistent Chat Server pool with 4 servers. A multiple-server topology is the same as the single-server topology except that multiple servers host Persistent Chat Server, and can scale higher. Multiple computers running Persistent Chat Server should reside in the same Active Directory Domain Services (AD DS) domain as Lync Server and the Compliance service.

The following figure shows all the components of a multiple-server topology with multiple computers running Persistent Chat Server, the optional Compliance service, and a separate compliance database.



- Multiple Persistent Chat Service role instances are supported
- All file stores and databases are shared
- Persistent Chat Web Components (File Upload/Download Web service *and* Persistent Chat Room Web Management application) run on Lync Server 13 Preview, Front End Server
- Lync Server Persistent Chat Compliance is collocated with Lync Server Persistent Chat Front End

Multiple-server topologies provide pooling of server functionality. In a server pool, the Persistent Chat services communicate and share data. For example, chat history that was originally posted to one Persistent Chat service is available from any Persistent Chat service in the system. A file that is uploaded through one Persistent Chat service can be accessed by any Persistent Chat service. Users can be connected to different Persistent Chat Server Front End Servers and can be chatting and communicating with each other.

The default port of TCP 8011 connects a server to a server pool, and is used by the Persistent Chat service to communicate between themselves, or for administrative purposes.

1.3.13.6 Technical Requirements for Persistent Chat Server

Technical Requirements for Persistent Chat Server

Microsoft Lync Server 2013 > Planning > Planning for Persistent Chat Server >

Topic Last Modified: *2013-01-06*

Each computer that hosts Persistent Chat Server must have access to an existing Lync Server 2013 topology with the following components:

- **Lync Server 2013, Front End Server.** The Front End Server is the foundation for Session Initiation Protocol (SIP) routing, which makes communication between computers running Persistent Chat Server and the Persistent Chat functionality possible. Before you begin to deploy Persistent Chat Server, verify the deployment of Lync Server 2013, Standard Edition, or a Lync Server Front End pool and any other internal computers running Lync Server, as appropriate to your organization.

The following sections describe the specific requirements for the Persistent Chat Server and the database that stores the Persistent Chat data.

Persistent Chat Server Requirements

For details about the recommended hardware for deploying Lync Server and the latest version of Persistent Chat Server, see Server Hardware Platforms in the Supportability documentation.

For details about the server and tools operating system support for Lync Server and Persistent Chat Server, see Server and Tools Operating System Support in the Supportability documentation.

For details about additional software required for deploying Persistent Chat Server, see the following table.

Persistent Chat Server Software Prerequisites

Software	Description
Message Queuing	Used by the Persistent Chat Server and Persistent Chat Compliance service, if deployed.

Persistent Chat Server Database Requirements

Persistent Chat Server uses the Persistent Chat database to store chat history, configuration, and user provisioning data. Optionally, it uses the Persistent Chat compliance database to store compliance data.

◆**Important:**
The Persistent Chat database (mgc) and the compliance database (mgccomp) can be located in the same instance of SQL Server or on different SQL Servers.

To prepare a database server platform, be sure that each computer meets the hardware requirements, and then install the prerequisite software.

The server platform for the Persistent Chat database servers requires the same hardware as the Lync Server back-end database server. For details, see Server Hardware Platforms in the Supportability documentation.

On the database server, be sure that one of the following software applications is installed:

- Microsoft SQL Server 2012. For details about how to install Microsoft SQL Server 2012, see "Install SQL Server 2012" at http://go.microsoft.com/fwlink/p/?LinkID=248559.
- Microsoft SQL Server 2008 R2. For details about how to install Microsoft SQL Server 2008 R2, see "SQL Server Installation (SQL Server 2008 R2)" at http://go.microsoft.com/fwlink/?LinkId=275702.

Persistent Chat Server Certificate Requirements

For details about acquiring certificates, creating the SQL Server database, and creating file stores, see Deploying Lync Server 2013 in the Deployment documentation.

1.3.13.7 Setting Up Systems and the Infrastructure for Persistent Chat Server

Setting Up Systems and the Infrastructure for Persistent Chat Server

Microsoft Lync Server 2013 > Planning > Planning for Persistent Chat Server >

Topic Last Modified: *2012-03-23*

Before deploying Lync Server 2013, Persistent Chat Server, you need to deploy the appropriate hardware and software for all Persistent Chat Server components.

In This Section

- Set Up System Platforms
- Install Lync Server 2013 Prerequisite Software

1.3.13.8 Deployment Checklist for Persistent Chat Server

Deployment Checklist for Persistent Chat Server

Microsoft Lync Server 2013 > Planning > Planning for Persistent Chat Server >

Topic Last Modified: *2012-10-16*

Deployment of Lync Server 2013, Persistent Chat Server requires that you deploy it in the correct sequence and that you complete all required deployment steps.

Deployment Sequence

You can deploy Persistent Chat Server after you deploy your initial topology, including at least one Lync Server 2013, Front End pool or one Lync Server 2013, Standard Edition server. This topic describes how to deploy Persistent Chat Server by adding it to an existing deployment.

Deployment Process

The following table lists the basic steps to deploy Persistent Chat Server and provides links for more details.

Persistent Chat Server Deployment Process

Task	Steps	Required roles and group memberships	Related topics
Install prerequisite hardware and software	On hardware that meets system requirements, install the following: • On the Persistent Chat Server Front End Servers: • An operating system that meets system requirements • Software prerequisites for computers running Lync Server 2013 • SQL Server on the server that will host Persistent Chat Server database If Persistent Chat Server compliance is required: • SQL Server on the server that will host Persistent Chat Server compliance database	Any user who is a member of the local Administrators group.	Supported Hardware in the Supportability documentation Server Software and Infrastructure Support in the Supportability documentation Determining Your System Requirements Technical Requirements for Persistent Chat Server
Create the appropriate internal topology to support Persistent Chat Server (and optionally, Persistent Chat compliance)	Run Topology Builder to add a Persistent Chat Server pool to your topology: • Add Persistent Chat Server components to the topology • Create a SQL Server database for the Persistent Chat Server store (and a backup SQL Server for disaster recovery) • Define a new Lync File Store or use an existing Lync File Store for Persistent Chat Server files • Associate the Lync	To define a topology, an account that is a member of the local Users group. To publish the topology, an account that is a member of the Domain Admins group and RTCUniversalServerAdmins group, and the user should also have full control permissions (read/	Adding Persistent Chat Server to Your Deployment in the Deployment documentation

	Server 2013 pool that can route requests to this Persistent Chat Server pool If Persistent Chat compliance is required: • Add Persistent Chat Compliance Store • Click the Persistent Chat Server pool definition check box for enabling compliance • Publish the topology If you install Persistent Chat Server on Standard Edition, the fully qualified domain name (FQDN) of the Persistent Chat Server pool must match the Standard Edition server, and the SQL Server databases are collocated on the SQL Server Express instance on the Standard Edition server	write/modify) on the Lync File Store for Persistent Chat Server files (so that Topology Builder can configure the required DACLs).	
Deploy Persistent Chat Server	Run the Lync Server setup on all the computers running Persistent Chat Server. The Persistent Chat Server setup is integrated into the Lync Server 2013 Deployment wizard that provides the following instructions: • Deploy local management store • Install Persistent Chat Server services • Request and assign certificates • Run and start the services	Any user who is a member of the local Administrators group.	Deploying Persistent Chat Server in the Deployment documentation
Create a Persistent Chat administrator	Add users to the CsPersistentChatAdministrator security group.	Any user who is a member of domain administrators.	Adding a Persistent Chat Administrator in the Deployment documentation
Configure Persistent Chat Server	Configure users: • User has to be enabled by policy to access Persistent Chat Server. By default, the policy is turned off for all users and can be defined at global/ site/pool/user	User must be a member of CsPersistentChatAdministrator. To change policy, user must be in CsUserAdministrator, at a minimum.	Configuring Persistent Chat Server in the Deployment documentation

	scopes. - Configure settings		

Important:
You can deploy one or more Persistent Chat Server pools. We support multiple Persistent Chat Server pools for regulatory reasons whereby data generated in a given region is required to stay in that region. For example, if you deploy a Persistent Chat Server pool in Chicago, and another in Zurich to comply with regulations for data in Switzerland, users can connect to rooms in both the Persistent Chat Server pools, provided they have access.

1.3.13.9 Capacity Planning for Persistent Chat Server

Capacity Planning for Persistent Chat Server

Microsoft Lync Server 2013 > Planning > Planning for Persistent Chat Server >

Topic Last Modified: *2012-10-05*

Persistent Chat Server can perform multi-user real-time chat that can persist for future retrieval and search. Unlike group instant messaging (IM) that is saved in a user's mailbox if conversation history is configured, a Persistent Chat Server session stays open longer, and the content is saved on a server, along with the messages, files, URLs, and other data that are part of an ongoing conversation.

Capacity planning is an important part of preparing to deploy Persistent Chat Server. This topic provides details about supported Persistent Chat Server topologies and capacity planning tables that you can use to determine the best configuration for your deployment. It also describes how to best manage Persistent Chat Server deployments that require greater capacity at peak times.

To download Persistent Chat Server, see "Microsoft Lync Server 13 Persistent Chat Server" at http://go.microsoft.com/fwlink/p/?linkId=209539.

For details about installing Persistent Chat Server, see Installing Persistent Chat Server and Configuring Persistent Chat Server in the Deployment documentation.

Support tools, such as Lync Server Planning Tool, can further assist you with capacity planning. For details about the Planning Tool, see Beginning the Planning Process in the Planning documentation.

Persistent Chat Server Supported Topologies

You can deploy Persistent Chat Server in single-server or multiple-server pools, and with single-pool or multiple-pool topology.

We now also support Persistent Chat Server on Standard Edition server for new Lync Server 2013 deployments. However, performance and scale will be affected, and because there is no high availability option for this new deployment, we expect you to use this primarily for the purposes of proof of concept, evaluation, and so on.

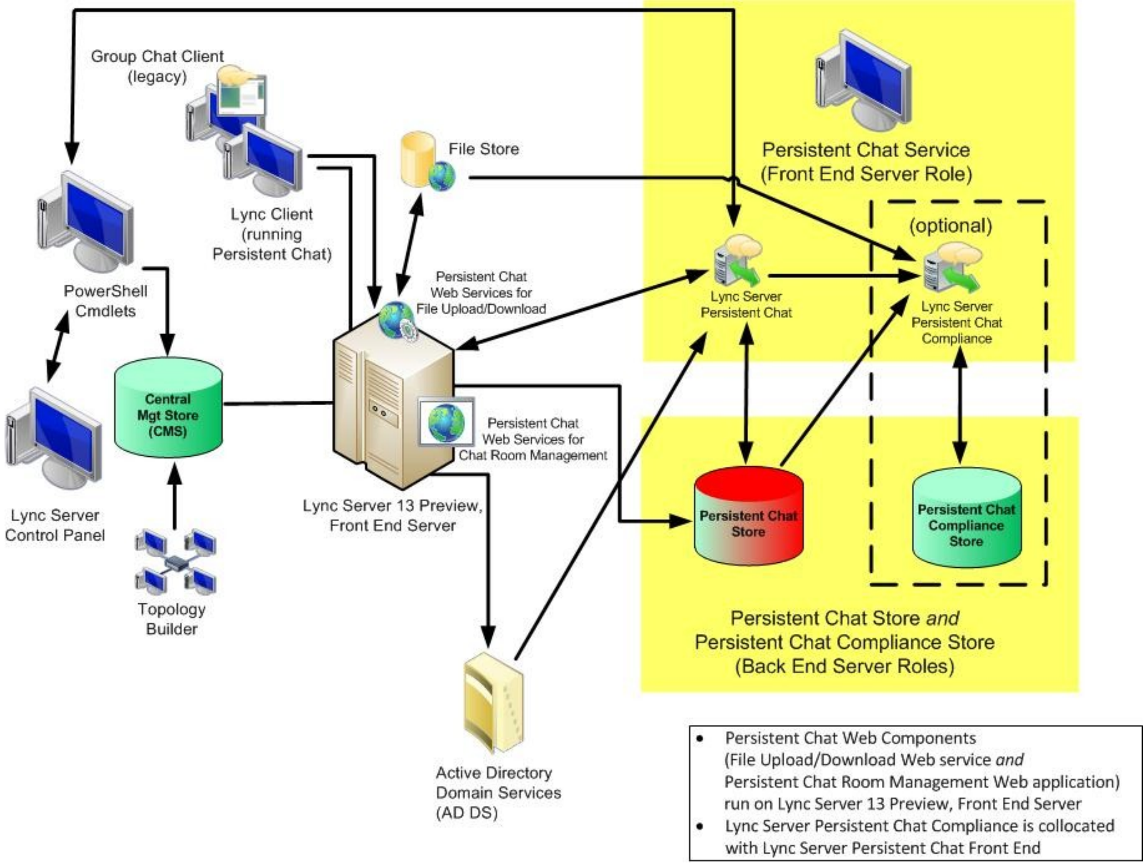
Note:
For additional details about both topologies, see Planning for Persistent Chat Server in this documentation set and Deploying Persistent Chat Server in the Deployment documentation.

Single-Server Topology

The minimum configuration and simplest deployment for Persistent Chat Server is a single Persistent Chat Server Front End Server topology. This deployment requires a single server that runs Persistent Chat Server (which optionally runs the Compliance service, if compliance is enabled), a server that hosts both the SQL Server database, and if compliance is required, the SQL Server database to store the compliance data.

> **Important:**
>
> You cannot add additional servers to a Persistent Chat Server pool that is started as a single-server deployment in Topology Builder. We recommend using the multiple-server pool topology, even if you're using a single server, so that you'll be able to add more servers later, if needed.

The following figure shows all required and optional components of a topology for a single Persistent Chat Server Front End Server with compliance.



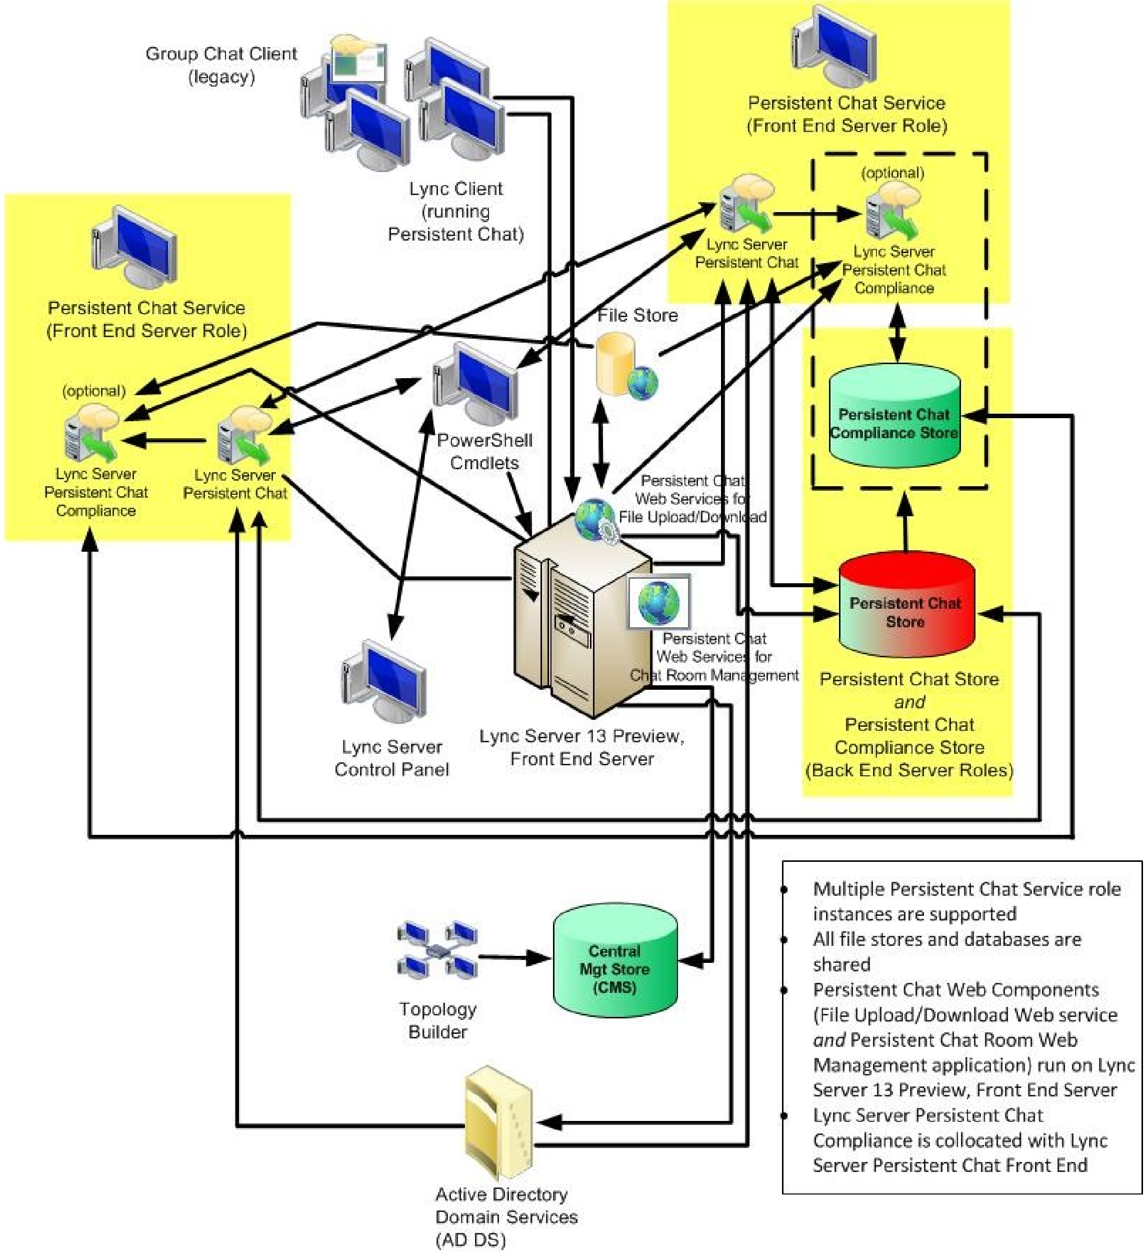
Group Chat Client (legacy)
Lync Client (running Persistent Chat)
File Store
Persistent Chat Service (Front End Server Role)
(optional)
PowerShell Cmdlets
Persistent Chat Web Services for File Upload/Download
Lync Server Persistent Chat
Lync Server Persistent Chat Compliance
Central Mgt Store (CMS)
Persistent Chat Web Services for Chat Room Management
Lync Server Control Panel
Lync Server 13 Preview, Front End Server
Persistent Chat Store
Persistent Chat Compliance Store
Topology Builder
Persistent Chat Store *and* Persistent Chat Compliance Store (Back End Server Roles)
Active Directory Domain Services (AD DS)

- Persistent Chat Web Components (File Upload/Download Web service *and* Persistent Chat Room Management Web application) run on Lync Server 13 Preview, Front End Server
- Lync Server Persistent Chat Compliance is collocated with Lync Server Persistent Chat Front End

Multiple-Server Topology

To provide greater capacity and reliability, you can deploy a multiple-server topology, as described in Planning for Persistent Chat Server. The multiple-server topology can include as many as four active computers running Persistent Chat Server (high availability and disaster recovery configurations will allow up to eight, but only four can be active and the remaining four on standby). Each server can support as many as 20,000 concurrent users, for a total of 80,000 concurrent users connected to a Persistent Chat Server pool with 4 servers. A multiple-server topology is the same as the single-server topology except that multiple servers host Persistent Chat Server, and can scale higher. Multiple computers running Persistent Chat Server should reside in the same Active Directory Domain Services (AD DS) domain as Lync Server and the Compliance service.

The following figure shows all the components of a multiple-server topology with multiple computers running Persistent Chat Server, the optional Compliance service, and a separate compliance database.



Group Chat Client (legacy)
Lync Client (running Persistent Chat)
Persistent Chat Service (Front End Server Role)
(optional)
Lync Server Persistent Chat
Lync Server Persistent Chat Compliance
Persistent Chat Service (Front End Server Role)
(optional)
Lync Server Persistent Chat Compliance
Lync Server Persistent Chat
File Store
PowerShell Cmdlets
Persistent Chat Web Services for File Upload/Download
Persistent Chat Compliance Store
Persistent Chat Store
Persistent Chat Web Services for Chat Room Management
Lync Server Control Panel
Lync Server 13 Preview, Front End Server
Persistent Chat Store *and* Persistent Chat Compliance Store (Back End Server Roles)
Central Mgt Store (CMS)
Topology Builder
Active Directory Domain Services (AD DS)

- Multiple Persistent Chat Service role instances are supported
- All file stores and databases are shared
- Persistent Chat Web Components (File Upload/Download Web service *and* Persistent Chat Room Web Management application) run on Lync Server 13 Preview, Front End Server
- Lync Server Persistent Chat Compliance is collocated with Lync Server Persistent Chat Front End

In a four-server Persistent Chat Server deployment, where 80,000 users can be simultaneously signed in to and using Persistent Chat, the load is distributed evenly at 20,000 users per server. If one server becomes unavailable, the users who are connected to that server will lose their access to Persistent Chat Server. The disconnected users will be automatically transferred to the remaining servers until the unavailable server is restored. Depending on the amount of Persistent Chat traffic on the network, this transfer can take a few minutes or longer. Because each of the remaining servers might be hosting as many as 30,000 users, we recommend that you restore the unavailable server as quickly as possible to avoid performance issues. Otherwise, you can make another

Persistent Chat Server available by using the Topology Builder or the Windows PowerShell cmdlet, **set-CsPersistentChatActiveServer**.

Persistent Chat Server Capacity Planning

The following tables can help you with capacity planning for Persistent Chat Server. They model how changing various Persistent Chat Server settings affect capacity capabilities.

Planning Your Maximum Capacity for Persistent Chat Server

Use the following sample table to determine the number of users you will be able to support.

Persistent Chat Server pool Maximum Capacity Sample

Active Persistent Chat service instances	*4*
Persistent Chat service instances	*8 (4 must be inactive; only a maximum of 4 can be active)*
Active users connected	*80,000*
Total provisioned users	150,000
Number of endpoints	120,000

In the preceding sample, the plan is to support the maximum number of users that Persistent Chat Server allows: four servers/instances of the Persistent Chat service (can have four more passive servers running Persistent Chat Server for high availability and disaster recovery) and 20,000 users per server, for a total of 80,000 active users.

Capacity Planning for Managing Persistent Chat Room Access

The following sample table can help you plan for managing Persistent Chat room access in a Persistent Chat Server pool.

Managing Chat Room Access Sample

	Small Chat Rooms	**Medium Chat Rooms**	**Large Chat Rooms**	**Total**
Size of chat rooms (number of users connected)	30 per room	150 per room	16,000 per room	
Chat rooms	32,000	1,067	10	33,077
% of rooms that are auditorium	1%	1%	50%	
% of rooms that are open	3%	3%	50%	
Open rooms (no explicit membership)	960	32	5	997
Non-open rooms (regular rooms with explicit membership)	31,040	1.035	5	32,080

Auditorium rooms (additional presenters entry)	0	32	5	
Rooms managed by direct membership	50%	10%	0%	
Rooms managed by user groups	50%	90%	100%	
User groups in each chat room's membership list for open rooms (not specified explicitly)	0	0	0	
Users in each chat room's membership list for non-open rooms	30	150	16,000	
User groups in each chat room's membership list for non-open rooms	3	5	10	
Users and user groups in each chat room's manager list (for open and non-open rooms)	6	6	6	
Users and user groups in each auditorium chat room's presenters list (for open and non-open rooms)	6	6	6	
User-based membership entities across all non-open rooms	465,600	15,520	-	
User-group-based membership entities across all non-open rooms	46,560	4656	50	
Users and user groups based entities across all auditorium chat rooms	0	192	50	

Users and user groups based manager entities across all chat rooms manager lists	192,000	6,400	60	
Active users per chat room	*30*	*150*	*16,000*	
Chat rooms per user	*12*	*2*	*2*	*16*
User groups in each chat room's membership list	*10*	*10*	*15*	
Rooms managed by user groups	*50%*	*50%*	*50%*	
User-group-based membership entities across all chat rooms	155,200	5173	68	
User-based membership entities across all chat rooms	465,600	77,600	72,000	
Users and user groups in each chat room's manager, presenter, and scope lists	6	6	6	
Users and user groups across all chat rooms' manager, presenter, and scope lists	192,000	6400	60	
Access control entries	704,160	26,768	160	731,088
Maximum access control entries				2,000,000

In the preceding sample, when you deploy the Persistent Chat Servers according to the recommended guidelines, they can handle up to 80,000 active users across a four-server pool with compliance enabled.

This sample shows chat rooms categorized as small (30 active users at any given time), medium (150 active users), and large (16,000 active users). The number of chat rooms of a certain size is computed based on the total number of:

- Active users in the system
- Active users in chat rooms of the given size
- Chat rooms of the given size that a single user joins

For each chat room, the preceding capacity planning table specifies the number of access control entries that are associated with the chat room, including entries that are assigned directly to the chat room. You can control access to individual chat rooms by using access control lists (ACLs). You can also control access at the category level. In an ACL, an individual access control entry can be either a user group—for example, a security group, a distribution list, or a single user. You can define access control entries for chat room managers, presenters, and members.

Important:

In planning your strategy for managing chat rooms, keep in mind that the total number of allowed access control entries is 2 million. If the calculated access control entries exceed 2 million, server performance could degrade significantly. To avoid this issue, whenever possible, be sure that your access control entries are user groups instead of individual users.

Capacity Planning for Managing Chat Room Access by Invitation

You can use the following capacity planning table to understand the number of invitations that Persistent Chat Server creates and stores in the Persistent Chat database when it is configured to send invitations. You manage invitations on the Category by using the **Chat Room Category settings** page in the Lync Server Control Panel, or by using the Windows PowerShell cmdlet, **set-csPersistentChatCategory**. You can manage invitations on a chat room (in line with what the category allows) by using the **Room Management** page launched from the Lync client, or by using a Windows PowerShell cmdlet, **set-csPersistentChatRoom**.

The sample data in the following table assumes that, on the **Chat room settings** page for 50 percent of all chat rooms, the **Invitations** option is set to **Yes**.

Important:

If the calculated value for the number of invitations that is generated by the server exceeds 1 million, server performance could degrade significantly. To avoid this issue, be sure that you minimize the number of chat rooms that are configured to send invitations or restrict the number of users who can join chat rooms that have been configured to send invitations.

Chat Room Access by Invitation Sample

	Small Chat Rooms	**Medium Chat Rooms**	**Large Chat Rooms**	**Total**
Users who can access chat room	30 per room	150 per room	16,000 per room	
Percentage of rooms that have invitations	50%	50%	50%	
Chat rooms configured to send invitations	*16,000*	*533*	*5*	
Users who can access the chat room	*60*	*225*	*16,000*	
Invitations generated by Persistent Chat Server	960,000	120,000	80,000	1,160,000
Maximum allowable				2,000,000

number of invitations				
Model 1 - Start with expected number of messages per room per day				
Chat Rate Per Room (per day)	50	500	100	650
Chat rate (per second) across all rooms	55.56	18.52	0.03	74
Model 2 - Start with number of messages posted per user per day				
Chat rate per user per day	15	5	0.1	20
Chat rate per room (per day)	38	375	800	1,213
Chat rate (per second) across all rooms	41.67	13.89	0.28	56

Persistent Chat Server Performance User Model

The following table describes the user model for Persistent Chat Server. It provides the basis for the capacity planning requirements and represents a typical organization with 80,000 concurrent users on four servers.

Persistent Chat Server Performance User Model

Number of active users connected	80,000
Number of Persistent Chat Server service instances	4
Size of small chat rooms	30 users
Size of medium chat rooms	150 users
Size of large chat rooms	16,000 users
Total number of chat rooms	33,077
Number of small chat rooms	32,000
Number of medium chat rooms	1,067
Number of large chat rooms	10
Total number of chat rooms per user	16
Number of small chat rooms per user	12
Number of medium chat rooms per user	2

Number of large chat rooms per user	2
Number of rooms joined per user	24
Peak join rate	10/second
Total chat rate	24/second
Chat rate for small chat rooms	22.22/second
Chat rate for medium chat rooms	1.67/second
Chat rate for large chat rooms	~0.15/second
Percentage of chat rooms configured for invitations	50%
Percentage of direct memberships	50%
Percentage of group memberships	50%
Average number of ancestor affiliations in Active Directory Domain Services (AD DS)	100 - 200
Number of subscribed contacts per user	80
Average number of endpoints per user	1.5
Average number of visible chat rooms per endpoint	1.5
Average number of visible chat rooms per user	2.25 (50% for 1 room and 50% for 2 rooms); Up to 6 rooms open, one per monitor
Number of participants polled per interval	25 per visible chat room
Length of polling interval	5 minutes
Number of participants polled per second	15,000
Number of presence changes per hour per user	6
Number of presence changes per second	133.33

1.3.14 Planning for Exchange Server Integration

Planning for Exchange Server Integration

Microsoft Lync Server 2013 > Planning >

Topic Last Modified: *2012-09-20*

When you deploy both Exchange and Lync Server in your organization, many features in both products are enhanced. This section contains information about these capabilities.

- Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013
- Planning for Exchange Unified Messaging Integration
- Hosted Exchange Unified Messaging Integration

1.3.14.1 Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013

Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013

Microsoft Lync Server 2013 > Planning > Planning for Exchange Server Integration >

Topic Last Modified: *2012-10-10*

Exchange and Lync Server have a long history of integration and compatibility. This integration is most noticeable within their respective client application. For example, Lync presence information can be reported in Microsoft Outlook; likewise, Lync can use Outlook calendar to automatically update that presence information. (For example, Lync can change your status to Busy any time your calendar shows that you have a meeting scheduled.) Although you do not have to run Exchange in order to run Lync Server (or vice-versa) there's little doubt that using the two products together epitomizes the very definition of the term "better together."

This is especially true with the release of Microsoft Lync Server 2013 and Microsoft Exchange Server 2013. In addition to features, such as unified messaging and IM and presence, that are found in Microsoft Exchange Server 2010 and Microsoft Lync Server 2010, the 2013 releases of the server products include a number of new capabilities. These capabilities include such things as:

- **Lync Archiving Integration**. In Lync Server 2013 administrators still have the option of having instant messaging and Web conferencing transcripts archived to SQL Server (the same way these transcripts were archived in Lync Server 2010). Alternatively, however, administrators can choose to have transcripts archived to Exchange 2013, storing those transcripts in the individual user mailboxes in the same way in which Exchange archives communications. That means a single repository for all your electronic communications (from both Exchange and Lync Server), which makes it much easier to search for and retrieve those archived communications should the need arise.
- **Unified Contact Store**. In Lync Server 2010, users had to maintain separate contact lists in Outlook and Lync; in fact, to ensure that you had the same contacts available in both products you had to maintain duplicate contact lists, one for Outlook and one for Lync. With Lync Server 2013, however, user contacts can be stored in Exchange 2013 and the unified contact store. Using a single contact store enables users to maintain just one set of contacts, with that same set of contacts being available in Lync 2013, Outlook 2013, and Outlook Web Access 2013.
- **High resolution photos**. Lync 2010 could only display small photos of your contacts; that's because those photos were stored in Active Directory, and Active Directory imposes a 48 pixel by 48 pixel size limitation on stored photos. With Lync Server 2013, however, photos can be stored in Microsoft Exchange; that allows for high-resolution photos as large as 648 pixels by 648 pixels. As you might expect, Lync 2013 has been upgraded to allow for the display of these high-resolution photographs.

Keep in mind that these new features require the use of both Lync Server 2013 and Exchange 2013. In addition to that, users who hope to take full advantage of these new capabilities must have accounts on Lync Server 2013 and Exchange 2013, and must be using the latest versions of the client software (e.g., Lync 2013). For example, the unified contact store is not available to users who have been homed on Lync Server 2010; likewise, high-resolution photos cannot be displayed in Lync 2010.

This documentation provides information on integrating Lync Server 2013 and Exchange 2013. including step-by-step information on enabling new features such archiving Integration and the unified contact store. What this documentation does not do is discuss the initial setup and configuration of these two products. For details about deploying Lync

Server 2013 see the Lync Server 2013 Tech Center at http://go.microsoft.com/fwlink/p/?LinkId=246127. For details about deploying Exchange 2013 see the Exchange 2013 Tech Center at http://go.microsoft.com/fwlink/p/?LinkId=268528.

Prerequisites for Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013

Planning > Planning for Exchange Server Integration > Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 >

Topic Last Modified: *2012-10-10*

Before you can integrate Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 you must ensure that all the prerequisite steps have been completed. As you might expect, integration cannot take place until both Exchange 2013 and Lync Server 2013 are fully installed and up and running. For details about installing Exchange, see the Exchange 2013 Planning and Deployment documentation at http://go.microsoft.com/fwlink/p/?LinkId=268539. For details about installing Lync Server 2013, see the planning and deployment documentation at http://go.microsoft.com/fwlink/p/?LinkId=254806.

After the servers are up and running you must assign server-to-server authentication certificates to both Lync Server 2013 and Exchange 2013; these certificates allow Lync Server and Exchange to exchange information and to communicate with one another. When you install Exchange 2013, a self-signed certificate with the name Microsoft Exchange Server Auth Certificate is created for you. This certificate, which can be found in the local computer certificate store, should be used for server-to-server authentication on Exchange 2013. For details about assigning certificates in Exchange 2013, see "Configure Mail Flow and Client Access" at http://go.microsoft.com/fwlink/p/?LinkId=268540.

For Lync Server 2013 you can use an existing Lync Server certificate as your server-to-server authentication certificate; for example, your default certificate can also be used as the OAuthTokenIssuer certificate. Lync Server 2013 allows you to use any Web server certificate as the certificate for server-to-server authentication provided that:

- The certificate includes the name of your SIP domain in the Subject field.
- The same certificate is configured as the OAuthTokenIssuer certificate on all of

your Front End Servers.
- The certificate has a length of at least 2048 bits.

For details about server-to-server authentication certificates for Microsoft Lync Server 2013, see Assigning a Server-to-Server Authentication Certificate to Microsoft Lync Server 2013.

After the certificates have been assigned you must then configure the autodiscover service on Exchange 2013. In Exchange 2013, the autodiscover service configures user profiles and provides access to Exchange services when users log on to the system. Users present the autodiscover service with their email address and password; in turn, the services provide the user with information such as:

- Connection information for both internal and external connectivity to Exchange 2013.
- The location of the user’s Mailbox server.
- URLs for Outlook features such as free/busy information, Unified Messaging, and the offline address book.
- Outlook Anywhere server settings.

The autodiscover service must be configured before you can integrate Lync Server 2013 and Exchange 2013. You can verify whether or not the autodiscover service has been configured by running the following command from the Exchange Management Shell and checking the value of the AutoDiscoverServiceInternalUri property:

```
Get-ClientAccessServer
```

If this value is blank, you must assign a URI to the autodiscover service. Typically this URI will look similar to this:

```
https://autodiscover.litwareinc.com/autodiscover/autodiscover.xml
```

You can assign the autodiscover URI by running a command similar to this:

```
Get-ClientAccessServer | Set-ClientAccessServer -AutoDiscoverServiceInternalUri "
```

For details about the autodiscover service, see "Understanding the Autodiscover Service" at http://go.microsoft.com/fwlink/p/?LinkId=268542.

After the autodiscover service has been configured you must then modify the Lync Server OAuth configuration settings; this ensures that that Lync Server knows where to find the autodiscover service. To modify the OAuth configuration settings in Lync Server 2013, run the following command from within the Lync Server Management Shell. When running this command, be sure that you specify the URI to the autodiscover service running on your Exchange server, and that you use **autodiscover.svc** to point to the service location instead of **autodiscover.xml** (which points to the XML file used by the service):

```
Set-CsOAuthConfiguration -Identity global -ExchangeAutodiscoverUrl "https://autod
```

Note:

The Identity parameter in the preceding command is optional; that's because Lync Server only allows you to have a single, global collection of OAuth configuration settings. Among other things, that means that you can configure the autodiscover URL by using this slightly-simpler command:
Set-CsOAuthConfiguration–ExchangeAutodiscoverUrl "https://autodiscover.litwareinc.com/autodiscover/autodiscover.svc"
If you are unfamiliar with the technology, OAuth is a standard authorization protocol used by a number of major websites. With OAuth, user credentials and passwords are not passed from one computer to another. Instead, authentication and authorization is based on the exchange of security tokens; these tokens grant access to a specific set of resources for a specific amount of time.

In addition to configuring the autodiscover service, you must also create a DNS record for the service that points to your Exchange server. For example, if your autodiscover service is located at autodiscover.litwareinc.com you will need to create a DNS record for autodiscover.litwareinc.com that resolves to the fully qualified domain name of your Exchange server (for example, atl-exchange-001.litwareinc.com).

1.3.14.1.2 Configuring Partner Applications in Microsoft Lync Server 2013 and Microsoft Exchange Server 2013

Configuring Partner Applications in Microsoft Lync Server 2013 and Microsoft Exchange Server 2013

Planning > Planning for Exchange Server Integration > Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 >

Topic Last Modified: *2012-11-12*

Server-to-server authentication typically involves three entities: the two servers that need to communicate with one another, and a third-party security token server. If two servers (for example, Server A and Server B) need to communicate, then both of those servers typically start by contacting a token server and obtain a mutually-trusted security token. Server A then present that security token to Server B (and vice-versa) as a way to guarantee both its authenticity and its trustworthiness.

However, that's a general rule. Lync Server 2013, Microsoft Exchange Server 2013, and Microsoft SharePoint Server 2013 do not need to use a third-party token server when communicating with one another; that's because these server products can create security tokens that can be accepted by one another without the need for a separate token server. (This capability is only available in Lync Server 2013, Exchange 2013, and SharePoint Server 2013. If you need to set up server-to-server authentication with other servers, including other Microsoft server products, then you will need to do so by using a third-party token server.)

In order to set up server-to-server authentication between Lync Server and Exchange you must do two things: 1) you must assign the appropriate certificates to each server; and, 2) you must configure each server to be a partner application of the other server: that means you must configure Lync Server 2013 to be a partner application for Exchange 2013, and you must configure Exchange 2013 to be a partner application for Lync Server 2013.

Configuring Lync Server 2013 to be a Partner Application for Exchange 2013

The easiest way to configure Lync Server 2013 to be a partner application with Exchange 2013 is to run the Configure-EnterprisePartnerApplication.ps1 script, a Windows PowerShell script that ships with Exchange 2013. To run this script, you must provide the URL for the Lync Server authentication metadata document; this will typically be the fully qualified domain name of the Lync Server 2013 pool followed by the suffix /metadata/json/1. For example:

```
https://atl-cs-001.litwareinc.com/metadata/json/1
```

To configure Lync Server as a partner application, open the Exchange Management Shell and run a command similar to this (assuming that Exchange has been installed on drive C: and that it uses the default folder path):

```
"C:\Program Files\Microsoft\Exchange Server\V15\Scripts\Configure-EnterprisePartn
```

After configuring the partner application it is recommended that you stop and restart Internet Information Services (IIS) on your Exchange mailbox and client access servers. You can restart IIS by using a command similar to this, which restarts the service on the computer atl-exchange-001:

```
iisreset atl-exchange-001
```

This command can be run from within the Exchange Management Shell or from any other command window run under administrator privileges.

Configuring Exchange 2013 to be a Partner Application for Lync Server 2013

After you have configured Lync Server 2013 to be a partner application for Exchange 2013, you must then configure Exchange to be a partner application for Lync Server. This can be done by using the Lync Server Management Shell and specifying the authentication metadata document for Exchange; this will typically be the URI of the Exchange autodiscover service followed by the suffix /metadata/json/1. For example:

```
https://autodiscover.litwareinc.com/autodiscover/metadata/json/1
```

In Lync Server, partner applications are configured by using the New-CsPartnerApplication cmdlet. In addition to specifying the metadata URI you should also set the application trust level to Full; this will allow Exchange to represent both itself and any authorized user in the realm. For example:

```
New-CsPartnerApplication -Identity Exchange -ApplicationTrustLevel Full -Metadata
```

Alternatively, you can create a partner application by copying and modifying the script code found in the Lync Server 2013 server-to-server authentication documentation. See the article Managing Server-to-Server Authentication (Oauth) and Partner Applications for more information.

If you have successfully configured partner applications for both Lync Server and Exchange that means that you have also successfully configured server-to-server authentication between the two products. Lync Server 2013 includes a Windows PowerShell cmdlet, Test-CsExStorageConnectivity, that enables you to verify that server-to-server authentication has been correctly configured and that the Lync Server Storage Service can connect to Exchange 2013. The cmdlet does this by connecting to the mailbox of an Exchange 2013 user, writing an item into the Conversation History folder for that user, and then, optionally, deleting that item.

To test the integration of Lync Server 2013 and Exchange 2013, run a command similar to this from within the Lync Server Management Shell:

```
Test-CsExStorageConnectivity -SipUri "sip:kenmyer@litwareinc.com"
```

In the preceding command, the SipUri represents the SIP address of a user with an account on Exchange 2013; your command will fail in this is not a valid user account.

If the test succeeds and connectivity has been established, you can then proceed to configure optional features such as archiving integration and the unified contact store.

Configuring Microsoft Lync Server 2013 to Use Microsoft Exchange Server 2013 Archiving

Planning > Planning for Exchange Server Integration > Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 >

Topic Last Modified: *2012-10-04*

Microsoft Lync Server 2013 gives administrators the option of having instant messaging and Web conferencing transcripts archived to a user's Microsoft Exchange Server 2013 mailbox rather than a SQL Server database. If you enable this option, transcripts are written to the Purges folder in the user's mailbox. The Purges folder is a hidden folder found in the Recoverable Items folder. Although this folder is not visible to end-users, the folder is indexed by the Exchange search engine and can be discovered by using Exchange mailbox search and/or Microsoft SharePoint Server 2013. Because information is stored in the same folder used by the Exchange In-Place Hold feature (responsible for archiving email and other Exchange communications), administrators can use a single tool to search for all the electronic communications archived for a user.

In order to archive transcripts to Exchange 2013 you must begin by configuring server-to-server authentication between the two servers. After server-to-server authentication is in place you can then carry out the following tasks in Microsoft Lync Server 2013 (note that, depending on your setup and configuration, you might not need to complete all of these tasks):

1. Enable Exchange archiving by modifying your Lync Server archiving configuration settings. This step is required for all deployments.
2. Enable archiving for internal and/or external communications for your users. This step is required for all deployments.
3. Configure the ExchangeArchivingPolicy property for each user. This step is only required in Lync Server and Exchange are located in different forests.

Step 1: Enabling Exchange Archiving

Archiving in Lync Server is primarily managed by using the archiving configuration settings. When you install Lync Server 2013 you are automatically given a single, global collection of these settings. (Administrators can optionally create new collections of archiving settings at the site scope.) By default, archiving is not enabled in the global settings, nor is Exchange archiving enabled in these settings. In order to use Exchange archiving administrators must configure both the EnableArchiving and the EnableExchangeArchiving properties in these configuration settings. The EnableArchiving property can be set to one of three possible values:

- **None**. Archiving is disabled. This is the default value. If EnableArchiving is set to None then nothing will be archived in either your Lync Server archiving database or in Exchange 2013.
- **ImOnly**. Only instant message transcripts are archived. If Exchange archiving is enabled these transcripts will be archived in Exchange 2013. If Exchange archiving is disabled then these transcripts will be archived to Lync Server.
- **ImAndWebConf**. Both instant message transcripts and Web conferencing transcripts are archived. If Exchange archiving is enabled these transcripts will be archived in Exchange 2013. If Exchange archiving is disabled then these transcripts will be archived to Lync Server.

The EnableExchangeArchiving property is a Boolean value: set EnableExchangeArchiving to True ($True) to enable Exchange archiving or set EnableExchangeArchiving to False ($False) to disable Exchange archiving. For example, this command enables the archiving of instant messaging transcripts and also enables Exchange archiving:

```
Set-CsArchivingConfiguration -Identity "global" -EnableArchiving ImOnly -EnableEx
```

To disable Exchange archiving, use a command similar to the following, which enables instant messaging archiving but disables archiving to Exchange (in other words, transcripts will be archived to Lync Server):

```
Set-CsArchivingConfiguration -Identity "global" -EnableArchiving ImOnly -EnableEx
```

Note:

If the EnableArchiving property is set to None then Lync Server will not archive instant messaging and Web conferencing transcripts at all. In that case, the server will simply ignore the value configured for EnableExchangeArchiving.

Exchange archiving can also be enabled (or disabled) by using the Lync Server Control Panel. To do that, complete the following procedure:

1. In Control Panel, click **Monitoring and Archiving**, and then click **Archiving Configuration**.
2. On the **Archiving Configuration** tab, double-click the collection of archiving settings to be modified (for example, the **Global** collection).
3. In the **Edit Archiving Setting** pane, click the **Archiving setting** dropdown list and select either **Archive IM sessions** (to archive just instant messaging sessions) or **Archive IM and web conferencing sessions** (to archive both instant messaging and Web conferencing sessions).
4. After choosing the items to be archived, select the **Exchange Server integration** checkbox to enable Exchange archiving. To disable Exchange archiving, clear this checkbox.

Note:

The **Exchange Server integration** checkbox will not be available if the **Archiving setting** is set to **Disable archiving**. You must enable archiving first and then enable Exchange archiving.

If Lync Server 2013 and Exchange 2013 are located in the same forest then archiving for individual users (or at least for users who have email accounts on Exchange 2013) is managed by using Exchange In-Place Hold policies. If you have users who are homed on a previous version of Exchange then archiving for those users will be managed by using Lync Server archiving policies. Note that only users with accounts on Exchange 2013 can have their Lync transcripts archived to Exchange.

If Lync Server 2013 and Exchange 2013 are located in different forests then archiving for individual users is managed by configuring the ExchangeArchivingPolicy property for each individual user account. See Step 3 for more information.

Step 2: Enabling the Archiving of Internal and/or External Communications

After you have enabled archiving (and Exchange archiving) you must then modify the appropriate archiving policies to ensure that user sessions are actually archived. Note that simply enabling archiving (Step 1) does not cause Lync Server to begin archiving instant messaging and Web conferencing transcripts. Instead, you must use archiving policies to enable internal and/or external archiving. When you install Lync Server 2013 you also install a single, global archiving policy that contains two properties:

- **ArchiveInternal**. When set to True ($True) indicates that internal communication sessions involving only users who have Active Directory accounts in your organization) will be archived.
- **ArchiveExternal**. When set to True ($True) indicates that internal

communication sessions (sessions involving at least one user who does not have an Active Directory account in your organization) will be archived.

By default, both of these property values are set to False, meaning that neither internal nor external communication sessions are archived. To modify the global policy, you can use the Lync Server Management Shell and the Set-CsArchivingPolicy cmdlet. This command enables the archiving of both internal and external communication sessions:

```
Set-CsArchivingPolicy -Identity "global" -ArchiveInternal $True -ArchiveExternal
```

Alternatively, you can use the New-CsArchivingPolicy to create a new policy at either the site scope or the per-user scope. For example, this command creates a new per-user archiving policy named RedmondArchivingPolicy:

```
New-CsArchivingPolicy -Identity "RedmondArchivingPolicy" -ArchiveInternal $True -
```

If you create a per-user policy you will then need to assign that policy to the appropriate users. For example:

```
Grant-CsArchivingPolicy -Identity "Ken Myer" -PolicyName  "RedmondArchivingPolicy
```

Archiving policies can also be managed by using the Lync Server Control Panel. Within the Control Panel, click **Monitoring and Archiving** and then click **Archiving Policy**. To modify an existing policy, double-click the policy (e.g., Global) and then, in the **Edit Archiving Policy** pane, select or clear the **Archive internal communications** and the **Archive external communications** checkboxes as needed. To create a new archiving policy, click **New** and then select either **Site policy** or **User policy**. If you create a new user policy then you must access the appropriate user accounts (from the **Users** tab) and assign those users the new policy.

Step 3: Configuring the ExchangeArchivingPolicy Property

If Lync Server 2013 and Exchange 2013 are located in different forests then it is not enough to simply enable Exchange archiving in the archiving configuration settings; that will not result in instant messaging and Web conferencing transcripts being archived in Exchange. Instead, you must also configure the ExchangeArchivingPolicy property on each of the relevant Lync Server user accounts. This property can be set to one of four possible values:

1. Uninitialized. Indicates that archiving will be based on the In-Place Hold settings configured for the user's Exchange mailbox; if In-Place Hold has not been enabled on the user's mailbox then the user will have his or her messaging and Web conferencing transcripts archived in Lync Server.
2. **UseLyncArchivingPolicy**. Indicates that the user's instant messaging and Web conferencing transcripts should be archived in Lync Server rather than in Exchange.
3. **NoArchiving**. Indicates that the user's instant messaging and Web conferencing transcripts should not be archived at all. Note that this setting overrides any Lync Server archiving policies assigned to the user.
4. **ArchivingToExchange**. Indicates that the user's instant messaging and Web conferencing transcripts should be archived to Exchange regardless of the In-Place Hold settings that have (or have not) been assigned to the user's mailbox.

For example, to configure a user account so that instant messaging and Web conferencing transcripts are always archived to Exchange you can use a command similar to this from the Lync Server Management Shell:

```
Set-CsUser -Identity "Ken Myer" -ExchangeArchivingPolicy ArchivingToExchange
```

If you want to set the same archiving policy for a group of users (for example, all the users homed on a specified Registrar pool) you can use a command similar to this:

```
Get-CsUser -Filter {RegistrarPool -eq "atl-cs-001.litwareinc.com"} | Set-CsUser -
```

Note that you must use the Lync Server Management Shell (and Windows PowerShell) in order to configure value of the ExchangeArchivingPolicy property. This property is not exposed to administrators in the Lync Server Control Panel.

If you would like to view a list of all the users who have been assigned a specific archiving policy then you can use a command similar to the following, which returns the Active Directory display name of all the users who have had the ExchangeArchivingPolicy property set to Uninitialized:

```
Get-CsUser | Where-Object {$_.ExchangeArchivingPolicy -eq "Uninitialized"} | Sele
```

Likewise, this command returns the display name of the users who have not have the ExchangeArchivingPolicy property set to UseLyncArchivingPolicy:

```
Get-CsUser | Where-Object {$_.ExchangeArchivingPolicy -ne "UseLyncArchivingPolicy
```

1.3.14.1.4 Configuring Microsoft SharePoint Server 2013 to Search for Archived Microsoft Lync Server 2013 Data

Configuring Microsoft SharePoint Server 2013 to Search for Archived Microsoft Lync Server 2013 Data

Planning > Planning for Exchange Server Integration > Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 >

Topic Last Modified: *2013-02-04*

One of the major advantages to storing instant messaging and Web conferencing transcripts in Microsoft Exchange Server 2013 instead of Microsoft Lync Server 2013 is the fact that storing data in the same location enables administrators to use a single tool to search for archived Exchange data and/or archived Lync Server data. Because all the data is stored in the same place (Exchange) any tool that can search for archived Exchange data can also search for archived Lync Server data.

One tool that makes it easy to search for archived data is Microsoft SharePoint Server 2013. If you would like to use SharePoint to search for Lync Server data, you must first complete all the steps involved in configuring Exchange archiving in Lync Server. After Exchange 2013 and Lync Server 2013 have been successfully integrated you must then install the Exchange Web Services Managed API Version 2.0 on your SharePoint Server; the setup program for that API can be downloaded from the Microsoft Downloads Center (http://go.microsoft.com/fwlink/p/?LinkId=258305). The downloaded file (EWSManagedAPI.msi) can be saved to any folder on your SharePoint server.

After the file has been downloaded complete the following procedure on the SharePoint server:

1. Open a command window by clicking **Start**, clicking **All Programs**, clicking **Accessories**, right-clicking **Command Prompt**, and then clicking **Run as administrator**.
2. In the command window, use the **cd** command to change the current directory to the folder where the file EWSManagedAPI.msi has been saved. For example, if you have saved the file to C:\Downloads type the following command in the command window and then press ENTER:

```
cd C:\Downloads
```

3. To install the API, type the following command then press ENTER:

```
msiexec /I EwsManagedApi.msi addlocal="ExchangeWebServicesApi_Feature,
```

4. After the API has been installed, reset IIS by typing the following command and pressing ENTER:

```
iisreset
```

After Exchange Web Services has been installed you must then configure server-to-server authentication between SharePoint Server 2013 and Exchange 2013. To do this, first open the SharePoint 2013 Management Shell and run the following set of command:

```
New-SPTrustedSecurityTokenIssuer -Name "Exchange" -MetadataEndPoint "https://auto
$service = Get-SPSecurityTokenServiceConfig
$service.HybridStsSelectionEnabled = $True
$service.AllowMetadataOverHttp = $False
$service.AllowOAuthOverHttp = $False
$service.Update()
```

Note:

Be sure and use the URI for your autodiscover service. Do not use the sample URI https://autodiscover.litwareinc.com/autodiscover/metadata/json/1.

After you have created the token issuer and configured the token service, run these commands, making sure to substitute the URL of your SharePoint site for the sample URL http://atl-sharepoint-001:

```
$exchange = Get-SPTrustedSecurityTokenIssuer "Exchange"
$app = Get-SPAppPrincipal -Site "https://atl-sharepoint-001" -NameIdentifier $exc
$site = Get-SPSite  "https://atl-sharepoint-001"
Set-SPAppPrincipalPermission -AppPrincipal $app -Site $site.RootWeb -Scope "SiteS
```

To configure server-to-server authentication for Exchange 2013, open the Exchange Management Shell and run a command similar to this (assuming that Exchange has been installed on drive C: and that it uses the default folder path):

```
"C:\Program Files\Microsoft\Exchange Server\V15\Scripts\Configure-EnterprisePartn
```

After configuring the partner application it is recommended that you stop and restart Internet Information Services (IIS) on all your Exchange mailbox and client access servers. You can restart IIS by using a command similar to this, which restarts the service on the computer atl-exchange-001:

```
iisreset atl-exchange-001
```

This command can be run from within the Exchange Management Shell or from any other command window.

Next, run a command similar to the following, which gives the specified user (in this example, kenmyer) the right to do discovery on Exchange:

```
Add-RoleGroupMember "Discovery Management" -Member "kenmyer"
```

After server-to-server authentication has been established between Exchange and SharePoint your next step is to create an eDiscovery site in SharePoint. That can be done by running commands similar to these from the SharePoint Management Shell:

```
$template = Get-SPWebTemplate | Where-Object {$_.Title -eq "eDiscovery Center"}
New-SPSite -Url "https://atl-sharepoint-001/sites/discovery" -OwnerAlias "kenmyer
```

Note:

"eDiscovery" is short for "electronic discovery," and typically refers to the process of looking through electronic archives for items that can be "reasonably calculated to lead to admissible evidence" in a court of law.

When the new site is ready, the next step is to configure Exchange 2013 to act as a result source for SharePoint. You can do that by completing the following procedure from the SharePoint 2013 Central Administration page:

1. On the Central Administration page click **Manage Service Applications** and then click **Search Service Application**.
2. On the Search Service Application: Search Administration page click **Result Sources** and then click **New Result Source**.
3. In the **New Result Source** pane enter a name for the new result source (for example, **Microsoft Exchange**) in the **Name** box. Select **Exchange** as the result source **Protocol**, and then enter the web services source URL for your Exchange server in the **Exchange Source URL** box. The source URL should look similar to this:
   https://atl-exchange-001.litwareinc.com/ews/exchange.asmx
4. Make sure that **Use Autodiscover** is not selected, and then click **OK**.

Finally, create a new eDiscovery case and a new eDiscovery set by completing the following procedure from the SharePoint Discovery site (for example, https://atl-sharepoint-001/sites/discovery):

1. On the Site Contents page click **Create a new case**.
2. On the Site Contents: New SharePoint Site page, enter the user's email alias (for example, **kenmyer**) in the **Title** box, then add that same URL to the **Web Site Address** box. That will result in a URL similar to this:
   https://atl-sharepoint-001/sites/eDiscovery/kenmyer
3. Click **Create**.
4. When the eDiscovery set page appears, click **new item** under **Identity and Preserve: Discovery Sets**.
5. On the New: Discovery Set page, enter the user's email alias in the **Discovery Set Name** box. Enter **eDiscovery Lync*** in the **Filter** box and then click **Add & Manage Sources**.
6. On the Add & Manage Sources page, enter the user's email alias in the first textbox under **Mailboxes**. Click the check mailbox icon located next to the textbook to verify that SharePoint can connect to the specified mailbox.
7. Click **OK**.
8. On the eDiscovery set page, click **Save** to save the new eDiscovery set.

At this point you can search the specified mailbox (kenmyer) and/or enable In-Place holds the same way you would for any other SharePoint content or result source.

1.3.14.1.5 Configuring Microsoft Lync Server 2013 to Use the Unified Contact Store

Configuring Microsoft Lync Server 2013 to Use the Unified Contact Store

Planning > Planning for Exchange Server Integration > Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 >

Topic Last Modified: *2013-01-16*

The unified contact store enables users to maintain a single contacts list and then have those contacts available in multiple applications, including Microsoft Lync 2013, Microsoft Outlook 2013, and Microsoft Outlook Web App 2013. When you enable the unified contact store for a user that user's contacts are not stored in Microsoft Lync Server 2013 and then retrieved using the SIP protocol. Instead, his or her contacts are stored in Microsoft Exchange Server 2013 and are retrieved by using Exchange Web Services.

Note:

Technically, contact information is stored in a pair of folders found in the user's Exchange 2013 mailbox. The contacts themselves are stored in a folder named Lync Contacts which is visible to end users; metadata about the contacts are stored in a subfolder that is not visible to end users.

Enabling the Unified Contact Store for a User

If you have already configured server-to-server authentication between Lync Server 2013 and Exchange 2013 then you have also enabled the use of the unified contact store; no additional server configuration is required. However, additional user account configuration is required in order to move a user's contacts into the unified contact store. By default, user contacts are kept in Lync Server and not in the unified contact store.

Access to the unified contact store is managed by using Lync Server user services policies. User server policies have only a single property (UcsAllowed); this property is used to determine the location where a user's contacts are stored. If a user is managed by a user services policy where UcsAllowed has been set to True ($True) then the user's contacts will be stored in in the unified contact store. If the user is managed by a user services policy where UcsAllowed has been set to False ($False) then his or her contacts will be stored in Lync Server.

When you install Lync Server 2013 a single user services policy (configured at the global scope) is installed as well. The UcsAllowed value in this policy is set to True, meaning that, by default, user contacts will be stored in the unified contact store (assuming this has been deployed and configured). If you want to migrate all of your user contacts to the unified contact store you do not have to do anything at all.

If you would prefer not to migrate all your contacts to the unified contact store you can disable the unified contact store for all users by setting the UcsAllowed property in the global policy to False:

```
Set-CsUserServicesPolicy -Identity global -UcsAllowed $False
```

After you have disabled the unified contact store in the global policy you can then create a per-user policy that enables the use of the unified contact store; this allows you to have some users keep their contacts in the unified contact store while other users continue to keep their contacts in Lync Server. You can create a per-user user services policy by using a command similar to this:

```
New-CsUserServicesPolicy -Identity "AllowUnifiedContactStore" -UcsAllowed $True
```

After you have created the new policy you must then assign that policy to any user who should have access to the unified contact store. Per-user policies can be assigned to users by using commands similar to this:

```
Grant-CsUserServicesPolicy -Identity "Ken Myer" -PolicyName "AllowUnifiedContactS
```

After the policy has been assigned Lync Server will begin to migrate the user's contacts to the unified contact store. After migration is complete, the user will then have his or her contacts stored in Exchange rather than Lync Server. If the user happens to be logged on to Lync 2013 at the time migration completes, a message box will appear and he or she will be asked to log off of Lync and then log back on in order to finalize the process. Users who have not been assigned this per-user policy will not have their contacts migrated to the unified contact store. That’s because those users are being managed by the global policy, and use of the unified contact store has been disabled in the global policy.

You can verify that a user's contacts have successfully been migrated to the unified contact store by running the Test-CsUnifiedContactStore cmdlet from within the Lync Server Management Shell:

```
Test-CsUnifiedContactStore -UserSipAddress "sip:kenmyer@litwareinc.com" -TargetFq
```

If Test-CsUnifiedContactStore succeeds that means that the contacts for the user sip:kenmyer@litwareinc.com have been migrated to the unified contact store.

Rolling Back the Unified Contact Store

If you need to remove a user's contacts from the unified contact store (for example, if the user needs to be rehomed on Microsoft Lync Server 2010 and thus can no longer use the unified contact store) you must do two things. First, you must assign the user a new user services policy, one that prohibits storing contacts in the unified contact store. (That is, a policy where the UcsAllowed property has been set to $False.) If you do not have such a policy you can create one using a command similar to this:

```
New-CsUserServicesPolicy -Identity NoUnifiedContactStore -UcsAllowed $False
```

You can then assign this new per-user policy (NoUnifiedContactStore) by using a command like this:

```
Grant-CsUserServicesPolicy -Identity "Ken Myer" -PolicyName NoUnifiedContactStore
```

The preceding command assigns the new policy to the user Ken Myer, and also prevents Ken's contacts from being migrated to the unified contact store.

Note:

In some cases you can achieve the same net effect by simply unassigning the user's current user services policy. For example, suppose Ken Myer has a per-user user services policy the enables the unified contact store, but your global policy prohibits the use of the unified contact store. In that case, you could unassign Ken's per-user services policy. When you do that, Ken will automatically be managed by the global policy, and thus will no longer have access to the unified contact store.
To unassign a previously-assigned per-user policy, use the same command as shown before, but this time set the PolicyName parameter to a null value:
Grant-CsUserServicesPolicy –Identity "Ken Myer" –PolicyName $Null

The terminology "prevents Ken's contacts from being migrated to the unified contact store" is important to keep in mind when working with the unified contact store. Simply assigning Ken a new user services policy will not move his contacts out of the unified contact store. When a user logs on to Lync Server 2013, the system checks the user's user services policy to see whether his or her contacts should be kept in the unified contact store. If the answer is yes (that is, if the UcsAllowed property is set to $True) then those contacts will be migrated to the unified contact store (assuming that those contacts are not already in the unified contact store). If the answer is no, then Lync Server simply ignores the user's contacts and moves on to its next task. That means that Lync Server will not automatically move a user's contacts from out of the unified contact store, regardless of the value of the UcsAllowed property.

That also means that, after assigning the user a new user services policy, you must then run the Invoke-CsUcsRollback cmdlet in order to move the user's contacts out of Exchange 2013 and back to Lync Server 2013. For example, after assigning Ken Myer a new user services policy you can then move his contacts out of the unified contact store by using the following command:

```
Invoke-CsUcsRollback -Identity "Ken Myer"
```

If you change the user services policy but do not run the Invoke-CsUcsRollback cmdlet

Ken's contacts will not be removed from the unified contact store. What if you run Invoke-CsUcsRollback but do not change Ken Myer's user services policy? In that case, Ken's contacts will be temporarily removed from the unified contact store. The fact that this removal is temporary is important to keep in mind. After Ken's contacts have been removed from the unified contact store, Lync Server 2013 will wait 7 days and then check to see which user services policy has been assigned to Ken. If Ken is still assigned a policy that enables the user of the unified contact store, then his contacts will automatically be moved back to into the contact store. To permanently remove contacts from the unified contact store you must change the user services policy in addition to running the Invoke-CsUcsRollback cmdlet.

1.3.14.1.6 Configuring the Use of High-Resolution Photos in Microsoft Lync Server 2013

Configuring the Use of High-Resolution Photos in Microsoft Lync Server 2013

Planning > Planning for Exchange Server Integration > Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 >

Topic Last Modified: *2012-10-22*

Microsoft Lync Server 2010 provided the ability for users to view photos of their contacts (and to make their own photos available to others). Typically these photos were stored as part of the user's thumbnailPhoto attribute in Active Directory. That placed a serious limitation on the size and resolution of the photos: the thumbnailPhoto attribute can only hold a photograph with a maximum size of 48 pixels by 48 pixels.

In Microsoft Lync Server 2013, however, photos can be stored in a user's Microsoft Exchange Server 2013 mailbox; that allows for photo sizes up to 648 pixels by 648 pixels. In addition to that, Exchange 2013 can automatically resize these photos for use in different products as needed. Typically that means three different photo sizes and resolutions:

- 48 pixels by 48 pixels, the size used for the Active Directory thumbnailPhoto attribute. If you upload a photo to Exchange 2013 Exchange will automatically create a 48 pixel by 48 pixel version of that photo and update the user's thumbnailPhoto attribute. Note, however, that the reverse is not true: if you manually update the thumbnailPhoto attribute in Active Directory the photo in the user's Exchange 2013 mailbox will not automatically be updated.
- 96 pixels by 96 pixels, for use in Microsoft Outlook 2013 Web App, Microsoft Outlook 2013, Microsoft Lync Web App, and Lync 2013.
- 648 pixels by 648 pixels for use in Lync 2013 and Microsoft Lync Web App.

Note:

If you have the resources, it is recommended that you upload 648x648 photos; that provides the maximum resolution and optimal picture quality in any of the Office 2013 applications. Each JPEG photo with a size of 648x648 and a depth of 24 bits results in a file size of approximately 240 kilobytes. That means you will need approximately 1 megabyte of disk space for every 4 user photos.

High-resolution photos, which are accessed by using Exchange Web Services, can be uploaded by users who are running Outlook 2013 Web App; users are only allowed to update their own photo. Administrators, however, can update the photo for any user by using the Exchange Management Shell and a series of Windows PowerShell commands similar to the following:

```
$photo = ([Byte]] $(Get-Content -Path "C:\Photos\Kenmyer.jpg" -Encoding Byte -Rea
Set-UserPhoto -Identity "Ken Myer" -PictureData $photo -Confirm:False
```

```
Set-UserPhoto -Identity "Ken Myer" -Save -Confirm:False
```

The first command in the preceding example uses the Get-Content cmdlet to read the contents of the file C:\Photos\Kenmyer.jpg and store that data in a variable named $photo. In the second command, the Exchange cmdlet Set-UserPhoto is used to upload the photo and attach that photo to Ken Myer's user account.

Note:

In this example, Ken Myer's Active Directory display name is used as the user account Identity. You can also reference a user account by using other identifiers such as the user's SMTP address or his or her User Principal Name. See the documentation for the Set-UserPhoto cmdlet at http://go.microsoft.com/fwlink/p/?LinkId=268536 for more information

Uploading the photo does not equate to assigning that photo to Ken Myer's user account. Instead, uploading the photo simply results in a preview of that photo to be displayed on the Outlook Web App Options page. To actually assign that photo to the user account the user must click **Save** on the Options page or the administrator must execute the third command in the example. That third command uses the Save parameter to assign the photo to Ken Myer's user account:

```
Set-UserPhoto -Identity "Ken Myer" -Save -Confirm:False
```

To verify that the new photo has been assigned to the user account, Ken Myer can log on to Lync 2013, select **Options**, and then select **My Picture**. The newly-uploaded photo should be displayed as Ken's personal photo. Alternatively, administrators can verify the photo for any user by starting Internet Explorer and navigating to a URL similar to this:

```
https://atl-mail-001.litwareinc.com/ews/Exchange.asmx/s/GetUserPhoto?email=kenmye
```

If the administrator can view the photo using Internet Explorer but the user cannot view his or her photo in Lync 2013, that typically indicates a connectivity problem with Exchange Web Services or with the Exchange autodiscover service.

1.3.14.1.7 Configuring Microsoft Exchange Server 2013 Unified Messaging for Microsoft Lync Server 2013 Voicemail

Configuring Microsoft Exchange Server 2013 Unified Messaging for Microsoft Lync Server 2013 Voicemail

Planning > Planning for Exchange Server Integration > Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 >

Topic Last Modified: *2013-02-04*

Microsoft Lync Server 2013 enables you to have voicemail messages stored in Microsoft Exchange Server 2013; those voicemail messages will then appear as email messages in your users' Inboxes. This capability was also found in the 2010 editions of Lync Server and Exchange; however, the process of configuring this "unified messaging" has been simplified in in the 2013 editions thanks to the introduction of the UM Call Router component. This component is installed on the Exchange 2013 Client Access server, and all calls to Exchange unified messaging (such as a voicemail) are first routed through the Call Router and then are redirected to the appropriate Mailbox server.

If you have already configured server-to-server authentication between Lync Server 2013 and Exchange 2013 then you are ready to setup unified messaging. To do so, you must first create and assign a new unified messaging dial plan on your Exchange server. For example, these two commands (run from within the Exchange Management Shell) configure a new 3-digit dial plan for Exchange:

```
New-UMDialPlan -Name "RedmondDialPlan" -VoIPSecurity "Secured" -NumberOfDigitsInE
Set-UMDialPlan "RedmondDialPlan" -ConfiguredInCountryOrRegionGroups "Anywhere,*,*
```

In the first command in the example, the VoIPSecurity parameter, and the parameter value "Secured" indicate that the signaling channel is encrypted by using Transport Layer Security (TLS). The URIType "SipName" indicates that messages will be sent and received using the SIP protocol, and the CountryOrRegionCode of 1 indicates that the dial plan applies to the US.

In the second command, the parameter value passed to the ConfiguredInCountryOrRegionGroups parameter specifies the in-country groups that can be used with this dial plan. The parameter value "Anywhere,*,*,*" sets the following:

- Group name ("Anywhere")
- AllowedNumberString (*, a wildcard character indicating that any number string is allowed)
- DialNumberString (*, a wildcard character indicating that any dialed number is allowed)
- TextComment (*, a wildcard character indicating that any text command is allowed)

Note:

Creating a new dial plan will also create a Default Mailbox Policy.

After creating and configuring the new dial plan you must add the new dial plan to your unified messaging server and then modify the startup mode of that server; in particular, you must set the startup mode to "Dual". You can perform both of these tasks from within the Exchange Management Shell:

```
Set-UmService -Identity "atl-exchangeum-001.litwareinc.com" -DialPlans "RedmondDi
```

After the unified messaging server has been configured you should next run the Enable-ExchangeCertificate cmdlet to ensure that your Exchange certificate is applied to the unified messaging service:

```
Enable-ExchangeCertificate -Server "atl-umserver-001.litwareinc.com" -Thumbprint
```

After the certificate has been correctly assigned you must then stop and restart the MsExchangeUM service on the unified messaging server. This service must be stopped and restarted any time you change the startup mode.

After finishing configuration of the unified messaging server you can then configure the UM Call Router:

```
Set-UMCallRouterSettings -Server "atl-exchange-001.litwareinc.com" -UMStartupMode
Enable-ExchangeCertificate -Server "atl-umserver-001.litwareinc.com" -Thumbprint
```

Because the startup mode has changed you must stop and restart the MsExchangeUMCR service on the computer hosting the UM Call Router.

To complete the unified messaging setup, you then need to create a UM mailbox policy and then use that policy to enable users for unified messaging. You can create a mailbox policy by using a command similar to this:

```
New-UMMailboxPolicy -Name "RedmondMailboxPolicy" -AllowedInCountryOrRegionGroups
```

And you can enable a user for unified messaging by using a command similar to this:

```
Enable-UMMailbox -Extensions 100 -SIPResourceIdentifier "kenmyer@litwareinc.com"
```

In the preceding command, the Extensions parameter represents the telephone extension number for the user. In this example, the user has the extension number 100.

After you have enabled his mailbox, the user kenmyer@litwareinc.com should be able to use Exchange unified messaging. You can verify that the user can connect to Exchange UM by running the Test-CsExUMConnectivity cmdlet from within the Lync Server Management Shell:

```
$credential = Get-Credential "litwareinc\kenmyer"
Test-CsExUMConnectivity -TargetFqdn "atl-cs-001.litwareinc.com" -UserSipAddress "
```

If you have a second user who has been enabled for unified messaging you can use the Test-CsExUMVoiceMail cmdlet to verify that this second user can leave a voicemail message for the first user.

```
$credential = Get-Credential "litwareinc\pilar"
Test-CsExUMVoiceMail -TargetFqdn "atl-cs-001.litwareinc.com" -ReceiverSipAddress
```

1.3.14.1.8 Integrating Microsoft Lync Server 2013 and Microsoft Outlook Web App 2013

Integrating Microsoft Lync Server 2013 and Microsoft Outlook Web App 2013

Planning > Planning for Exchange Server Integration > Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 >

Topic Last Modified: *2013-02-03*

In addition to integrating with Microsoft Outlook 2013, Microsoft Lync Server 2013 can be fully integrated with Microsoft Outlook Web App 2013; among other things, this adds instant messaging and presence to Outlook Web App, and enables your unified contact list to be shared between Outlook Web App and Microsoft Lync 2013. In order to integrate Lync Server 2013 and Outlook Web App, you must first verify that the Unified Communications Managed API 4.0 Runtime has been installed in your Microsoft Exchange Server 2013 backend server. You can do this by looking for the existence of the following registry value:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSExchange OWA \InstantMessaging\ImplementationDLLPath

The ImplementationDLLPath should point to the folder location for the file Microsoft.Rtc.Internal.Ucweb.dll. If it does not, or if the registry value does not exist, then you should download and install the UCMA Runtime setup program from the Microsoft Download Center at http://www.microsoft.com/en-us/download/details.aspx?id=34992. Information on how to install the UCMA Runtime can be found on that same web page.

Backward Compatibility

Lync Server 2013 can be integrated with the Microsoft Exchange Server 2010 versions of both unified messaging and Outlook Web App. For more information, see the article Deploying On-Premises Exchange UM to Provide Lync Server 2010 Voice Mail at http://technet.microsoft.com/en-us/library/gg398768.aspx. If you integrate with Exchange 2010 you will not have Lync Server specific features such as the unified contact store and Lync-to-Exchange archiving.

Microsoft Lync 2013 can also be used in conjunction with Exchange 2010 and Outlook 2010. Once again, however, new functionality such as the unified contact store and high-resolution photos will not be available to Lync 2013 users. These new capabilities require both Lync Server 2013 and Exchange 2013.

Creating a Trusted Application Pool for Outlook Web App

If you have installed the Microsoft Exchange Unified Messaging Call Router service and the Microsoft Exchange Unified Messaging service on the same computer then there is no need to create a trusted application pool for Outlook Web App. (This assumes that the server in question is hosting a SipName UM dial plan.) If you are using a single computer to host both of these services then you can skip to the section of this document titled **Enabling Instant Messaging on Outlook Web App**.

Lync Server 2013 can autodiscover any Exchange servers that host a SipName UM dial plan; these servers are automatically added to the Lync Server Known Servers List. There is no need to create a trusted application pool and add these servers to the Known Servers List. In fact, doing so will cause Outlook Web App integration to stop working.

Note:

This is due to the fact that the Lync Server topology will now have two entries for the same computer: the autodiscovered entry, and the manually-added entry. To fix the problem, and to get Outlook Web App working again, use Windows PowerShell to remove the trusted pool and trusted application entries for the server. See the help topics for the Remove-CsTrustedApplicationPool and Remove-CsTrustedApplication cmdlets for more information.

If these two services are running on separate computers then, after you have verified that the Unified Communications Managed API 4.0 Runtime has been installed, you must create a Lync Server trusted application pool and a trusted application associated with Outlook Web App; that will add the server to the Known Servers List. To do that, first run a command similar to this from within the Lync Server Management Shell:

```
New-CsTrustedApplicationPool -Identity atl-owa-001.litwareinc.com -Registrar atl-
```

In the preceding command, atl-owa-001.litwareinc.com is the fully qualified domain name of the Outlook Web App pool; this must be the same name that appears in the Subject Name and Subject Alternative Name (SAN) fields of the certificate that provides access to Outlook Web App. Likewise, atl-cs-001.litwareinc.com is the fully qualified domain name of the Lync Server 2013 pool that will host the new trusted application pool. Note, too that the specified site, Redmond, represents the SiteID of the Lync Server site. The SiteID is not necessarily the same as the site's DisplayName; you can retrieve SiteIDs for your Lync Server sites by running the following command from the Lync Server Management Shell:

```
Get-CsSite | Select-Object DisplayName, SiteID
```

After creating the trusted application pool, use a command similar to the following to configure an application Identity and a port for Outlook Web App:

```
New-CsTrustedApplication -ApplicationId OutlookWebApp -TrustedApplicationPoolFqdn
```

In the preceding command, the ApplicationID is simply a friendly identifier used to distinguish trusted applications. The ApplicationID can be any text string that does not include blank spaces or other prohibited characters. (To ensure that you create a valid identifier, it is recommended that you use only letters and numbers when specifying an ApplicationId.) The value assigned to the Port parameter is also left to the administrator's discretion: this can be any available network port.

After creating the trusted application you must run the following command to enable the changes to your Lync Server topology:

```
Enable-CsTopology
```

Note that you must also add your Exchange client access and mailbox server to all of your SIP Uri dial plans. In turn, this will configure the servers as trusted SIP peers with the ExUmRouting topology for Lync Server.

Enabling Instant Messaging on Outlook Web App

With Lync Server correctly configured you can then begin to configure Outlook Web App. The first step in that process is to enable instant messaging on all your Outlook Web App virtual directories on your front end servers. (There is no need to enable instant messaging for the virtual directories on your backend servers. In fact, it is recommended that you do not enable instant messaging on your backend servers.) Instant messaging can be enabled on the client access servers by running the following command from within the Exchange Management Shell:

```
Get-OwaVirtualDirectory | Set-OwaVirtualDirectory -InstantMessagingEnabled $True
```

Note:

By default, instant messaging is enabled when you install Outlook Web App; that is, the InstantMessagingEnabled property is set to True. However, you must still run the preceding command in order to set the instant messaging type to OCS. By default, InstantMessagingType is set to None.

Next you must add the following two lines to Outlook Web App Web.config file (this file is typically located in the folder C:\Program Files\Microsoft\Exchange Server\V15 \ClientAccess\Owa). These two lines should be added under the <AppSettings> node in the Web.config file, and this procedure should be carried out only on the backend servers where Outlook Web App has been installed:

```
<add key="IMCertificateThumbprint" value="EA5A332496CC05DA69B75B66111C0F78A110D22
<add key="IMServerName" value="atl-cs-001.litwareinc.com"/>
```

In the preceding example, the value for IMCertificateThumbprint must be the thumbprint for the Exchange 2013 certificate that is installed on your backend servers. You can retrieve that information by running the following command from the Exchange Management Shell:

```
Get-ExchangeCertificate
```

Note, too that the value assigned to IMServerName is the fully qualified domain name of the Lync Server pool where you created the trusted application pool for Outlook Web App.

The certificate that you use for Outlook Web App must be a certificate that is trusted by Lync Server. One way to ensure that the certificate will be trusted by both Lync Server and Exchange is to use your internal certificate authority to create a certificate on the mailbox server, making sure that the server FQDN is used for the subject name and that this FQDN appears in the certificate alternate name field. After the certificate has been created it can then be imported to your backend servers. The net result is that the same certificate is used for two purposes: 1) communication between Exchange unified messaging and Lync Server; and, 2) the integration between Outlook Web App and Lync Server.

After you have updated the Web.config file you should then run the following command on the Exchange backend server in order to recycle the Outlook Web App pool:

```
C:\Windows\System32\Inetsrv\Appcmd.exe recycle apppool /apppool.name:"MSExchangeO
```

If the recycle operation succeeds you will see the following message in the Exchange Management Shell:

```
"MSExchangeOWAAppPool" successfully recycled
```

Configuring Outlook Web App Mailbox Policies

At this point you can use the following command to configure instant messaging on the appropriate Outlook Web App mailbox policy (or policies). For example, this command, run on one of your mailbox servers, enables instant messaging on the Default policy:

```
Set-OwaMailboxPolicy -Identity "Default" -InstantMessagingEnabled $True -InstantM
```

And this command enables instant messaging for all your Outlook Web App mailbox policies:

```
Get-OwaMailboxPolicy | Set-OwaMailboxPolicy -InstantMessagingEnabled $True -Insta
```

After the mailbox policy has been enabled then all users managed by that policy will have full integration between Lync Server and Outlook Web App, provided that:

- The user has a mailbox on Exchange 2013.
- The user has been enabled for Lync Server 2013.
- The user has a valid SIP proxy address.

Disabling Instant Messaging in Outlook Web App

As noted previously, instant messaging is enabled by default in Outlook Web App. That means that, if you do not integrate Outlook Web App with Lync Server, users will see blank presence icons and an error message each time they log on to Outlook Web App. To prevent this problem, use the following Exchange Management Shell command to disable instant messaging in Outlook web App:

```
Get-OwaVirtualDirectory | Set-OwaVirtualDirectory -InstantMessagingEnabled $False
```

Verifying Integration With Outlook Web App

To verify that instant messaging and presence have been integrated with Outlook Web App, sign on to Outlook Web App 2013. In the upper right-hand corner of the screen, you will see your Exchange display name. If there is a presence icon next to your name (for example, a green icon indicating that your current status is Available) that indicates that you have successfully integrated Lync Server and Outlook Web App.

After the initial sign-on to Outlook Web App, check to see if an event with the Event ID 112 (and the source MSExchange OWA) has been written to the event log on the mailbox server. This event indicates that the Instant Messaging Endpoint Manager was successfully initialized. If instant messaging does not appear to be working then, on the mailbox server, look for log files in the folder C:\Program Files\Microsoft\Exchange server \V15\Logging\OWA\InstantMessaging. If either the Logging or the InstantMessaging folders do not exist that indicates that integration has failed. In that case, you can use SIPStack tracing on Lync Server (All Levels and All Flags) to try and determine why integration failed.

1.3.14.2 Planning for Exchange Unified Messaging Integration

Planning for Exchange Unified Messaging Integration

Microsoft Lync Server 2013 > Planning > Planning for Enterprise Voice >

Topic Last Modified: *2012-10-13*

Lync Server 2013 supports integration with Exchange Unified Messaging (UM) for combining voice messaging and email messaging into a single messaging infrastructure. In Microsoft Exchange Server 2007 Service Pack 1 (SP1) and Microsoft Exchange Server 2010, Exchange Unified Messaging (UM) is one of several Exchange server roles that you can install and configure.

In Microsoft Exchange Server 2013, Exchange UM runs as a service on an Exchange Mailbox server. For Lync Server 2013 Enterprise Voice deployments, Unified Messaging combines voice messaging and email messaging into a single store that is available from a telephone (Outlook Voice Access) or a computer. Unified Messaging and Lync Server 2013 work together to provide call answering, Outlook Voice Access, and auto-attendant services to users of Enterprise Voice.

For more information about the architecture changes in Microsoft Exchange Server 2013, see “Voice Architecture Changes” in the Microsoft Exchange Server 2013 documentation at http://go.microsoft.com/fwlink/p/?LinkId=266730.

For these features to be supported in an on-premises Exchange UM deployment, you must be running one of the following:

- Microsoft Exchange Server 2007 Service Pack 1 (SP1) or latest service pack
- Microsoft Exchange Server 2010 or latest service pack
- Microsoft Exchange Server 2013
- Features of Integrated Unified Messaging and Lync Server 2013
- Components and Topologies for On-Premises Unified Messaging
- Guidelines for Integrating On-Premises Unified Messaging and Lync Server 2013
- Deployment Process for Integrating On-Premises Unified Messaging and Lync Server 2013

1.3.14.2.1 Features of Integrated Unified Messaging and Lync Server 2013

Features of Integrated Unified Messaging and Lync Server 2013

Planning > Planning for Enterprise Voice > Planning for Exchange Unified Messaging Integration >

Topic Last Modified: *2012-10-01*

Lync Server 2013, Enterprise Voice uses the Exchange Unified Messaging (UM) infrastructure to provide call answering, call notification, voice access (including voice mail), and auto-attendant services.

Call Answering

Call answering is the receiving of voice messages on behalf of users whose calls are not answered or are busy. It includes playing a personal greeting, recording a message, and submitting the message to be queued for delivery to the user's mailbox, which is stored on the Exchange mailbox server.

If a caller leaves a message, the message is routed to the user's Inbox. If a caller chooses not to leave a message, a missed call notification is stored in the user's mailbox. Users can then access their Inbox by using the Microsoft Outlook messaging and collaboration client, Outlook Web Access, the Exchange ActiveSync technology, or Outlook Voice Access. The subject and priority of calls can be displayed in a way similar to that of email.

Outlook Voice Access

Outlook Voice Access enables an Enterprise Voice user to access not just voice mail, but also the Exchange inbox, including email, calendar, and contacts from a telephony interface. The subscriber access number is assigned by an Exchange UM administrator.

Auto Attendant

Auto attendant is an Exchange UM feature that can be used to configure a phone number that outside users can dial to reach company representatives. In particular, it provides a series of voice prompts that assist an external caller in navigating a menu system. The list of available options is configured on the Exchange UM server by the Exchange UM administrator.

Fax Services

Exchange UM includes fax features, which enable users to receive incoming faxes in their Exchange mailboxes. For details, see "Unified Messaging" in the Microsoft Exchange Server documentation at http://go.microsoft.com/fwlink/p/?linkId=135652.

Note:

Fax services provided by the Exchange UM server are not available in Lync Server deployments that are integrated with Microsoft Exchange Server 2010, Exchange 2010 with the latest service pack, or Exchange 2013.

1.3.14.2.2 Components and Topologies for On-Premises Unified Messaging

Components and Topologies for On-Premises Unified Messaging

Server Software and Infrastructure Support > Voice Support > Exchange Unified Messaging (UM) Support >

Topic Last Modified: *2012-09-25*

This topic describes the Microsoft Exchange Server 2013 components required to provide Exchange Unified Messaging (UM) features to Lync Server 2013 deployment. It also describes the supported topologies for on-premises Exchange UM integration.

Exchange Server Components

To provide the Exchange UM features and services described in Features of Integrated Unified Messaging and Lync Server 2013 to Enterprise Voice users in your organization, you must deploy an Microsoft Exchange Mailbox server and Client Access server, which hosts user mailboxes and provides a single storage location for email and voice mail. Exchange UM runs as a service on Exchange Mailbox and Client Access servers.

For details about Exchange UM components in Microsoft Exchange Server 2007 and Microsoft Exchange Server 2010, see Deploying On-Premises Exchange UM to Provide Lync Server 2013 Voice Mail in the Deployment documentation.

Supported Topologies

You can deploy Lync Server 2013 and Exchange Unified Messaging (UM) in the same forest or multiple forests. If the deployment spans multiple forests, you must perform the Exchange integration steps for each Exchange UM forest. Furthermore, you must configure each Microsoft Exchange forest to trust the Lync Server 2013 forest and the Lync Server 2013 forest to trust each Exchange UM forest. In addition to this forest trust, the Exchange UM settings for all users must be set on the user objects in the Lync Server 2013 forest.

Lync Server 2013 supports the following topologies for Exchange UM integration:

- Single forest
- Single domain (that is, a single forest with a single domain). Lync Server 2013, Microsoft Exchange, and users all reside in the same domain.
- Multiple domain (that is, a root domain with one or more child domains). Lync Server 2013, and Microsoft Exchange servers are deployed in different domains from the domain where you create users. Exchange UM servers can be deployed in different domains from the Lync Server 2013 pool they support.
- Multiple forest (that is, resource forest). Lync Server 2013 is deployed in a single forest, and then users are distributed across multiple forests. The users' Exchange UM attributes must be replicated over to the Lync Server 2013 forest.

  Note:
  Exchange can be deployed in multiple forests. Each Exchange organization can provide Exchange UM to its users, or Exchange UM can be deployed in the same forest as Lync Server 2013.

1.3.14.2.3 Guidelines for Integrating On-Premises Unified Messaging and Lync Server 2013

Guidelines for Integrating On-Premises Unified Messaging and Lync Server 2013

See Also

Planning > Planning for Enterprise Voice > Planning for Exchange Unified Messaging Integration >

***Topic Last Modified:** 2012-09-25*

The following are guidelines and best practices to consider when you deploy Enterprise Voice:

Important:
Exchange Unified Messaging (UM) supports IPv6 only if you are also using UCMA 4.

- Deploy a Lync Server 2013 Standard Edition server or a Front End pool. For details about installation, see Deploying Lync Server 2013 in the Deployment documentation.
- Work with Exchange administrators to confirm which tasks each of you will perform to assure a smooth and successful integration.
- Deploy the Exchange Mailbox server roles in each Exchange Unified Messaging (UM) forest where you want to enable users for Exchange UM. For details about installing Exchange server roles, see the Microsoft Exchange Server 2013 documentation.

  Important:
  When Exchange Unified Messaging (UM) is installed, it is configured to use a self-signed certificate.
  The self-signed certificate, however, does not enable Lync Server 2013 and Exchange UM to trust each other, which is why it is necessary to request a separate certificate from a certification authority that both servers trust.

- If Lync Server 2013 and Exchange UM are installed in different forests, configure each Exchange forest to trust the Lync Server 2013 forest and the Lync Server 2013 forest to trust each Exchange forest. Also, set the users' Exchange UM settings on the user objects in the Lync Server 2013 forest, typically by using a script or a cross-forest tool, such as Identity Lifecycle Manager (ILM).
- If necessary, install the Exchange Management Console to manage your Unified Messaging servers.
- Obtain valid phone numbers for Outlook Voice Access and auto attendant.

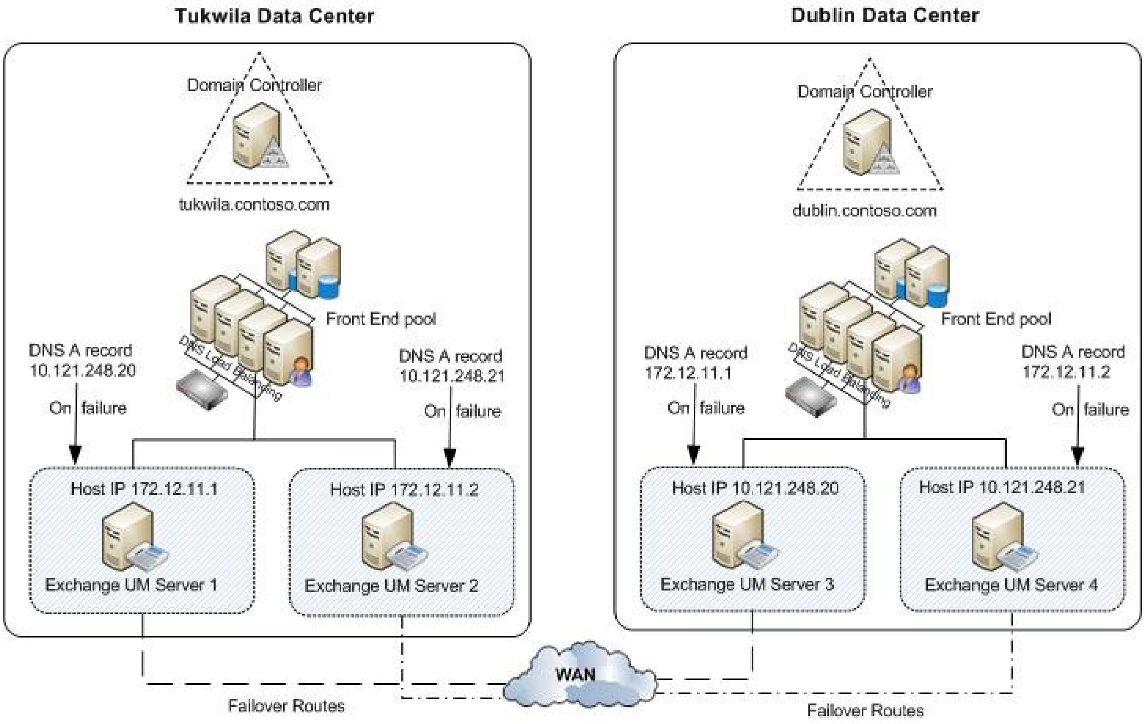
- If you are using a version of Exchange UM earlier than Microsoft Exchange Server 2010 Service Pack 1 (SP1), coordinate names for Exchange UM SIP URI dial plans and Enterprise Voice dial plans.

Deploying Redundant Exchange UM Servers

Important:

We recommend that you deploy a minimum of two servers on which Exchange UM services is running for each Exchange UM SIP URI dial plan that you configure for your organization. In addition to providing expanded capacity, deploying redundant servers provides high availability. In the event of an server failure, Lync Server 2013 can be configured to fail over to another server.

The following example configurations provide Exchange UM resiliency.

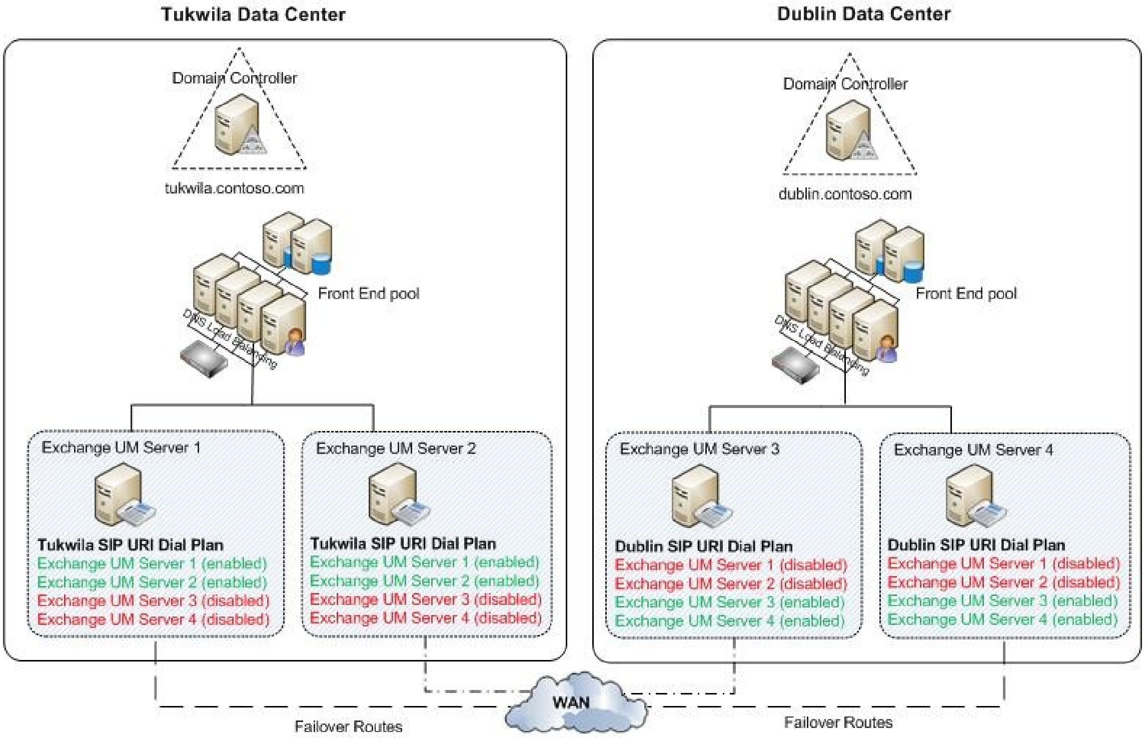


In Example 1, Exchange UM servers 1 and 2 are enabled in the Tukwila data center, and Exchange UM servers 3 and 4 are enabled in the Dublin data center. In the event of an Exchange UM outage in Tukwila, the Domain Name System (DNS) A records for servers 1 and 2 should be configured to point to servers 3 and 4, respectively. In the event of an Exchange UM outage in Dublin, the DNS A records for servers 3 and 4 should be configured to point to servers 1 and 2, respectively.

Note:

For Example 1, you should also assign one of following certificate on each Exchange UM server:

- Use a certificate with a wildcard in the Subject Alternative Name (SAN).
- Put the fully qualified domain name (FQDN) of each of the four Exchange UM servers in the SAN.



Tukwila Data Center
Domain Controller
tukwila.contoso.com
Front End pool
DNS Load Balancing
Exchange UM Server 1
Tukwila SIP URI Dial Plan
Exchange UM Server 1 (enabled)
Exchange UM Server 2 (enabled)
Exchange UM Server 3 (disabled)
Exchange UM Server 4 (disabled)
Exchange UM Server 2
Tukwila SIP URI Dial Plan
Exchange UM Server 1 (enabled)
Exchange UM Server 2 (enabled)
Exchange UM Server 3 (disabled)
Exchange UM Server 4 (disabled)
Dublin Data Center
Domain Controller
dublin.contoso.com
Front End pool
DNS Load Balancing
Exchange UM Server 3
Dublin SIP URI Dial Plan
Exchange UM Server 1 (disabled)
Exchange UM Server 2 (disabled)
Exchange UM Server 3 (enabled)
Exchange UM Server 4 (enabled)
Exchange UM Server 4
Dublin SIP URI Dial Plan
Exchange UM Server 1 (disabled)
Exchange UM Server 2 (disabled)
Exchange UM Server 3 (enabled)
Exchange UM Server 4 (enabled)
WAN
Failover Routes
Failover Routes

In Example 2, under ordinary operating conditions Exchange UM servers 1 and 2 are enabled in the Tukwila data center, and Exchange UM servers 3 and 4 are enabled in the Dublin data center. All four servers are included in the Tukwila users' SIP URI dial plan; however, servers 3 and 4 are disabled. In the event of an Exchange UM outage in Tukwila, for example, Exchange UM servers 1 and 2 should be disabled and Exchange UM servers 3 and 4 should be enabled so the Tukwila Exchange UM traffic will be routed to the servers in Dublin.

For details about how to enable or disable Unified Messaging on Exchange 2013, see “Integrate Exchange 2013 UM with Lync Server” at http://go.microsoft.com/fwlink/p/?LinkId=265372.

For details about how to enable or disable Unified Messaging on Microsoft Exchange Server 2010, see:

- "Enable Unified Messaging on Exchange 2010" at http://go.microsoft.com/fwlink/p/?LinkId=204418.
- "Disable Unified Messaging on Exchange 2010" at http://go.microsoft.com/fwlink/p/?LinkId=204416.

1.3.14.2.4 Deployment Process for Integrating On-Premises Unified Messaging and Lync Server 2013

Deployment Process for Integrating On-Premises Unified Messaging and Lync Server 2013

Planning > Planning for Enterprise Voice > Planning for Exchange Unified Messaging Integration >

Topic Last Modified: *2012-12-17*

If you want to integrate Exchange Unified Messaging (UM) with Lync Server 2013, you must perform the tasks described in this topic. Also be sure that you review the planning and deployment best practices described in Guidelines for Integrating On-Premises Unified Messaging and Lync Server 2013. This topic assumes that you have deployed Lync Server 2013 with a collocated Mediation Server and that you have enabled users for Lync Server 2013, but not necessarily that you have performed all deployment and configuration steps to enable Enterprise Voice, as described in Deploying Enterprise Voice in the Deployment documentation.

Unified Messaging Integration Process

◆**Important:**
It is important that you coordinate with your organization’s Exchange administrators to confirm the tasks that each of you will perform to help ensure a smooth, successful integration.

Phase	Steps	Required groups and roles	Deployment documentation
Deploy one of the following: • Microsoft Exchange Server 2007 Service Pack 1 (SP2) or latest service pack • Microsoft Exchange Server 2010 or latest service pack • Microsoft Exchange Server 2013	If you are using Microsoft Exchange Server 2013, install the following Exchange Server roles in either the same forest or a different forest as Lync Server 2013: • Client Access • Mailbox If Microsoft Exchange Server 2013 and Exchange Unified Messaging (UM) are installed in different forests, configure each Exchange forest to trust the Lync Server 2013 forest. If you are using Exchange 2010, install the following Exchange Server roles in either the same forest or a different forest as Lync Server 2013: • Unified Messaging • Hub Transport • Client Access • Mailbox If Lync Server 2013 and Exchange Unified	Enterprise administrators (if this is the first Exchange Server in the organization) -OR- Exchange Organization administrator (if this is not the first Exchange Server in the organization)	See the appropriate documentation for your version of Exchange Server: • Exchange Server 2007 deployment documentation at http://go.microsoft.com/fwlink/p/?LinkId=268694. • Exchange Server 2010 or latest service pack deployment documentation at http://go.microsoft.com/fwlink/p/?LinkId=268695. • Microsoft Exchange Server 2013 Planning and Deployment at http://go.microsoft.com/fwlink/p/?LinkId=266569.

	Messaging (UM) are installed in different forests, configure each Exchange forest to trust the Lync Server 2013 forest.		
Install certificates.	Download and install certificates for each Exchange UM server from a trusted root certificate authority (CA). The certificates are required for mutual Transport Level Security (MTLS) between the servers running Exchange UM and Lync Server 2013.	Administrators	Configure Certificates on the Server Running Microsoft Exchange Server Unified Messaging
Create and configure a new Exchange UM SIP dial plan.	On the Exchange UM server, create a SIP dial plan based on your organization’s specific deployment requirements.	Exchange Organization administrator	For Exchange 2007 SP1 or latest service pack, see "How to Create a Unified Messaging SIP URI Dial Plan" at http://go.microsoft.com/fwlink/p/?linkId=268632. For Exchange 2010 or latest service pack, see "Create a UM Dial Plan" at http://go.microsoft.com/fwlink/p/?linkId=268674. For Exchange 2013, see Unified Messaging at http://go.microsoft.com/fwlink/p/?LinkId=266579.
Configure security settings for the Exchange UM SIP dial plan.	To encrypt Enterprise Voice traffic, configure the security settings on the Exchange UM SIP dial plan as **SIP Secured** or **Secured**. This is an especially important step if you have deployed or plan to deploy Lync Phone Edition devices in your environment. For Lync Phone Edition devices to function in an environment with Exchange UM integration, Lync Server encryption settings must	Exchange Organization administrator	Configure Unified Messaging on Microsoft Exchange For Exchange 2007 SP1 or latest service pack, see also: "How to Configure Security on a Unified Messaging Dial Plan" at http://go.microsoft.com/fwlink/p/?LinkId=268696. For Exchange 2010 or latest service pack, see also:

	align with the Exchange UM dial plan security settings. For details, refer to the Deployment documentation.		"Configure VoIP Security on a UM Dial Plan" http://go.microsoft.com/fwlink/p/?LinkId=268697. For Exchange 2013, see Unified Messaging at http://go.microsoft.com/fwlink/p/?LinkId=266579.
Add Unified Messaging servers to the Exchange UM SIP dial plan.	To enable a newly installed Unified Messaging server to answer and process incoming calls, you must add the Unified Messaging server to a UM dial plan. In this case, add the server to the Exchange UM SIP dial plan.	Administrators Exchange Server administrators	For Exchange 2007 SP1 or latest service pack, see "How to Add Unified Messaging Server to a Dial Plan" at http://go.microsoft.com/fwlink/p/?linkId=268681. For Exchange 2010 or latest service pack, see "View or Configure the Properties of a UM Server" at http://go.microsoft.com/fwlink/p/?linkId=268682. For Exchange 2013, see Unified Messaging at http://go.microsoft.com/fwlink/p/?LinkId=266579.
Configure mailboxes with SIP addresses.	Assign SIP addresses to the mailboxes of Enterprise Voice users who will be using Exchange UM features.	Lync Server 2013 administrator Exchange Recipient administrator	For Exchange 2007 SP1 or latest service pack, see "How to Add, Remove, or Modify a SIP Address for a UM-Enabled User" at http://go.microsoft.com/fwlink/p/?LinkId=268698. For Exchange 2010 or latest service pack, see "Modify a SIP Address for a UM-Enabled User" at http://go.microsoft.com/fwlink/p/?LinkId=268699. For Exchange 2013, see Unified Messaging at http://go.microsoft.com/fwlink/p/?LinkId=266579.
Run the exchucutil.ps1	On the server running Exchange UM services,	Exchange Organization	Configure Unified

script.	open the Exchange Management Shell and run the exchucutil.ps1 script, which does the following: • Grants Lync Server 2013 permission to read Exchange UM Active Directory Domain Services (AD DS) objects, specifically, the SIP dial plans created in the previous task. • Creates a Unified Messaging IP gateway object in Active Directory for each Lync Server 2013 Enterprise Edition pool or Standard Edition server that hosts users who are enabled for Enterprise Voice. • Creates an Exchange UM hunt group for each gateway. The hunt group pilot identifier will be the name of the dial plan that is associated with the corresponding gateway. These need to be mapped 1:1 if there is more than one dial plan.	administrator Exchange Recipient administrator	Messaging on Microsoft Exchange

Configure Lync Server 2013 dial plans.	If you are integrating with Exchange 2007 SP1 or latest service pack, or Exchange 2010, create a new Enterprise Voice dial plan with a name that matches the Exchange UM dial plan fully qualified domain name (FQDN). **Note:** You will need to do this for each UM Dial plan. If you are integrating with Exchange 2010 SP1, ensure that suitable global/site-level or pool-level Enterprise Voice dial plans have been configured. **Note:** If you are integrating with Exchange 2010 SP1, the Lync Server dial plan and Exchange UM SIP dial plan names do not need to match.	RTCUniversalServerAdmins	Configuring Dial Plans
Run the Exchange UM Integration tool.	On the Lync Server 2013, run **ocsumutil.exe**, which: - Creates Subscriber Access and Auto Attendant contact objects. - Validates that there is an Enterprise Voice dial plan with a name that matches the Exchange UM dial plan FQDN. If you are running Exchange 2010 SP1 or later, the dial plan names do not need to match, and you can ignore the	RTCUniversalServerAdmins *and* RTCUniversalUserAdmins **Important:** To run ocsumutil.exe successfully, the user must belong to both of these groups. **Note:** To create Contact objects, the user who runs ocsumutil.exe must have the correct permission to the Active Directory	Configure Lync Server 2013 to Work with Unified Messaging on Microsoft Exchange Server

	tool's warning about this. This tool works by scanning the Active Directory for Exchange UM settings and allowing the Lync Server 2013 administrator to view, create, and edit contact objects.	organizational unit (OU) where the new contact objects are stored. This permission can be granted by running the **Grant-CsOUPermission** cmdlet. For details, see the Lync Server Management Shell documentation.	
If necessary, perform other Enterprise Voice configuration steps.	If you have not already configured Enterprise Voice settings on your servers or users, do one or more of the following: • Deploy and configure Public switched telephone network (PSTN) gateways and Mediation Servers • Define voice policies, PSTN usage records, and outbound call routes. • Enable users for Enterprise Voice. • Optionally, configure specific users with dial plans. Other configuration steps may be required depending on the Enterprise Voice features that you enable.	RTCUniversalServerAdmins RTCUniversalUserAdmins	See topics in the following sections: • Configuring Voice Policies, PSTN Usage Records, and Voice Routes • Deploying Enterprise Voice

Enable Enterprise Voice users for Exchange UM.	On the Exchange UM server, ensure that a Unified Messaging mailbox policy has been created and that each user has a unique extension number assignment, and then enable the user for Unified Messaging.	Exchange Recipient administrator	For Exchange 2007 SP1 or latest service pack, see "How to Enable a User for Unified Messaging" at http://go.microsoft.com/fwlink/p/?LinkId=268700. For Exchange 2010 or latest service pack, see "Enable a User for Unified Messaging" at http://go.microsoft.com/fwlink/p/?LinkId=268701. For Exchange 2013, see Unified Messaging at http://go.microsoft.com/fwlink/p/?LinkId=266579.

1.3.14.3 Hosted Exchange Unified Messaging Integration

Hosted Exchange Unified Messaging Integration

Microsoft Lync Server 2013 > Planning > Planning for Enterprise Voice >

Topic Last Modified: *2012-09-20*

In addition to the support that previous Lync Server 2013 releases have provided for integration with *on-premises* deployments of Exchange Unified Messaging (UM), Lync Server 2013 introduces support for integration with *hosted* Exchange UM. Hosted Exchange UM enables Lync Server 2013 to provide voice messaging to your users if you transfer some or all of them to a hosted Exchange service provider such as Microsoft Exchange Online.

Lync Server 2013 Enterprise Voice uses the Exchange UM infrastructure to provide call answering, call notification, voice access (including voice mail), and auto attendant services. For details, see Features of Integrated Unified Messaging and Lync Server 2013.

1.3.14.3.1 Hosted Exchange UM Architecture and Routing

Hosted Exchange UM Architecture and Routing

Planning > Planning for Enterprise Voice > Hosted Exchange Unified Messaging Integration >

Topic Last Modified: *2012-03-26*

This section provides an overview of the architecture for on-premises and hosted

Exchange UM integration, including supported modes, shared SIP space, and routing considerations.

- Hosted Exchange UM Integration Architecture
- Hosted Exchange UM Routing

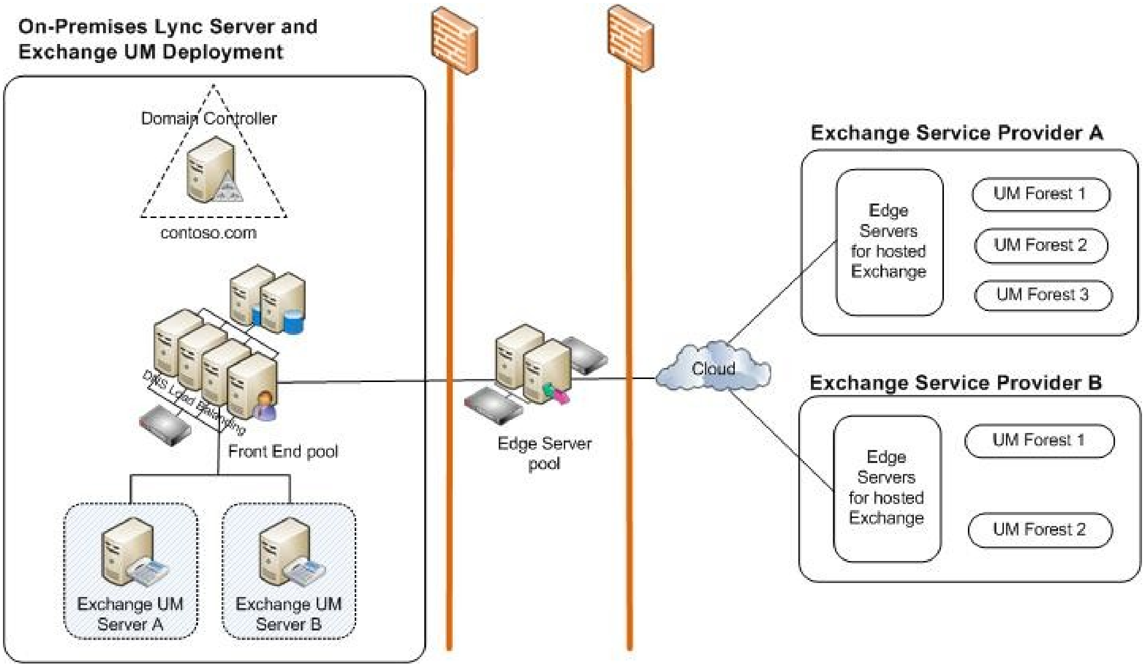
1.3.14.3.1.1 Hosted Exchange UM Integration Architecture

Hosted Exchange UM Integration Architecture

Planning for Enterprise Voice > Hosted Exchange Unified Messaging Integration > Hosted Exchange UM Architecture and Routing >

Topic Last Modified: *2012-09-25*

The Lync Server 2013 ExUM Routing application supports integration with an on-premises Exchange Unified Messaging (UM) deployment, with Exchange UM hosted by a service provider, or with a combination of the two. The following diagram shows all three possibilities.



The following modes are supported:

- **On-premises deployment:** Lync Server 2013 and Exchange UM are both deployed on local servers within your enterprise.
- **Cross-premises deployment:** Lync Server 2013 is deployed on local servers within your enterprise and Exchange UM is hosted in an online service provider's facility, such as a Microsoft Exchange Online data center.
- **Mixed deployment:** Your Lync Server 2013 deployment has some user mailboxes homed on local Exchange servers within your enterprise and some mailboxes homed in a hosted Exchange service data center.

> **Note:**
> The mixed deployment can be used as a transitional solution during evaluation and phased migration of users to hosted Exchange UM, or a permanent solution if you opt to keep some users' Exchange UM services on-

premises after transferring others.

Shared SIP Address Space

To integrate Lync Server 2013 with an on-premises Exchange UM deployment, you grant Lync Server 2013 permission to read Exchange UM Active Directory Domain Services objects. This approach does not work for integration with hosted Exchange UM, however, because Lync Server 2013 and Exchange UM are installed in separate forests with no trust between them.

To integrate Lync Server 2013 with hosted Exchange UM, you must configure a *shared SIP address space*. In this configuration, the same SIP domain address space is available to both Lync Server 2013 and the hosted Exchange UM service provider.

Note:

Use of the shared SIP address space is similar to the approach used in a cross-premises Lync Server 2013 environment, in which some users are homed in the on-premises deployment and some are homed in a hosted deployment (such as Lync Online). The SIP domain is split between them. When you integrate Lync Server 2013 with hosted Exchange UM, ensure that you include the Exchange UM service provider in the shared SIP address space.

To configure the shared SIP address space for integrating with an Exchange UM service provider, you need to configure your Edge Server as follows:

1. Configure the Edge Server for federation by running the **Set-CsAccessEdgeConfiguration** cmdlet to set the following parameters:
   - **UseDnsSrvRouting** specifies that Edge Servers will rely on DNS SRV records when sending and receiving federation requests.
   - **AllowFederatedUsers** specifies whether internal users are allowed to communicate with users from federated domains. This property also determines whether internal users can communicate with users in a split domain scenario.
   - **EnablePartnerDiscovery** specifies whether Lync Server 2013 will use DNS records to try to discover partner domains that are not listed in the Active Directory allowed domains list. If False, Lync Server 2013 will federate only with domains that are found on the allowed domains list. This parameter is required if you use DNS service routing. In most deployments, the value is set to false to avoid opening up federation to all partners.
2. Replicate the Central Management store to the Edge Server and verify the replication. For details, see Export Your Topology and Copy It to External Media for Edge Installation in the Deployment documentation.
3. Configure a *hosting provider* on the Edge Server by running the **New-CsHostingProvider** cmdlet to set the following parameters:
   - **Identity** specifies a unique string value identifier for the hosting provider that you are creating, for example, **Hosted Exchange UM**.
   - **Enabled** indicates whether the network connection between your domain and the hosting provider is enabled. Must be set to **True**.
   - **EnabledSharedAddressSpace** indicates whether the hosting provider will be used in a shared SIP address space scenario. Must be set to **True**.
   - **HostsOCSUsers** indicates whether the hosting provider is used to host Lync Server 2013 accounts. Must be set to **False**.
   - **ProxyFQDN** specifies the fully qualified domain name (FQDN) for the proxy server used by the hosting provider, for example, **proxyserver.fabrikam.com**. Contact your hosting provider for this information. This value cannot be modified. If the hosting provider changes its proxy server, you will need to delete and then recreate the entry for that provider.
   - **IsLocal** indicates whether the proxy server used by the hosting provider is contained within your Lync Server 2013 topology. Must be set to **False**.

1.3.14.3.1.2 Hosted Exchange UM Routing

Hosted Exchange UM Routing

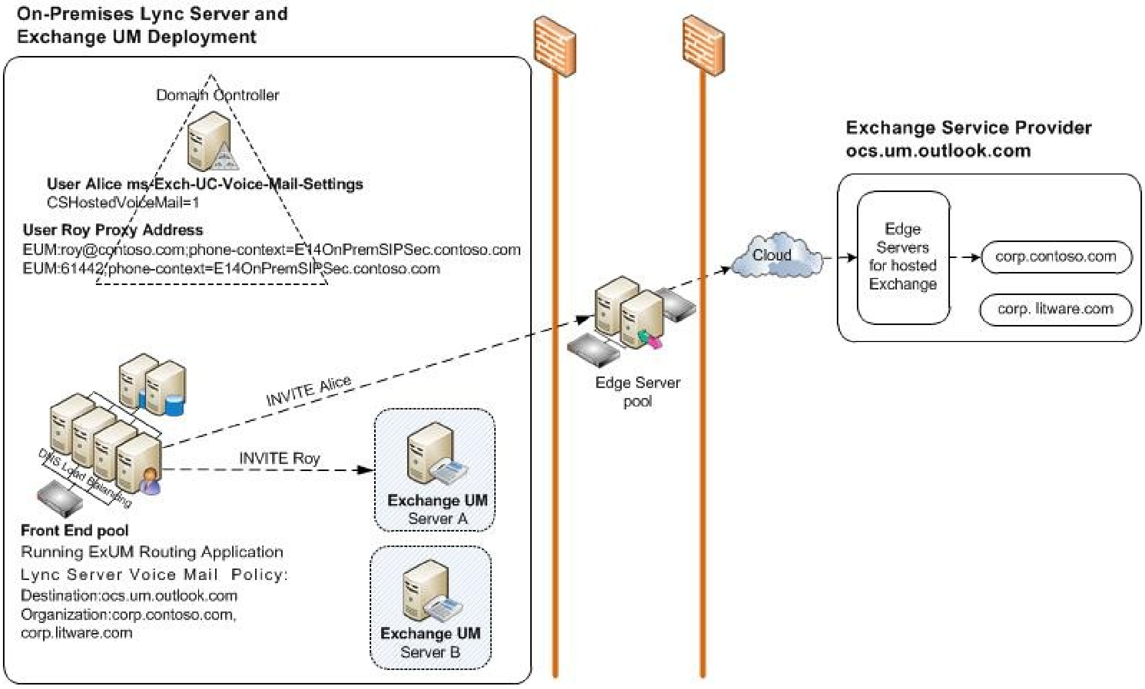
Planning for Enterprise Voice > Hosted Exchange Unified Messaging Integration > Hosted Exchange UM Architecture and Routing >

Topic Last Modified: *2012-10-01*

The Exchange UM Routing application runs on the Front End Server to route calls, either to an on-premises Microsoft Exchange Server Unified Messaging (UM) deployment or to hosted Exchange UM service.

The ExUM Routing Application

The Lync Server 2013 Exchange UM Routing application uses information from user account settings and from hosted voice mail policy parameters to determine how to route calls for hosted voice messaging, as shown in the following diagram.



On-Premises Lync Server and Exchange UM Deployment
Domain Controller
User Alice ms-Exch-UC-Voice-Mail-Settings
CSHostedVoiceMail=1
User Roy Proxy Address
EUM:roy@contoso.com;phone-context=E14OnPremSIPSec.contoso.com
EUM:61442;phone-context=E14OnPremSIPSec.contoso.com
DNS Load Balancing
INVITE Alice
INVITE Roy
Front End pool
Running ExUM Routing Application
Lync Server Voice Mail Policy:
Destination:ocs.um.outlook.com
Organization:corp.contoso.com,
corp.litware.com
Exchange UM
Server A
Exchange UM
Server B
Edge Server
pool
Cloud
Exchange Service Provider
ocs.um.outlook.com
Edge
Servers
for hosted
Exchange
corp.contoso.com
corp. litware.com

Exchange UM routing can be configured to route calls to users who are enabled for on-premises Exchange UM, to users who are enabled for hosted Exchange UM, or to a combination of the two.

For example, suppose that Roy’s mailbox and Exchange UM service are homed in an on-premises Exchange deployment.

- The proxy address information from Roy’s user account provides the information that the ExUM Routing application uses to route his calls to an on-premises Exchange UM server.

Alice’s mailbox and Exchange UM service are located at a hosted Exchange service provider’s data center. Routing for her Exchange UM calls is configured as follows:

- The values set in the msExchUCVoiceMailSettings attribute of Alice’s user account tell the ExUM Routing application to check for routing details in a hosted voice mail policy.

> **Note:**
> The value of the msExchUCVoiceMailSettings attribute can be set by either the Exchange service provider or the Lync Server 2013 administrator. In the example shown in the preceding diagram, the value (CsHostedVoiceMail=1) was set by the Lync Server 2013 administrator to enable hosted voice mail for Alice. For details about this attribute, see Hosted Exchange User Management.

- The hosted voice mail policy that is assigned to Alice's user account provides routing details:
  - Destination is the hosted Exchange UM service provider (ls.ExUm.<*hostedExchangeServer*>.com in this example).
  - Organizations are identified by the tenant IDs, which are the routing FQDNs for SIP messages for Exchange Server tenants that are located on ls.ExUm.<*hostedExchangeServer*>.com (corp.contoso.com and corp.litwareinc.com in this example).

    > **Note:**
    > The FQDN for Exchange Online is exap.um.outlook.com.

    For details, see Hosted Voice Mail Policies.

> **Note:**
> If both the msExchUCVoiceMailSettings attribute and the UM proxy address settings are present in a user account, the msExchUCVoiceMailSettings attribute takes precedence.

1.3.14.3.2 Hosted Voice Mail Policies

Hosted Voice Mail Policies

Planning > Planning for Enterprise Voice > Hosted Exchange Unified Messaging Integration >

Topic Last Modified: *2012-10-01*

A *hosted voice mail policy* provides information to the Lync Server 2013 ExUM Routing application about where to route calls for users whose mailboxes are located on a hosted Exchange service.

> **Note:**
> Hosted voice mail policies are required only for Lync Server 2013 integration with hosted Exchange UM. They are not needed for integration with on-premises Exchange UM.

Hosted Voice Mail Policy Scope

Hosted voice mail policy scope determines the hierarchical level at which the policy applies. You can configure hosted voice mail policies with the following scope levels:

- The *global* policy can potentially affect all users in the Lync Server 2013 deployment. If a user is enabled for hosted Exchange UM access and has not been assigned a per-user policy, and if a site policy has not been assigned to the user's site, the global policy applies. The global policy is installed with Lync Server 2013. You can modify it to meet your needs, but you cannot rename or delete it.
- A *site* policy can affect all users that are homed on the site for which the policy is defined. If a user is configured for hosted Exchange UM access and has not been assigned a per-user policy, the site policy applies.
- A *per-user* policy can affect only individual users or groups. To enforce a per-user policy, you must explicitly assign the policy to individual users, groups, and contact objects.

> **Note:**

In most cases, only one hosted voice mail policy is required. You can often modify the global policy to meet all your needs. If you deploy multiple hosted voice mail policies, all such policies have per-user scope.

Hosted Voice Mail Policy Attributes

A voice mail policy defines two attributes that the Lync Server 2013 ExUM Routing application inserts in the request URI of an INVITE message that is sent to the hosted Exchange UM implementation:

- **Destination:** The fully qualified domain name (FQDN) of the hosted Exchange UM service. This value is used by the on-premises Lync Server Edge Server for routing purposes.

  Note:

  The FQDN for Exchange Online is exap.um.outlook.com.

- **Organization:** The FQDN of the tenant on the hosted Exchange UM service that homes your Lync Server 2013 users' mailboxes. A voice mail policy can contain multiple organizations. If more than one organization is included in the policy, this attribute must be a comma-separated list of the Exchange Server tenants that home your Lync Server 2013 user mailboxes.

Note:

The tenant administrator of your hosted Exchange UM service will provide the necessary values for your Destination and Organization attribute settings. To configure your policy, you must run the New-CsHostedVoicemailPolicy cmdlet or use the Set-CsHostedVoicemailPolicy cmdlet to modify one that exists (for example, the global policy).

For details about managing hosted voice mail policies, see the Lync Server Management Shell documentation for the following cmdlets:

- New-CsHostedVoicemailPolicy
- Set-CsHostedVoicemailPolicy
- Get-CsHostedVoicemailPolicy

Per-User Voice Mail Policy Assignment

If your hosted voice mail policy is defined with per-user scope, you must explicitly assign it. You can run the Grant-CsHostedVoicemailPolicy cmdlet to assign the policy to individual users or groups.

For details about assigning or removing a per-user hosted voice mail policy, see the Lync Server Management Shell documentation for the following cmdlets:

- Grant-CsHostedVoicemailPolicy
- Remove-CsHostedVoicemailPolicy

1.3.14.3.3 Hosted Exchange User Management

Hosted Exchange User Management

Planning > Planning for Enterprise Voice > Hosted Exchange Unified Messaging Integration >

Topic Last Modified: *2012-10-18*

To provide voice mail services for Lync Server 2013 users whose mailboxes are located on a hosted Exchange service, you must enable their user accounts for hosted voice mail.

Note:

Before a Lync Server 2013 user can be enabled for hosted voice mail, a hosted voice mail policy that applies to the corresponding user account must be deployed. The policy can be global, site, or per-user in scope, as long as it applies to the user whom you want to enable. For details, see Hosted Voice Mail Policies.

The msExchUCVoiceMailSettings Attribute

Lync Server 2013 introduces a new user attribute named **msExchUCVoiceMailSettings**, which is created as part of the Lync Server 2013 Active Directory schema preparation. This multivalued attribute holds voice mail settings that are shared by Lync Server 2013 and the hosted Exchange service.

The hosted Exchange service may in some cases set the value of the msExchUCVoiceMailSettings attribute in the process of enabling Exchange UM, or during the process of transferring mailboxes to a hosted Exchange Server. If this attribute is not set by Exchange, the Lync Server 2013 administrator must set it by running the Set-CsUser cmdlet, as described earlier in this topic.

The attribute’s key/value pairs and their authors are shown in the following table.

The msExchUCVoiceMailSettings Attribute Key/Value Pairs

Value	Author	Meaning
ExchangeHostedVoiceMail=1	Exchange	User has been enabled for hosted UM access by Exchange Server. The Exchange UM Routing application will check the user’s hosted voice mail policy for routing details.
ExchangeHostedVoiceMail=0	Exchange	User has been disabled for hosted UM access by Exchange Server.
CsHostedVoiceMail=1	Lync Server	User has been enabled for hosted UM access by Lync Server 2013. The Lync Server 2013 ExUM Routing application will check the user’s hosted voice mail policy for routing details.
CsHostedVoiceMail=0	Lync Server	User has been disabled for hosted UM access by Lync Server 2013.

Note:

If the attribute already has values other than one of the Lync Server 2013 key/value pairs (CSHostedVoiceMail=0 or CSHostedVoiceMail=1), a warning will indicate that the attribute may be managed by a different application. For example, a warning is displayed if the key/value pair ExchangeHostedVoiceMail=0 or ExchangeHostedVoiceMail=1 is already present. In that case, you can change the value by editing it the Active Directory, or run the following cmdlet to set the value to null:
Set-CsUser –identity user –HostedVoicemail $null

Enabling Users for Hosted Voice Mail

To enable a user’s voice mail calls to be routed to hosted Exchange UM, you must run the Set-CsUser cmdlet to set the value of the *HostedVoiceMail* parameter. This parameter also signals Lync Server 2013 to light up the “call voice mail” indicator.

- The following example enables Pilar Ackerman’s user account for hosted voice mail:

  ```
  Set-CsUser -Identity "Pilar Ackerman" -HostedVoiceMail $True
  ```

  The cmdlet verifies that a hosted voice mail policy (global, site-level or per-user) applies to this user. If no policy applies, the cmdlet fails.
- The following example disables Pilar Ackerman’s user account for hosted voice mail:

  ```
  Set-CsUser -Identity "Pilar Ackerman" -HostedVoiceMail $False
  ```

  The cmdlet verifies that no hosted voice mail policy (global, site-level or per-user) applies to this user. If a policy does apply, the cmdlet fails.

For details about using the Set-CsUser cmdlet, see the Lync Server Management Shell documentation.

1.3.14.3.4 Hosted Exchange Contact Object Management

Hosted Exchange Contact Object Management

Planning > Planning for Enterprise Voice > Hosted Exchange Unified Messaging Integration >

Topic Last Modified: *2012-09-25*

You need to configure a Contact object for each auto-attendant number and subscriber access number in your cross-premises deployment.

For integration with hosted Exchange UM, ocsumutil.exe cannot be used to manage Contact objects, because it depends on Active Directory Exchange UM settings. In a cross-premises deployment, Lync Server 2013 and hosted Exchange UM are installed in separate forests with no trust between them. For security reasons, Lync Server 2013 administrators have no direct access to Exchange UM Active Directory settings. As a result, Lync Server 2013 provides a different model for managing Contact objects in a *shared SIP address space* that is accessible to both Lync Server 2013 and the hosted Exchange UM service.

Hosted Contact Object Workflow

The following are the general steps for working with your hosted Exchange tenant administrator to manage contact objects:

1. The Exchange administrator requests phone numbers for the Exchange UM subscriber access and auto-attendant Contact objects.
2. The Lync Server 2013 administrator creates a Contact object for each phone number and assigns a hosted voice mail policy to each Contact object.
3. The Lync Server 2013 administrator provides the phone numbers to the Exchange administrator.
4. The Exchange administrator assigns the phone numbers to appropriate Exchange UM dial plans for auto attendants and subscriber access.

Note:

There is no need to configure any Lync Server 2013 dial plan settings on the Contact objects as there is with on-premises deployments.

Configuring Hosted Contact Objects

Note:

Before Lync Server 2013 Contact objects can be enabled for hosted Exchange UM, a hosted voice mail policy that applies to them must be deployed. The policy can be of global, site-level, or per-user scope, as long as it applies to the contact object you want to enable. For details, see Hosted Voice Mail Policies.

To configure hosted auto-attendant and subscriber access Contact objects in a cross-premises deployment, you must use the following cmdlets:

- **New-CsExUmContact** creates a new Contact object for hosted UM.
- **Set-CsExUmContact** modifies an existing Contact object for hosted Exchange UM.

The following example creates an auto-attendant Contact object:

```
New-CsExUmContact -SipAddress sip:exumaa1@fabrikam.com -RegistrarPool RedmondPool
```

This example creates a new Exchange UM Contact object with the SIP address sip:exumaa1@fabrikam.com. The name of the pool where the Lync Server 2013 Registrar service is running is RedmondPool.litwareinc.com. The Active Directory organizational unit where this information will be stored is OU=ExUmContacts,DC=litwareinc,DC=com. The phone number of the Contact object is 2065554567. The optional -AutoAttendant $True parameter specifies that this object is an auto-attendant Contact object. Setting the -AutoAttendant parameter to False (the default) specifies a subscriber access Contact object.

For details about the New-CsExUmContact and Set-CsExUmContact cmdlets, see the Lync Server Management Shell documentation.

1.3.14.3.5 Deployment Process for Integrating Hosted Exchange UM with Lync Server 2013

Deployment Process for Integrating Hosted Exchange UM with Lync Server 2013

Planning > Planning for Enterprise Voice > Hosted Exchange Unified Messaging Integration >

Topic Last Modified: *2012-09-25*

Effective planning for integrating Lync Server 2013 with hosted Exchange Unified Messaging (UM) requires that you take into account the following:

- Prerequisites for integrating Lync Server 2013 with hosted Exchange UM
- Steps required during the integration process

Deployment Prerequisites for Integrating with Hosted Exchange UM

Before you can begin the integration process, you must already have deployed Lync Server 2013 (at a minimum, a Front End pool or a Standard Edition server), an Edge Server, and Lync 2013 or Lync 2010 clients.

Integration Process

The following table provides an overview of the hosted Exchange UM integration process. For details about deployment steps, see Providing Lync Server 2013 Users Voice Mail on Hosted Exchange UM in the Deployment documentation.

Phase	Steps	Rights and permissions	Deployment documentation
Configure the Edge Server.	1. Configure the Edge Server for federation. 2. Manually replicate data to the Edge Server. 3. Configure the hosting provider on the Edge Server.	RTCUniversalServerAdmins	Configure the Edge Server for Integration with Hosted Exchange UM
Configure hosted voice mail policy.	1. Either modify the global hosted voice mail policy or create a new hosted voice mail policy with Site or Per-User scope. 2. For policies with Per-User scope, assign the policy to users or groups.	RTCUniversalServerAdmins	Manage Hosted Voice Mail Policies
Enable users for hosted voice mail.	- Configure user accounts for users whose mailboxes are on a hosted Exchange service.	RTCUniversalUserAdmins	Enable Users for Hosted Voice Mail
Configure hosted contact objects.	1. Create auto-attendant Contact objects for hosted Exchange UM. 2. Create Subscriber Access contact objects for hosted Exchange UM.	RTCUniversalUserAdmins **Note:** To create, modify or remove contact objects, the user who runs the New-CsExUmContact, Set-CsExUmContact or Remove-CsExUmContact cmdlet must have the correct permission to the Active Directory organizational unit where the new contact objects are stored. This permission can be granted by running the Grant-CsOUPermission cmdlet. For details, see the Lync Server Management Shell documentation.	Create Contact Objects for Hosted Exchange UM

1.3.15 Planning for Clients and Devices in Lync Server 2013

Planning for Clients and Devices in Lync Server 2013

Microsoft Lync Server 2013 > Planning >

Topic Last Modified: *2012-06-04*

The topics in this section describe how to plan for Lync Server 2013 clients and devices in your organization.

- Planning for Clients
- Planning for Mobile Clients
- Planning for Devices

1.3.15.1 Planning for Clients

Planning for Clients

Microsoft Lync Server 2013 > Planning > Planning for Clients and Devices in Lync Server 2013 >

Topic Last Modified: *2013-02-12*

The topics in this section discuss planning considerations for deploying Microsoft Lync Server 2013 clients. Whether you are deploying a new Lync Server 2013 installation or migrating from a previous deployment, these topics provide important client planning information.

- Clients for Lync Server 2013
- Client Comparison Tables
- Client System Requirements
- Client Policies and Settings
- Lync 2013 Compatibility
- Client Interoperability in Lync 2013

1.3.15.1.1 Clients for Lync Server 2013

Clients for Lync Server 2013

See Also

Microsoft Lync Server 2013 > Planning > Planning Primer: Planning for Your Organization >

Topic Last Modified: *2013-02-19*

Lync Server 2013 supports several types of client software that you can deploy to your organization’s users, including computer-installed client software, web-based clients, and mobile devices. This topic outlines the clients that you can use. For a detailed comparison of the features provided by Lync Server 2013 clients, see Client Comparison Tables.

Lync 2013

Lync 2013 is the full-featured client for Lync Server. The Lync 2013 user interface has been fully redesigned and includes newly integrated features, such as Persistent Chat (Lync 2010 had a separate client for chat functionality), tabbed conversations, video preview, and multiparty video. For a summary of changes, see What's New for Clients.

Lync 2013 client setup is part of the Office setup program on the installation media.

Online Meeting Add-in for Lync 2013

The Online Meeting Add-in for Lync 2013 supports meeting management from within Microsoft Outlook messaging and collaboration client. The Online Meeting Add-in for Lync 2013 software installs automatically with Lync 2013.

Lync Web Scheduler

Lync Web Scheduler is a web-based meeting scheduling and management tool for users who don't have access to Microsoft Outlook, or who are on an operating system not based on Windows. With Lync Web Scheduler, users can create new meetings, modify existing meetings, and send invitations using their preferred email program.

Lync Web App

Lync Web App is the web-based conferencing client for Lync Server 2013 meetings. In this release, the addition of computer audio and video to Lync Web App provides a complete in-meeting experience for anyone who does not have a Lync client installed locally. Meeting participants have access to all collaboration and sharing features and presenter meeting controls.

If Lync 2013 is not installed on a user's computer and the user clicks a meeting link in a meeting request, Lync Web App opens. You can also configure the Meeting Join page to allow users to join meetings by using previous versions of clients; see Configuring the Meeting Join Page in the Deployment documentation.

Because of the enhancements to Lync Web App, an updated version of Microsoft Lync 2010 Attendee is not available for Lync Server 2013. Lync Web App is the client of choice for participants outside your organization. With Lync Web App, no local client installation is required, although audio, video, and sharing features require installation of a plug-in during first use.

Lync 2013 Basic

Lync 2013 Basic is a downloadable client for customers who have a licensed, on-premises Lync Server 2013 deployment and customers who subscribe to a Microsoft Office 365 plan that does not include the full Lync 2013 client. The Lync Basic client includes enhanced presence, contacts, instant messaging (IM), Lync meetings, and basic voice functionality. Features not supported in Lync Basic include multiparty video, OneNote integration, virtual desktop infrastructure (VDI) support, skill search, recording, Enterprise Voice features, and advanced call handling (for example, call forwarding and Team Call). For details, see Client Comparison Tables.

Lync Windows Store App

The Lync Windows Store app is a touch-optimized Lync app designed specifically for Windows 8 and Windows RT. Users can download the app through the Windows Store by searching for "Lync." For more information, see Client Comparison Tables, Lync Windows Store App Requirements, and Deploying Lync Windows Store App.

Lync 2013 for Mobile Devices

Lync 2013 mobile apps now include voice over IP (VoIP) and video over IP capabilities, in addition to contacts, presence, and IM features. Mobile users can choose to communicate with others through IM, voice calls, or video calls by using either Wi-Fi or their cellular data connection. With a single click of the meeting link in a calendar item, mobile users can join voice and video meetings. For more information about Lync 2013 mobile apps, see Planning for Mobile Clients.

Supported Clients from Previous Releases

Lync Server 2013 supports the following clients from previous server releases. You can make certain previous clients available to users when they join meetings. For details, see Configuring the Meeting Join Page in the Deployment documentation.

- **Lync 2010** Lync 2010 provides a full desktop experience, including IM, enhanced presence, voice, video, sharing, and telephony. However, none of the new features introduced in Lync Server 2013 will be available until the user's client is upgraded to Lync 2013.
- **Lync 2010 Mobile** Lync Server 2013 supports all of the Microsoft Lync 2010 Mobile mobile apps. Microsoft Lync 2010 Mobile provides IM, enhanced presence, and telephony for users in your organization who are connecting from a smartphone or a phone running a Professional edition of Windows Mobile. You can instruct your users to install Microsoft Lync 2010 Mobile by directing them to the app marketplace for their mobile phone. For details, see "Planning for Mobile Clients" in the Lync Server 2010 documentation at http://go.microsoft.com/fwlink/p/?LinkID=235955.
- **Lync Phone Edition** Lync Phone Edition software for intelligent IP phones (for example, USB-attached phones) has not been updated for Lync Server 2013. Lync Phone Edition continues to be supported in for placing and receiving calls, enhanced presence, and client audio capabilities for conferences.
- **Lync 2010 Attendant** The Microsoft Lync 2010 Attendant integrated call-management program enables a receptionist to manage multiple conversations at the same time through rapid call handling, IM, and onscreen routing.

1.3.15.1.2 Client Comparison Tables

Client Comparison Tables

Planning > Planning for Clients and Devices in Lync Server 2013 > Planning for Clients >

Topic Last Modified: *2013-03-08*

The following tables compare the features and capabilities of clients running on Microsoft Lync Server 2013 in the following categories:

- Enhanced Presence Support
- Contacts and Contact Groups Support
- IM Support
- Conferencing Support
- Telephony Support
- External Users Support
- Archiving and Compliance Support

Note:

- These tables indicate the features that are available to Lync users in an on-premises deployment of Lync Server 2013. The same features are also available to Lync Online and Office 365 users unless otherwise indicated. For details about Lync Online subscription plans, see the Lync Online Service Description at http://go.microsoft.com/fwlink/p/?LinkId=282430.

- For information about Lync 2013 for mobile clients, see Mobile Client Comparison Tables.
- Lync Server 2013 supports the following previously released clients: Lync 2010, Lync 2010 Mobile, Lync Phone Edition, and Lync 2010 Attendant. For information about these clients, see the Lync 2010 version of the Client Comparison Tables at http://go.microsoft.com/fwlink/p/?LinkID=213798.

Enhanced Presence Support

Feature/ capability	Lync 2013	Lync Windows Store app	Lync 2013 Basic	Lync Web App	Lync 2010 Attendant	Lync Phone Edition	Communicator for Mac 2011	Lync for Mac 2011
Publish and view status	?	?	?		?	?	?	?
View status based on calendar free/busy information	?	?	?		?	?	?	?
View status notes and Out of Office messages	?	?	?		?	?	?	?
Add a custom location	?		?					
Add a custom note	?	?	?		?		?	?

Contacts and Contact Groups Support

Feature/ capability	Lync 2013	Lync Windows Store app	Lync 2013 Basic	Lync Web App	Lync 2010 Attendant	Lync Phone Edition	Communicator for Mac 2011	Lync for Mac 2011

Spelling checker		?						?
Skill search (with SharePoint Server integration) [1]	?	?			?			
Persistent Chat (Group Chat) integration[2]	?		?					

[1] Skill search is available with on-premises Lync Server 2013 and on-premises SharePoint 2013.

[2] Persistent Chat is not available to Lync Online and/or Office 365 users.

Conferencing Support

Note:

- Lync meeting features are not available in Lync Online Standalone Plan 1.
- In Lync-to-Lync sessions, a Lync Online Plan 1 user can participate in desktop sharing and application sharing if they are invited by a user who has access to sharing features.
- For details, see the Lync Online Service Description at http://go.microsoft.com/fwlink/?LinkID=282430.

Feature/ capability	**Lync 2013**	**Lync Windows Store app**	**Lync 2013 Basic**	**Lync Web App**	**Lync 2010 Attendant**	**Lync Phone Edition**	**Communicator for Mac 2011**	**Lync for Mac 2011**
Add computer audio	?	?	?	?	?	?	?	?
Add video	?	?	?	?			?	?
View multiparty video	?	?		?				?
Use in-meeting presenter controls	?		?	?				?
Access detailed meeting roster	?	?	?	?	?			?
Participate in multiparty IM	?	?	?	?	?		?	?
Share the desktop (if enabled)	?		?	? (requires plug-in)			?[1]	?[1]
Share a program (if enabled)	?		?	? (requires plug-in)				View only
Add anonymous participants (if enabled)	?		?	?				?
Use dial-in audio conferencing	?	?	?	?	?			?
Initiate a	?		?					?

meeting								
Add Microsoft PowerPoint files	?		?	?				View only, annotations not available
Navigate Microsoft PowerPoint files	?		?	?				?
Use OneNote meeting notes	?			?				
Use a whiteboard	?		?	?				
Conduct polls	?		?	?				
Share files	?		?	?				?

[1] Participants cannot control desktops that are shared by Lync for Mac 2011 or Communicator for Mac 2011 users. Lync for Mac 2011 and Communicator for Mac 2011 users can control desktops shared by Windows users.

Telephony Support

Note:

Lync Voice features are limited to certain Lync Online subscription plans. For details, see the "Lync Voice Features" topic in the Lync Online Service Description at http://go.microsoft.com/fwlink/?LinkID=282430.

Feature/ capability	**Lync 2013**	**Lync Windows Store app**	**Lync 2013 Basic**	**Lync Web App**	**Lync 2010 Attendant**	**Lync Phone Edition**	**Communicator for Mac 2011**	**Lync for Mac 2011**
Initiate a voice call	?	?	?		?	?	?	?
Click to call a contact	?	?	?		?	?	?	?
Transfer a call	?	?			?	?		?
Manage call forwarding	?	?			?	?		?

Manage team call settings	?				?			
Manage delegates	?							
Initiate a call to a Response Group	?				?			
Support emergency services (E9-1-1)	?	?	?		?	?		
Connect to voice mail	?	?			?	?		
Make calls on behalf of another contact (manager/delegate scenario)	?							
Handle another's calls if configured as a delegate	?				?	?		
Manage a high volumes of calls					?			

External Users Support

Feature/ capability	Lync 2013	Lync Windows Store app	Lync 2013 Basic	Lync Web App	Lync 2010 Attendant	Lync Phone Edition	Communicator for Mac 2011	Lync for Mac 2011
Initiate IM with a public contact	?	?	?		?		?	?
Initiate IM with a federate	?	?	?		?		?	?

d contact								
Conduct two-party or multiparty calls with external users	?	?	?		?	?	?	?

Archiving and Compliance Support

Feature/ capability	Lync 2013	Lync Windows Store app	Lync 2013 Basic	Lync Web App	Lync 2010 Attendant	Lync Phone Edition	Communicator for Mac 2011	Lync for Mac 2011
Provide client-side archiving [1]	?				?		?	?
Provide client-side recording [2]	?							

[1] Application sharing archiving and desktop sharing archiving is unavailable in Lync Online subscription plans.

[2] Client-side recording is unavailable in certain Lync Online standalone plans. For details, see the Lync Online Service Description at http://go.microsoft.com/fwlink/?LinkID=282430.

1.3.15.1.3 Client System Requirements

Client System Requirements

Planning > Planning for Clients and Devices in Lync Server 2013 > Planning for Clients >

Topic Last Modified: *2012-11-06*

This section describes the hardware and software requirements for Lync 2013 clients.

- Lync Client Hardware Support
- Lync Client Video Requirements
- Lync Client Software Support
- Lync Web App Supported Platforms
- Lync Windows Store App Requirements

1.3.15.1.3.1 Lync Client Hardware Support

Lync Client Hardware Support

Supportability > Supported Hardware > Client and Device Hardware Support >

Topic Last Modified: *2012-12-14*

This section describes the recommended hardware for Lync 2013 and the Online Meeting Add-in for Lync 2013.

Recommended Hardware for Lync 2013 and the Online Meeting Add-in for Lync 2013

System component	Minimum requirement
Computer/processor	Intel Pentium 4, AMD Athlon 64, or equivalent
Memory	2 gigabytes (GB) of RAM
Data and Voice	Minimum 1.6 gigahertz (GHz) or faster processor. We recommend 2.0 gigahertz (32-bit or 64- bit).
Video	See Lync Client Video Requirements
Display resolution	1024x768 required
Graphics hardware	• Support for Microsoft DirectX 9 application programming interface • 128 megabytes (MB) of graphics memory (minimum). We recommend 256 MB of graphics memory. • Windows Display Driver Model driver • Pixel Shader 2.0 in hardware • 32 bits per pixel
Telephony	Microphone and speakers, headset with microphone, or equivalent device(s). Recommended devices: • Phones with the "Optimized for Microsoft Lync" logo (see Phones and Devices Qualified for Microsoft Lync at http://go.microsoft.com/fwlink/p/?LinkID=208938 for a list) • Phones that run Lync Phone Edition
Video source	USB 2.0 video camera or Polycom CX5000 HD device (RoundTable device)
Bandwidth Requirements	See Network Bandwidth Requirements for Media Traffic

1.3.15.1.3.2 Lync Client Video Requirements

Lync Client Video Requirements

Planning for Clients and Devices in Lync Server 2013 > Planning for Clients > Client System Requirements >

Topic Last Modified: *2012-12-07*

This section describes video hardware support for Lync 2013 video calls and describes how to determine the expected video quality for various computer configurations.

Lync 2013 introduces hardware acceleration for video encoding and decoding based on the H.264/MPEG-4 Part 10 Advanced Video Coding standard. This feature allows computers with lower CPU clock speeds to encode and decode higher resolution video. Video hardware requirements vary depending on the computer configuration and the video resolution wanted.

Video Hardware Requirements

Feature	Requirement
Hardware accelerated H.264 decoding using DirectX Video Acceleration (DXVA)	• Graphics card must support DirectX 9.0 and must expose the DXVA2_ModeH264_VLD_NoFGT decoding mode. • The latest graphics card driver must be installed. **Note:** For details about decoding modes, see http://go.microsoft.com/fwlink/p/?LinkId=268530.
Hardware accelerated H.264 encoding: Chipset Requirements	The following hardware accelerated video encoding solutions are supported: • Second and third generation Intel HD Graphics 2000, 2500, 3000, and 4000 chipsets (or later versions) with integrated hardware video encoders. • Intel HD Graphics driver 15.28.9.2884 or the latest driver containing the following: • Display driver 9.17.10.2884 or the latest driver • Hardware media foundation transform (HMFT) version 3.12.10.31 or the latest HMFT
Hardware accelerated H.264 encoding: Camera Requirements	USB video cameras with integrated H.264 hardware encoder that conforms to the USB Video Class (UVC) specification version 1.5. **Note:** Lync 2013 supports UVC 1.5 cameras with Windows 8, which includes support for UVC 1.5. Because Windows 7 does not include support for UVC 1.5, Lync 2013 treats UVC 1.5 cameras as regular cameras with no hardware encoding support.

Determining H.264 Video Encoding and Decoding Capabilities

Generally, there are four major factors that determine the maximum encoding and decoding capability of a particular computer configuration:

- Support for hardware accelerated decoding by using DXVA
- Support for hardware accelerated encoding
- Number of physical cores
- Windows Experience Index (WEI)

The Windows System Assessment Tool (WinSAT) determines the WEI. When you run the WinSAT tool, it generates a Formal.Assessment XML document on the computer in the %windir%\Performance\WinSAT\DataStore directory. This XML file contains the following two scores that are of particular importance for determining encoding and decoding capabilities:

- The VideoEncodeScore indicates the software-based video encoding capability of the computer.
- The GraphicsScore value indicates the hardware accelerated encoding capability of the computer.

The following three tables explain the maximum encoding and decoding capability for different PC types depending on what hardware acceleration they support. For resolutions of 640x360 and higher, the maximum supported frame rate is 30 frames per second (fps). For resolutions lower than 640x360, the maximum supported frame rate is 15 fps.

Computer Without DXVA And Without Hardware Accelerated Encoder

Capable Encoder Resolution	Capable Decoder Resolution	Requirement
424x240	424x240 (640x360 at 15fps for receive only scenarios)	1 Core and VideoEncodeScore ≥ 4.0
640x360	640x360	2 Cores and VideoEncodeScore ≥ 4.5
640x360	1280x720	2 Cores and VideoEncodeScore ≥ 4.5
640x360	1920x1080	4 Cores and VideoEncodeScore ≥ 4.5
1280x720	1280x720	4 Cores and VideoEncodeScore ≥ 7.3
1280x720	1920x1080	4 Cores and VideoEncodeScore ≥ 7.3
1920x1080	1920x1080	N/A

Computer With DXVA But Without Hardware Accelerated Encoder

Capable Encoder Resolution	Capable Decoder Resolution	Requirement
424x240	1920x1080	1 Core and VideoEncodeScore ≥ 3.0
640x360	1920x1080	2 Cores and VideoEncodeScore ≥ 4.5
960x540	1920x1080	2 Cores and VideoEncodeScore ≥ 6.0
1280x720	1920x1080	4 Cores and VideoEncodeScore ≥ 6.7
1920x1080	1920x1080	4 Cores and VideoEncodeScore ≥ 8.2

Note:

The WinSAT score on Windows 7 is limited to a maximum of 7.9. Therefore, the encoding capability for a computer without a hardware accelerated encoder can only be achieved on Windows 8, where the maximum WinSAT score is 9.9.

Computer With DXVA And With Intel HD Graphics Hardware Accelerated Encoder

Capable Encoder Resolution	Capable Decoder Resolution	Requirement
1280x720	1920x1080	All 2nd and 3rd generation Intel HD Graphics
1920x1080	1920x1080	2nd and 3rd generation Intel HD Graphics and GraphicsScore ≥ 5.0

1.3.15.1.3.3 Lync Client Software Support

Lync Client Software Support

See Also

Microsoft Lync Server 2013 > Supportability > Client and Device Software and Infrastructure Support >

Topic Last Modified: *2013-03-07*

This section summarizes software support for Lync 2013 and the Online Meeting Add-in for Lync 2013.

Note:

The Online Meeting Add-in for Lync 2013, which supports meeting management from within the Outlook messaging and collaboration client, installs automatically with Lync 2013.

Software Requirements for Lync 2013 and the Online Meeting Add-in for Lync 2013

System component	Minimum requirement
Windows Operating system	Windows 8 Windows 7 operating system Windows Server 2008 R2 with latest service pack
Installation and updates	Administrator rights and permissions
Browser	Windows Internet Explorer 10 Internet browser Windows Internet Explorer 9 Internet browser Windows Internet Explorer 8 Internet browser Windows Internet Explorer 7 Internet browser Mozilla Firefox web browser **Note:** If you are using Lync with Microsoft Exchange Online and your organization has deployed an authenticating HTTP proxy, Internet Explorer 9 or Internet Explorer 8 is required.
Microsoft Office Integration	For the full set of integration features: • Outlook 2013 messaging and collaboration client • Outlook 2010 messaging and collaboration client

Microsoft Exchange Integration	For the full set of integration features: • Microsoft Exchange Server 2013 • Microsoft Exchange Server 2010

Macintosh Operating Systems

Lync 2013 is available only for Windows. However, Lync Server 2013 supports the following clients on computers that are running Mac OS 10.5.8 or latest service pack or release (Intel-based) operating systems. For details about supported features, see Client Comparison Tables.

- Microsoft Lync for Mac 2011 (see "Lync for Mac 2011 Deployment Guide" at http://go.microsoft.com/fwlink/p/?LinkId=268786)
- Microsoft Communicator for Mac 2011 (see "Communicator for Mac 2011 Deployment Guide" at http://go.microsoft.com/fwlink/p/?LinkId=268787)

Lync Web App Browsers

Lync Web App supports specific combinations of operating systems and browsers. For details, see Lync Web App Supported Platforms in the Planning documentation.

Microsoft Office Supportability

Lync Server 2013 clients support integration with various versions of Microsoft Office, as summarized in this section.

- Lync 2013 integration features are supported on Outlook 2013 and Microsoft Outlook 2010.
- Lync 2013 integration features are supported on Microsoft Exchange Server 2013 and Microsoft Exchange Server 2010.
- Certain Lync 2013 integration features are supported on Microsoft Office 2007 and Microsoft Office 2003 Service Pack 3 (SP3). For integration with Microsoft Office 2007 to work correctly, you may have to install an update to Microsoft Office 2007. For details about the Outlook update, see Microsoft Knowledge Base article 936864, "Description of the 2007 Office hotfix package" at http://go.microsoft.com/fwlink/p/?linkid=3052&kbid=936864.
- The Online Meeting Add-in for Lync 2013 is supported with Office 2013, Microsoft Office 2010, Microsoft Office 2007, and the Microsoft Office 2003 suites.

Using Mandatory Profiles

If users are planning to use Lync 2013 conferencing features, they should not use Active Directory Domain Services (AD DS) mandatory profiles to sign in to the Lync 2013 client. Because mandatory profiles are read-only user profiles, the public key infrastructure (PKI) keys that are required for Lync 2013 conferencing cannot be saved to the profile. For details, see Microsoft Knowledge Base article 2552221, "Lync 2010 conferencing feature fails when the user is signed in using a mandatory user profile," at http://go.microsoft.com/fwlink/p/?linkid=3052&kbid=2552221.

1.3.15.1.3.4 Lync Web App Supported Platforms

Lync Web App Supported Platforms

Planning for Clients and Devices in Lync Server 2013 > Planning for Clients > Client System Requirements >

Topic Last Modified: *2013-02-19*

To use Lync Web App, you must have one of the following supported operating system and browser combinations.

Note:

A plug-in is required for certain Lync Web App features, including computer-based voice, video, sharing, and viewing of ongoing screen sharing. The first time users initiate a sharing session, they will be prompted to download the required sharing plug-in.

Supported Operating System and Browser Combinations for Lync Web App

Operating system	32-bit Internet Explorer 10	64-bit Internet Explorer 10	32-bit Internet Explorer 9	64-bit Internet Explorer 9	32-bit Internet Explorer 8	64-bit Internet Explorer 8	32-bit Version of Firefox 12.X	64-bit Version of Safari 5.X	32-bit Version of Chrome 18.x
Windows 8 (Intel based)[1]	Yes	Yes	N/A	N/A	N/A	N/A	Yes	N/A	Yes
Windows 7 with SP1[2]	Yes[3]	Yes[3]	Yes	Yes	Yes	Yes	Yes	No	Yes
Windows Vista with Service Pack 2 (SP2)[4]	N/A	No	Yes	No	Yes	No	Yes	No	Yes
Windows XP with Service Pack 3 (SP3)[4]	N/A	N/A	N/A	N/A	Yes	No	Yes	No	Yes
Windows Server 2008 R2 with SP1[2]	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No	Yes
Windows Server 2008 with SP2[4]	Yes	No	Yes	No	Yes	No	Yes	No	Yes

Mac OS-x (Intel-based)[2]	N/A	N/A	N/A	N/A	N/A	N/A	Yes	Yes	Yes

[1] The plug-in required to use computer-based audio, video, application viewing, application sharing, desktop viewing, and desktop sharing can be installed only if you're running Internet Explorer 10 for the desktop. These features are not available with Internet Explorer 10 (non-desktop).

[2] On supported Windows 7, Windows Server 2008 R2, and Macintosh operating systems, all features are available including computer-based voice, video, application viewing, application sharing, desktop viewing, and desktop sharing. To use these features, you must install a plug-in when prompted.

Note:

Macintosh operating systems do not support application sharing. Consequently, Lync Web App will not support application sharing with Macintosh operating systems.

[3] This combination will be supported when available.

[4] On supported Windows XP, Windows Vista, and Windows Server 2008 operating systems, computer-based voice and video are not available. Application viewing, application sharing, desktop viewing, and desktop sharing are available.

1.3.15.1.3.5 Lync Windows Store App Requirements

Lync Windows Store App Requirements

See Also

Planning for Clients and Devices in Lync Server 2013 > Planning for Clients > Client System Requirements >

Topic Last Modified: *2013-02-20*

Organizations with an on-premises deployment of Lync Server must meet the following requirements to support Lync Windows Store app.

Note:

For Lync Server 2010, run the cumulative update for Lync Server 2010: February 2012 (available at http://go.microsoft.com/fwlink/?linkid=3052&kbid=2670352) or later on all servers. To enable users to join meetings, run the cumulative update for Lync Server 2010: October 2012 (available at http://go.microsoft.com/fwlink/?linkid=3052&kbid=2737915) on the servers.

- Enable the Autodiscover, Lync Web App, and Web Ticket services on the server.
- Enable certificate authentication on the Registrar.
- Publish the DNS alias (CNAME) resource records for the Autodiscover service.
- Make sure the Certificate Revocation List (CRL) Distribution Point (CDP) for the certificates issued to Lync server points to an HTTP resource instead of an LDAP resource.
- Configure HTTP proxies in the enterprise to allow Lync server related HTTP traffic. Add exceptions for the Autodiscover, Lync Web App, and WebTicket services, if necessary.

If your organization subscribes to Lync Online or Office 365 and you are using your own domain name, you must take some extra steps to set up your network for autodiscovery of the Lync servers. The network configuration requirements are the same for Lync Windows Store app and Lync on mobile devices. Follow the instructions “Set up your network” in the Office 365 wiki article “Set up Lync mobile devices,” available at http://go.microsoft.com/fwlink/?LinkId=271822.

Concepts

Deploying Lync Windows Store App

1.3.15.1.4 Client Policies and Settings

Client Policies and Settings

Planning > Planning for Clients and Devices in Lync Server 2013 > Planning for Clients >

Topic Last Modified: *2012-06-18*

This topic provides an overview of the client-related settings and policies that you can configure in Lync Server 2013. Lync Server 2013 includes the following tools for managing and configuring clients:

- **Lync Server 2013 Control Panel** A web-based graphical user interface for managing and configuring servers, users, clients, and devices.
- **Lync Server Management Shell** A management interface with a rich set of Windows PowerShell command-line interface cmdlets and a number of pre-defined scripts.
- **Lync 2013 Group Policy** A set of policies that you can configure for clients by using the Office Group Policy Administrative Template. Certain client bootstrapping policies must be configured before you deploy Lync 2013 clients. Other optional settings from Lync 2010 continue to be honored in Lync 2013.

This section describes changes to client-related settings in Lync Server 2013.

In this Section

- New and Changed Settings for Lync 2013
- Group Policy Settings for Lync 2013

1.3.15.1.4.1 New and Changed Settings for Lync 2013

New and Changed Settings for Lync 2013

Planning for Clients and Devices in Lync Server 2013 > Planning for Clients > Client Policies and Settings >

Topic Last Modified: *2012-12-04*

This topic discusses changes to Lync Server Management Shell cmdlets that relate directly to client management. Lync Server 2013 introduces several new parameters, and deprecates parameters for features that can be configured through other means.

New Client Management Parameters

New	Lync Server Management Shell Cmdlet	Description

TracingLevel	CsClientPolicy	When set to True, software tracing will be enabled in Lync; when set to False, software tracing will be disabled. Software tracing involves keeping a detailed record of everything that a program does (including tracking API calls). Tracing is mostly useful to developers and to application support personnel.This setting is equivalent to the Communications Server 2007 R2 Group Policy setting "Turn on tracing for Communicator." The settings are as follows: • Off = Tracing is disabled and the user cannot change this setting. • Light = Minimal tracing is performed, and the user cannot change this setting. • On = Verbose tracing is performed, and the user cannot change this setting. By default TracingLevel is set to a null value. That means that minimal tracing is performed, but the user can enable or disable this minimal tracing.
EnableMediaRedirection	CsClientPolicy	When set to True ($True) allows audio and video streams to be separated from other network traffic, In turn, this allows client devices to do encoding and decoding of audio and video locally. Media redirection typically results in lower bandwidth usage, higher server scalability, and a more-optimal user experience compared to similar techniques such as device remoting or codec compression.
AllowLargeMeetings	CsConferencing	When set to True, all Lync Meetings are treated as "large meetings." With a large meeting, restrictions are placed on the number of notifications that are sent to participants, in addition to the size of the meeting roster that is transmitted by default.
DisablePowerPointAnnotations	CsConferencing	When set to True ($True) users won't be able to add annotations to PowerPoint slides used in a conference. However (depending on the value of the AllowAnnotations property), users will still have access to other whiteboarding features. The default value is False, meaning that PowerPoint annotations are allowed.
AllowSharedNotes	CsConferencing	When set to True (the default value)

		any open OneNote notebooks linked to the conference will automatically be updated with information such as conference participants and details about content shared during the conference.
EnableInviteCustomization	CsMeetingConfiguration	Used along with the other new CsMeetingConfiguration parameters to customize the meeting invitations generated by the Online Meeting Add-in for Lync 2013.
LogoURL	CsMeetingConfiguration	Adds your organization’s logo to all invitations generated by the Online Meeting Add-in for Lync 2013. You specify the URL of a GIF or JPG image.
HelpURL	CsMeetingConfiguration	Adds your organization’s help or support URL to all invitations generated by the Online Meeting Add-in for Lync 2013.
LegalURL	CsMeetingConfiguration	Adds legal text or disclaimer text to all invitations generated by the Online Meeting Add-in for Lync 2013. You specify the URL for the location of the text.
CustomFooterText	CsMeetingConfiguration	Adds a custom footer to all invitations generated by the Online Meeting Add-in for Lync 2013. You specify the URL for the location of the custom footer text.

Deprecated Client Management Parameters

Parameter	**Lync Server Management Shell Cmdlet**	**Description**
EnableSQMData	CsClientPolicy	The EnableSQMData parameter of the Set-CSClientPolicy cmdlet has been removed in Lync Server 2013. Instead, you can use the shared Group Policy setting for Software Quality Management (SQM) data to determine the user interface for the Customer Experience Improvement option in the Lync client General options page: HKEY_CURRENT_USER \Software\Policies\Microsoft \Office\Common\QMEnable Values: 1 = Display and select the check box (the user can clear

		the check box) 0 = Turn off and disable the check box (user can't override) Null = The value is determined by Office setup, and the check box is displayed for users to set as they choose
AllowExchangeContactStore	CsClientPolicy	This parameter has been removed. Instead, when you deploy Lync Server 2013 and publish the topology, unified contact store is enabled for all users by default. This means that all a user's contacts are kept in Exchange and are available in Lync, Outlook, and Outlook Web Access. You can use the Set-CsUserServicesPolicy cmdlet to customize which users have unified contact store available. You can enable users globally, by site, by tenant, or by individuals or groups of individuals. For details, see Enable Users for Unified Contact Store.
MAPIPollInterval	CsClientPolicy	This parameter is not used by Lync 2013. In previous releases, this parameter specified how often the client retrieved MAPI data from Exchange public folders

1.3.15.1.4.2 Group Policy Settings for Lync 2013

Group Policy Settings for Lync 2013

Planning for Clients and Devices in Lync Server 2013 > Planning for Clients > Client Policies and Settings >

Topic Last Modified: *2012-10-03*

In previous versions of Lync and Office Communicator, a stand-alone Communicator.adm administrative template was available for configuring client Group Policy settings. For Lync 2013, new administrative template files (.admx and .adml files) are included along with the Office Group Policy Administrative Template. The availability of Lync 2013 .admx and .adml files allows you to download templates and centrally manage Group Policy settings for all your Office programs and language packs. For details, see “Office 2013 Administrative Template files (ADMX, ADML)” in the Office 2013 documentation at http://

go.microsoft.com/fwlink/p/?linkid=267516.

Client Bootstrapping Policies

There are several client bootstrapping policies that you should configure before users sign in to the server for the first time. Because these policies take effect before the client signs in and begins receiving in-band provisioning settings from the server, you can use Group Policy to configure them. For more information, see Configuring Client Bootstrapping Policies in the Deployment documentation.

1.3.15.1.5 Lync 2013 Compatibility

Lync 2013 Compatibility

See Also

Planning > Planning for Clients and Devices in Lync Server 2013 > Planning for Clients >

Topic Last Modified: *2013-02-20*

This section describes the compatibility of Lync 2013 with various versions of Microsoft Office suites, Microsoft Exchange Server, Windows operating systems, and selected public instant messaging (IM) clients.

Office and Lync 2013

The following table describes the Lync 2013 features that are supported by various versions of Office.

Lync 2013 and Microsoft Office Compatibility

Feature	Microsoft Office 2003 with Service Pack 3 (SP3) (required) or the latest service pack (recommended)	Microsoft Office 2007	Microsoft Office 2010	Microsoft Office 2013
Customize Outlook meeting invitations (add logo, help URL, disclaimer, footer text)	No	No	No	Yes
In Outlook, configure meeting option to mute attendee audio and video by default	No	No	No	Yes
Unified Contact Store for managing	No	No	No	Yes (requires Exchange 2013)[1]

Contacts lists across Office and Lync				
High-resolution pictures	No	No	No	Yes (requires Exchange 2013)[1]
Lync 2013 setup integrated into the Office setup program	No	No	No	Yes
OneNote shared notes	No	No	No	Yes
PowerPoint 2013 presentation content	Yes	Yes	Yes	Yes
Presence status in the Microsoft Outlook To and Cc fields	Presence status appears on hover	Presence status is always shown	Presence status is always shown	Presence status is always shown
Reply with conference call from the availability menu	No	Yes	Yes (from the contact card)	Yes (from the contact card)
Presence status in a meeting request on the Scheduling Assistant tab	No	Yes	Yes	Yes
Reply with IM, or call from the toolbar or ribbon in a received email message	No	Yes	Yes	Yes
Presence status in the Outlook From field	Yes	Yes	Yes	Yes
Reply with IM or voice from availability menu	Yes	Yes	Yes (from the contact card)	Yes (from the contact card)
IM and presence in Microsoft Word and Microsoft Excel files (smart tags enabled)	Yes	Yes	Microsoft Word only	Microsoft Word only
IM and presence in Microsoft SharePoint sites (Outlook must be installed)	Yes	Yes	Yes	Yes

[1] For more information, see Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013 in the Planning documentation.

The following features are available only with Office 2010 or Office 2013:

- Contact card with expanded options, such as video call and desktop sharing
- Quick search from the Find a Contact field in Outlook
- Reply with an IM or call from the Outlook Home ribbon in the Mail, Calendar, Contacts, and Tasks folders
- Lync Contacts list in Outlook To-Do Bar
- Office Backstage (File tab) presence status, program sharing, and file transfer
- Presence menu in Microsoft Office SharePoint Workspace 2010 (formerly Microsoft Office Groove 2007)
- Presence menu extensibility

Exchange Server and Lync 2013

The following table describes Lync 2013 support for various versions of Exchange Server. Outlook must be installed on the client computer to handle Extended MAPI calls, and some features require the use of Exchange Web Services (EWS).

Lync 2013 and Exchange Server Compatibility

Exchange Server version	Lync 2013 support
Exchange Server 2013	Same as Exchange Server 2010 support, with the addition of Unified Contact Store, high-resolution pictures, and archiving integration. **Note:** For details, see Integrating Microsoft Lync Server 2013 and Microsoft Exchange Server 2013.
Exchange Server 2010	Same as Exchange Server 2007 support, with the addition of Exchange contact sync.
Exchange Server 2007 with Service Pack 1 (SP1) (required) or the latest service pack (recommended)	The following features are available only through EWS: • Read or delete items in the Conversation History folder • Read or delete voice mail items • Display extended free/busy information and meeting subject and location Public folders are optional in Exchange Server 2007 with Service Pack 1 (SP1) (required) or the latest service pack or release (recommended).
Exchange Server 2003	Outlook MAPI only. EWS-only features are not available (see the previous row).

Windows and Lync 2013

For information about Lync 2013 and Windows supportability, see Lync Client Software Support in the Planning documentation.

Macintosh and Lync 2013

Lync Server 2013 supports certain clients on computers that are running Macintosh operating systems. For details, see Lync Client Software Support in the Planning documentation.

Public Instant Messaging Clients and Lync 2013

If you have configured your server for public IM connectivity, Lync supports the following capabilities with public IM networks. Presence status is filtered to those presence states supported by the public IM client. For details, see Planning for Public Instant Messaging Connectivity in the Planning documentation and Manage External Access Policy for Your Organization in the Operations documentation.

In addition, the XMPP integration feature of Lync Server 2013 lets users exchange instant messages and presence information with users of public IM providers that use Extensible Messaging and Presence Protocol, such as Google Talk. For details, see Planning for Extensible Messaging and Presence Protocol (XMPP) Federation in the Planning documentation.

Lync 2013 and Public IM Clients Compatibility

Client	Supported Capabilities
Windows Live Messenger	IM, basic presence, audio/video (A/V)*
AOL	IM and basic presence
Yahoo!	IM and basic presence
Google Talk	IM and basic presence

*A/V is supported with the latest version of Windows Live Messenger. If you are implementing audio/video (A/V) federation with Windows Live Messenger, you must also modify the server encryption level. By default, the encryption level is Required. You must change this setting to Supported by using the Lync Server Management Shell.

Important:

- As of September 1st, 2012, the Microsoft Lync Public IM Connectivity User Subscription License ("PIC USL") is no longer available for purchase for new or renewing agreements. Customers with active licenses will be able to continue to federate with Yahoo! Messenger until the service shut down date (exact date TBD, but no sooner than June 2013).
- The PIC USL is a per-user per-month subscription license that is required for Lync Server or Office Communications Server to federate with Yahoo! Messenger. Microsoft's ability to provide this service has been contingent upon support from Yahoo!, the underlying agreement for which is winding down.
- More than ever, Lync is a powerful tool for connecting across organizations and with individuals around the world. Federation with Windows Live Messenger requires no additional user/device licenses beyond the Lync Standard CAL. Skype federation will be added to this list, enabling Lync users to reach hundreds of millions of people with IM and voice.

1.3.15.1.6 Client Interoperability in Lync 2013

Client Interoperability in Lync 2013

Planning > Planning for Clients and Devices in Lync Server 2013 > Planning for Clients >

Topic Last Modified: *2013-01-11*

This topic discusses the ability of Microsoft Lync Server 2013 clients to coexist and interact with clients from earlier versions of Lync Server and Office Communications Server.

Server and Client Compatibility

The following table shows the supported combinations of client versions and server versions. This table indicates whether sign-in is supported when the client attempts to connect to the server indicated. Lync Server 2013 supports the previous client version. Also, unlike previous releases, Lync Server 2010 supports the new Lync 2013 clients. This allows organizations who are upgrading from Lync Server 2010 to roll out new clients independent of Lync Server upgrades.

Client	Lync Server 2013	Lync Server 2010	Office Communications Server 2007 R2
Lync 2013	Supported	Supported	Not Supported
Lync Web App 2013	Supported	Not Supported	Not Supported
Lync 2010	Supported	Supported	Not Supported
Lync 2010 Attendant	Supported	Supported	Not Supported
Lync 2010 Group Chat	Not Applicable	Supported[1]	Not Applicable
Lync Web App 2010	Not Supported	Supported	Not Supported
Lync 2010 Attendee	Not Supported[2]	Supported	Not Supported
Office Communicator 2007 R2	Interoperable[3]	Supported	Supported
Microsoft Office Communications Server 2007 R2 Attendant	Not Supported	Supported	Supported
Office Communicator 2007	Not Supported	Supported	Supported
Office Live Meeting 2007	Not Supported	Supported	Supported

[1] In Microsoft Lync Server 2010, group chat functionality was available with Group Chat Server, a third-party trusted application for Lync Server 2010. Lync 2013 clients are not compatible with Lync Server 2010, Group Chat.

[2] Lync Web App 2013 now provides a full in-meeting experience, including computer audio and video, and is considered the replacement for Lync 2010 Attendee.

[3] The presence and IM features in Office Communicator 2007 R2 are compatible with Lync Server 2013, but conferencing features are not. During migration from Office Communications Server 2007 R2, Office Communicator 2007 R2 is suitable for presence and IM interoperability, but users should use Lync Web App 2013 to join Lync Server 2013 meetings.

Interoperability among Clients

With the Lync Server 2013 release, various client versions can interact seamlessly in both peer-to-peer and conferencing scenarios. This section discusses feature availability when users interact with other users who are using different versions of clients and servers.

Peer-to-Peer Feature Support

Peer-to-peer features are supported for users who are homed on different versions of the server and who are using different client versions. The end-user experience and available features are consistent with the capabilities of the user's client and the version of the server the user is signed in to. In other words:

- If a user is signed in to Lync Server 2013 with an older client, the user will have the same experience he or she is used to. None of the new features introduced in Lync Server 2013 will be available until the user's client is upgraded.
- If a user is signed in to Lync Server 2010 with a Lync 2013 client, any new features not supported by Lync Server 2010 will be unavailable until the user is moved to Lync Server 2013.

The following table compares feature availability in peer-to-peer sessions where the client is signed in to either Lync Server 2013 or Lync Server 2010.

Note:

Lync Web App and Lync 2010 Attendee are meeting-only clients and aren't included in this table.

Client	Instant Messaging	Presence	Voice	Video	Application Sharing	File Transfer
Lync 2013	Yes	Yes	Yes	Yes	Yes	Yes
Lync 2010	Yes	Yes	Yes	Yes	Yes	Yes
Lync 2010 Attendant	Yes	Yes	Yes			
Lync 2010 Mobile	Yes	Yes				
Lync Phone Edition	Yes	Yes	Yes			
Office Communicator 2007 R2	Yes	Yes	Yes	Yes	Yes[1]	Yes
Public IM (AOL, Yahoo!)	Yes	Yes				
Public IM	Yes	Yes	Yes	Yes		

(MSN, Windows Live Messenger)						

Important:

- As of September 1st, 2012, the Microsoft Lync Public IM Connectivity User Subscription License ("PIC USL") is no longer available for purchase for new or renewing agreements. Customers with active licenses will be able to continue to federate with Yahoo! Messenger until the service shut down date (exact date TBD, but no sooner than June 2013).
- The PIC USL is a per-user per-month subscription license that is required for Lync Server or Office Communications Server to federate with Yahoo! Messenger. Microsoft's ability to provide this service has been contingent upon support from Yahoo!, the underlying agreement for which is winding down.
- More than ever, Lync is a powerful tool for connecting across organizations and with individuals around the world. Federation with Windows Live Messenger requires no additional user/device licenses beyond the Lync Standard CAL. Skype federation will be added to this list, enabling Lync users to reach hundreds of millions of people with IM and voice.

[1] In Office Communicator 2007 R2, only desktop sharing (and not program sharing) is available.

Conferencing Feature Support

In Lync Server 2013 meetings, conferencing features are supported for users who are homed on different versions of the server and who are using different clients and client versions. When clients join a Lync Server 2013 meeting, users have access to the features and capabilities shown in this table.

Client	Peer-to-peer IM	Voice	Video	Application Sharing	PowerPoint	File Transfer	Whiteboard	Polling
Lync 2013	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Lync Web App	Yes	Yes	Yes	Yes	Yes[2]	Yes	Yes	Yes
Lync 2010	Yes	Yes	Yes	Yes	Yes[3]	Yes	Yes	Yes
Office Communicator 2007 R2	Yes	Yes	Yes	Yes[1]		[4]		

[1] In Office Communicator 2007 R2, only desktop sharing (and not program sharing) is available.

[2] Lync Server 2013 uses an updated mechanism for uploading PowerPoint files. Lync Web App users who join a meeting that was originally scheduled on Lync Server 2010 can view and navigate PowerPoint presentations, but cannot upload PowerPoint files.

[3] If the meeting was scheduled on Lync Server 2013 and PowerPoint slides were uploaded by a Lync 2013 client, Lync 2010 users have view-only access to the slides.

[4] In Office Communicator 2007 R2, file transfer is supported in peer-to-peer sessions, but not in conferencing sessions.

Scheduling Add-in Support

Server support for the various scheduling add-ins is consistent with server and client version compatibility. In general, the following scheduling add-ins are supported on Lync Server 2013. However, previous versions of add-ins do not provide new Lync 2013 add-in features, such as the option to mute all attendee audio and video upon meeting entry.

- **Online Meeting Add-in for Lync 2013** Provides the same features as the Online Meeting Add-in for Lync 2010, with the addition of attendee mute controls, which allow meeting organizers to schedule conferences that have attendee audio and video muted by default. Administrators can also customize the organization’s meeting invitations by adding a custom logo, a support URL, a legal disclaimer URL, or custom footer text.
- **Online Meeting Add-in for Lync 2010** Provides scheduling for Lync meetings and removes the capability to schedule Office Live Meeting conferences.
- **Office Communicator 2007 R2 Conferencing Add-in** Provides scheduling for both Office Live Meeting conferences and Office Communicator 2007 R2 conferences.

Note:

Live Meeting conferences cannot be scheduled on Lync Server 2013.

Scheduling Client	Lync Server 2013	Lync Server 2010	Office Communications Server 2007 R2
Online Meeting Add-in for Lync 2013 (can be used with Office 2013, Outlook 2010, and Outlook 2007)	Supported	Supported (new add-in features not available)	Not Supported
Lync 2013 Web Scheduler	Supported	Not Supported	Not Supported
Online Meeting Add-in for Lync 2010	Supported	Supported	Not Supported
Office Communicator 2007 R2 Conferencing Add-in	Not Supported	Supported	Supported

Support for Joining Meetings

All of the clients that Lync Server 2013 supports are allowed to join Lync 2013 meetings. Because Lync Web App is a web component of the server, in cases where Lync Web App is used to join a Lync Server 2013 meeting, the newer version of Lync Web App is always used.

Lync 2013 clients can join meetings hosted on Lync 2010 and Office Communications Server 2007 R2 with scaled-down functionality. In-meeting features are limited by the version of the server on which the meeting is hosted.

1.3.15.2 Planning for Mobile Clients

Planning for Mobile Clients

Microsoft Lync Server 2013 > Planning > Planning for Clients and Devices in Lync Server 2013 >

Topic Last Modified: *2013-02-19*

Lync 2013 mobile clients provide enhanced presence, IM, Lync meetings, and voice and video calls over the Internet or the cellular connection. For a matrix that lists the features and capabilities of mobile clients and compares them to the desktop client, see Mobile Client Comparison Tables.

Note:

Lync Server 2013 also supports Lync 2010 mobile clients. For more information, see "Planning for Mobile Clients" in the Lync Server 2010 TechNet Library at http://go.microsoft.com/fwlink/p/?LinkID=235955.

- Lync for Windows Phone Requirements
- Lync for iPhone and iPad Requirements
- Mobile Client Deployment Process

1.3.15.2.1 Mobile Client Comparison Tables

Mobile Client Comparison Tables

Planning > Planning for Clients and Devices in Lync Server 2013 > Planning for Mobile Clients >

Topic Last Modified: *2013-03-12*

The following tables compare the features and capabilities among Lync 2013 mobile clients and the Lync 2013 desktop client in the following categories:

- Sign-in, sign-out, and push notifications
- Enhanced presence
- Contacts and contact groups
- Instant messaging (IM)
- Lync-to-Lync audio and video
- Conferencing
- Telephony
- External users
- Archiving and compliance

These tables indicate the features that are available to Lync users in an on-premises deployment of Lync Server 2013. The same features are also available to Lync Online and Microsoft Office 365 users, unless otherwise indicated in the table footnotes.

Note:

- For online help and resources for end users, see "Microsoft Lync 2013 for Mobile Clients" at http://go.microsoft.com/fwlink/?LinkId=286237.
- To compare the features available in other Lync 2013 clients, see Client Comparison Tables.
- Lync Server 2013 also supports Lync 2010 mobile apps. For details, see "Mobile Client Comparison Tables" in the Lync Server 2010 documentation at http://go.microsoft.com/fwlink/p/?LinkID=234777.

Sign-in and Push Notifications

Feature/	Lync 2013	Windows Phone	iPhone	iPad

Capability	desktop client			
Lync session remains signed in	?	?[1]	?[1]	?[1]
Support for push notifications		?		
Country code populates based on region settings			?	?
Account information for multiple users can be cached on the same device	?			

[1] On Windows Phone, Lync signs out automatically if the user has not used the application for a period of time, as follows:

- If the user has enabled push notifications, Lync signs out after 36 hours.
- If the user has not enabled push notifications, Lync signs out after 1 hour.

On iPhone and iPad, Lync signs out automatically if the user has not used the application for a period of time, as follows:

- If the mobile client has not contacted the server for 10 days due to loss of network connectivity or other issues.

Enhanced Presence Support in Lync Mobile Clients

Feature/ Capability	Lync 2013 desktop client	Windows Phone	iPhone	iPad
Publish and view status	?	?	?	?
View status based on calendar free/ busy information	?	?	?	?
View status notes and Out of Office messages	?	?	?	?
Add a custom location	?			
Add a custom note	?	?	?	?
Publish status based on calendar free/ busy information	?[1]			
Set manual presence state	?	?	?	?

(such as Busy, Do Not Disturb, and so on)				

[1] Lync mobile clients do not update a user’s presence based on the user’s free/busy calendar information. If a mobile client user is also signed in to the Lync desktop client, the desktop client updates the user’s presence based on the user’s free/busy calendar information. If the user is signed in to a mobile client only, the user’s presence does not update based on free/busy calendar information.

Contacts and Contact Groups Support in Lync Mobile Clients

Feature/ capability	**Lync 2013 desktop client**	**Windows Phone**	**iPhone**	**iPad**
View Contacts list	?	?	?	?
View contact groups	?	?	?	?
View Frequent Contacts group	?			
Modify Contacts list	?			
Tag contacts for status change alerts	?			
Control privacy relationships	?			
Search the corporate address book	?	?	?	?
Search Contacts list	?	?	?	?
Manage contact groups	?			
Expand distribution groups	?	?	?	?
Search for Response Groups	?[1]	?	?	?
Display or hide contact photos	?	?	?	?

[1] Not available to Lync Online and/or Office 365 users.

Instant Messaging Support in Lync Mobile Clients

Feature/ capability	Lync 2013 desktop client	Windows Phone	iPhone	iPad
Initiate instant messaging (IM) with a contact	?	?	?	?
Participate in multiparty IM	?	?[1]	?[1]	?[1]
Invite others from within the conversation window	?			
Display current conversations	?	?	?	?
Navigate among multiple IM conversations	?	?	?	?
Automatically log IM conversations in Exchange	?			
Send an IM conversation as an email message	?	?	?	?
Initiate an email to a contact	?	?	?	?
View missed IM invitations	?	?	?	?
Vibrate with incoming IM		?[2]	?	?
Send location in an IM				

[1] Mobile users cannot initiate multiparty IM or add users to an existing IM, but they can participate in multiparty IM if invited.

[2] This device vibrates every time an IM is received even if the current message in the IM conversation is displayed

Lync-to-Lync Audio and Video

Feature/ Capability	Lync 2013 desktop client	Windows Phone	iPhone	iPad

Lync-to-Lync voice	?	?	?	?
Lync-to-Lync video	?	?	?	?

Conferencing Support in Lync Mobile Clients

Feature/ Capability	**Lync 2013 desktop client**	**Windows Phone**	**iPhone**	**iPad**
Click a link in the meeting reminder to join a meeting (public switched telephone network (PSTN))	?	?[1]	?[1]	?[1]
Click a link in the meeting reminder to join a video or VoIP meeting	?	?	?	?
Participate in multiparty IM	?	?	?	?
Use dial-out conferencing (server calls the mobile device)	?	?[2]	?[2]	?[2]
Use dial-in audio conferencing	?[3]			
View meeting video	?	?	?	?
View multiparty video (gallery view)	?			
Wait in meeting lobby	?	?	?	?
Use in-meeting presenter controls	?			
Access detailed meeting roster for audio conferences	?	?	?	?
Access detailed meeting roster for IM conferences	?	?	?	?

Share desktop or program	?			
View shared desktop or program	?			?
View shared PowerPoint	?			?
Use meeting tools (present Microsoft PowerPoint files, use whiteboard, conduct polls, share files)	?			
Navigate a list of your meetings		?	?	?

[1] For Office 365 users, this feature is available for audio conferencing provider (ACP)-enabled meetings only.

[2] Not available to Office 365 users.

[3] For Lync Online and/or Office 365 users, this feature is available from third-party audio conferencing providers.

Telephony Support in Lync Mobile Clients

Feature/ Capability	Lync 2013 desktop client	Windows Phone	iPhone	iPad
In Lync, tap the call icon to call a contact	?[1]	?[2]	?[2]	?[2]
Transfer a call	?[1]			
Manage call forwarding	?[3]	?	?	?
Manage team call settings	?[3]			
Manage delegates	?[3]			
Initiate a call to a Response Group	?[3]			
Support emergency services	?[4]			
Make calls on behalf of another contact	?[3]			

(manager/ delegate scenario)				
Handle another contact's calls, if configured as a delegate	?[3]	?[3]	?[3]	?[3]
Use Call via Work (Lync Server 2013 places your outgoing calls so that the receiver's caller ID displays your work number instead of your mobile number)		?[3]	?[3]	?[3]
Access voice mail	?[4]	?	?	?
Use the keypad in Lync	?	?[3]	?[3]	?[3]

[1] For Lync Online and/or Office 365 users, this feature is available for PC to PC calls. PSTN calls are supported by Lync to phone mobile partners.

[2] For on-premises Lync Server 2013 users, on Windows Phone, iPhone, and iPad devices, the user taps the call icon in the contact card and accepts the callback from Lync Server 2013. For Office 365 users, on Windows Phone, iPhone, and iPad devices, when the user taps the call button, a dialog box opens asking the user to confirm that he or she wants to call the number.

[3] Not available to Lync Online and/or Office 365 users.

[4] For Lync Online and/or Office 365 users, this feature is supported by Microsoft partners.

External User Support in Lync Mobile Clients

Feature/ Capability	Lync 2013 desktop client	Windows Phone	iPhone	iPad
Initiate IM with a public contact	?	?	?	?
Initiate IM with a federated contact	?	?	?	?
Conduct two-party calls with external users	?			
Conduct multiparty calls	?			

with external users				
Use Call via Work to reach a federated contact on their mobile phone by calling their published work number[1]		?[2]	?[2]	?[2]

[1] By default, federated users are assigned the External Contacts privacy relationship. To be able to reach a federated contact on their mobile phone by calling their published work number, the federated contact must manually assign you the Colleagues privacy relationship.

[2] Not available to Office 365 users.

Archiving and Compliance Support in Lync Mobile Clients

Feature/ Capability	**Lync 2013 desktop client**	**Windows Phone**	**iPhone**	**iPad**
Provide client-side archiving	?			
Provide client-side recording	?[1]			

[1] Not available to Lync Online and/or Office 365 users.

1.3.15.2.2 Lync for Windows Phone Requirements

Lync for Windows Phone Requirements

Planning > Planning for Clients and Devices in Lync Server 2013 > Planning for Mobile Clients >

Topic Last Modified: *2013-02-20*

Microsoft Lync 2013 for Windows Phone provides instant messaging (IM), enhanced presence, and telephony for users in your organization who are connecting from a smartphone or a Windows Professional mobile device. Mobile devices enable users to extend the reach of Lync 2013. This topic describes planning considerations for Lync 2013 for Windows Phone that include identifying prerequisites and technical requirements, required components, and deployment guidance.

Lync for Windows Phone Prerequisites

Following are the Lync 2013 for Windows Phone prerequisites.

- Windows Phone 8, codenamed "Apollo," or the latest version.
- The Windows Phone device must have the latest updates available from Microsoft. For details, see Windows Phone 8 update history at http://go.microsoft.com/fwlink/p/?LinkID=281961.
- The device must have 12 MB of available disk space.
- The user must have a voice and data plan from a carrier.

1.3.15.2.3 Lync for iPhone and iPad Requirements

Lync for iPhone and iPad Requirements

Planning > Planning for Clients and Devices in Lync Server 2013 > Planning for Mobile Clients >

Topic Last Modified: *2013-02-20*

To support Microsoft Lync 2013 for iPhone or Microsoft Lync 2013 for iPad, the device must meet the following requirements:

- iPhone 4 mobile digital device with Apple iOS 6 or the latest version.
- iPad 2 or a later version mobile digital device with Apple iOS 6 or the latest version.
- iPad mini mobile digital device with Apple iOS 6 or the latest version.

1.3.15.2.4 Mobile Client Deployment Process

Mobile Client Deployment Process

Planning > Planning for Clients and Devices in Lync Server 2013 > Planning for Mobile Clients >

Topic Last Modified: *2013-02-20*

After a deployment of Microsoft Lync Server 2013 has been completed, users can install the Lync 2013 app from the mobile marketplace that they are accustomed to using for their specific device.

Lync Mobile Deployment Process

Phase	Steps	Permissions	Documentation
Perform pre-setup tasks.	1. Verify Lync Server 2013 deployment. 2. Verify certificate requirements.	Administrator	Planning for Mobility in the server planning documentation. Deploying Mobility in the server deployment documentation. Certificate Infrastructure Requirements in the server planning documentation.
Install the Lync	1. Install prerequisites.	Administrator	Installation

application on a test device.	2. Install from the marketplace specific to the mobile device.		instructions specific to the mobile device in Deploying Mobile Clients.
Configure the client.	• Configure sign-in settings and server information.	Administrator	Deploying Mobile Clients
Test mobile scenarios.	1. Test instant messaging (IM) and presence. 2. Test dial-out conferencing. 3. Search for a contact in the corporate directory. 4. Test push notifications.	Administrator	Verification instructions specific to the mobile device in Deploying Mobile Clients.
Install the Lync application on mobile phones.	1. Install prerequisites. 2. Install from the marketplace specific to the mobile device.	User	Installation instructions specific to the mobile device in Deploying Mobile Clients.
